C9.2.72 FDOT (4-way, multiple and indexed vector)

Multi-vector 8-bit floating-point dot product by indexed element to single-precision

This instruction calculates the fused sum-of-products of a group of four 8-bit floating-point values held in the corresponding 32-bit elements of the two or four first source vectors and the indexed 32-bit element of the second source vector. The single-precision sum-of-products are scaled by $2^{-\text{UInt(FPMR.LSCALE)}}$, before being destructively added without intermediate rounding to the corresponding single-precision elements of the ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

The 8-bit floating-point groups within the second source vector are specified using an immediate index that selects the same group position within each 128-bit vector segment.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

C9.2.74 FDOT (4-way, multiple vectors)

Multi-vector 8-bit floating-point dot product to single-precision

This instruction calculates the fused sum-of-products of a group of four 8-bit floating-point values held in the corresponding 32-bit elements of the two or four first and second source vectors. The single-precision sum-of-products are scaled by $2^{-\text{UInt(FPMR.LSCALE)}}$, before being destructively added without intermediate rounding to the corresponding single-precision elements of the ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

C9.2.78 FDOT (2-way, multiple and indexed vector, FP16 to FP32)

Multi-vector half-precision dot product by indexed element to single-precision

This instruction calculates the fused sum-of-products of a pair of half-precision values held in the corresponding 32-bit elements of the two or four first source vectors and the indexed 32-bit element of the second source vector, without intermediate rounding. The single-precision sum-of-products are destructively added to the corresponding single-precision elements of the ZA single-vector groups.

The half-precision pairs within the second source vector are specified using an immediate index that selects the same pair position within each 128-bit vector segment. The element index range is from 0 to 3.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

```

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

For the “Two ZA single-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA single-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<index>

Is the immediate index of a pair of 16-bit elements within each 128-bit vector segment, in the range 0 to 3, encoded in the “i2” field.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV 32;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV 32;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m);
    let operand3 : bits(VL) = ZAvector{}(vec);

C9.2.81 FMAX (multiple and single vector)

Multi-vector floating-point maximum by vector

This instruction determines the maximum of floating-point elements of the second source vector and the corresponding floating-point elements of the two or four first source vectors and destructively places the results in the corresponding elements of the two or four first source vectors.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

Assembler Symbols

<Zdn1>

For the “Two registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4.

<T>

Is the size specifier, encoded in “size”:

size	<T>
01	H
10	S
11	D

<Zdn2>

Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2 plus 1.

<Zm1>

For the “Two registers” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zdn4>

Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4 plus 3.

<Zm4>

Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as “Zm” times 4 plus 3.

C9.2.89 FMLA (multiple and indexed vector)

Multi-vector floating-point fused multiply-add by indexed element

This instruction multiplies the indexed element of the second source vector by the corresponding floating-point elements of the two or four first source vectors and destructively adds these values without intermediate rounding to the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 6 classes: Two ZA single-vectors of half-precision elements, Two ZA single-vectors of single-precision elements, Two ZA single-vectors of double-precision elements, Four ZA single-vectors of half-precision elements, Four ZA single-vectors of single-precision elements, and Four ZA single-vectors of double-precision elements

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

For the “Two ZA single-vectors of double-precision elements”, “Two ZA single-vectors of half-precision elements”, and “Two ZA single-vectors of single-precision elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA single-vectors of double-precision elements”, “Four ZA single-vectors of half-precision elements”, and “Four ZA single-vectors of single-precision elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<index>

For the “Four ZA single-vectors of half-precision elements” and “Two ZA single-vectors of half-precision elements” variants: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “Four ZA single-vectors of single-precision elements” and “Two ZA single-vectors of single-precision elements” variants: is the element index, in the range 0 to 3, encoded in the “i2” field.

Assembler Symbols

<T>

Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

For the “Two ZA single-vectors” and “Two ZA single-vectors of half-precision elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA single-vectors” and “Four ZA single-vectors of half-precision elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm1>

For the “Two ZA single-vectors” and “Two ZA single-vectors of half-precision elements” variants: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 2.

For the “Four ZA single-vectors” and “Four ZA single-vectors of half-precision elements” variants: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

<Zm4>

Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as “Zm” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let vbase : bits(32) = X{}(v);
```

C9.2.92 FMLAL (multiple and indexed vector, FP8 to FP16)

Multi-vector 8-bit floating-point multiply-add by indexed element to half-precision

This instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the indexed element of the second source vector to half-precision format and multiplies the corresponding elements. The intermediate products are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$ before being destructively added without intermediate rounding to the overlapping 16-bit half-precision elements of the ZA double-vector groups.

The 8-bit floating-point elements within the second source vector are specified using a 4-bit immediate index that selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

C9.2.95 FMLAL (multiple and indexed vector, FP16 to FP32)

Multi-vector half-precision multiply-add by indexed element to single-precision

This instruction widens all 16-bit half-precision elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively adds these values without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The half-precision elements within the second source vector are specified using a 3-bit immediate index that selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

For the “One ZA double-vector” variant: is the first vector select offset, encoded as “off3” field times 2.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the first vector select offset, encoded as “off2” field times 2.

