Non-Confidential

C7.2.246 MOV (to general)

Move vector element to general-purpose register

This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of UMOV. This means:

- The encodings in this description are named to match the encodings of UMOV.
- The description of UMOV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Advanced SIMD

(FEAT_AdvSIMD)

31	30	29	28							21	20				16	15	14				11	10	9			5	4			0
0	Q	0	0	1	1	1	0	0	0	0	x	x	x	0	0	0	0	1	1	1	1	1	Rn				Rd			
		op											imm5						imm4											

Encoding for the 32-bit variant

Applies when `(Q == 0 && imm5 == xx100)`

```
MOV  <Wd>, <Vn>.S[<index>]
```

is equivalent to

```
UMOV  <Wd>, <Vn>.S[<index>]
```

and is always the preferred disassembly.

Encoding for the 64-bit variant

Applies when `(Q == 1 && imm5 == x1000)`

```
MOV  <Xd>, <Vn>.D[<index>]
```

is equivalent to

```
UMOV  <Xd>, <Vn>.D[<index>]
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>

Is the 32-bit name of the general-purpose destination register, encoded in the “Rd” field.

<Vn>

Is the name of the SIMD&FP source register, encoded in the “Rn” field.

<index>

For the “32-bit” variant: is the element index encoded in “imm5<4:3>”.

For the “64-bit” variant: is the element index encoded in “imm5<4>”.

Non-Confidential

C7.2.247 MOVI

Move immediate (vector)

This instruction places an immediate constant into every vector element of the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD

C7.2.248 MUL (by element)

Multiply (vector, by element)

This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.255 ORR (vector, immediate)

Bitwise inclusive OR (vector, immediate)

This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise OR between each result and an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Shifted immediate

(FEAT_AdvSIMD)

Encoding for the 16-bit variant

Applies when `(cmode == 10x1)`

```
ORR  <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Encoding for the 32-bit variant

Applies when `(cmode == 0xx1)`

```
ORR  <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let rd : integer = UInt(Rd);
let datasize : integer{} = 64 << UInt(Q);
let imm64 : bits(64) = AdvSIMDExpandImm(op, cmode, a::b::c::d::e::f::g::h);
let imm : bits(datasize) = Replicate{}(imm64);
```

Assembler Symbols

<Vd>

Is the name of the SIMD&FP register, encoded in the “Rd” field.

<T>

For the “16-bit” variant: is an arrangement specifier, encoded in “Q”:

Q	<T>
0	4H

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

1	8H

For the “32-bit” variant: is an arrangement specifier, encoded in “Q”:

Q	<T>
0	2S
1	4S

<imm8>

Is an 8-bit immediate encoded in “a:b:c:d:e:f:g:h”.

<amount>

For the “16-bit” variant: is the shift amount encoded in “cmode<1>”:

cmode<1>	<amount>
0	0
1	8

defaulting to 0 if LSL is omitted.

For the “32-bit” variant: is the shift amount encoded in “cmode<2:1>”:

cmode<2:1>	<amount>
00	0
01	8
10	16
11	24

defaulting to 0 if LSL is omitted.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(datasize) = V{}(rd);
V{datasize}(rd) = operand OR imm;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C7.2.256 ORR (vector, register)

Bitwise inclusive OR (vector, register)

This instruction performs a bitwise OR between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (vector).

Three registers of the same type

(FEAT_AdvSIMD)

31	30	29	28	27 25	24	23 22	21	20 16	15 11	10	9 5	4 0

C7.2.257 PMUL

Polynomial multiply

This instruction multiplies corresponding elements in the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

For information about multiplying polynomials see Polynomial arithmetic over {0, 1}.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

C7.2.258 PMULL, PMULL2

Polynomial multiply long

This instruction multiplies corresponding elements in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials, see Polynomial arithmetic over {0, 1}.

The `PMULL` instruction extracts each source vector from the lower half of each source register. The `PMULL2` instruction extracts each source vector from the upper half of each source register.

The `PMULL` and `PMULL2` variants that operate on 64-bit source elements are defined only when FEAT_PMULL is implemented.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

(FEAT_AdvSIMD)

31	30	29	28	27 25	24	23 22	21	20 16	15 12	11 10	9 5	4 0
0	Q	0	0	1 1 1	0	size	1	Rm	1 1 1 0	0 0	Rn	Rd
		U							opcode			

Encoding

```
PMULL{2}  <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
if size == '01' || size == '10' then EndOfDecode(Decode_UNDEF); end;
if size == '11' && !IsFeatureImplemented(FEAT_PMULL) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let esize : integer{} = 8 << UInt(size);
let datasize : integer{} = 64;
let part : integer = UInt(Q);
let elements : integer = datasize DIV esize;
```

Assembler Symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

C7.2.259 RADDHN, RADDHN2

Rounding add returning high narrow

This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see ADDHN.

The `RADDHN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `RADDHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

(FEAT_AdvSIMD)

31	30	29	28	27 25	24	23 22	21	20 16	15 14	13	12	11 10	9 5	4 0

C7.2.265 RSHRN, RSHRN2

Rounding shift right narrow (immediate)

This instruction reads each unsigned integer value from the vector in the source SIMD&FP register, right shifts each result by an immediate value, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SHRN.

The `RSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `RSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector

C7.2.266 RSUBHN, RSUBHN2

Rounding subtract returning high narrow

This instruction subtracts each vector element of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are rounded. For truncated results, see SUBHN.

The `RSUBHN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `RSUBHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.272 SADDL, SADDL2

Signed add long (vector)

This instruction adds each vector element in the lower or upper half of the first source SIMD&FP register to the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The `SADDL` instruction extracts each source vector from the lower half of each source register. The `SADDL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.273 SADDLP

Signed add long pairwise

This instruction adds pairs of adjacent signed integer values from the vector in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.274 SADDLV

Signed add long across vector

This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.275 SADDW, SADDW2

Signed add wide

This instruction adds vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the results in a vector, and writes the vector to the SIMD&FP destination register.

The `SADDW` instruction extracts the second source vector from the lower half of the second source register. The `SADDW2` instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

C7.2.276 SCVTF (vector, fixed-point)

Signed fixed-point convert to floating-point (vector)

This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.278 SCVTF (scalar, fixed-point)

Signed fixed-point convert to floating-point (scalar)

This instruction converts the signed value in the 32-bit or 64-bit general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Is the 32-bit name of the general-purpose source register, encoded in the “Rn” field.

<fbits>

For the “32-bit to double-precision”, “32-bit to half-precision”, and “32-bit to single-precision” variants: is the number of bits after the binary point in the fixed-point source, in the range 1 to 32, encoded as 64 minus “scale”.

For the “64-bit to double-precision”, “64-bit to half-precision”, and “64-bit to single-precision” variants: is the number of bits after the binary point in the fixed-point source, in the range 1 to 64, encoded as 64 minus “scale”.

<Xn>

Is the 64-bit name of the general-purpose source register, encoded in the “Rn” field.

<Sd>

Is the 32-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the “Rd” field.

Operation

```
AArch64_CheckFPEnabled();

let merge : boolean = IsMerging(FPCR());
let fltsize : integer{} = if merge then 128 else decode_fltsize;
var fltval : bits(fltsize) = if merge then V{fltsize}(d) else Zeros{fltsize};
let intval : bits(intsize) = X{}(n);
let rounding : FPRounding = FPRoundingMode(FPCR());

fltval[0+:decode_fltsize] = FixedToFP{decode_fltsize, intsize}(intval, fracbits, unsigned,
                                                               FPCR(), rounding);

V{fltsize}(d) = fltval;
```

C7.2.279 SCVTF (scalar, integer)

Signed integer convert to floating-point (scalar)

This instruction converts the signed integer value in the general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.281 SDOT (by element)

Dot product signed arithmetic (vector, by element)

This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

Vector

C7.2.297 SHADD

Signed halving add

This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are truncated. For rounded results, see SRHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

(FEAT_AdvSIMD)

C7.2.299 SHLL, SHLL2

Shift left long (by element size)

This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, left shifts each result by the element size, writes the final result to a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The `SHLL` instruction extracts vector elements from the lower half of the source register. The `SHLL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector

(FEAT_AdvSIMD)

31	30	29	28	27 25	24	23 22	21 17	16 12	11 10	9 5	4 0
0	Q	1	0	1 1 1	0	size	1 0 0 0 0	1 0 0 1 1	1 0	Rn	Rd
		U						opcode			

Encoding

```
SHLL{2}  <Vd>.<Ta>, <Vn>.<Tb>, #<shift>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);

if size == '11' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let datasize : integer{} = 64;
let part : integer = UInt(Q);
let elements : integer = datasize DIV esize;

let shift : integer = esize;
```

Assembler Symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Ta>

Is an arrangement specifier, encoded in “size”:

size	<Ta>
00	8H
01	4S
10	2D
11	RESERVED

<Vn>

Is the name of the SIMD&FP source register, encoded in the “Rn” field.

<Tb>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<Tb>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	x	RESERVED

<shift>

Is the left shift amount, which must be equal to the source element width in bits, encoded in “size”:

size	<shift>
00	8
01	16
10	32
11	RESERVED

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(datasize) = Vpart{}(n, part);
var result : bits(2*datasize);
var element : integer;

for e = 0 to elements-1 do
    element = SInt(operand[e*:esize]) << shift;
```

C7.2.300 SHRN, SHRN2

Shift right narrow (immediate)

This instruction reads each unsigned integer value from the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The results are truncated. For rounded results, see RSHRN.

The `SHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Vector

(FEAT_AdvSIMD)

31	30	29	28	27 25	24 23	22 19	18 16	15 12	11	10	9 5	4 0

C7.2.301 SHSUB

Signed halving subtract

This instruction subtracts the elements in the vector in the second source SIMD&FP register from the corresponding elements in the vector in the first source SIMD&FP register, shifts each result right one bit, places each result into elements of a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

C7.2.302 SLI

Shift left and insert (immediate)

This instruction reads each vector element in the source SIMD&FP register, left shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the left of each vector element in the source register are lost.

Figure C7-3 shift left by 3 for an 8-bit vector element

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

(FEAT_AdvSIMD)

31	30	29	28	27–25	24	23	22–19	18–16	15–11	10	9–5	4–0

C7.2.306 SM3TT1A

SM3TT1A

This instruction takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive-OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive-OR.
- The result of the exclusive-OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

Advanced SIMD

C7.2.307 SM3TT1B

SM3TT1B

This instruction takes three 128-bit vectors from three source SIMD&FP registers and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a 32-bit majority function between the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the 32-bit majority function.
- The result of the exclusive-OR of the top 32-bit element of the second source vector, Vn, with a rotation left by 12 of the top 32-bit element of the first source vector.
- A 32-bit element indexed out of the third source vector, Vm.

The result of this addition is returned as the top element of the result. The other elements of the result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 9.

C7.2.308 SM3TT2A

SM3TT2A

This instruction takes three 128-bit vectors from three source SIMD&FP register and a 2-bit immediate index value, and returns a 128-bit result in the destination SIMD&FP register. It performs a three-way exclusive-OR of the three 32-bit fields held in the upper three elements of the first source vector, and adds the resulting 32-bit value and the following three other 32-bit values:

- The bottom 32-bit element of the first source vector, Vd, that was used for the three-way exclusive-OR.
- The 32-bit element held in the top 32 bits of the second source vector, Vn.
- A 32-bit element indexed out of the third source vector, Vm.

A three-way exclusive-OR is performed of the result of this addition, the result of the addition rotated left by 9, and the result of the addition rotated left by 17. The result of this exclusive-OR is returned as the top element of the returned result. The other elements of this result are taken from elements of the first source vector, with the element returned in bits<63:32> being rotated left by 19.

C7.2.312 SMAX

Signed maximum (vector)

This instruction compares corresponding elements in the vectors in the two source SIMD&FP registers, places the larger of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.316 SMINP

Signed minimum pairwise

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the smallest of each pair of signed integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.317 SMINV

Signed minimum across vector

This instruction compares all the vector elements in the source SIMD&FP register, and writes the smallest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are signed integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.318 SMLAL, SMLAL2 (by element)

Signed multiply-add long (vector, by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element in the second source SIMD&FP register, and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

The `SMLAL` instruction extracts vector elements from the lower half of the first source register. The `SMLAL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.322 SMMLA (vector)

Signed 8-bit integer matrix multiply-accumulate to 32-bit integer (vector)

This instruction multiplies the 2x8 matrix of signed 8-bit integer values in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

Encoding

```
SMMLA  <Vd>.4S, <Vn>.16B, <Vm>.16B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_I8MM) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let op1_unsigned : boolean = FALSE;
let op2_unsigned : boolean = FALSE;
```

Assembler Symbols

<Vd>

Is the name of the SIMD&FP third source and destination register, encoded in the “Rd” field.

<Vn>

Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm>

Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(128) = V{}(n);
let operand2 : bits(128) = V{}(m);
let addend : bits(128)   = V{}(d);

V{128}(d) = MatMulAdd(addend, operand1, operand2, op1_unsigned, op2_unsigned);
```

Operational Information

Arm expects that the SMMLA (vector) instruction will deliver a peak integer multiply throughput that is at least as high as can be achieved using two SDOT (vector) instructions, with a goal that it should have significantly higher throughput.

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C7.2.323 SMOV

Signed move vector element to general-purpose register

This instruction reads the signed integer from the source SIMD&FP register, sign-extends it to form a 32-bit or 64-bit value, and writes the result to destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Advanced SIMD

C7.2.324 SMULL, SMULL2 (by element)

Signed multiply long (vector, by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the result in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `SMULL` instruction extracts vector elements from the lower half of the first source register. The `SMULL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.325 SMULL, SMULL2 (vector)

Signed multiply long (vector)

This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, places the results in a vector, and writes the vector to the destination SIMD&FP register.

The destination vector elements are twice as long as the elements that are multiplied.

The `SMULL` instruction extracts each source vector from the lower half of each source register. The `SMULL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

C7.2.326 SQABS

Signed saturating absolute value

This instruction reads each vector element from the source SIMD&FP register, puts the absolute value of the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.328 SQDMLAL, SQDMLAL2 (by element)

Signed saturating doubling multiply-add long (by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMLAL` instruction extracts vector elements from the lower half of the first source register. The `SQDMLAL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.329 SQDMLAL, SQDMLAL2 (vector)

Signed saturating doubling multiply-add long

This instruction multiplies corresponding signed integer values in the lower or upper half of the vectors of the two source SIMD&FP registers, doubles the results, and accumulates the final results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMLAL` instruction extracts each source vector from the lower half of each source register. The `SQDMLAL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.330 SQDMLSL, SQDMLSL2 (by element)

Signed saturating doubling multiply-subtract long (by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, and subtracts the final results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMLSL` instruction extracts vector elements from the lower half of the first source register. The `SQDMLSL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.334 SQDMULL, SQDMULL2 (by element)

Signed saturating doubling multiply long (by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the final results in a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQDMULL` instruction extracts the first source vector from the lower half of the first source register. The `SQDMULL2` instruction extracts the first source vector from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Vector and Scalar

C7.2.339 SQRDMLSH (by element)

Signed saturating rounding doubling multiply subtract returning high half (by element)

This instruction multiplies the vector elements of the first source SIMD&FP register with the value of a vector element of the second source SIMD&FP register without saturating the multiply results, doubles the results, and subtracts the most significant half of the final results from the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, FPSR.QC, is set if saturation occurs.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.341 SQRDMULH (by element)

Signed saturating rounding doubling multiply returning high half (by element)

This instruction multiplies each vector element in the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, doubles the results, places the most significant half of the final results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SQDMULH.