<offs2>

For the “One ZA double-vector” variant: is the second vector select offset, encoded as “off3” field times 2 plus 1.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the second vector select offset, encoded as “off2” field times 2 plus 1.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<index>

Is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

<Zn1>

For the “Two ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV 32;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV 32;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 2);

for r = 0 to nreg-1 do
    let op1 : bits(VL) = Z{}(n+r);
    let op2 : bits(VL) = Z{}(m);
    for i = 0 to 1 do
        let op3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let segmentbase : integer = e - (e MOD eltspersegment);
            let s : integer = 2 * segmentbase + index;
            let elem1 : bits(16) = op1[(2 * e + i)*:(16)];
            let elem2 : bits(16) = op2[s*:(16)];
            let elem3 : bits(32) = op3[e*:(32)];
            result[e*:(32)] = FPMulAddH_ZA(elem3, elem1, elem2,
                                                   FPCR());
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;

C9.2.98 FMLALL (multiple and indexed vector)

Multi-vector 8-bit floating-point multiply-add by indexed element to single-precision

This instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format and multiplies the corresponding elements. The intermediate products are scaled by $2^{-\text{UInt(FPMR.LSCALE)}}$ before being destructively added without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA quad-vector groups.

The 8-bit floating-point elements within the second source vector are specified using a 4-bit immediate index that selects the same element position within each 128-bit vector segment.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA quad-vector, Two ZA quad-vectors, and Four ZA quad-vectors

<index>

Is the element index, in the range 0 to 15, encoded in the “i4h:i4l” fields.

<Zn1>

For the “Two ZA quad-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA quad-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckFPMREnabled();
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV 32;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV 32;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 4);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m);
    for i = 0 to 3 do
        let operand3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let segmentbase : integer = e - (e MOD eltspersegment);
            let s : integer = 4 * segmentbase + index;
            let element1 : bits(8) = operand1[(4 * e + i)*:8];
            let element2 : bits(8) = operand2[s*:8];
            let element3 : bits(32) = operand3[e*:32];
            result[e*:32] = FP8MulAddFP{32}(element3, element1, element2, FPCR(), FPMR());
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;
```

C9.2.99 FMLALL (multiple and single vector)

Multi-vector 8-bit floating-point multiply-add by vector to single-precision

This instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the second source vector to single-precision format and multiplies the corresponding elements. The intermediate products are scaled by $2^{-\mathrm{UInt(FPMR.LSCALE)}}$ before being destructively added without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA quad-vector groups.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA quad-vector, Two ZA quad-vectors, and Four ZA quad-vectors

One ZA quad-vector

C9.2.101 FMLS (multiple and indexed vector)

Multi-vector floating-point fused multiply-subtract by indexed element

This instruction multiplies the indexed element of the second source vector by the corresponding floating-point elements of the two or four first source vectors and destructively subtracts these values without intermediate rounding from the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 6 classes: Two ZA single-vectors of half-precision elements, Two ZA single-vectors of single-precision elements, Two ZA single-vectors of double-precision elements, Four ZA single-vectors of half-precision elements, Four ZA single-vectors of single-precision elements, and Four ZA single-vectors of double-precision elements

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

For the “Two ZA single-vectors of double-precision elements”, “Two ZA single-vectors of half-precision elements”, and “Two ZA single-vectors of single-precision elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA single-vectors of double-precision elements”, “Four ZA single-vectors of half-precision elements”, and “Four ZA single-vectors of single-precision elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<index>

For the “Four ZA single-vectors of half-precision elements” and “Two ZA single-vectors of half-precision elements” variants: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “Four ZA single-vectors of single-precision elements” and “Two ZA single-vectors of single-precision elements” variants: is the element index, in the range 0 to 3, encoded in the “i2” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For the “Four ZA single-vectors of double-precision elements” and “Two ZA single-vectors of double-precision elements” variants: is the element index, in the range 0 to 1, encoded in the “i1” field.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV esize;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);

for r = 0 to nreg-1 do
    let op1 : bits(VL) = Z{}(n+r);
    let op2 : bits(VL) = Z{}(m);

C9.2.102 FMLS (multiple and single vector)

Multi-vector floating-point fused multiply-subtract by vector

This instruction multiplies the corresponding floating-point elements of the two or four first source vector with the corresponding elements of the second source vector and destructively subtracts these values without intermediate rounding from the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors, Two ZA single-vectors of half-precision elements, Four ZA single-vectors, and Four ZA single-vectors of half-precision elements

C9.2.104 FMLSL (multiple and indexed vector)

Multi-vector half-precision multiply-subtract by indexed element from single-precision

This instruction widens all 16-bit half-precision elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively subtracts these values without intermediate rounding from the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The half-precision elements within the second source vector are specified using a 3-bit immediate index that selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

C9.2.106 FMLSL (multiple vectors)

Multi-vector half-precision multiply-subtract from single-precision

This instruction widens all 16-bit half-precision elements in the two or four first and second source vectors to single-precision format, then multiplies the corresponding elements and destructively subtracts these values without intermediate rounding from the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The double-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA double-vectors and Four ZA double-vectors

Two ZA double-vectors

C9.2.107 FMOP4A (widening, 2-way, FP8 to FP16)

8-bit floating-point quarter-tile sum of outer products to half-precision, accumulating

This instruction generates four independent quarter-tile 8-bit floating-point sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 16-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_H \div 2 \times 2$ sub-matrix of 8-bit floating-point values held in the half-vectors of the first source vectors by the $2 \times SVL_H \div 2$ sub-matrix of 8-bit floating-point values held in the half-vectors of the second source vectors. Each 16-bit container of the first source vectors holds 2 elements of each row of a $SVL_H \div 2 \times 2$ sub-matrix. Similarly, each 16-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_H \div 2$ sub-matrix.

This instruction widens the sub-matrices of 8-bit floating-point values held in the first source vectors to half-precision values and multiplies them by the corresponding widened sub-matrices of 8-bit floating-point values in the second source vectors to half-precision values. The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ half-precision sums of outer products are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$, before being destructively added to the half-precision destination tile. This is equivalent to performing a downscaled 2-way dot product and accumulate to each of the destination tile elements.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.108 FMOP4A (widening, 4-way)

8-bit floating-point quarter-tile sum of outer products to single-precision, accumulating

This instruction generates four independent quarter-tile 8-bit floating-point sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit floating-point values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit floating-point values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

This instruction widens the sub-matrices of 8-bit floating-point values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of 8-bit floating-point values in the second source vectors to single-precision values. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ single-precision sums of outer products are scaled by $2^{-UInt(FPMR.LSCALE)}$, before being destructively added to the single-precision destination tile. This is equivalent to performing a downscaled 4-way dot product and accumulate to each of the destination tile elements.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.109 FMOP4A (widening, 2-way, FP16 to FP32)

Half-precision quarter-tile sum of outer products to single-precision, accumulating

This instruction generates four independent quarter-tile half-precision sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of half-precision values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of half-precision values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix.

The instruction widens the sub-matrices of half-precision values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of half-precision values in the second source vectors to single-precision values. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ single-precision sums of outer products are then destructively added to the single-precision destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.110 FMOP4A (non-widening)

Floating-point quarter-tile outer product, accumulating

This instruction generates four independent quarter-tile floating-point outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 16-bit, 32-bit, or 64-bit element ZA tile.

In case of the half-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_H \div 2 \times 1$ sub-matrix of half-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_H \div 2$ sub-matrix of half-precision values held in the half-vectors of the second source vectors. In case of the single-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_S \div 2 \times 1$ sub-matrix of single-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_S \div 2$ sub-matrix of single-precision values held in the half-vectors of the second source vectors. In case of the double-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_D \div 2 \times 1$ sub-matrix of double-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_D \div 2$ sub-matrix of double-precision values held in the half-vectors of the second source vectors.

The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ half-precision outer products in case of the half-precision variant, $SVL_S \div 2 \times SVL_S \div 2$ single-precision outer products in case of the single-precision variant, or $SVL_D \div 2 \times SVL_D \div 2$ double-precision outer products in case of the double-precision variant are destructively added to the destination ZA tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 12 classes: Half-precision, single and multiple vectors, Half-precision, single vectors, Half-precision, multiple and single vectors, Half-precision, multiple vectors, Single-precision, single and multiple vectors, Single-precision, single vectors, Single-precision, multiple and single vectors, Single-precision, multiple vectors, Double-precision, single and multiple vectors, Double-precision, single vectors, Double-precision, multiple and single vectors, and Double-precision, multiple vectors

C9.2.111 FMOP4S (widening)

Half-precision quarter-tile sum of outer products to single-precision, subtracting

This instruction generates four independent quarter-tile half-precision sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of half-precision values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of half-precision values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix.

The instruction widens the sub-matrices of half-precision values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of half-precision values in the second source vectors to single-precision values. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ single-precision sums of outer products are then destructively subtracted from the single-precision destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.112 FMOP4S (non-widening)

Floating-point quarter-tile outer product, subtracting

This instruction generates four independent quarter-tile floating-point outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 16-bit, 32-bit, or 64-bit element ZA tile.

In case of the half-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_H \div 2 \times 1$ sub-matrix of half-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_H \div 2$ sub-matrix of half-precision values held in the half-vectors of the second source vectors. In case of the single-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_S \div 2 \times 1$ sub-matrix of single-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_S \div 2$ sub-matrix of single-precision values held in the half-vectors of the second source vectors. In case of the double-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_D \div 2 \times 1$ sub-matrix of double-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_D \div 2$ sub-matrix of double-precision values held in the half-vectors of the second source vectors.

The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ half-precision outer products in case of the half-precision variant, $SVL_S \div 2 \times SVL_S \div 2$ single-precision outer products in case of the single-precision variant, or $SVL_D \div 2 \times SVL_D \div 2$ double-precision outer products in case of the double-precision variant are destructively subtracted from the destination ZA tile. This is equivalent to performing a single multiply-subtract from each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 12 classes: Half-precision, single and multiple vectors, Half-precision, single vectors, Half-precision, multiple and single vectors, Half-precision, multiple vectors, Single-precision, single and multiple vectors, Single-precision, single vectors, Single-precision, multiple and single vectors, Single-precision, multiple vectors, Double-precision, single and multiple vectors, Double-precision, single vectors, Double-precision, multiple and single vectors, and Double-precision, multiple vectors

C9.2.113 FMOPA (widening, 2-way, FP8 to FP16)

8-bit floating-point sum of outer products to half-precision, accumulating

This instruction works with a 16-bit element ZA tile.

This instruction widens the $SVL_H \times 2$ sub-matrix of 8-bit floating-point values held in the first source vector to half-precision values and multiplies it by the widened $2 \times SVL_H$ sub-matrix of 8-bit floating-point values in the second source vector to half-precision values.

Each source vector is independently predicated by a corresponding governing predicate. When a 8-bit source element is Inactive it is treated as having the value +0.0, but if both groups of source vector elements that correspond to a 16-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting $SVL_H \times SVL_H$ half-precision sum of outer products are scaled by $2^{-UInt(FPMR.LSCALE[3:0])}$, before being destructively added to the half-precision destination tile. This is equivalent to performing a downscaled 2-way dot product and accumulate to each of the destination tile elements.

Each 16-bit container of the first source vector holds 2 consecutive column elements of each row of a $SVL_H \times 2$ sub-matrix. Similarly, each 16-bit container of the second source vector holds 2 consecutive row elements of each column of a $2 \times SVL_H$ sub-matrix.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

C9.2.114 FMOPA (widening, 4-way)

8-bit floating-point sum of outer products to single-precision, accumulating

This instruction works with a 32-bit element ZA tile.

This instruction widens the $SVL_S \times 4$ sub-matrix of 8-bit floating-point values held in the first source vector to single-precision values and multiplies it by the widened $4 \times SVL_S$ sub-matrix of 8-bit floating-point values in the second source vector to single-precision values.

Each source vector is independently predicated by a corresponding governing predicate. When a 8-bit source element is Inactive it is treated as having the value +0.0, but if both groups of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting $SVL_S \times SVL_S$ single-precision sum of outer products are scaled by $2^{-UInt(FPMR.LSCALE)}$, before being destructively added to the single-precision destination tile. This is equivalent to performing a downscaled 4-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix. Similarly, each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

C9.2.115 FMOPA (widening, 2-way, FP16 to FP32)

Half-precision sum of outer products to single-precision, accumulating

This instruction works with a 32-bit element ZA tile.

This instruction widens the $SVL_S \times 2$ sub-matrix of half-precision values held in the first source vector to single-precision values and multiplies it by the widened $2 \times SVL_S$ sub-matrix of half-precision values in the second source vector to single-precision values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting $SVL_S \times SVL_S$ single-precision sum of outer products is then destructively added to the single-precision destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a $SVL_S \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a $2 \times SVL_S$ sub-matrix.

This instruction follows SME ZA-targeting floating-point behaviors.

C9.2.116 FMOPA (non-widening)

Floating-point outer product, accumulating

The half-precision variant works with a 16-bit element ZA tile.

The single-precision variant works with a 32-bit element ZA tile.

The double-precision variant works with a 64-bit element ZA tile.

This instruction generates an outer product of the first source vector and the second source vector. In case of the half-precision variant, the first source is $SVL_H \times 1$ vector and the second source is $1 \times SVL_H$ vector. In case of the single-precision variant, the first source is $SVL_S \times 1$ vector and the second source is $1 \times SVL_S$ vector. In case of the double-precision variant, the first source is $SVL_D \times 1$ vector and the second source is $1 \times SVL_D$ vector.

Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is Inactive the corresponding destination tile element remains unmodified.

The resulting outer product, $SVL_H \times SVL_H$ in case of half-precision variant, $SVL_S \times SVL_S$ in case of single-precision variant or $SVL_D \times SVL_D$ in case of double-precision variant, is then destructively added to the destination tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 3 classes: Half-precision, Single-precision, and Double-precision

C9.2.117 FMOPS (widening)

Half-precision sum of outer products to single-precision, subtracting

This instruction works with a 32-bit element ZA tile.

This instruction widens the $SVL_S \times 2$ sub-matrix of half-precision values held in the first source vector to single-precision values and multiplies it by the widened $2 \times SVL_S$ sub-matrix of half-precision values in the second source vector to single-precision values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting $SVL_S \times SVL_S$ single-precision sum of outer products is then destructively subtracted from the single-precision destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a $SVL_S \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a $2 \times SVL_S$ sub-matrix.

This instruction follows SME ZA-targeting floating-point behaviors.

Assembler Symbols

<Zd1>

For the “Two registers” variant: is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 4.

<T>

Is the size specifier, encoded in “size”:

size	<T>
01	H
10	S
11	D

<Zd2>

Is the name of the second scalable vector register of the destination multi-vector group, encoded as “Zd” times 2 plus 1.

<Zn1>

For the “Two registers” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm1>

For the “Two registers” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zd4>

Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as “Zd” times 4 plus 3.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

<Zm4>

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

Assembler Symbols

<Zdn1>

For the “Two registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4.

<T>

Is the size specifier, encoded in “size”:

size	<T>
01	H
10	S
11	D

<Zdn2>

Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2 plus 1.

<Zm1>

For the “Two registers” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zdn4>

Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4 plus 3.

<Zm4>

Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as “Zm” times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
var results : array [[4]] of bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(dn+r);
    let operand2 : bits(VL) = Z{}(m+r);
    for e = 0 to elements-1 do
        let element1 : bits(esize) = operand1[e*:esize];
        let element2 : integer = SInt(operand2[e*:esize]);
        results[[r]][e*:esize] = FPScale{esize}(element1, element2, FPCR());
```