If any of the results overflows, they are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.343 SQRSHL

Signed saturating rounding shift left (register)

This instruction takes each vector element in the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see SQSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.344 SQRSHRN, SQRSHRN2

Signed saturating rounded shift right narrow (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. The results are rounded. For truncated results, see SQSHRN.

The `SQRSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SQRSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.347 SQSHL (register)

Signed saturating shift left (register)

This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see SQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.348 SQSHLU

Signed saturating shift left unsigned (immediate)

This instruction reads each signed integer value in the vector of the source SIMD&FP register, shifts each value by an immediate value, saturates the shifted result to an unsigned integer value, places the result in a vector, and writes the vector to the destination SIMD&FP register. The results are truncated. For rounded results, see UQRSHL.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.349 SQSHRN, SQSHRN2

Signed saturating shift right narrow (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts and truncates each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are half as long as the source vector elements. For rounded results, see SQRSHRN.

The `SQSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SQSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.352 SQXTN, SQXTN2

Signed saturating extract narrow

This instruction reads each vector element from the source SIMD&FP register, saturates the value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. All the values in this instruction are signed integer values.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQXTN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SQXTN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.353 SQXTUN, SQXTUN2

Signed saturating extract unsigned narrow

This instruction reads each signed integer value in the vector of the source SIMD&FP register, saturates the value to an unsigned integer value that is half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `SQXTUN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SQXTUN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.354 SRHADD

Signed rounding halving add

This instruction adds corresponding signed integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see SHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.355 SRI

Shift right and insert (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each vector element by an immediate value, and inserts the result into the corresponding vector element in the destination SIMD&FP register such that the new zero bits created by the shift are not inserted but retain their existing value. Bits shifted out of the right of each vector element of the source register are lost.

Figure C7-4 shift right by 3 for an 8-bit vector element

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.356 SRSHL

Signed rounding shift left (register)

This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts it by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see SSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Assembler Symbols

<d>

Is the number of the SIMD&FP destination register, encoded in the “Rd” field.

<n>

Is the number of the SIMD&FP source register, encoded in the “Rn” field.

<shift>

For the “Scalar” variant: is the right shift amount, in the range 1 to 64, encoded as `128 - UInt(“immh:immb”)`.

For the “Vector” variant: is the right shift amount, in the range 1 to the element width in bits, encoded in “immh:immb”:

immh	<shift>
0001	16 - UInt(immh:immb)
001x	32 - UInt(immh:immb)
01xx	64 - UInt(immh:immb)
1xxx	128 - UInt(immh:immb)

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<T>

Is an arrangement specifier, encoded in “immh:Q”:

immh	Q	<T>
0001	0	8B
0001	1	16B
001x	0	4H
001x	1	8H
01xx	0	2S

C7.2.359 SSHL

Signed shift left (register)

This instruction takes each signed integer value in the vector of the first source SIMD&FP register, shifts each value by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see SRSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.360 SSHLL, SSHLL2

Signed shift left long (immediate)

This instruction reads each vector element from the source SIMD&FP register, left shifts each vector element by the specified shift amount, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The `SSHLL` instruction extracts vector elements from the lower half of the source register. The `SSHLL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias SXTL, SXTL2.

Vector

C7.2.363 SSUBL, SSUBL2

Signed subtract long

This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are signed integer values. The destination vector elements are twice as long as the source vector elements.

The `SSUBL` instruction extracts each source vector from the lower half of each source register. The `SSUBL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

C7.2.364 SSUBW, SSUBW2

Signed subtract wide

This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. All the values in this instruction are signed integer values.

The `SSUBW` instruction extracts the second source vector from the lower half of the second source register. The `SSUBW2` instruction extracts the second source vector from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

(FEAT_AdvSIMD)

let esize : integer{} = 8 << UInt(size);
let datasize : integer{} = 64;
let part : integer = UInt(Q);
let elements : integer = datasize DIV esize;
```

Assembler Symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Ta>

Is an arrangement specifier, encoded in “size”:

size	<Ta>
00	8H
01	4S
10	2D
11	RESERVED

<Vn>

Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm>

Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

<Tb>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<Tb>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	x	RESERVED

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(2*datasize) = V{}(n);
let operand2 : bits(datasize) = Vpart{}(m, part);
var result : bits(2*datasize);
var element1 : integer;
var element2 : integer;
var sum : integer;

for e = 0 to elements-1 do
    element1 = SInt(operand1[e*:(2*esize)]);
    element2 = SInt(operand2[e*:esize]);
    sum = element1 - element2;
    result[e*:(2*esize)] = sum[2*esize-1:0];
end;

V{2*datasize}(d) = result;
```

C7.2.365 ST1 (multiple structures)

Store multiple single-element structures from one, two, three, or four registers

This instruction stores elements to memory from one, two, three, or four SIMD&FP registers, without interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	1D
11	1	2D

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Vt3>

Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<Vt4>

Is the name of the fourth SIMD&FP register to be transferred, encoded as “Rt” plus 3 modulo 32.

<imm>

For the “One register, immediate offset” variant: is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#8

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Q	<imm>
1	#16

For the “Two registers, immediate offset” variant: is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#16
1	#32

For the “Three registers, immediate offset” variant: is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#24
1	#48

For the “Four registers, immediate offset” variant: is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#32
1	#64

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

Shared Decode

```
let datasize : integer{} = 64 << UInt(Q);
let esize : integer{} = 8 << UInt(size);
let elements : integer = datasize DIV esize;

var rpt : integer;                // number of iterations
let selem : integer = 1; // structure elements

case opcode of
    when '0010' => rpt = 4;    // LD/ST1 (4 registers)

```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#16
1	#32

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

C7.2.368 ST2 (single structure)

Store single 2-element structure from one lane of two registers

This instruction stores a 2-element structure to memory from corresponding elements of two SIMD&FP registers.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

(FEAT_AdvSIMD)

Encoding for the 8-bit variant

Applies when `(opcode == 000)`

```
ST2  { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>]
```

Encoding for the 16-bit variant

Applies when `(opcode == 010 && size == x0)`

```
ST2  { <Vt>.H, <Vt2>.H }[<index>], [<Xn|SP>]
```

Encoding for the 32-bit variant

Applies when `(opcode == 100 && size == 00)`

```
ST2  { <Vt>.S, <Vt2>.S }[<index>], [<Xn|SP>]
```

Encoding for the 64-bit variant

Applies when `(opcode == 100 && S == 0 && size == 01)`

```
ST2  { <Vt>.D, <Vt2>.D }[<index>], [<Xn|SP>]
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
var t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = ARBITRARY : integer;
let wback : boolean = FALSE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
var t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = TRUE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<index>

For the “8-bit”, “8-bit, immediate offset”, and “8-bit, register offset” variants: is the element index, encoded in “Q:S:size”.

For the “16-bit”, “16-bit, immediate offset”, and “16-bit, register offset” variants: is the element index, encoded in “Q:S:size<1>”.

For the “32-bit”, “32-bit, immediate offset”, and “32-bit, register offset” variants: is the element index, encoded in “Q:S”.

For the “64-bit”, “64-bit, immediate offset”, and “64-bit, register offset” variants: is the element index, encoded in “Q”.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Vt3>

Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#24
1	#48

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

C7.2.371 ST4 (multiple structures)

Store multiple 4-element structures from four registers

This instruction stores multiple 4-element structures to memory from four SIMD&FP registers, with interleaving. Every element of each register is stored.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: No offset and Post-index

No offset

(FEAT_AdvSIMD)

31	30	29 28	27	26	25	24 23	22	21 16	15 12	11 10	9 5	4 0
0	Q	0 0	1	1	0	0 0	0	0 0 0 0 0 0	0 0 0 0	size	Rn	Rt
							L		opcode			

Encoding

```
ST4  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = ARBITRARY : integer;
let wback : boolean = FALSE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Post-index

(FEAT_AdvSIMD)

31	30	29 23	22	21	20 16	15 12	11 10	9 5	4 0
0	Q	0 0 1 1 0 0 1	0	0	Rm	0 0 0 0	size	Rn	Rt
			L			opcode			

Encoding for the Immediate offset variant

Applies when `(Rm == 11111)`

```
ST4  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>
```

Encoding for the Register offset variant

Applies when `(Rm != 11111)`

```
ST4  { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>
```

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_AdvSIMD) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = TRUE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = wback || n != 31;
```

Assembler Symbols

<Vt>

Is the name of the first or only SIMD&FP register to be transferred, encoded in the “Rt” field.

<T>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<T>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	0	RESERVED
11	1	2D

<Vt2>

Is the name of the second SIMD&FP register to be transferred, encoded as “Rt” plus 1 modulo 32.

<Vt3>

Is the name of the third SIMD&FP register to be transferred, encoded as “Rt” plus 2 modulo 32.

<Vt4>

Is the name of the fourth SIMD&FP register to be transferred, encoded as “Rt” plus 3 modulo 32.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

Is the post-index immediate offset, encoded in “Q”:

Q	<imm>
0	#32

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Q	<imm>
1	#64

<Xm>

Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the “Rm” field.

Shared Decode

```
let datasize : integer{} = 64 << UInt(Q);
let esize : integer{} = 8 << UInt(size);
let elements : integer = datasize DIV esize;

let rpt : integer = 1;
let selem : integer = 4;

// .1D format only permitted with LD1 & ST1
if size::Q == '110' && selem != 1 then EndOfDecode(Decode_UNDEF); end;
```

Operation

```
AArch64_CheckFPAdvSIMDEnabled();

var address : bits(64);

C7.2.373 STBFADD, STBFADDL

Atomic BFloat16 floating-point add, without return

This instruction atomically loads a 16-bit value from memory, adds it to the BFloat16 value held in a register, and stores the result back to memory.

- `STBFADDL` stores to memory with release semantics.
- `STBFADD` has no release semantics.

This instruction:

- Disables alternative floating-point behaviors, as if FPCR.AH is 0.
- Generates only the default NaN, as if FPCR.DN is 1.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

C7.2.374 STBFMAX, STBFMAXL

Atomic BFloat16 floating-point maximum, without return

This instruction atomically loads a 16-bit value from memory, calculates the BFloat16 maximum with the value held in a register, and stores the result back to memory.

- `STBFMAXL` stores to memory with release semantics.
- `STBFMAX` has no release semantics.

This instruction:

- Disables alternative floating-point behaviors, as if FPCR.AH is 0.
- Generates only the default NaN, as if FPCR.DN is 1.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

C7.2.375 STBFMAXNM, STBFMAXNML

Atomic BFloat16 floating-point maximum number, without return

This instruction atomically loads a 16-bit value from memory, calculates the BFloat16 maximum number with the value held in a register, and stores the result back to memory.

- `STBFMAXNML` stores to memory with release semantics.
- `STBFMAXNM` has no release semantics.

This instruction:

- Disables alternative floating-point behaviors, as if FPCR.AH is 0.
- Generates only the default NaN, as if FPCR.DN is 1.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

C7.2.378 STFADD, STFADDL

Atomic floating-point add, without return

This instruction atomically loads a 16-bit, 32-bit, or 64-bit value from memory, performs a floating-point add with the value held in a register, and stores the result back to memory.

- `STFADDL` stores to memory with release semantics.
- `STFADD` has no release semantics.

This instruction:

- Disables alternative floating-point behaviors, as if FPCR.AH is 0.
- Generates only the default NaN, as if FPCR.DN is 1.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

This instruction atomically loads a 16-bit, 32-bit, or 64-bit value from memory, calculates the floating-point minimum number with the value held in a register, and stores the result back to memory.

- `STFMINNML` stores to memory with release semantics.
- `STFMINNM` has no release semantics.

This instruction:

- Disables alternative floating-point behaviors, as if FPCR.AH is 0.
- Generates only the default NaN, as if FPCR.DN is 1.
- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.

For more information about memory ordering semantics, see Load-Acquire, Store-Release.

For information about addressing modes, see Load/Store addressing modes.

C7.2.383 STL1 (SIMD&FP)

Store-release a single-element structure from one lane of one register

This instruction stores the specified element of a SIMD&FP register to memory.

The instruction also has memory ordering semantics, as described in Load-Acquire, Load-AcquirePC, and Store-Release. For information about addressing modes, see Load/Store addressing modes.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

64-bit

C7.2.385 STNP (SIMD&FP)

Store pair of SIMD&FP registers, with non-temporal hint

This instruction stores a pair of SIMD&FP registers to memory, issuing a hint to the memory system that the access is non-temporal. The address used for the store is calculated from an address from a base register value and an immediate offset. For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point non-temporal pair.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Signed offset

C7.2.387 STR (immediate, SIMD&FP)

Store SIMD&FP register (immediate offset)

This instruction stores a single SIMD&FP register to memory. The address that is used for the store is calculated from a base register value and an immediate offset.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 3 classes: Post-index, Pre-index, and Unsigned offset

Assembler Symbols

<Bt>

Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the signed immediate byte offset, in the range -256 to 255, encoded in the “imm9” field.

<Ht>

Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<St>

Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Dt>

Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Qt>

Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<pimm>

For the “8-bit” variant: is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the “imm12” field.

For the “16-bit” variant: is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the “imm12” field as <pimm>/2.

For the “32-bit” variant: is the optional positive immediate byte offset, a multiple of 4 in the range 0 to 16380, defaulting to 0 and encoded in the “imm12” field as <pimm>/4.

For the “64-bit” variant: is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the “imm12” field as <pimm>/8.