C9.2.127 FSUB

Multi-vector floating-point subtract from ZA array vectors

This instruction destructively subtracts all elements of the two or four source vectors from the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors, Two ZA single-vectors of half-precision elements, Four ZA single-vectors, and Four ZA single-vectors of half-precision elements

Two ZA single-vectors

C9.2.128 FTMOPA (widening, 2-way, FP8 to FP16)

8-bit floating-point sparse sum of outer products to half-precision, accumulating

This instruction generates 8-bit floating-point sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 16-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 8-bit floating-point values from each overlapping 16-bit containers of the two $SVL_H \times 2$ sub-matrices in the first source vectors by the two 8-bit floating point values from the corresponding 16-bit container of the $2 \times SVL_H$ sub-matrix in the second source vector. The two selected elements from each overlapping 16-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two $SVL_H \times 2$ sub-matrices. Each 16-bit container of the second source vector holds 2 elements of columns of a compressed $2 \times SVL_H$ sub-matrix.

The 2-in-4 8-bit floating values from overlapping 16-bit containers of the first source vectors are selected by 4-bit control in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 16-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The instruction widens the selected elements of sub-matrices of 8-bit floating-point values held in the first source vectors to half-precision values and multiplies them by the corresponding widened elements of sub-matrix of 8-bit floating-point values in the second source vector to half-precision values. The resulting $SVL_H \times SVL_H$ half-precision sum of outer products is scaled by $2^{-UInt(FPMR.LSCALE[3:0])}$, before being destructively added to the half-precision destination tile. This is equivalent to performing a downscaled 2-way dot product and accumulate to each of the destination tile elements.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

This instruction is unpredicated.

C9.2.129 FTMOPA (widening, 4-way)

8-bit floating-point sparse sum of outer products to single-precision, accumulating

This instruction generates 8-bit floating-point sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit floating-point values from each overlapping 32-bit containers of the two $SVL_S \times 4$ sub-matrices in the first source vectors by the four 8-bit floating-point values from the corresponding 32-bit container of the $4 \times SVL_S$ sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two $SVL_S \times 4$ sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed $4 \times SVL_S$ sub-matrix.

The two sets of 2-in-4 8-bit floating values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The instruction widens the selected elements of sub-matrices of 8-bit floating-point values held in the first source vectors to single-precision values and multiplies them by the corresponding widened elements of sub-matrix of 8-bit floating-point values in the second source vector to single-precision values. The resulting $SVL_S \times SVL_S$ single-precision sum of outer products is scaled by $2^{-UInt(FPMR.LSCALE)}$, before being destructively added to the single-precision destination tile. This is equivalent to performing a downscaled 4-way dot product and accumulate to each of the destination tile elements.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

C9.2.130 FTMOPA (widening, 2-way, FP16 to FP32)

Half-precision sparse sum of outer products to single-precision, accumulating

This instruction generates half-precision sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 half-precision values from each overlapping 32-bit containers of the two $SVL_S \times 2$ sub-matrices in the first source vectors by the two half-precision values from the corresponding 32-bit container of the $2 \times SVL_S$ sub-matrix in the second source vector. The two selected elements from each overlapping 32-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two $SVL_S \times 2$ sub-matrices. Each 32-bit container of the second source vector holds 2 elements of columns of a compressed $2 \times SVL_S$ sub-matrix.

The 2-in-4 half-precision values from overlapping 32-bit containers of the first source vectors are selected by 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 32-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The instruction widens the selected elements of sub-matrices of half-precision values held in the first source vectors to single-precision values and multiplies them by the corresponding widened elements of sub-matrix of half-precision values in the second source vector to single-precision values. The resulting $SVL_S \times SVL_S$ single-precision sum of outer products is then destructively added to the single-precision destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

C9.2.131 FTMOPA (non-widening)

Floating-point sparse outer product, accumulating

This instruction generates floating-point outer product by multiplying the 1-in-2 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the destination ZA tile elements.

In case of the half-precision variant, the outer product is generated by multiplying the selected 1-in-2 half-precision value from each overlapping 16-bit containers of the two $SVL_H \times 1$ sub-matrices in the first source vectors by the half-precision value from the corresponding 16-bit container of the compressed $1 \times SVL_H$ sub-matrix in the second source vector. In case of the single-precision variant, the outer product is generated by multiplying the selected 1-in-2 single-precision value from each overlapping 32-bit containers of the two $SVL_S \times 1$ sub-matrices in the first source vectors by the single-precision value from the corresponding 32-bit container of the compressed $1 \times SVL_S$ sub-matrix in the second source vector.

The 1-in-2 floating-point value in the first source vectors is selected by 2-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the result. If both bits of the 2-bit control corresponding to the elements of the first source vectors are 1, only the element corresponding to the least significant bit is selected.

The instruction multiplies the selected elements of sub-matrices of floating-point values held in the first source vectors by the corresponding elements of sub-matrix of floating-point values in the second source vector. The resulting outer product, $SVL_H \times SVL_H$ in case of the half-precision variant or $SVL_S \times SVL_S$ in case of the single-precision variant, is then destructively added to the destination tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Half-precision and Single-precision

Half-precision

Assembler Symbols

<ZAda>

For the “Half-precision” variant: is the name of the ZA tile ZA0-ZA1, encoded in the “ZAda” field.

For the “Single-precision” variant: is the name of the ZA tile ZA0-ZA3, encoded in the “ZAda” field.

<Zn1>

Is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

<Zk>

Is the name of the control vector register Z20-Z23 or Z28-Z31, encoded in the “K:Zk” fields.

<index>

Is the control segment index, in the range 0 to 3, encoded in the “i2” field.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let dim : integer{} = VL DIV esize;

C9.2.132 FVDOT (FP8 to FP16)

Multi-vector 8-bit floating-point vertical dot product by indexed element to half-precision

This instruction calculates the fused sum-of-products of each vertical pair of 8-bit floating-point values held in the corresponding elements of the two first source vectors with horizontal pair of 8-bit floating-point values in the indexed 16-bit group of the corresponding 128-bit segment of the second source vector. The half-precision sum-of-products are scaled by $2^{-\mathrm{UInt(FPMR.LSCALE[3:0])}}$, before being destructively added without intermediate rounding to the corresponding half-precision elements of the two ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by `FPMR.F8S1` and `FPMR.F8S2` respectively.

The 8-bit floating-point pairs within the second source vector are specified using an immediate index that selects the same pair position within each 128-bit vector segment.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The `vector group` symbol `VGx2` indicates that the ZA operand consists of two ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

C9.2.136 LD1B (scalar plus immediate, strided registers)

Contiguous load of bytes to multiple strided vectors (immediate index)

This instruction performs a contiguous load of unsigned bytes to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and immediate index that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: Two registers and Four registers

Two registers

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as “T:‘0’:Zt”.

For the “Four registers” variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as “T:‘00’:Zt”.

<Zt2>

For the “Two registers” variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as “T:‘1’:Zt”.