For the “128-bit” variant: is the optional positive immediate byte offset, a multiple of 16 in the range 0 to 65520, defaulting to 0 and encoded in the “imm12” field as <pimm>/16.

let extend_type : ExtendType = DecodeRegExtend(option);
let shift : integer{} = if S == '1' then scale else 0;
```

Assembler Symbols

<Bt>

Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Wm>

When `option<0>` is set to 0, is the 32-bit name of the general-purpose index register, encoded in the “Rm” field.

<Xm>

When `option<0>` is set to 1, is the 64-bit name of the general-purpose index register, encoded in the “Rm” field.

<extend>

For the “8-bit with extended register offset” variant: is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW
110	SXTW
111	SXTX

For the “128-bit”, “16-bit”, “32-bit”, and “64-bit” variants: is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted, encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount>

For the “8-bit with extended register offset” and “8-bit with shifted register offset” variants: is the index shift amount, it must be `#0`, encoded in “S” as 0 if omitted, or as 1 if present.

For the “16-bit” variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

C7.2.389 STTNP (SIMD&FP)

Store unprivileged pair of SIMD&FP registers, with non-temporal hint

This instruction stores a pair of SIMD&FP registers to memory, issuing a hint to the memory system that the access is non-temporal. The address used for the store is calculated from an address from a base register value and an immediate offset. For information about non-temporal pair instructions, see Load/Store SIMD and Floating-point non-temporal pair.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the Effective value of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the Effective value of HCR_EL2().{E2H, TGE} is '11'.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Signed offset

Assembler Symbols

<Bt>

Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<simm>

Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the “imm9” field.

<Ht>

Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<St>

Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Dt>

Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

<Qt>

Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the “Rt” field.

Shared Decode

```
let t : integer{} = UInt(Rt);
let n : integer{} = UInt(Rn);
let datasize : integer{} = 8 << scale;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = n != 31;
```

Operation

```
AArch64_CheckFPEnabled();
var address : bits(64);

let privileged : boolean = PSTATE.EL != EL0;
let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_STORE, nontemporal, tagchecked,
                                                    privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP{64}();
else
    address = X{64}(n);
end;

address = AddressAdd(address, offset, accdesc);

Mem{datasize}(address, accdesc) = V{datasize}(t);
```

C7.2.392 SUB (vector)

Subtract (vector)

This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

(FEAT_AdvSIMD)

31	30	29	28	27 25	24	23 22	21	20 16	15 11	10	9 5	4 0

C7.2.393 SUBHN, SUBHN2

Subtract returning high narrow

This instruction subtracts each vector element in the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are signed integer values.

The results are truncated. For rounded results, see RSUBHN.

The `SUBHN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `SUBHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

C7.2.394 SUDOT (by element)

Dot product with signed and unsigned integers (vector, by element)

This instruction performs the dot product of the four signed 8-bit integer values in each 32-bit element of the first source register with the four unsigned 8-bit integer values in an indexed 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination vector.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

31	30	29	28	27 25	24	23	22	21	20	19 16	15 12	11	10	9 5	4 0

C7.2.395 SUQADD

Signed saturating accumulate of unsigned value

This instruction adds the unsigned integer values of the vector elements in the source SIMD&FP register to corresponding signed integer values of the vector elements in the destination SIMD&FP register, and writes the resulting signed integer values to the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.396 SXTL, SXTL2

Signed extend long

This instruction duplicates each vector element in the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are signed integer values.

The `SXTL` instruction extracts the source vector from the lower half of the source register. The `SXTL2` instruction extracts the source vector from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of SSHLL, SSHLL2. This means:

- The encodings in this description are named to match the encodings of SSHLL, SSHLL2.
- The description of SSHLL, SSHLL2 gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Vector

C7.2.397 TBL

Table vector lookup

This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the result for that lookup is 0. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.398 TBX

Table vector lookup extension

This instruction reads each value from the vector elements in the index source SIMD&FP register, uses each result as an index to perform a lookup in a table of bytes that is described by one to four source table SIMD&FP registers, places the lookup result in a vector, and writes the vector to the destination SIMD&FP register. If an index is out of range for the table, the existing value in the vector element of the destination register is left unchanged. If more than one source register is used to describe the table, the first source register describes the lowest bytes of the table.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.399 TRN1

Transpose vectors (primary)

This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places each result into consecutive elements of a vector, and writes the vector to the destination SIMD&FP register. Vector elements from the first source register are placed into even-numbered elements of the destination vector, starting at zero, while vector elements from the second source register are placed into odd-numbered elements of the destination vector.

Note

By using this instruction with `TRN2`, a 2 x 2 matrix can be transposed.

Figure C7-5 TRN1 and TRN2 halfword operations where Q = 0

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.402 UABAL, UABAL2

Unsigned absolute difference and accumulate long

This instruction subtracts the vector elements in the lower or upper half of the second source SIMD&FP register from the corresponding vector elements of the first source SIMD&FP register, and accumulates the absolute values of the results into the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

The `UABAL` instruction extracts each source vector from the lower half of each source register. The `UABAL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.407 UADDLP

Unsigned add long pairwise

This instruction adds pairs of adjacent unsigned integer values from the vector in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.408 UADDLV

Unsigned sum long across vector

This instruction adds every vector element in the source SIMD&FP register together, and writes the scalar result to the destination SIMD&FP register. The destination scalar is twice as long as the source vector elements. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.409 UADDW, UADDW2

Unsigned add wide

This instruction adds the vector elements of the first source SIMD&FP register to the corresponding vector elements in the lower or upper half of the second source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register. All the values in this instruction are unsigned integer values.

The `UADDW` instruction extracts vector elements from the lower half of the second source register. The `UADDW2` instruction extracts vector elements from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.410 UCVTF (vector, fixed-point)

Unsigned fixed-point convert to floating-point (vector)

This instruction converts each element in a vector from fixed-point to floating-point using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.412 UCVTF (scalar, fixed-point)

Unsigned fixed-point convert to floating-point (scalar)

This instruction converts the unsigned value in the 32-bit or 64-bit general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.413 UCVTF (scalar, integer)

Unsigned integer convert to floating-point (scalar)

This instruction converts the unsigned integer value in the general-purpose source register to a floating-point value using the rounding mode that is specified by the FPCR, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see Floating-point exceptions and exception traps.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.415 UDOT (by element)

Dot product unsigned arithmetic (vector, by element)

This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note

ID_AA64ISAR0_EL1.DP indicates whether this instruction is supported.

C7.2.420 UMAXP

Unsigned maximum pairwise

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements in the two source SIMD&FP registers, writes the largest of each pair of unsigned integer values into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.421 UMAXV

Unsigned maximum across vector

This instruction compares all the vector elements in the source SIMD&FP register, and writes the largest of the values as a scalar to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.425 UMLAL, UMLAL2 (by element)

Unsigned multiply-add long (vector, by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register and accumulates the results with the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `UMLAL` instruction extracts vector elements from the lower half of the first source register. The `UMLAL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.428 UMLSL, UMLSL2 (vector)

Unsigned multiply-subtract long (vector)

This instruction multiplies corresponding vector elements in the lower or upper half of the two source SIMD&FP registers, and subtracts the results from the vector elements of the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied. All the values in this instruction are unsigned integer values.

The `UMLSL` instruction extracts each source vector from the lower half of each source register. The `UMLSL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

(FEAT_AdvSIMD)

C7.2.429 UMMLA (vector)

Unsigned 8-bit integer matrix multiply-accumulate to 32-bit integer (vector)

This instruction multiplies the 2x8 matrix of unsigned 8-bit integer values in the first source vector by the 8x2 matrix of unsigned 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

Encoding

```
UMMLA  <Vd>.4S, <Vn>.16B, <Vm>.16B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_I8MM) then EndOfDecode(Decode_UNDEF); end;
let d : integer{} = UInt(Rd);
let n : integer{} = UInt(Rn);
let m : integer{} = UInt(Rm);
let op1_unsigned : boolean = TRUE;
let op2_unsigned : boolean = TRUE;
```

Assembler Symbols

<Vd>

Is the name of the SIMD&FP third source and destination register, encoded in the “Rd” field.

<Vn>

Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm>

Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(128) = V{}(n);
let operand2 : bits(128) = V{}(m);
let addend : bits(128)   = V{}(d);

V{128}(d) = MatMulAdd(addend, operand1, operand2, op1_unsigned, op2_unsigned);
```

Operational Information

Arm expects that the UMMLA (vector) instruction will deliver a peak integer multiply throughput that is at least as high as can be achieved using two UDOT (vector) instructions, with a goal that it should have significantly higher throughput.

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C7.2.430 UMOV

Unsigned move vector element to general-purpose register

This instruction reads the unsigned integer from the source SIMD&FP register, zero-extends it to form a 32-bit or 64-bit value, and writes the result to the destination general-purpose register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias MOV (to general).

Advanced SIMD

<Ts>

Is an element size specifier, encoded in “imm5”:

imm5	<Ts>
xx000	RESERVED
xxxx1	B
xxx10	H
xx100	S

<index>

For the “32-bit” variant: is the element index encoded in “imm5”:

imm5	<index>
xx000	RESERVED
xxxx1	UInt(imm5<4:1>)
xxx10	UInt(imm5<4:2>)
xx100	UInt(imm5<4:3>)

For the “64-bit” variant: is the element index encoded in “imm5<4>”.

<Xd>

Is the 64-bit name of the general-purpose destination register, encoded in the “Rd” field.

Alias Conditions

Alias	Of variant	Is preferred when
MOV (to general)	32-bit	imm5 IN {'xx100'}
MOV (to general)	64-bit	imm5 IN {'x1000'}

Operation

```
if index == 0 then
    AArch64_CheckFPEnabled();
else
    AArch64_CheckFPAdvSIMDEnabled();
end;
let operand : bits(idxdsize) = V{}(n);

X{datasize}(d) = ZeroExtend{datasize}(operand[index*:esize]);
```

C7.2.431 UMULL, UMULL2 (by element)

Unsigned multiply long (vector, by element)

This instruction multiplies each vector element in the lower or upper half of the first source SIMD&FP register by the specified vector element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the elements that are multiplied.

The `UMULL` instruction extracts vector elements from the lower half of the first source register. The `UMULL2` instruction extracts vector elements from the upper half of the first source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.434 UQRSHL

Unsigned saturating rounding shift left (register)

This instruction takes each vector element of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding vector element of the second source SIMD&FP register, places the results into a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are rounded. For truncated results, see UQSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.435 UQRSHRN, UQRSHRN2

Unsigned saturating rounded shift right narrow (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are rounded. For truncated results, see UQSHRN.

The `UQRSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `UQRSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.437 UQSHL (register)

Unsigned saturating shift left (register)

This instruction takes each element in the vector of the first source SIMD&FP register, shifts the element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift. The results are truncated. For rounded results, see UQRSHL.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.438 UQSHRN, UQSHRN2

Unsigned saturating shift right narrow (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, saturates each shifted result to a value that is half the original width, puts the final result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see UQRSHRN.

The `UQSHRN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `UQSHRN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.440 UQXTN, UQXTN2

Unsigned saturating extract narrow

This instruction reads each vector element from the source SIMD&FP register, saturates each value to half the original width, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values.

If saturation occurs, the cumulative saturation bit FPSR.QC is set.

The `UQXTN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `UQXTN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

C7.2.442 URHADD

Unsigned rounding halving add

This instruction adds corresponding unsigned integer values from the two source SIMD&FP registers, shifts each result right one bit, places the results into a vector, and writes the vector to the destination SIMD&FP register.

The results are rounded. For truncated results, see UHADD.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.443 URSHL

Unsigned rounding shift left (register)

This instruction takes each element in the vector of the first source SIMD&FP register, shifts the vector element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Assembler Symbols

<d>

Is the number of the SIMD&FP destination register, encoded in the “Rd” field.

<n>

Is the number of the first SIMD&FP source register, encoded in the “Rn” field.

<shift>

For the “Scalar” variant: is the right shift amount, in the range 1 to 64, encoded as `128 - UInt(“immh:immb”)`.

For the “Vector” variant: is the right shift amount, in the range 1 to the element width in bits, encoded in “immh:immb”:

immh	<shift>
0001	16 - UInt(immh:immb)
001x	32 - UInt(immh:immb)
01xx	64 - UInt(immh:immb)
1xxx	128 - UInt(immh:immb)

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

<T>

Is an arrangement specifier, encoded in “immh:Q”:

immh	Q	<T>
0001	0	8B
0001	1	16B
001x	0	4H
001x	1	8H
01xx	0	2S

C7.2.447 USDOT (by element)

Dot product with unsigned and signed integers (vector, by element)

This instruction performs the dot product of the four unsigned 8-bit integer values in each 32-bit element of the first source register with the four signed 8-bit integer values in an indexed 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

C7.2.449 USHL

Unsigned shift left (register)

This instruction takes each element in the vector of the first source SIMD&FP register, shifts each element by a value from the least significant byte of the corresponding element of the second source SIMD&FP register, places the results in a vector, and writes the vector to the destination SIMD&FP register.

If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift. For a rounding shift, see URSHL.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.450 USHLL, USHLL2

Unsigned shift left long (immediate)

This instruction reads each vector element in the lower or upper half of the source SIMD&FP register, shifts the unsigned integer value left by the specified number of bits, places the result into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The `USHLL` instruction extracts vector elements from the lower half of the source register. The `USHLL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This instruction is used by the alias UXTL, UXTL2.

Vector

C7.2.452 USMMLA (vector)

Unsigned and signed 8-bit integer matrix multiply-accumulate to 32-bit integer (vector)

This instruction multiplies the 2x8 matrix of unsigned 8-bit integer values in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2 to Armv8.5, this is an OPTIONAL instruction. From Armv8.6 it is mandatory for implementations that include Advanced SIMD to support it. ID_AA64ISAR1_EL1.I8MM indicates whether this instruction is supported.

Vector

(FEAT_I8MM)

let op2_unsigned : boolean = FALSE;
```

Assembler Symbols

<Vd>

Is the name of the SIMD&FP third source and destination register, encoded in the “Rd” field.

<Vn>

Is the name of the first SIMD&FP source register, encoded in the “Rn” field.

<Vm>

Is the name of the second SIMD&FP source register, encoded in the “Rm” field.

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand1 : bits(128) = V{}(n);
let operand2 : bits(128) = V{}(m);
let addend : bits(128)   = V{}(d);

V{128}(d) = MatMulAdd(addend, operand1, operand2, op1_unsigned, op2_unsigned);
```

Operational Information

Arm expects that the USMMLA (vector) instruction will deliver a peak integer multiply throughput that is at least as high as can be achieved using two USDOT (vector) instructions, with a goal that it should have significantly higher throughput.

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

C7.2.453 USQADD

Unsigned saturating accumulate of signed value

This instruction adds the signed integer values of the vector elements in the source SIMD&FP register to corresponding unsigned integer values of the vector elements in the destination SIMD&FP register, and accumulates the resulting unsigned integer values with the vector elements of the destination SIMD&FP register.

If overflow occurs with any of the results, those results are saturated. If saturation occurs, the cumulative saturation bit FPSR.QC is set.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

C7.2.454 USRA

Unsigned shift right and accumulate (immediate)

This instruction reads each vector element in the source SIMD&FP register, right shifts each result by an immediate value, and accumulates the final results with the vector elements of the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The results are truncated. For rounded results, see URSRA.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

Scalar

(FEAT_AdvSIMD)

C7.2.455 USUBL, USUBL2

Unsigned subtract long

This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element of the first source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. All the values in this instruction are unsigned integer values. The destination vector elements are twice as long as the source vector elements.

The `USUBL` instruction extracts each source vector from the lower half of each source register. The `USUBL2` instruction extracts each source vector from the upper half of each source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

C7.2.456 USUBW, USUBW2

Unsigned subtract wide

This instruction subtracts each vector element in the lower or upper half of the second source SIMD&FP register from the corresponding vector element in the first source SIMD&FP register, places the result in a vector, and writes the vector to the SIMD&FP destination register. All the values in this instruction are unsigned integer values.

The vector elements of the destination register and the first source register are twice as long as the vector elements of the second source register.

The `USUBW` instruction extracts vector elements from the lower half of the second source register. The `USUBW2` instruction extracts vector elements from the upper half of the second source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

C7.2.457 UXTL, UXTL2

Unsigned extend long

This instruction copies each vector element from the lower or upper half of the source SIMD&FP register into a vector, and writes the vector to the destination SIMD&FP register. The destination vector elements are twice as long as the source vector elements.

The `UXTL` instruction extracts vector elements from the lower half of the source register. The `UXTL2` instruction extracts vector elements from the upper half of the source register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

This is an alias of USHLL, USHLL2. This means:

- The encodings in this description are named to match the encodings of USHLL, USHLL2.
- The description of USHLL, USHLL2 gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Vector

(FEAT_AdvSIMD)

Encoding

```
UXTL{2}  <Vd>.<Ta>, <Vn>.<Tb>
```

is equivalent to

```
USHLL{2}  <Vd>.<Ta>, <Vn>.<Tb>, #0
```

and is the preferred disassembly when `BitCount(immh) == 1`.

Assembler Symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

C7.2.458 UZP1

Unzip vectors (primary)

This instruction reads corresponding even-numbered vector elements from the two source SIMD&FP registers, starting at zero, places the result from the first source register into consecutive elements in the lower half of a vector, and the result from the second source register into consecutive elements in the upper half of a vector, and writes the vector to the destination SIMD&FP register.

Note

This instruction can be used with `UZP2` to de-interleave two vectors.

Figure C7-7 UZP1 and UZP2 with the arrangement specifier 8B

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

C7.2.461 XTN, XTN2

Extract narrow

This instruction reads each vector element from the source SIMD&FP register, narrows each value to half the original width, places the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements.