For the “Four registers” variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as “T:‘01’:Zt”.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded as “imm4” times 2.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded as “imm4” times 4.

<Zt3>

Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as “T:‘10’:Zt”.

<Zt4>

Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as “T:‘11’:Zt”.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();

C9.2.138 LD1B (scalar plus scalar, tile slice)

Contiguous load of bytes to 8-bit element ZA tile slice

This instruction performs a contiguous load of bytes to an 8-bit element ZA tile slice. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 8-bit elements in a vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset that is added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as “T:‘0’:Zt”.

For the “Four registers” variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as “T:‘00’:Zt”.

<Zt2>

For the “Two registers” variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as “T:‘1’:Zt”.

For the “Four registers” variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as “T:‘01’:Zt”.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the general-purpose offset register, encoded in the “Rm” field.

<Zt3>

Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as “T:‘10’:Zt”.

<Zt4>

Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as “T:‘11’:Zt”.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mbytes : integer{} = esize DIV 8;
var offset : bits(64);

C9.2.141 LD1D (scalar plus scalar, tile slice)

Contiguous load of doublewords to 64-bit element ZA tile slice

This instruction performs a contiguous load of doublewords to a 64-bit element ZA tile slice. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 64-bit elements in a vector. The immediate offset is in the range 0 to 1. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset that is multiplied by 8 and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

C9.2.145 LD1Q

Contiguous load of quadwords to 128-bit element ZA tile slice

This instruction performs a contiguous load of quadwords to a 128-bit element ZA tile slice. The slice number in the tile is selected by the slice index register, modulo the number of 128-bit elements in a Streaming SVE vector. The memory address is generated by scalar base and optional scalar offset that is multiplied by 16 and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

SME

(FEAT_SME)

31	30 29	28 25	24 21	20 16	15	14 13	12 10	9 5	4	3 0
1	1 1	0 0 0 0	1 1 1 0	Rm	V	Rs	Pg	Rn	0	ZAt

Encoding

```
LD1Q  { <ZAt><HV>.Q[<Ws>, <offs>] }, <Pg>/Z, [<Xn|SP>{, <Xm>, LSL #4}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('0'::Pg);
let s : integer = UInt('011'::Rs);
let t : integer = UInt(ZAt);
let offset : integer = 0;
let esize : integer{} = 128;
let vertical : boolean = V == '1';
```

Assembler Symbols

<ZAt>

Is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the “ZAt” field.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs>

Is the slice index offset, with implicit value 0.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the “Rm” field.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let dim : integer = VL DIV esize;
var base : bits(64);
var addr : bits(64);
let mask : bits(PL) = P{}(g);
var moffs : bits(64) = X{}(m);
let index : bits(32) = X{}(s);
let slice : integer = (UInt(index) + offset) MOD dim;
var result : bits(VL);
let mbytes : integer{} = esize DIV 8;
let contiguous : boolean = TRUE;
let nontemporal : boolean = FALSE;
let tagchecked : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescSME(MemOp_LOAD, nontemporal, contiguous,
                                                  tagchecked);

if n == 31 then
    if (AnyActiveElement{PL}(mask, esize) ||
          ConstrainUnpredictableBool(Unpredictable_CHECKSPNONEACTIVE)) then
        CheckSPAlignment();
    end;
    base = SP{64}();
else
    base = X{64}(n);
end;

for e = 0 to dim - 1 do
    addr = AddressAdd(base, UInt(moffs) * mbytes, accdesc);

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as “T:‘0’:Zt”.

For the “Four registers” variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as “T:‘00’:Zt”.

<Zt2>

For the “Two registers” variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as “T:‘1’:Zt”.

For the “Four registers” variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as “T:‘01’:Zt”.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded as “imm4” times 2.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded as “imm4” times 4.

<Zt3>

Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as “T:‘10’:Zt”.

<Zt4>

Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as “T:‘11’:Zt”.

Operation

```
CheckStreamingSVEEnabled();

C9.2.149 LDNT1B (scalar plus immediate, strided registers)

Contiguous load non-temporal of bytes to multiple strided vectors (immediate index)

This instruction performs a contiguous non-temporal load of bytes to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and immediate index that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

C9.2.150 LDNT1B (scalar plus scalar, strided registers)

Contiguous load non-temporal of bytes to multiple strided vectors (scalar index)

This instruction performs a contiguous non-temporal load of bytes to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

C9.2.154 LDNT1H (scalar plus scalar, strided registers)

Contiguous load non-temporal of halfwords to multiple strided vectors (scalar index)

This instruction performs a contiguous non-temporal load of halfwords to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

C9.2.157 LDR (array vector)

Load ZA array vector

This instruction performs a contiguous load of bytes to a ZA array vector from the memory address generated by a 64-bit scalar base plus an optional immediate offset multiplied by the current vector length in bytes. The ZA array vector is selected by the sum of the vector select register and the same immediate offset, modulo the number of bytes in a Streaming SVE vector.

This instruction is unpredicated.

The load is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

C9.2.159 LUTI2 (two registers)

Lookup table read with 2-bit indexes (two registers)

This instruction copies 8-bit, 16-bit or 32-bit elements from ZT0 to two destination vectors using packed 2-bit indices from a segment of the source vector register. A segment corresponds to a portion of the source vector that is consumed in order to fill the destination vector. The segment is selected by the vector segment index modulo the total number of segments.

This instruction is unpredicated.

It has encodings from 2 classes: Consecutive and Strided

Consecutive

Assembler Symbols

<Zd1>

For the “Consecutive” variant: is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 2.

For the “Strided” variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 of the destination multi-vector group, encoded as “D:‘0’:Zd”.

<T>

For the “Consecutive” variant: is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	RESERVED

For the “Strided” variant: is the size specifier, encoded in “size<0>”:

size<0>	<T>
0	B
1	H

<Zd2>

For the “Consecutive” variant: is the name of the second scalable vector register of the destination multi-vector group, encoded as “Zd” times 2 plus 1.

For the “Strided” variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 of the destination multi-vector group, encoded as “D:‘1’:Zd”.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

<index>

Is the vector segment index, in the range 0 to 7, encoded in the “i3” field.