The `XTN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `XTN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Assembler Symbols

2

Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in “Q”:

Q	2
0	[absent]
1	[present]

<Vd>

Is the name of the SIMD&FP destination register, encoded in the “Rd” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb>

Is an arrangement specifier, encoded in “size:Q”:

size	Q	<Tb>
00	0	8B
00	1	16B
01	0	4H
01	1	8H
10	0	2S
10	1	4S
11	x	RESERVED

<Vn>

Is the name of the SIMD&FP source register, encoded in the “Rn” field.

<Ta>

Is an arrangement specifier, encoded in “size”:

size	<Ta>
00	8H
01	4S
10	2D
11	RESERVED

Operation

```
AArch64_CheckFPAdvSIMDEnabled();
let operand : bits(2*datasize) = V{}(n);
var result : bits(datasize);
var element : bits(2*esize);

for e = 0 to elements-1 do
    element = operand[e*:(2*esize)];
    result[e*:esize] = element[esize-1:0];
end;
Vpart{datasize}(d, part) = result;
```

Operational Information

C7.2.462 ZIP1

Zip vectors (primary)

This instruction reads adjacent vector elements from the lower half of two source SIMD&FP registers as pairs, interleaves the pairs and places them into a vector, and writes the vector to the destination SIMD&FP register. The first pair from the first source register is placed into the two lowest vector elements, with subsequent pairs taken alternately from each source register.

Note

This instruction can be used with `ZIP2` to interleave two vectors.

Figure C7-9 ZIP1 and ZIP2 with the arrangement specifier 8B

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Chapter C8
SVE Instruction Descriptions

This chapter describes the SVE instructions. It contains the following sections:

- About the SVE instructions
- Alphabetical list of SVE instructions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

C8.1 About the SVE instructions

Alphabetical list of SVE instructions gives full descriptions of the SVE instructions that are in the following instruction groups:

- Loads and store instructions associated with the SVE registers.
- Data processing instructions with SVE registers.

A64 instruction set encoding provides an overview of the instruction encodings as well as of the instruction classes within their functional groups.

Non-Confidential

C8.2 Alphabetical list of SVE instructions

This section lists every section in the SVE category of the A64 instruction set. For details of the format used, see Structure of the A64 assembler language.

Non-Confidential

C8.2.1 ABS

Absolute value (predicated)

This instruction calculates the absolute value of the signed integer in each active element of the source vector, and places the results in the corresponding elements of the destination vector. If the value in an element of the source vector is the most negative value, the result for that element is the same as the value in that element of the source vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

It has encodings from 2 classes: Merging and Zeroing

Merging

(FEAT_SVE || FEAT_SME)

31–29	28–25	24	23–22	21	20	19	18–16	15–13	12–10	9–5	4–0
0 0 0	0 0 1 0	0	size	0	1	0	1 1 0	1 0 1	Pg	Zn	Zd
					M		opc				

Encoding

```
ABS  <Zd>.<T>, <Pg>/M, <Zn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Zd);
let merging : boolean = TRUE;
```

Zeroing

(FEAT_SVE2p2 || FEAT_SME2p2)

31–29	28–25	24	23–22	21	20	19	18–16	15–13	12–10	9–5	4–0
0 0 0	0 0 1 0	0	size	0	0	0	1 1 0	1 0 1	Pg	Zn	Zd
					M		opc				

Encoding

```
ABS  <Zd>.<T>, <Pg>/Z, <Zn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2p2) && !IsFeatureImplemented(FEAT_SME2p2) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Zd);
let merging : boolean = FALSE;
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        var element : integer = SInt(operand[e*:esize]);
        element = Abs(element);
        result[e*:esize] = element[esize-1:0];

    end;
end;
Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant of this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.2 ADCLB

Add with carry long (bottom)

This instruction adds the even-numbered elements of the first source vector and the 1-bit carry from the least-significant bit of the odd-numbered elements of the second source vector to the even-numbered elements of the destination and accumulator vector. The 1-bit carry output is placed in the corresponding odd-numbered element of the destination vector.

SVE2

(FEAT_SVE2 || FEAT_SME)

31–29	28–25	24	23	22	21	20–16	15–14	13–11	10	9–5	4–0
0 1 0	0 0 1 0	1	0	sz	0	Zm	1 1	0 1 0	0 (T)	Zn	Zda

Encoding

```
ADCLB  <Zda>.<T>, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 32 << UInt(sz);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let da : integer = UInt(Zda);
```

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<T>

Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let pairs : integer = VL DIV (esize * 2);
let operand : bits(VL) = Z{}(n);
let carries : bits(VL) = Z{}(m);
var result : bits(VL) = Z{}(da);

for p = 0 to pairs-1 do
    let element1 : bits(esize) = result[(2*p + 0)*:esize];
    let element2 : bits(esize) = operand[(2*p + 0)*:esize];
    let carry_in : bit = carries[(2*p + 1)*:esize][0];

    let (res, nzcv) = AddWithCarry{esize}(element1, element2, carry_in);
    let carry_out : bit = nzcv[1];

    result[(2*p + 0)*:esize] = res;
    result[(2*p + 1)*:esize] = ZeroExtend{esize}(carry_out);
end;

Z{VL}(da) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

Non-Confidential

C8.2.5 ADD (immediate)

Add immediate (unpredicated)

This instruction adds an unsigned immediate to each element of the source vector, and destructively places the results in the corresponding elements of the source vector. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

SVE

(FEAT_SVE || FEAT_SME)

31–29	28–25	24	23–22	21	20–19	18–16	15–14	13	12–5	4–0
0 0 1	0 0 1 0	1	size	1	0 0	0 0 0 (opc)	1 1	sh	imm8	Zdn

Encoding

```
ADD  <Zdn>.<T>, <Zdn>.<T>, #<imm>{, <shift>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size::sh == '001' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let dn : integer = UInt(Zdn);
var imm : integer = UInt(imm8);
if sh == '1' then imm = imm << 8; end;
```

Assembler Symbols

<Zdn>

Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T>

Is the size specifier, encoded in "size":

size	<T>
00	B
01	H
10	S
11	D

<imm>

Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<shift>

Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #8

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;

```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is CONSTRAINED UNPREDICTABLE:

- The MOVPRFX must be unpredicated.
- The MOVPRFX must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.15 ADR

Calculate vector address

This instruction optionally sign-extends or zero-extends the least significant 32 bits of each element from a vector of offsets or indices in the second source vector, and scales each index by 2, 4, or 8. The scaled indices are then added to a vector of base addresses from the first source vector, and the resulting addresses are placed in the destination vector. This instruction is unpredicated.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: Packed offsets, Unpacked 32-bit signed offsets, and Unpacked 32-bit unsigned offsets

Packed offsets

(FEAT_SVE)

31–29	28–25	24	23	22	21	20–16	15–12	11–10	9–5	4–0
0 0 0	0 0 1 0	0	1	sz	1	Zm	1 0 1 0	msz	Zn	Zd

Encoding

```
ADR  <Zd>.<T>, [<Zn>.<T>, <Zm>.<T>{, <mod> <amount>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 32 << UInt(sz);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
let osize : integer{} = esize;
let unsigned : boolean = TRUE;
let mbytes : integer{} = 1 << UInt(msz);
```

Unpacked 32-bit signed offsets

Unpacked 32-bit unsigned offsets

(FEAT_SVE)

31 29	28 25	24	23 22	21	20 16	15 12	11 10	9 5	4 0
0 0 0	0 0 1 0	0	0 1	1	Zm	1 0 1 0	msz	Zn	Zd
			opc						

Encoding

```
ADR  <Zd>.D, [<Zn>.D, <Zm>.D, UXTW{<amount>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 64;
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
let osize : integer{} = 32;
let unsigned : boolean = TRUE;
let mbytes : integer{} = 1 << UInt(msz);
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Zn>

Is the name of the base scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the offset scalable vector register, encoded in the “Zm” field.

<mod>

Is the index extend and shift specifier, encoded in “msz”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

msz	<mod>
00	[absent]
x1	LSL
10	LSL

<amount>

Is the index shift amount, encoded in “msz”:

msz	<amount>
00	[absent]
01	#1
10	#2
11	#3

Operation

```
CheckNonStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let base : bits(VL) = Z{}(n);
let offs : bits(VL) = Z{}(m);
var result : bits(VL);

for e = 0 to elements-1 do
    let addr : bits(esize) = base[e*:esize];
    let offselt : bits(osize) = offs[e*:esize][osize-1:0];
    let offset : integer = if unsigned then UInt(offselt) else SInt(offselt);
    result[e*:esize] = addr + (offset * mbytes);
end;

Z{VL}(d) = result;
```

C8.2.16 AESD (indexed)

Multi-vector AES single round decryption

This instruction reads a 16-byte state array from each 128-bit segment of the two or four first source vectors, together with a round key from the indexed 128-bit segment of the corresponding 512-bit portion of the second source vector. Each state array undergoes a single round of the AddRoundKey(), InvShiftRows(), and InvSubBytes() transformations in accordance with the AES standard. Each updated state array is destructively placed in the corresponding segment of the two or four first source vectors.

When the vector length is less than 512 bits, the most significant bits of the index are ignored to select the indexed 128-bit segment of the second source vector. This instruction is unpredicated.

This instruction is legal when executed in Streaming SVE mode if both FEAT_SSVE_AES and FEAT_SVE_AES2 are implemented.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SVE_AES2)

31–29	28–25	24	23–22	21	20–19	18–17	16	15–13	12–11	10	9–5	4–1	0

C8.2.22 AESIMC

AES inverse mix columns

This instruction reads a 16-byte state array from each 128-bit segment of the source register, and performs a single round of the InvMixColumns() transformation on each state array in accordance with the AES standard. Each updated state array is destructively placed in the corresponding segment of the first source vector. This instruction is unpredicated.

ID_AA64ZFR0_EL1.AES indicates whether this instruction is implemented.

This instruction is legal when executed in Streaming SVE mode if one of the following is true:

- Both FEAT_SSVE_AES and FEAT_SVE_AES are implemented.
- FEAT_SME_FA64 is implemented and enabled.

SVE2

C8.2.24 AND (predicates)

Bitwise AND predicates

This instruction performs a bitwise AND between the active elements of the first source predicate and the corresponding elements of the second source predicate, and places the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction does not set the condition flags.

This instruction is used by the alias MOV (predicate, zeroing).

Not setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
AND  <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8;
let g : integer = UInt(Pg);
let n : integer = UInt(Pn);
let m : integer = UInt(Pm);
let d : integer = UInt(Pd);
let setflags : boolean = FALSE;
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the first source scalable predicate register, encoded in the “Pn” field.

<Pm>

Is the name of the second source scalable predicate register, encoded in the “Pm” field.

Alias Conditions

Alias	Is preferred when
MOV (predicate, zeroing)	S == '0' && Pn == Pm

```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.26 AND (immediate)

Bitwise AND with immediate (unpredicated)

This instruction performs a bitwise AND between an immediate and each 64-bit element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32, or 64 bits. This instruction is unpredicated.

This instruction is used by the pseudo-instruction BIC (immediate).

C8.2.29 ANDS

Bitwise AND predicates, setting the condition flags

This instruction performs a bitwise AND between the active elements of the first source predicate and the corresponding elements of the second source predicate, and places the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This instruction is used by the alias MOVS (predicated).

Setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
ANDS  <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8;
let g : integer = UInt(Pg);
let n : integer = UInt(Pn);
let m : integer = UInt(Pm);
let d : integer = UInt(Pd);
let setflags : boolean = TRUE;
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the first source scalable predicate register, encoded in the “Pn” field.

<Pm>

Is the name of the second source scalable predicate register, encoded in the “Pm” field.

Alias Conditions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alias	Is preferred when
MOVS (predicated)	S == '1' && Pn == Pm

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(PL) = P{}(n);
let operand2 : bits(PL) = P{}(m);
var result : bits(PL);
let psize : integer{} = esize DIV 8;

for e = 0 to elements-1 do
    let element1 : bit = PredicateElement{PL}(operand1, e, esize);
    let element2 : bit = PredicateElement{PL}(operand2, e, esize);
    if ActivePredicateElement{PL}(mask, e, esize) then
        result[e*:psize] = ZeroExtend{psize}(element1 AND element2);
    else
        result[e*:psize] = ZeroExtend{psize}('0');
    end;
end;

if setflags then
    PSTATE.[N,Z,C,V] = PredTest{PL}(mask, result, esize);
end;
P{PL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction that is dependent on the NZCV condition flags written by this instruction might be significantly delayed.

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.32 ASR (wide elements, predicated)

Arithmetic shift right by 64-bit wide elements (predicated)

This instruction shifts right, preserving the sign bit, active elements of the first source vector by the corresponding overlapping 64-bit elements of the second source vector and destructively places the results in the corresponding elements of the first source vector. The shift amount is a vector of unsigned 64-bit doubleword elements in which all bits are significant, and not used modulo the destination element size. Inactive elements in the destination vector register remain unmodified.

C8.2.41 BF1CVT, BF2CVT

8-bit floating-point convert to BFloat16

This instruction converts each even-numbered 8-bit floating-point element of the source vector to BFloat16 while downscaling the value, and places the results in the overlapping 16-bit elements of the destination vector. BF1CVT scales the values by $2^{-\text{UInt(FPMR.LSCALE[5:0])}}$. BF2CVT scales the values by $2^{-\text{UInt(FPMR.LSCALE2[5:0])}}$.

The 8-bit floating-point encoding format for BF1CVT is selected by `FPMR.F8S1`. The 8-bit floating-point encoding format for BF2CVT is selected by `FPMR.F8S2`.

This instruction is unpredicated.

It has encodings from 2 classes: BF1CVT and BF2CVT

C8.2.45 BFCLAMP

BFloat16 clamp to minimum/maximum number

This instruction clamps each BFloat16 element in the destination vector to between the BFloat16 minimum value in the corresponding element of the first source vector and the BFloat16 maximum value in the corresponding element of the second source vector and destructively places the clamped results in the corresponding elements of the destination vector.

Regardless of the value of FPCR.AH, the behavior is as follows for each minimum number and maximum number operation:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is default NaN.

This instruction follows SVE2 non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

C8.2.49 BFDOT (vectors)

BFloat16 dot product to single-precision

This instruction delimits the source vectors into pairs of BFloat16 elements.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the source vectors. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the source vectors.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Honors FPCR.AH when generating a default NaN result, otherwise disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, this instruction:

- Performs a fused sum-of-products of each pair of adjacent BFloat16 elements in the source vectors. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the source vectors.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.BF16 indicates whether this instruction is implemented.

C8.2.50 BFDOT (indexed)

BFloat16 dot product by indexed element to single-precision

This instruction delimits the source vectors into pairs of BFloat16 elements. The BFloat16 pairs within the second source vector are specified using an immediate index that selects the same BFloat16 pair position within each 128-bit vector segment. The index range is from 0 to 3.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Honors FPCR.AH when generating a default NaN result, otherwise disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, this instruction:

- Performs a fused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.BF16 indicates whether this instruction is implemented.

C8.2.51 BFMAX

BFloat16 maximum (predicated)

This instruction determines the maximum of active BFloat16 elements of the first source vector and the corresponding BFloat16 elements of the second source vector, and destructively places the results in the corresponding elements of the first source vector.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

Inactive elements in the destination vector register remain unmodified.

This instruction follows SVE2 non-widening BFloat16 numerical behaviors.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

C8.2.56 BFMLA (indexed)

BFloat16 fused multiply-add by indexed element

This instruction multiplies all BFloat16 elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively added without intermediate rounding to the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to 7.