```

Assembler Symbols

<Zd1>

For the “Consecutive” variant: is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 4.

For the “Strided” variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 of the destination multi-vector group, encoded as “D:‘00’:Zd”.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	RESERVED

<Zd4>

For the “Consecutive” variant: is the name of the fourth scalable vector register of the destination multi-vector group, encoded as “Zd” times 4 plus 3.

For the “Strided” variant: is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 of the destination multi-vector group, encoded as “D:‘11’:Zd”.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

<index>

Is the vector segment index, in the range 0 to 1, encoded in the “i1” field.

<Zd2>

Is the name of the second scalable vector register Z4-Z7 or Z20-Z23 of the destination multi-vector group, encoded as “D:‘01’:Zd”.

<Zd3>

Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 of the destination multi-vector group, encoded as “D:‘10’:Zd”.

C9.2.165 LUTI4 (single)

Lookup table read with 4-bit indexes (single)

This instruction copies 8-bit, 16-bit or 32-bit elements from ZT0 to one destination vector using packed 4-bit indices from a segment of the source vector register. A segment corresponds to a portion of the source vector that is consumed in order to fill the destination vector. The segment is selected by the vector segment index modulo the total number of segments.

This instruction is unpredicated.

C9.2.166 MOV (tile to vector, two registers)

Move ZA two-slice operand to Z two-vector operand

This instruction operates on a horizontal or vertical ZA two-slice operand within a ZA tile of the specified element size.

The first slice of the two-slice operand is selected by rounding down the sum of the slice index register and the immediate offset to the nearest lower multiple of 2, modulo the number of slices in the tile.

The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

This is an alias of MOVA (tile to vector, two registers). This means:

- The encodings in this description are named to match the encodings of MOVA (tile to vector, two registers).
- The description of MOVA (tile to vector, two registers) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 4 classes: 8-bit, 16-bit, 32-bit, and 64-bit

8-bit

C9.2.168 MOV (array to vector, two registers)

Move two ZA single-vector groups to Z two-vector operand

This instruction operates on two ZA single-vector groups.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The `vector group` symbol `VGx2` indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The `vector group` symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This is an alias of MOVA (array to vector, two registers). This means:

- The encodings in this description are named to match the encodings of MOVA (array to vector, two registers).
- The description of MOVA (array to vector, two registers) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C9.2.170 MOV (tile to vector, single)

Move ZA tile slice to Z vector

This instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1. Inactive elements in the destination vector remain unmodified.

This is an alias of MOVA (tile to vector, single). This means:

- The encodings in this description are named to match the encodings of MOVA (tile to vector, single).
- The description of MOVA (tile to vector, single) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 5 classes: 8-bit, 16-bit, 32-bit, 64-bit, and 128-bit

8-bit

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs>

For the “8-bit” variant: is the slice index offset, in the range 0 to 15, encoded in the “off4” field.

For the “16-bit” variant: is the slice index offset, in the range 0 to 7, encoded in the “off3” field.

For the “32-bit” variant: is the slice index offset, in the range 0 to 3, encoded in the “off2” field.

For the “64-bit” variant: is the slice index offset, in the range 0 to 1, encoded in the “o1” field.

For the “128-bit” variant: is the slice index offset, with implicit value 0.

<ZAn>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAn” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAn” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAn” field.

For the “128-bit” variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the “ZAn” field.

Operation

The description of MOVA (tile to vector, single) gives the operational pseudocode for this instruction.

Operational Information

The description of MOVA (tile to vector, single) gives the operational information for this instruction.

C9.2.171 MOV (vector to tile, two registers)

Move Z two-vector operand to ZA two-slice operand

This instruction operates on a horizontal or vertical ZA two-slice operand within a ZA tile of the specified element size.

The first slice of the two-slice operand is selected by rounding down the sum of the slice index register and the immediate offset to the nearest lower multiple of 2, modulo the number of slices in the tile.

The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

This is an alias of MOVA (vector to tile, two registers). This means:

- The encodings in this description are named to match the encodings of MOVA (vector to tile, two registers).
- The description of MOVA (vector to tile, two registers) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 4 classes: 8-bit, 16-bit, 32-bit, and 64-bit

8-bit

C9.2.173 MOV (vector to array, two registers)

Move Z two-vector operand to two ZA single-vector groups

This instruction operates on two ZA single-vector groups.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The `vector group` symbol `VGx2` indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The `vector group` symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This is an alias of MOVA (vector to array, two registers). This means:

- The encodings in this description are named to match the encodings of MOVA (vector to array, two registers).
- The description of MOVA (vector to array, two registers) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C9.2.175 MOV (vector to tile, single)

Move Z vector to ZA tile slice

This instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1. Inactive elements in the destination slice remain unmodified.

This is an alias of MOVA (vector to tile, single). This means:

- The encodings in this description are named to match the encodings of MOVA (vector to tile, single).
- The description of MOVA (vector to tile, single) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 5 classes: 8-bit, 16-bit, 32-bit, 64-bit, and 128-bit

8-bit

Assembler Symbols

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs>

For the “8-bit” variant: is the slice index offset, in the range 0 to 15, encoded in the “off4” field.