This instruction follows SVE2 non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

C8.2.67 BFMMLA (widening)

BFloat16 matrix multiply-accumulate to single-precision

This instruction multiplies the 2×4 matrix of BFloat16 values held in each 128-bit segment of the first source vector by the 4×2 matrix of BFloat16 values in the corresponding segment of the second source vector.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Calculates the intermediate single-precision results as a sum of two unfused sum-of-products using two pairs of adjacent BFloat16 values from each of the source vectors, and rounds the results before accumulation into the 2×2 matrix of single-precision results in the corresponding segment of the destination vector. This is equivalent to accumulating a 4-way dot product per destination element.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Honors FPCR.AH when generating a default NaN result, otherwise disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, this instruction:

- Calculates the intermediate single-precision results as a sum of two fused sum-of-products using two pairs of adjacent BFloat16 values from each of the source vectors, and rounds the results before accumulation into the 2×2 matrix of single-precision results in the destination vector. This is equivalent to accumulating a 4-way dot product per destination element.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

This instruction is unpredicated and vector length agnostic.

ID_AA64ZFR0_EL1.BF16 indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.74 BGRP

Group bits to right or left as selected by bitmask

This instruction separates bits in each element of the first source vector by gathering from the bit positions indicated by nonzero bits in the corresponding mask element of the second source vector to the lowest-numbered contiguous bits of the corresponding destination element, and from positions indicated by zero bits to the highest-numbered bits of the destination element, preserving the bit order within each group. This instruction is unpredicated.

ID_AA64ZFR0_EL1.BitPerm indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled, or FEAT_SSVE_BitPerm is implemented.

C8.2.75 BIC (immediate)

Bitwise clear bits using immediate (unpredicated)

This instruction performs a bitwise clear bits using an immediate with each 64-bit element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32, or 64 bits. This instruction is unpredicated.

This is a pseudo-instruction of AND (immediate). This means:

- The encodings in this description are named to match the encodings of AND (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of AND (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C8.2.81 BRKAS

Break after first true condition, setting the condition flags

This instruction sets the destination predicate elements up to and including the first active and true source element to true, then sets subsequent elements to false. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

Setting the condition flags

(FEAT_SVE || FEAT_SME)

C8.2.93 CADD

Complex integer add

This instruction adds the real and imaginary components of the integral complex numbers from the first source vector to the complex numbers from the second source vector that have first been rotated by 90 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, equivalent to multiplying the complex numbers in the second source vector by ±j beforehand. The results are destructively placed in the corresponding elements of the first source vector. This instruction is unpredicated.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

C8.2.94 CDOT (vectors)

Complex integer dot product

This instruction delimits the source vectors into pairs of 8-bit or 16-bit signed integer complex numbers. Within each pair, the complex numbers in the first source vector are multiplied by the corresponding complex numbers in the second source vector and the resulting wide real or wide imaginary part of the product is accumulated into a 32-bit or 64-bit destination vector element that overlaps all four of the elements that comprise a pair of complex number values in the first source vector.

As a result each instruction implicitly deinterleaves the real and imaginary components of their complex number inputs, so that the destination vector accumulates 4×wide real sums or 4×wide imaginary sums.

The complex numbers in the second source vector are rotated by 0, 90, 180, or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, by performing the following transformations prior to the dot product operations:

- If the rotation is #0, the imaginary parts of the complex numbers in the second source vector are negated. The destination vector therefore accumulates the real parts of a complex dot product.
- If the rotation is #90, the real and imaginary parts of the complex numbers the second source vector are swapped. The destination vector therefore accumulates the imaginary parts of a complex dot product.
- If the rotation is #180, there is no transformation. The destination vector therefore accumulates the real parts of a complex conjugate dot product.
- If the rotation is #270, the real parts of the complex numbers in the second source vector are negated and then swapped with the imaginary parts. The destination vector therefore accumulates the imaginary parts of a complex conjugate dot product.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

C8.2.95 CDOT (indexed)

Complex integer dot product by indexed element

This instruction delimits the source vectors into pairs of 8-bit or 16-bit signed integer complex numbers. Within each pair, the complex numbers in the first source vector are multiplied by the corresponding complex numbers in the second source vector and the resulting wide real or wide imaginary part of the product is accumulated into a 32-bit or 64-bit destination vector element that overlaps all four of the elements that comprise a pair of complex number values in the first source vector.

As a result each instruction implicitly deinterleaves the real and imaginary components of their complex number inputs, so that the destination vector accumulates 4×wide real sums or 4×wide imaginary sums.

The complex numbers in the second source vector are rotated by 0, 90, 180, or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, by performing the following transformations prior to the dot product operations:

- If the rotation is #0, the imaginary parts of the complex numbers in the second source vector are negated. The destination vector therefore accumulates the real parts of a complex dot product.
- If the rotation is #90, the real and imaginary parts of the complex numbers the second source vector are swapped. The destination vector therefore accumulates the imaginary parts of a complex dot product.
- If the rotation is #180, there is no transformation. The destination vector therefore accumulates the real parts of a complex conjugate dot product.
- If the rotation is #270, the real parts of the complex numbers in the second source vector are negated and then swapped with the imaginary parts. The destination vector therefore accumulates the imaginary parts of a complex conjugate dot product.

The indexed form of these instructions select a single pair of complex numbers within each 128-bit segment of the second source vector as the multiplier for all pairs of complex numbers within the corresponding 128-bit segment of the first source vector. The complex number pairs within the second source vector are specified using an immediate index that selects the same complex number pair position within each 128-bit vector segment. The index range is from 0 to one less than the number of complex number pairs per 128-bit segment.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

It has encodings from 2 classes: 8-bit to 32-bit and 16-bit to 64-bit

8-bit to 32-bit

C8.2.96 CLASTA (scalar)

Conditionally extract element after last to general-purpose register

This instruction extracts and zero-extends the element after the Last active element, or if the Last active element is the final element it extracts element zero, from the source vector register, and destructively places the zero-extended value in the destination and first source general-purpose register. If there are no Active elements, the least significant element-size bits of the destination and first source general-purpose register are destructively zero-extended.

C8.2.97 CLASTA (SIMD&FP scalar)

Conditionally extract element after last to SIMD&FP scalar register

This instruction extracts and zero-extends the element after the Last active element, or if the Last active element is the final element it extracts element zero, from the source vector register, and destructively places the zero-extended value in the destination and first source SIMD & floating-point scalar register. If there are no Active elements, the least significant element-size bits of the destination and first source SIMD & floating-point scalar register are destructively zero-extended.

C8.2.98 CLASTA (vectors)

Conditionally extract element after last to vector register

This instruction extracts the element after the Last active element, or if the Last active element is the final element it extracts element zero, from the second source vector register, and then replicates the extracted element to destructively fill the destination and first source vector. If there are no Active elements, the destination and source vector are unmodified.

C8.2.104 CMLA (vectors)

Complex integer multiply-add

This instruction multiplies the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the integral numbers in the first source vector by the corresponding complex number in the second source vector rotated by 0, 90, 180, or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

This instruction then adds the products to the corresponding components of the complex numbers in the addend vector, and destructively places the results in the corresponding elements of the addend vector. This instruction is unpredicated.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.105 CMLA (indexed)

Complex integer multiply-add by indexed element

This instruction multiplies the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the integral numbers in each 128-bit segment of the first source vector by the specified complex number in the corresponding the second source vector segment rotated by 0, 90, 180, or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

This instruction then adds the products to the corresponding components of the complex numbers in the addend vector, and destructively places the results in the corresponding elements of the addend vector. This instruction is unpredicated.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

It has encodings from 2 classes: 16-bit and 32-bit

16-bit

(FEAT_SVE2 || FEAT_SME)

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “16-bit” variant: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “32-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “16-bit” variant: is the element index, in the range 0 to 3, encoded in the “i2” field.

For the “32-bit” variant: is the element index, in the range 0 to 1, encoded in the “i1” field.

<const>

Is the const specifier, encoded in “rot”:

rot	<const>
00	#0
01	#90
10	#180
11	#270

Operation

```
CheckSVEEnabled();

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

<imm>

For the “Equal”, “Greater than”, “Greater than or equal”, “Less than”, “Less than or equal”, and “Not equal” variants: is the signed immediate operand, in the range -16 to 15, encoded in the “imm5” field.

For the “Higher”, “Higher or same”, “Lower”, and “Lower or same” variants: is the unsigned immediate operand, in the range 0 to 127, encoded in the “imm7” field.

```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction that is dependent on the predicate register or NZCV condition flags written by this instruction might be significantly delayed.

C8.2.108 CMP<cc> (vectors)

Compare vectors

This instruction compares active integer elements in the first source vector with the corresponding elements in the second source vector, and places the boolean results of the specified comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

<cc>	Comparison
EQ	equal
GE	signed greater than or equal
GT	signed greater than
HI	unsigned higher than
HS	unsigned higher than or same
NE	not equal

This instruction is used by the pseudo-instructions CMPLE (vectors), CMPLO (vectors), CMPLS (vectors), and CMPLT (vectors).

It has encodings from 6 classes: Equal, Greater than, Greater than or equal, Higher, Higher or same, and Not equal

C8.2.109 CMPLE (vectors)

Compare signed less than or equal to vector, setting the condition flags

This instruction compares active signed integer elements in the first source vector being less than or equal to the corresponding signed elements in the second source vector, and places the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This is a pseudo-instruction of CMP<cc> (vectors). This means:

- The encodings in this description are named to match the encodings of CMP<cc> (vectors).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CMP<cc> (vectors) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C8.2.110 CMPLO (vectors)

Compare unsigned lower than vector, setting the condition flags

This instruction compares active unsigned integer elements in the first source vector being lower than the corresponding unsigned elements in the second source vector, and places the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This is a pseudo-instruction of CMP<cc> (vectors). This means:

C8.2.112 CMPLT (vectors)

Compare signed less than vector, setting the condition flags

This instruction compares active signed integer elements in the first source vector being less than the corresponding signed elements in the second source vector, and places the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This is a pseudo-instruction of CMP<cc> (vectors). This means:

- The encodings in this description are named to match the encodings of CMP<cc> (vectors).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CMP<cc> (vectors) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C8.2.113 CNOT

Logically invert boolean condition (predicated)

This instruction logically inverts the boolean value in each active element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

Boolean TRUE is any nonzero value in a source, and one in a result element. Boolean FALSE is always zero.

It has encodings from 2 classes: Merging and Zeroing

    end;
end;
Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant of this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.115 CNTB, CNTD, CNTH, CNTW

Set scalar to multiple of predicate constraint element count

This instruction determines the number of active elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then places the result in the scalar destination.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 4 classes: Byte, Doubleword, Halfword, and Word

C8.2.119 CPY (immediate, zeroing)

Copy signed integer immediate to vector elements (zeroing)

This instruction copies a signed integer immediate to each Active element in the destination vector. Inactive elements in the destination vector register are set to zero.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

This instruction is used by the alias MOV (immediate, zeroing).

C8.2.120 CPY (immediate, merging)

Copy signed integer immediate to vector elements (merging)

This instruction copies a signed integer immediate to each Active element in the destination vector. Inactive elements in the destination vector register remain unmodified.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

This instruction is used by the alias MOV (immediate, merging).

This instruction is used by the pseudo-instruction FMOV (zero, predicated).

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.123 CTERMEQ, CTERMNE

Compare and terminate loop

This instruction detects termination conditions in serialized vector loops by testing whether the comparison between the scalar source operands holds true. If the comparison is not successful, the instruction tests the state of the !Last condition flag (C), which indicates whether the previous flag-setting predicate instruction selected the last element of the vector partition.

The Z and C condition flags are preserved by this instruction. The N and V condition flags are set as a pair to generate one of the following conditions for a subsequent conditional instruction:

Condition	N	V	Meaning
GE	0	0	Continue loop (compare failed and last element not selected)
LT	0	1	Terminate loop (last element selected)
LT	1	0	Terminate loop (compare succeeded)
GE	1	1	Never generated

The scalar source operands are 32-bit or 64-bit general-purpose registers of the same size.

It has encodings from 2 classes: Equal and Not equal

Equal

C8.2.124 DECB, DECD, DECH, DECW (scalar)

Decrement scalar by multiple of predicate constraint element count

This instruction determines the number of active elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement the scalar destination.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 4 classes: Byte, Doubleword, Halfword, and Word

Byte

1x010	#uimm5
1xx00	#uimm5
11101	MUL4
11110	MUL3
11111	ALL

<imm>

Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the “imm4” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let count : integer = DecodePredCount(pat, esize);
let operand1 : bits(VL) = Z{}(dn);
var result : bits(VL);

for e = 0 to elements-1 do
    result[e*:esize] = operand1[e*:esize] - (count * imm);

end;
Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is CONSTRAINED UNPREDICTABLE:

- The MOVPRFX must be unpredicated.
- The MOVPRFX must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.127 DECP (vector)

Decrement vector by count of true predicate elements

This instruction determines the number of true elements in the source predicate and then uses the result to decrement all destination vector elements.

The predicate size specifier may be omitted in assembler source code, but this is deprecated and will be prohibited in a future release of the architecture.

SVE

(FEAT_SVE || FEAT_SME)

C8.2.128 DUP (immediate)

Broadcast signed immediate to vector elements (unpredicated)

This instruction unconditionally broadcasts the signed integer immediate into each element of the destination vector. This instruction is unpredicated.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

This instruction is used by the alias MOV (immediate, unpredicated).

This instruction is used by the pseudo-instruction FMOV (zero, unpredicated).

SVE

C8.2.130 DUP (indexed)

Broadcast indexed element to vector (unpredicated)

This instruction unconditionally broadcasts the indexed source vector element into each element of the destination vector. This instruction is unpredicated.

The immediate element index is in the range of 0 to 63 (bytes), 31 (halfwords), 15 (words), 7 (doublewords) or 3 (quadwords). Selecting an element beyond the accessible vector length causes the destination vector to be set to zero.

This instruction is used by the alias MOV (SIMD&FP scalar, unpredicated).

SVE

C8.2.133 EON

Bitwise exclusive-OR with inverted immediate (unpredicated)

This instruction performs a bitwise exclusive-OR between an inverted immediate and each 64-bit element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32, or 64 bits. This instruction is unpredicated.

This is a pseudo-instruction of EOR (immediate). This means:

- The encodings in this description are named to match the encodings of EOR (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of EOR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C8.2.136 EOR (vectors, predicated)

Bitwise exclusive-OR (predicated)

This instruction performs a bitwise exclusive-OR between the active elements of the first source vector and the corresponding elements of the second source vector, and destructively places the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

SVE

(FEAT_SVE || FEAT_SME)

```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.137 EOR (immediate)

Bitwise exclusive-OR with immediate (unpredicated)

This instruction performs a bitwise exclusive-OR between an immediate and each 64-bit element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32, or 64 bits. This instruction is unpredicated.

This instruction is used by the pseudo-instruction EON.

C8.2.141 EORS

Bitwise exclusive-OR predicates, setting the condition flags

This instruction performs a bitwise exclusive-OR between the active elements of the first source predicate and the corresponding elements of the second source predicate, and places the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This instruction is used by the alias NOTS.

Setting the condition flags

(FEAT_SVE || FEAT_SME)

C8.2.145 EXT

Extract vector from pair of vectors

This instruction copies the indexed byte up to the last byte of the first source vector to the bottom of the result vector, then fills the remainder of the result starting from the first byte of the second source vector. The result is destructively placed in the destination and first source vector, or constructively placed in the destination vector. This instruction is unpredicated.

An index that is greater than or equal to the vector length in bytes is treated as zero, resulting in the first source vector being copied to the result unchanged.

It has encodings from 2 classes: Constructive and Destructive

Constructive

(FEAT_SVE2 || FEAT_SME)

31 29	28 25	24 23	22	21	20 16	15 13	12 10	9 5	4 0
0 0 0	0 0 1 0	1 0	1	1	imm8h	0 0 0	imm8l	Zn	Zd

Encoding

```
EXT  <Zd>.B, { <Zn1>.B, <Zn2>.B }, #<imm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8;
let dst : integer = UInt(Zd);
let s1 : integer = UInt(Zn);
let s2 : integer = (s1 + 1) MOD 32;
let position : integer{} = UInt(imm8h::imm8l) * 8;
```

Destructive

(FEAT_SVE || FEAT_SME)

31 29	28 25	24 23	22	21	20 16	15 13	12 10	9 5	4 0
0 0 0	0 0 1 0	1 0	0	1	imm8h	0 0 0	imm8l	Zm	Zdn

Encoding

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Zn1>

Is the name of the first scalable vector register of the source multi-vector group, encoded in the “Zn” field.

<Zn2>

Is the name of the second scalable vector register of the source multi-vector group, encoded in the “Zn” field.

<imm>

Is the unsigned immediate operand, in the range 0 to 255, encoded in the “imm8h:imm8l” fields.

<Zdn>

Is the name of the first source and destination scalable vector register, encoded in the “Zdn” field.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(s1);
let operand2 : bits(VL) = Z{}(s2);
var result : bits(VL);

let concat : bits(VL*2) = operand2 :: operand1;

if position >= VL then
    result = concat[VL-1:0];
else
    result = concat[(position+VL)-1:position];
end;

Z{VL}(dst) = result;
```

Operational Information

For the Constructive variant:

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

For the Destructive variant:

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

The destructive variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the destructive variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.152 FACLE

Floating-point absolute compare less than or equal

This instruction compares active absolute values of floating-point elements in the first source vector being less than or equal to the corresponding absolute values of elements in the second source vector, and places the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction does not set the condition flags.

This is a pseudo-instruction of FAC<cc>. This means:

- The encodings in this description are named to match the encodings of FAC<cc>.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of FAC<cc> gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C8.2.157 FADDA

Floating-point add strictly-ordered reduction, accumulating in scalar

This instruction adds the floating-point values in a SIMD&FP scalar source and all active lanes of the vector source and destructively places the result in the SIMD&FP scalar source register. Vector elements are processed strictly in order from low to high, with the scalar source providing the initial value. Inactive elements in the source vector are ignored.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.161 FAMAX

Floating-point absolute maximum (predicated)

This instruction determines the maximum absolute value from active floating-point elements of the first source vector and the corresponding floating-point elements of the second source vector, and destructively places the results in the corresponding elements of the first source vector.

Regardless of the value of FPCR.AH, the behavior is as follows:

- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is the default NaN, with the sign bit set to 0.
- Denormalized inputs and results are never flushed to zero, as if FPCR.{FZ, FZ16, FIZ} are all 0.
- Denormalized inputs never generate an Input Denormal floating-point exception.

Inactive elements in the destination vector register remain unmodified.

Operational Information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.163 FCADD

Floating-point complex add (predicated)

This instruction adds the real and imaginary components of the active floating-point complex numbers from the first source vector to the complex numbers from the second source vector that have first been rotated by 90 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, equivalent to multiplying the complex numbers in the second source vector by ±j beforehand. The results are destructively placed in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

C8.2.164 FCLAMP

Floating-point clamp to minimum/maximum number

This instruction clamps each floating-point element in the destination vector to between the floating-point minimum value in the corresponding element of the first source vector and the floating-point maximum value in the corresponding element of the second source vector and destructively places the clamped results in the corresponding elements of the destination vector.

Regardless of the value of FPCR.AH, the behavior is as follows for each minimum number and maximum number operation:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is default NaN.

This instruction is unpredicated.

C8.2.167 FCMLA (vectors)

Floating-point complex multiply-add (predicated)

This instruction multiplies the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the floating-point complex numbers in the first source vector by the corresponding complex number in the second source vector rotated by 0, 90, 180, or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

This instruction then destructively adds the products to the corresponding components of the complex numbers in the addend and destination vector, without intermediate rounding.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element. Inactive elements in the destination vector register remain unmodified.

Operational Information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is CONSTRAINED UNPREDICTABLE:

- The MOVPRFX can be predicated or unpredicated.
- A predicated MOVPRFX must use the same governing predicate register as this instruction.
- A predicated MOVPRFX must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The MOVPRFX must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.168 FCMLA (indexed)

Floating-point complex multiply-add by indexed element

This instruction multiplies the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the floating-point complex numbers in each 128-bit segment of the first source vector by the specified complex number in the corresponding the second source vector segment rotated by 0, 90, 180, or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

This instruction then destructively adds the products to the corresponding components of the complex numbers in the addend and destination vector, without intermediate rounding.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

The complex numbers within the second source vector are specified using an immediate index that selects the same complex number position within each 128-bit vector segment. The index range is from 0 to one less than the number of complex numbers per 128-bit segment. This instruction is unpredicated.

It has encodings from 2 classes: Half-precision and Single-precision

Half-precision

C8.2.169 FCMLE (vectors)

Floating-point compare less than or equal to vector

This instruction compares active floating-point elements in the first source vector being less than or equal to the corresponding elements in the second source vector, and places the boolean results of the comparison in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction does not set the condition flags.

This is a pseudo-instruction of FCM<cc> (vectors). This means:

- The encodings in this description are named to match the encodings of FCM<cc> (vectors).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of FCM<cc> (vectors) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<const>

Is a floating-point immediate value expressible as $\pm n \div 16 \times 2^r$, where n and r are integers such that $16 \leq n \leq 31$ and $-3 \leq r \leq 4$, i.e. a normalized binary floating-point encoding with 1 sign bit, 3-bit exponent, and 4-bit fractional part, encoded in the “imm8” field.

Alias Conditions

Alias	Is preferred when
FMOV (immediate, predicated)	Unconditionally

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
var result : bits(VL) = Z{}(d);

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        result[e*:esize] = imm;
    end;
end;

Z{VL}(d) = result;
```

Operational Information

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is CONSTRAINED UNPREDICTABLE:

- The MOVPRFX can be predicated or unpredicated.
- A predicated MOVPRFX must use the same governing predicate register as this instruction.
- A predicated MOVPRFX must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The MOVPRFX must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.172 FCVT

Floating-point convert (predicated)

This instruction converts the size and precision of each active floating-point element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

Since the input and result types have a different size the smaller type is held unpacked in the least significant bits of elements of the larger size. When the input is the smaller type the upper bits of each source element are ignored. When the result is the smaller type the results are zero-extended to fill each destination element.

It has encodings from 12 classes: Half-precision to single-precision, merging, Half-precision to single-precision, zeroing, Half-precision to double-precision, merging, Half-precision to double-precision, zeroing, Single-precision to half-precision, merging, Single-precision to half-precision, zeroing, Single-precision to double-precision, merging, Single-precision to double-precision, zeroing, Double-precision to half-precision, merging, Double-precision to half-precision, zeroing, Double-precision to single-precision, merging, and Double-precision to single-precision, zeroing

C8.2.176 FCVTNT (unpredicated)

Single-precision convert to interleaved 8-bit floating-point (top)

This instruction converts each single-precision element of the pair of source vectors to 8-bit floating-point while scaling the value by $2^{SInt(FPMR.NSCALE)}$, and places the two-way interleaved results in the corresponding odd-numbered 8-bit elements of the destination vector, leaving the even-numbered elements unchanged. The 8-bit floating-point encoding format is selected by `FPMR.F8D`.

This instruction is unpredicated.

C8.2.178 FCVTX

Double-precision convert to single-precision, rounding to odd (predicated)

This instruction converts active double-precision elements from the source vector to single-precision, rounding to Odd, and places the results in the even-numbered 32-bit elements of the destination vector, while setting the odd-numbered elements to zero. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

Rounding to Odd (aka Von Neumann rounding) permits a two-step conversion from double-precision to half-precision without incurring intermediate rounding errors.

It has encodings from 2 classes: Double-precision to single-precision, merging and Double-precision to single-precision, zeroing

Operational Information

For the Double-precision to single-precision, merging variant:

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant of this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.180 FCVTZS

Floating-point convert to signed integer, rounding toward zero (predicated)

This instruction converts to the signed integer nearer to zero from each active floating-point element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

If the input and result types have a different size the smaller type is held unpacked in the least significant bits of elements of the larger size. When the input is the smaller type the upper bits of each source element are ignored. When the result is the smaller type the results are sign-extended to fill each destination element.

It has encodings from 14 classes: Half-precision to 16-bit, merging, Half-precision to 16-bit, zeroing, Half-precision to 32-bit, merging, Half-precision to 32-bit, zeroing, Half-precision to 64-bit, merging, Half-precision to 64-bit, zeroing, Single-precision to 32-bit, merging, Single-precision to 32-bit, zeroing, Single-precision to 64-bit, merging, Single-precision to 64-bit, zeroing, Double-precision to 32-bit, merging, Double-precision to 32-bit, zeroing, Double-precision to 64-bit, merging, and Double-precision to 64-bit, zeroing

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let element : bits(esize) = operand[e*:esize];
        let res : bits(d_esize) = FPToFixed{d_esize, s_esize}(element[s_esize-1:0], 0, unsigned,
                                                                FPCR(), rounding);
        result[e*:esize] = Extend{esize}(res, unsigned);
    end;
end;

Z{VL}(d) = result;
```

Operational Information

For the Half-precision to 16-bit, merging, Half-precision to 32-bit, merging, Half-precision to 64-bit, merging, Single-precision to 32-bit, merging, Single-precision to 64-bit, merging, Double-precision to 32-bit, merging, Double-precision to 64-bit, merging variants:

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant of this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.181 FCVTZU

Floating-point convert to unsigned integer, rounding toward zero (predicated)

This instruction converts to the unsigned integer nearer to zero from each active floating-point element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

If the input and result types have a different size the smaller type is held unpacked in the least significant bits of elements of the larger size. When the input is the smaller type the upper bits of each source element are ignored. When the result is the smaller type the results are zero-extended to fill each destination element.

It has encodings from 14 classes: Half-precision to 16-bit, merging, Half-precision to 16-bit, zeroing, Half-precision to 32-bit, merging, Half-precision to 32-bit, zeroing, Half-precision to 64-bit, merging, Half-precision to 64-bit, zeroing, Single-precision to 32-bit, merging, Single-precision to 32-bit, zeroing, Single-precision to 64-bit, merging, Single-precision to 64-bit, zeroing, Double-precision to 32-bit, merging, Double-precision to 32-bit, zeroing, Double-precision to 64-bit, merging, and Double-precision to 64-bit, zeroing

C8.2.184 FDOT (4-way, vectors)

8-bit floating-point dot product to single-precision

This instruction calculates the fused sum-of-products of a group of four 8-bit floating-point values held in each 32-bit element of the first source and second source vectors. The single-precision sum-of-products are scaled by $2^{-\mathrm{UInt(FPMR.LSCALE)}}$, before being destructively added without intermediate rounding to the corresponding single-precision elements of the destination vector.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

C8.2.185 FDOT (4-way, indexed)

8-bit floating-point dot product by indexed element to single-precision

This instruction calculates the fused sum-of-products of a group of four 8-bit floating-point values held in each 32-bit element of the first source vector and a group of four 8-bit floating-point values in an indexed 32-bit element of the second source vector. The single-precision sum-of-products are scaled by $2^{-\mathrm{UInt(FPMR.LSCALE)}}$, before being destructively added without intermediate rounding to the corresponding single-precision elements of the destination vector.

The 8-bit floating-point groups within the second source vector are specified using an immediate index that selects the same group position within each 128-bit vector segment. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

C8.2.189 FDOT (2-way, indexed, FP16 to FP32)

Half-precision dot product by indexed element to single-precision

This instruction calculates the fused sum-of-products of a pair of half-precision values held in each 32-bit element of the first source vector and a pair of half-precision values in an indexed 32-bit element of the second source vector, without intermediate rounding, and then destructively adds the single-precision sum-of-products to the corresponding single-precision element of the destination vector.

The half-precision pairs within the second source vector are specified using an immediate index that selects the same pair position within each 128-bit vector segment. The index range is from 0 to 3.

This instruction is unpredicated.

C8.2.191 FEXPA

Floating-point exponential accelerator

This instruction calculates an exponentiation acceleration operation on each floating-point element in the source vector, where the result sign is zero, the result exponent field is copied from a set of significant bits of the input fraction, and the result fraction is inserted from a lookup table indexed by the least-significant input fraction bits, and returns each result in the corresponding element of the destination vector.

This instruction is fully defined by its bit-manipulation semantics, does not generate floating-point exceptions, and does not guarantee NaN propagation.

For double-precision variants, the result element exponent is copied from the source element bits<16:6>, and the result fraction is set based on the source element to the rounded value of $2^{52} \times (2^{bits<5:0>/64} - 1)$.

For single-precision variants, the result element exponent is copied from the source element bits<13:6>, and the result fraction is set based on the source element to the rounded value of $2^{23} \times (2^{bits<5:0>/64} - 1)$.

For half-precision variants, the result element exponent is copied from the source element bits<9:5>, and the result fraction is set based on the source element to the rounded value of $2^{10} \times (2^{bits<4:0>/32} - 1)$.

This instruction is unpredicated.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled, or FEAT_SSVE_FEXPA is implemented.

Note

For a double-precision input value x in the range 70,368,744,177,655 <= x < 70,368,744,179,711, the operation performed by this instruction is equivalent to calculating $2^{x-70,368,744,178,687}$.
For a single-precision input value x in the range 131,073 <= x < 131,327, the operation performed by this instruction is equivalent to calculating $2^{x-131,199}$.
For a half-precision input value x in the range 33 <= x < 63, the operation performed by this instruction is equivalent to calculating 2^{x-47}.

C8.2.193 FLOGB

Floating-point base 2 logarithm as integer

This instruction returns the signed integer base 2 logarithm of each floating-point input element |x| after normalization.

This is the unbiased exponent of x used in the representation of the floating-point value, such that, for positive x, x = significand $\times$ $2^{exponent}$.

The integer results are placed in elements of the destination vector that have the same width (esize) as the floating-point input elements:

- If x is normal, the result is the base 2 logarithm of x.
- If x is subnormal, the result corresponds to the normalized representation.
- If x is infinite, the result is $2^{(esize-1)}$-1.
- If x is ±0.0 or NaN, the result is -$2^{(esize-1)}$.

Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

It has encodings from 2 classes: Merging and Zeroing

Merging

C8.2.195 FMAX (immediate)

Floating-point maximum with immediate (predicated)

This instruction determines the maximum of an immediate and each active floating-point element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate may take the value +0.0 or +1.0 only.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if the element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if the element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both the element and the immediate are zeros, regardless of the sign of either zero, the result is the immediate.
- If the element is a NaN, regardless of the value of FPCR.DN, the result is the immediate.

Inactive elements in the destination vector register remain unmodified.

C8.2.196 FMAX (vectors)

Floating-point maximum (predicated)

This instruction determines the maximum of active floating-point elements of the first source vector and the corresponding floating-point elements of the second source vector, and destructively places the results in the corresponding elements of the first source vector.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

Inactive elements in the destination vector register remain unmodified.

C8.2.197 FMAXNM (immediate)

Floating-point maximum number with immediate (predicated)

This instruction determines the maximum number value of an immediate and each active floating-point element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate may take the value +0.0 or +1.0 only.

Regardless of the value of FPCR.AH, the behavior is as follows:

- Negative zero compares less than positive zero.
- If the element is a quiet NaN, the result is the immediate value.
- When FPCR.DN is 0, if the element is a signaling NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if the element is a signaling NaN, the result is default NaN.

Inactive elements in the destination vector register remain unmodified.

C8.2.203 FMAXQV

Floating-point maximum reduction of quadword vector segments

This instruction calculates a floating-point maximum of the same element numbers from each 128-bit source vector segment using a recursive pairwise reduction, and places each result into the corresponding element number of the 128-bit SIMD&FP destination register. Inactive elements in the source vector are treated as -Infinity.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either value is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both values are zeros, regardless of the sign of either zero, the result is the second value.
- If either value is a NaN, regardless of the value of FPCR.DN, the result is the second value.

C8.2.205 FMIN (immediate)

Floating-point minimum with immediate (predicated)

This instruction determines the minimum of an immediate and each active floating-point element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate may take the value +0.0 or +1.0 only.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if the element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if the element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both the element and the immediate are zeros, regardless of the sign of either zero, the result is the immediate.
- If the element is a NaN, regardless of the value of FPCR.DN, the result is the immediate.

Inactive elements in the destination vector register remain unmodified.

C8.2.210 FMINNMQV

Floating-point minimum number recursive reduction of quadword vector segments

This instruction calculates a floating-point minimum number of the same element numbers from each 128-bit source vector segment using a recursive pairwise reduction, and places each result into the corresponding element number of the 128-bit SIMD&FP destination register. Inactive elements in the source vector are treated as the default NaN.

Regardless of the value of FPCR.AH, the behavior is as follows:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is default NaN.

C8.2.212 FMINP

Floating-point minimum pairwise

This instruction calculates the minimum value of each pair of adjacent floating-point elements within each source vector, and interleaves the results from corresponding lanes. The interleaved result values are destructively placed in the first source vector.

When FPCR.AH is 0, the behavior is as follows for each pairwise operation:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows for each pairwise operation:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

C8.2.216 FMLA (indexed)

Floating-point fused multiply-add by indexed element

This instruction multiplies all floating-point elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively added without intermediate rounding to the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment. This instruction is unpredicated.

It has encodings from 3 classes: Half-precision, Single-precision, and Double-precision

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “Half-precision” and “Single-precision” variants: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “Double-precision” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “Half-precision” variant: is the immediate index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “Single-precision” variant: is the immediate index, in the range 0 to 3, encoded in the “i2” field.

For the “Double-precision” variant: is the immediate index, in the range 0 to 1, encoded in the “i1” field.

C8.2.217 FMLALB (vectors, FP8 to FP16)

8-bit floating-point multiply-add to half-precision (bottom)

This instruction widens the even 8-bit elements in the first and second source vectors to half-precision format and multiplies the corresponding elements. The intermediate products are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$ before being destructively added without intermediate rounding to the half-precision elements of the destination vector that overlap with the corresponding 8-bit floating-point elements in the source vectors. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

C8.2.224 FMLALLBT (indexed)

8-bit floating-point multiply-add by indexed element to single-precision (bottom top)

This instruction widens the second 8-bit element of each 32-bit container in the first source vector and the indexed element from the corresponding 128-bit segment in the second source vector to single-precision format and multiplies the corresponding elements. The intermediate products are scaled by $2^{-\mathrm{UInt(FPMR.LSCALE)}}$ before being destructively added without intermediate rounding to the single-precision elements of the destination vector that overlap with the corresponding 8-bit floating-point elements in the first source vector. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

C8.2.231 FMLALT (vectors, FP16 to FP32)

Half-precision multiply-add to single-precision (top)

This instruction widens the odd-numbered half-precision elements in the first source vector and the corresponding elements in the second source vector to single-precision format and then destructively multiplies and adds these values without intermediate rounding to the single-precision elements of the destination vector that overlap with the corresponding half-precision elements in the source vectors. This instruction is unpredicated.

C8.2.233 FMLS (vectors)

Floating-point fused multiply-subtract (predicated)

This instruction multiplies the active floating-point elements of the first source vector by the corresponding floating-point elements of the second source vector, and subtracts the result from elements of the third source (addend) vector without intermediate rounding. The results are destructively placed in the destination and third source (addend) vector. Inactive elements in the destination vector register remain unmodified.

C8.2.234 FMLS (indexed)

Floating-point fused multiply-subtract by indexed element

This instruction multiplies all floating-point elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively subtracted without intermediate rounding from the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment. This instruction is unpredicated.

It has encodings from 3 classes: Half-precision, Single-precision, and Double-precision

Half-precision

(FEAT_SVE || FEAT_SME)

31–29	28–25	24	23	22	21	20–19	18–16	15–12	11	10	9–5	4–0

C8.2.238 FMLSLT (indexed)

Half-precision multiply-subtract by indexed element from single-precision (top)

This instruction widens the odd-numbered half-precision elements in the first source vector and the indexed element from the corresponding 128-bit segment in the second source vector to single-precision format and then destructively multiplies and subtracts these values without intermediate rounding from the single-precision elements of the destination vector that overlap with the corresponding half-precision elements in the first source vector. This instruction is unpredicated.

Single-precision

C8.2.239 FMMLA (widening, FP8 to FP16)

8-bit floating-point matrix multiply-accumulate to half-precision

This instruction multiplies the 2×4 matrix of 8-bit floating-point values held in each 64-bit segment of the first source vector by the 4×2 matrix of 8-bit floating-point values in the corresponding segment of the second source vector. The intermediate half-precision results calculated as a fused sum-of-products using four adjacent 8-bit floating-point values from each of the source vectors, are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$, before being destructively added without intermediate rounding to the 2×2 half-precision matrix in the corresponding segment of the destination vector. This is equivalent to accumulating 4-way dot product per destination element.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.242 FMMLA (non-widening)

Floating-point matrix multiply-accumulate

This instruction supports single-precision and double-precision data types in a 2x2 matrix contained in segments of 128 or 256 bits, respectively. It multiplies the 2x2 matrix in each segment of the first source vector by the 2x2 matrix in the corresponding segment of the second source vector. The intermediate products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the 2x2 matrix held in the corresponding segment of the addend and destination vector. This is equivalent to performing a 2-way dot product per destination element. This instruction is unpredicated. The single-precision variant is vector length agnostic. The double-precision variant requires that the Effective SVE vector length is at least 256 bits.

ID_AA64ZFR0_EL1.F32MM indicates whether the single-precision variant is implemented.

ID_AA64ZFR0_EL1.F64MM indicates whether the double-precision variant is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit element and 64-bit element

32-bit element

C8.2.247 FMSB

Floating-point fused multiply-subtract to multiplicand (predicated)

This instruction multiplies the active floating-point elements of the first source vector by the corresponding floating-point elements of the second source vector, and subtracts the result from elements of the third (addend) vector without intermediate rounding. The results are destructively placed in the destination and first source (multiplicand) vector. Inactive elements in the destination vector register remain unmodified.

C8.2.251 FMUL (indexed)

Floating-point multiply by indexed element

This instruction multiplies all floating-point elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The results are placed in the corresponding elements of the destination vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment. This instruction is unpredicated.

It has encodings from 3 classes: Half-precision, Single-precision, and Double-precision

Half-precision

C8.2.252 FMULX

Floating-point multiply extended (predicated)

This instruction multiplies active floating-point elements of the first source vector by the corresponding floating-point elements of the second source vector except that $\infty \times 0.0$ gives 2.0 instead of NaN, and destructively places the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

The instruction can be used with `FRECPX` to safely convert arbitrary elements in mathematical vector space to unit vectors or direction vectors with length 1.

end;

Z{VL}(d) = result;
```

Operational Information

For the Merging variant:

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant of this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.267 FRSQRTS

Floating-point reciprocal square root step (unpredicated)

This instruction multiplies the floating-point elements of the first source vector by the corresponding floating-point elements of the second source vector, subtracts the products from 3.0 and divides the results by 2.0 without any intermediate rounding, and places the results in the corresponding elements of the destination vector. This instruction is unpredicated.

This instruction can be used to perform a single Newton-Raphson iteration for calculating the reciprocal square root of a vector of floating-point values.

C8.2.275 FTMAD

Floating-point trigonometric multiply-add coefficient

This instruction multiplies each element of the first source vector by the absolute value of the corresponding element of the second source vector and performs a fused addition of each product with a value obtained from a table of hard-wired coefficients, and destructively places the results in the first source vector. This instruction is unpredicated.

The coefficients are selected by a combination of the sign bit in the second source element and an immediate index in the range 0 to 7.

`FTMAD` can be combined with `FTSMUL` and `FTSSEL` to calculate values for sin(x) and cos(x). For more information, see `FTSMUL`. The coefficients are intended to provide accurate results for `FTSMUL` inputs in the range $-\pi/4 < x \leq \pi/4$.

For double-precision operations, the coefficients are:

element2<63>	Index	Hexadecimal	Approximate value
0	0	`0x3FF0000000000000`	1
0	1	`0xBFC5555555555543`	-1/3!
0	2	`0x3F8111111110F30C`	1/5!
0	3	`0xBF2A01A019B92FC6`	-1/7!
0	4	`0x3EC71DE351F3D22B`	1/9!
0	5	`0xBE5AE5E2B60F7B91`	-1/11!
0	6	`0x3DE5D8408868552F`	1/13!
0	7	`0x0000000000000000`	0
1	0	`0x3FF0000000000000`	1
1	1	`0xBFE0000000000000`	-1/2!
1	2	`0x3FA5555555555536`	1/4!
1	3	`0xBF56C16C16C13A0B`	-1/6!
1	4	`0x3EFA01A019B1E8D8`	1/8!
1	5	`0xBE927E4F7282F468`	-1/10!
1	6	`0x3E21EE96D2641B13`	1/12!
1	7	`0xBDA8F76380FBB401`	-1/14!

For single-precision operations, the coefficients are:

element2<63>	Index	Hexadecimal	Approximate value
0	0	`0x3F800000`	1
0	1	`0xBE2AAAAB`	-1/3!
0	2	`0x3C088886`	1/5!
0	3	`0xB95008B9`	-1/7!
0	4	`0x36369D6D`	1/9!
0	5	`0x00000000`	0
0	6	`0x00000000`	0

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

element2<63>	Index	Hexadecimal	Approximate value
0	7	0x00000000	0
1	0	0x3F800000	1
1	1	0xBF000000	-1/2!
1	2	0x3D2AAAA6	1/4!
1	3	0xBAB60705	-1/6!
1	4	0x37CD37CC	1/8!
1	5	0x00000000	0
1	6	0x00000000	0
1	7	0x00000000	0

For half-precision operations, the coefficients are:

element2<63>	Index	Hexadecimal	Approximate value
0	0	0x3C00	1
0	1	0xB155	-1/3!
0	2	0x2030	1/5!
0	3	0x0000	0
0	4	0x0000	0
0	5	0x0000	0
0	6	0x0000	0
0	7	0x0000	0

C8.2.276 FTSMUL

Floating-point trigonometric starting value

This instruction multiplies each element of the first source vector by itself, replaces the sign-bit of each product with the least-significant bit of the corresponding element of the second source vector, and places the results in the destination vector. This instruction is unpredicated.

`FTSMUL` can be combined with `FTMAD` and `FTSSEL` to calculate values for sin(x) and cos(x). The use of the second operand is consistent with it holding an integer corresponding to the desired sine-wave quadrant when used in conjunction with `FTMAD`.

Note: `FTSMUL`, `FTMAD`, and `FTSSEL` can be used to calculate values for sin(k) and correspondingly cos(k-π/2) using an intermediate value x, in the range $-\pi/4 < x \leq \pi/4$, and a quadrant q where $k = q\pi/2 + x$, using a Taylor Series approximation. `FTSMUL` can be used to calculate x^2, and to insert q<0> into the most-significant bit, indicating the desired odd versus even Taylor Series to be used in `FTMAD`. Repeated uses of `FTMAD` can be performed on this value with decreasing immediate index operands, to produce a single accumulated value approximating the Taylor Series result with a single outstanding factor. `FTSSEL` can be used to apply the final factor of x, 1.0, -x, or -1.0, dependent on the corresponding sine-wave quadrant q<1:0>, to produce a final sin() or cos() value.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.277 FTSSEL

Floating-point trigonometric select coefficient

This instruction selects either the element of the first source vector or the value 1.0, based on bit<0> of the corresponding element of the second source element, negates the result if bit<1> of the corresponding element of the second source element is set, and places the results in the destination vector. This instruction is unpredicated.

`FTSSEL` can be combined with `FTSMUL` and `FTMAD` to calculate values for sin(k) and cos(k). For more information, see `FTSMUL`. The use of the second operand is consistent with it holding an integer corresponding to the desired sine-wave quadrant.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.279 HISTSEG

Count matching elements in vector segments

This instruction compares each 8-bit byte element of the first source vector with all of the elements in the corresponding 128-bit segment of the second source vector and places the count of matching elements in the corresponding element of the destination vector. This instruction is unpredicated.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

SVE2

(FEAT_SVE2)

C8.2.280 INCB, INCD, INCH, INCW (scalar)

Increment scalar by multiple of predicate constraint element count

This instruction determines the number of active elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 4 classes: Byte, Doubleword, Halfword, and Word

11110	MUL3
11111	ALL

<imm>

Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the “imm4” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let count : integer = DecodePredCount(pat, esize);
let operand1 : bits(VL) = Z{}(dn);
var result : bits(VL);

for e = 0 to elements-1 do
    result[e*:esize] = operand1[e*:esize] + (count * imm);

end;
Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a MOVPRFX instruction. The MOVPRFX must conform to all of the following requirements, otherwise the behavior of the MOVPRFX and this instruction is CONSTRAINED UNPREDICTABLE:

- The MOVPRFX must be unpredicated.
- The MOVPRFX must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

Encoding

```
INDEX  <Zd>.<T>, <R><n>, #<imm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Rn);
let d : integer = UInt(Zd);
let imm : integer = SInt(imm5);
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<R>

Is a width specifier, encoded in “size”:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

size	<R>
00	W
01	W
10	W
11	X

<n>

Is the number [0-30] of the source general-purpose register or the name ZR (31), encoded in the “Rn” field.

<imm>

Is the signed immediate operand, in the range -16 to 15, encoded in the “imm5” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(esize) = X{}(n);
let element1 : integer = SInt(operand1);
var result : bits(VL);

for e = 0 to elements-1 do
    let index : integer = element1 + e * imm;
    result[e*:esize] = index[esize-1:0];
end;

Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

Non-Confidential

C8.2.287 INDEX (scalars)

Create index starting from and incremented by general-purpose register

This instruction populates the destination vector by setting the first element to the first signed scalar integer operand and monotonically incrementing the value by the second signed scalar integer operand for each subsequent element. The scalar source operands are general-purpose registers in which only the least significant bits corresponding to the vector element size are used and any remaining bits are ignored. This instruction is unpredicated.

SVE

(FEAT_SVE || FEAT_SME)

31 29	28 25	24	23 22	21	20 16	15 12	11 10	9 5	4 0
0 0 0	0 0 1 0	0	size	1	Rm	0 1 0 0	1 1	Rn	Zd

Encoding

```
INDEX  <Zd>.<T>, <R><n>, <R><m>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let d : integer = UInt(Zd);
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<R>

Is a width specifier, encoded in “size”:

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let dest : bits(VL) = Z{}(dn);
let src : bits(esize) = X{}(m);
Z{VL}(dn) = dest[(VL-esize)-1:0] :: src;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.290 LASTA (scalar)

Extract element after last to general-purpose register

This instruction extracts the element after the Last active element to a general-purpose register. If there is an Active element, the element after the Last active element modulo the number of elements from the final source vector register is extracted. If there are no Active elements, element zero is extracted. Then the extracted element is zero-extended and placed in the destination general-purpose register.

C8.2.295 LD1B (scalar plus immediate, consecutive registers)

Contiguous load of bytes to multiple consecutive vectors (immediate index)

This instruction performs a contiguous load of unsigned bytes to elements of two or four consecutive vector registers from the memory address generated by a 64-bit scalar base and immediate index that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2 || FEAT_SVE2p1)

31	30	29	28	25	24	23	22	20	19	16	15	14	13	12	10	9	5	4	1	0
1	0	1	0 0 0 0		0	0	1 0 0		imm4		0	0	0	PNg		Rn		Zt		0
												msz								N

Encoding

```
LD1B  { <Zt1>.B-<Zt2>.B }, <PNg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) && !IsFeatureImplemented(FEAT_SVE2p1) then
    EndOfDecode(Decode_UNDEF);
end;
let n : integer = UInt(Rn);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 2;
let t : integer = UInt(Zt::'0');
let esize : integer{} = 8;
let offset : integer = SInt(imm4);
```

Four registers

(FEAT_SME2 || FEAT_SVE2p1)

31	30	29	28	25	24	23	22	20	19	16	15	14	13	12	10	9	5	4	2	1	0

Non-Confidential

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) && !IsFeatureImplemented(FEAT_SVE2p1) then
    EndOfDecode(Decode_UNDEF);
end;
let n : integer = UInt(Rn);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 4;
let t : integer = UInt(Zt::'00');
let esize : integer{} = 8;
let offset : integer = SInt(imm4);
```

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 2.

For the “Four registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 4.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” times 2 plus 1.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded as “imm4” times 2.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded as “imm4” times 4.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as “Zt” times 4 plus 3.

Operation

```
if IsFeatureImplemented(FEAT_SVE2p1) then CheckSVEEnabled(); else CheckStreamingSVEEnabled(); end;

C8.2.296 LD1B (scalar plus scalar, consecutive registers)

Contiguous load of bytes to multiple consecutive vectors (scalar index)

This instruction performs a contiguous load of unsigned bytes to elements of two or four consecutive vector registers from the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2 || FEAT_SVE2p1)

31	30	29	28–25	24	23	22	21	20–16	15	14	13	12–10	9–5	4–1	0
1	0	1	0 0 0 0	0	0	0	0	Rm	0	0	0	PNg	Rn	Zt	0
										msz					N

Encoding

```
LD1B  { <Zt1>.B-<Zt2>.B }, <PNg>/Z, [<Xn|SP>, <Xm>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) && !IsFeatureImplemented(FEAT_SVE2p1) then
    EndOfDecode(Decode_UNDEF);
end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 2;
let t : integer = UInt(Zt::'0');
let esize : integer{} = 8;
```

Four registers

(FEAT_SME2 || FEAT_SVE2p1)

31	30	29	28–25	24	23	22	21	20–16	15	14	13	12–10	9–5	4–2	1	0

```

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 2.

For the “Four registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 4.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” times 2 plus 1.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the general-purpose offset register, encoded in the “Rm” field.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as “Zt” times 4 plus 3.

Operation

C8.2.300 LD1B (scalar plus vector)

Gather load unsigned bytes to vector (vector index)

This instruction performs a gather load of unsigned bytes to Active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally sign-extended or zero-extended from 32 to 64 bits. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 32-bit unpacked unscaled offset, 32-bit unscaled offset, and 64-bit unscaled offset

32-bit unpacked unscaled offset

(FEAT_SVE)

31–29	28–25	24–23	22	21	20–16	15	14	13	12–10	9–5	4–0

Assembler Symbols

<Zt>

Is the name of the scalable vector register to be transferred, encoded in the “Zt” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Zm>

Is the name of the offset scalable vector register, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<mod>

Is the index extend and shift specifier, encoded in “xs”:

xs	<mod>
0	UXTW
1	SXTW

Operation

```
CheckNonStreamingSVEEnabled();
let VL : integer{} = CurrentVL();

C8.2.305 LD1D (scalar plus scalar, single register)

Contiguous load unsigned doublewords to vector (scalar index)

This instruction performs a contiguous load of unsigned doublewords to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 8 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

The 128-bit element variant is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 64-bit element and 128-bit element

64-bit element

Assembler Symbols

<Zt>

Is the name of the scalable vector register to be transferred, encoded in the “Zt” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the base scalable vector register, encoded in the “Zn” field.

<imm>

Is the optional unsigned immediate byte offset, a multiple of 2 in the range 0 to 62, defaulting to 0, encoded in the “imm5” field.

Operation

```
CheckNonStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
var base : bits(VL);
var result : bits(VL);
var data : bits(msize);
let mbytes : integer{} = msize DIV 8;
let contiguous : boolean = FALSE;
let nontemporal : boolean = FALSE;
let predicated : boolean = TRUE;
let tagchecked : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescSVE(MemOp_LOAD, nontemporal, contiguous,
                                                  predicated, tagchecked);

if AnyActiveElement{PL}(mask, esize) then
    base = Z{VL}(n);
end;

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let baddr : bits(64) = ZeroExtend{}(base[e*:esize]);
        let addr : bits(64) = AddressAdd(baddr, offset * mbytes, accdesc);

C8.2.310 LD1H (scalar plus immediate, single register)

Contiguous load unsigned halfwords to vector (immediate index)

This instruction performs a contiguous load of unsigned halfwords to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 3 classes: 16-bit element, 32-bit element, and 64-bit element

C8.2.312 LD1H (scalar plus vector)

Gather load unsigned halfwords to vector (vector index)

This instruction performs a gather load of unsigned halfwords to Active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then optionally multiplied by 2. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 6 classes: 32-bit scaled offset, 32-bit unpacked scaled offset, 32-bit unpacked unscaled offset, 32-bit unscaled offset, 64-bit scaled offset, and 64-bit unscaled offset

32-bit scaled offset

C8.2.314 LD1RB

Load and broadcast unsigned byte to vector

This instruction loads a single unsigned byte from a memory address generated by a 64-bit scalar base address plus an immediate offset that is in the range 0 to 63.

The loaded data is broadcast into all Active elements of the destination vector, setting the Inactive elements to zero. If all elements are inactive, then the instruction will not perform a read from Device memory or cause a data abort.

It has encodings from 4 classes: 8-bit element, 16-bit element, 32-bit element, and 64-bit element

8-bit element

(FEAT_SVE || FEAT_SME)

31–29	28–25	24–23	22	21–16	15	14–13	12–10	9–5	4–0
1 0 0	0 0 1 0	0 0	1	imm6	1	0 0	Pg	Rn	Zt
		dtypeh				dtypel			

Encoding

```
LD1RB  { <Zt>.B }, <Pg>/Z, [<Xn|SP>{, #<imm>}]
```

Decode for this encoding

```

C8.2.317 LD1ROB (scalar plus immediate)

Contiguous load and replicate thirty-two bytes (immediate index)

This instruction loads thirty-two contiguous bytes to elements of a 256-bit (octaword) vector from the memory address generated by a 64-bit scalar base address and immediate index that is a multiple of 32 in the range -256 to +224 added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero.

The resulting 256-bit vector is then replicated to fill the destination vector. The instruction requires that the Effective SVE vector length is at least 256 bits.

Only the first thirty-two predicate elements are used and higher numbered predicate elements are ignored.

ID_AA64ZFR0_EL1.F64MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.320 LD1ROD (scalar plus scalar)

Contiguous load and replicate four doublewords (scalar index)

This instruction loads four contiguous doublewords to elements of a 256-bit (octaword) vector from the memory address generated by a 64-bit scalar base address and scalar index that is multiplied by 8 and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero.

The resulting 256-bit vector is then replicated to fill the destination vector. The instruction requires that the Effective SVE vector length is at least 256 bits.

Only the first four predicate elements are used and higher numbered predicate elements are ignored.

ID_AA64ZFR0_EL1.F64MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.326 LD1RQB (scalar plus scalar)

Contiguous load and replicate sixteen bytes (scalar index)

This instruction loads sixteen contiguous bytes to elements of a short, 128-bit (quadword) vector from the memory address generated by a 64-bit scalar base address and scalar index that is added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero. The resulting short vector is then replicated to fill the long destination vector. Only the first sixteen predicate elements are used and higher numbered predicate elements are ignored.

SVE

(FEAT_SVE || FEAT_SME)

31 29	28 25	24 23	22 21	20 16	15 13	12 10	9 5	4 0

C8.2.333 LD1RSB

Load and broadcast signed byte to vector

This instruction loads a single signed byte from a memory address generated by a 64-bit scalar base address plus an immediate offset that is in the range 0 to 63.

The loaded data is broadcast into all Active elements of the destination vector, setting the Inactive elements to zero. If all elements are inactive, then the instruction will not perform a read from Device memory or cause a data abort.

It has encodings from 3 classes: 16-bit element, 32-bit element, and 64-bit element

16-bit element

(FEAT_SVE || FEAT_SME)

C8.2.338 LD1SB (scalar plus immediate)

Contiguous load signed bytes to vector (immediate index)

This instruction performs a contiguous load of signed bytes to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 3 classes: 16-bit element, 32-bit element, and 64-bit element

16-bit element

C8.2.344 LD1SH (scalar plus vector)

Gather load signed halfwords to vector (vector index)

This instruction performs a gather load of signed halfwords to Active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then optionally multiplied by 2. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 6 classes: 32-bit scaled offset, 32-bit unpacked scaled offset, 32-bit unpacked unscaled offset, 32-bit unscaled offset, 64-bit scaled offset, and 64-bit unscaled offset

Assembler Symbols

<Zt>

Is the name of the scalable vector register to be transferred, encoded in the “Zt” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Zm>

Is the name of the offset scalable vector register, encoded in the “Zm” field.

<mod>

Is the index extend and shift specifier, encoded in “xs”:

xs	<mod>
0	UXTW
1	SXTW

Operation

```
CheckNonStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
var base : bits(64);
let mask : bits(PL) = P{}(g);
var offset : bits(VL);
var result : bits(VL);
var data : bits(msize);

C8.2.353 LD1W (scalar plus scalar, single register)

Contiguous load unsigned words to vector (scalar index)

This instruction performs a contiguous load of unsigned words to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 4 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

The 128-bit element variant is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 32-bit element, 64-bit element, and 128-bit element

32-bit element

C8.2.354 LD1W (scalar plus vector)

Gather load unsigned words to vector (vector index)

This instruction performs a gather load of unsigned words to Active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then optionally multiplied by 4. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 6 classes: 32-bit scaled offset, 32-bit unpacked scaled offset, 32-bit unpacked unscaled offset, 32-bit unscaled offset, 64-bit scaled offset, and 64-bit unscaled offset

32-bit scaled offset

C8.2.355 LD2B (scalar plus immediate)

Contiguous load two-byte structures to two vectors (immediate index)

This instruction performs a contiguous load of two-byte structures, each to the same element number in two vector registers from the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 2 in the range -16 to 14 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the two vector registers, or equivalently to the two consecutive bytes in memory that make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the two destination vector registers.

C8.2.357 LD2D (scalar plus immediate)

Contiguous load two-doubleword structures to two vectors (immediate index)

This instruction performs a contiguous load of two-doubleword structures, each to the same element number in two vector registers from the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 2 in the range -16 to 14 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the two vector registers, or equivalently to the two consecutive doublewords in memory that make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the two destination vector registers.

```

Assembler Symbols

<Zt1>

Is the name of the first scalable vector register to be transferred, encoded in the "Zt" field.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as "Zt" plus 1 modulo 32.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>

Is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded as "imm4" times 2.

Assembler Symbols

<Zt1>

Is the name of the first scalable vector register to be transferred, encoded in the "Zt" field.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as "Zt" plus 1 modulo 32.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>

Is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded as "imm4" times 2.

C8.2.364 LD2W (scalar plus scalar)

Contiguous load two-word structures to two vectors (scalar index)

This instruction performs a contiguous load of two-word structures, each to the same element number in two vector registers from the memory address generated by a 64-bit scalar base and a 64-bit scalar index register scaled by the element size (`LSL` option) and added to the base address. After each structure access the index value is incremented by two. The index register is not updated by the instruction.

Each predicate element applies to the same element number in each of the two vector registers, or equivalently to the two consecutive words in memory that make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the two destination vector registers.

Assembler Symbols

<Zt1>

Is the name of the first scalable vector register to be transferred, encoded in the "Zt" field.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as "Zt" plus 1 modulo 32.

<Zt3>

Is the name of the third scalable vector register to be transferred, encoded as "Zt" plus 2 modulo 32.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>

Is the optional signed immediate vector offset, a multiple of 3 in the range -24 to 21, defaulting to 0, encoded in the "imm4" field.

C8.2.370 LD3H (scalar plus scalar)

Contiguous load three-halfword structures to three vectors (scalar index)

This instruction performs a contiguous load of three-halfword structures, each to the same element number in three vector registers from the memory address generated by a 64-bit scalar base and a 64-bit scalar index register scaled by the element size (`LSL` option) and added to the base address. After each structure access the index value is incremented by three. The index register is not updated by the instruction.

Each predicate element applies to the same element number in each of the three vector registers, or equivalently to the three consecutive halfwords in memory that make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the three destination vector registers.

C8.2.376 LD4B (scalar plus scalar)

Contiguous load four-byte structures to four vectors (scalar index)

This instruction performs a contiguous load of four-byte structures, each to the same element number in four vector registers from the memory address generated by a 64-bit scalar base and a 64-bit scalar index register and added to the base address. After each structure access the index value is incremented by four. The index register is not updated by the instruction.

Each predicate element applies to the same element number in each of the four vector registers, or equivalently to the four consecutive bytes in memory that make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the four destination vector registers.

C8.2.381 LD4Q (scalar plus immediate)

Contiguous load four-quadword structures to four vectors (immediate index)

This instruction performs a contiguous load of four-quadword structures, each to the same element number in four vector registers from the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 4 in the range -32 to 28 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the four vector registers, or equivalently to the four consecutive quadwords in memory that make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the four destination vector registers.

C8.2.387 LDFF1B (scalar plus vector)

Gather load first-fault unsigned bytes to vector (vector index)

This instruction performs a gather load with first-faulting behavior of unsigned bytes to Active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally sign-extended or zero-extended from 32 to 64 bits. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 32-bit unpacked unscaled offset, 32-bit unscaled offset, and 64-bit unscaled offset

32-bit unpacked unscaled offset

(FEAT_SVE)

Encoding

```
LDFF1B  { <Zt>.D }, <Pg>/Z, [<Xn|SP>, <Zm>.D, <mod>]
```

Decode for this encoding

C8.2.389 LDFF1D (scalar plus scalar)

Contiguous load first-fault doublewords to vector (scalar index)

This instruction performs a contiguous load with first-faulting behavior of doublewords to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 8 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.391 LDFF1H (vector plus immediate)

Gather load first-fault unsigned halfwords to vector (immediate index)

This instruction performs a gather load with first-faulting behavior of unsigned halfwords to Active elements of a vector register from memory addresses generated by a vector base plus immediate index. The index is a multiple of 2 in the range 0 to 62. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit element and 64-bit element

32-bit element

C8.2.392 LDFF1H (scalar plus scalar)

Contiguous load first-fault unsigned halfwords to vector (scalar index)

This instruction performs a contiguous load with first-faulting behavior of unsigned halfwords to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 2 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 16-bit element, 32-bit element, and 64-bit element

16-bit element