For the “16-bit” variant: is the slice index offset, in the range 0 to 7, encoded in the “off3” field.

For the “32-bit” variant: is the slice index offset, in the range 0 to 3, encoded in the “off2” field.

For the “64-bit” variant: is the slice index offset, in the range 0 to 1, encoded in the “o1” field.

For the “128-bit” variant: is the slice index offset, with implicit value 0.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

<ZAd>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAd” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAd” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAd” field.

For the “128-bit” variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the “ZAd” field.

Operation

The description of MOVA (vector to tile, single) gives the operational pseudocode for this instruction.

Operational Information

The description of MOVA (vector to tile, single) gives the operational information for this instruction.

C9.2.176 MOVA (tile to vector, two registers)

Move ZA two-slice operand to Z two-vector operand

This instruction operates on a horizontal or vertical ZA two-slice operand within a ZA tile of the specified element size.

The first slice of the two-slice operand is selected by rounding down the sum of the slice index register and the immediate offset to the nearest lower multiple of 2, modulo the number of slices in the tile.

The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

This instruction is used by the alias MOV (tile to vector, two registers).

It has encodings from 4 classes: 8-bit, 16-bit, 32-bit, and 64-bit

8-bit

Assembler Symbols

<Zd1>

Is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 2.

<Zd2>

Is the name of the second scalable vector register of the destination multi-vector group, encoded as “Zd” times 2 plus 1.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs1>

For the “8-bit” variant: is the first slice index offset, encoded as “off3” field times 2.

For the “16-bit” variant: is the first slice index offset, encoded as “off2” field times 2.

For the “32-bit” variant: is the first slice index offset, encoded as “o1” field times 2.

For the “64-bit” variant: is the first slice index offset, with implicit value 0.

<offs2>

For the “8-bit” variant: is the second slice index offset, encoded as “off3” field times 2 plus 1.

For the “16-bit” variant: is the second slice index offset, encoded as “off2” field times 2 plus 1.

For the “32-bit” variant: is the second slice index offset, encoded as “o1” field times 2 plus 1.

For the “64-bit” variant: is the second slice index offset, with implicit value 1.

<ZAn>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAn” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAn” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAn” field.

Assembler Symbols

<Zd1>

Is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 4.

<Zd4>

Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as “Zd” times 4 plus 3.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs1>

For the “8-bit” variant: is the first slice index offset, encoded as “off2” field times 4.

For the “16-bit” variant: is the first slice index offset, encoded as “o1” field times 4.

For the “32-bit” and “64-bit” variants: is the first slice index offset, with implicit value 0.

<offs4>

For the “8-bit” variant: is the fourth slice index offset, encoded as “off2” field times 4 plus 3.

For the “16-bit” variant: is the fourth slice index offset, encoded as “o1” field times 4 plus 3.

For the “32-bit” and “64-bit” variants: is the fourth slice index offset, with implicit value 3.

<ZAn>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAn” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAn” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAn” field.

C9.2.178 MOVA (array to vector, two registers)

Move two ZA single-vector groups to Z two-vector operand

This instruction operates on two ZA single-vector groups.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The `vector group` symbol `VGx2` indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The `vector group` symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This instruction is used by the alias MOV (array to vector, two registers).

C9.2.180 MOVA (tile to vector, single)

Move ZA tile slice to Z vector

This instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination vector remain unmodified.

This instruction is used by the alias MOV (tile to vector, single).

It has encodings from 5 classes: 8-bit, 16-bit, 32-bit, 64-bit, and 128-bit

8-bit

```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs>

For the “8-bit” variant: is the slice index offset, in the range 0 to 15, encoded in the “off4” field.

For the “16-bit” variant: is the slice index offset, in the range 0 to 7, encoded in the “off3” field.

For the “32-bit” variant: is the slice index offset, in the range 0 to 3, encoded in the “off2” field.

For the “64-bit” variant: is the slice index offset, in the range 0 to 1, encoded in the “o1” field.

For the “128-bit” variant: is the slice index offset, with implicit value 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<ZAn>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAn” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAn” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAn” field.

For the “128-bit” variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the “ZAn” field.

Alias Conditions

Alias	Is preferred when

C9.2.181 MOVA (vector to tile, two registers)

Move Z two-vector operand to ZA two-slice operand

This instruction operates on a horizontal or vertical ZA two-slice operand within a ZA tile of the specified element size.

The first slice of the two-slice operand is selected by rounding down the sum of the slice index register and the immediate offset to the nearest lower multiple of 2, modulo the number of slices in the tile.

The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

This instruction is used by the alias MOV (vector to tile, two registers).

It has encodings from 4 classes: 8-bit, 16-bit, 32-bit, and 64-bit

8-bit

Assembler Symbols

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs1>

For the “8-bit” variant: is the first slice index offset, encoded as “off3” field times 2.

For the “16-bit” variant: is the first slice index offset, encoded as “off2” field times 2.

For the “32-bit” variant: is the first slice index offset, encoded as “o1” field times 2.

For the “64-bit” variant: is the first slice index offset, with implicit value 0.

<offs2>

For the “8-bit” variant: is the second slice index offset, encoded as “off3” field times 2 plus 1.

For the “16-bit” variant: is the second slice index offset, encoded as “off2” field times 2 plus 1.

For the “32-bit” variant: is the second slice index offset, encoded as “o1” field times 2 plus 1.

For the “64-bit” variant: is the second slice index offset, with implicit value 1.

<Zn1>

Is the name of the first scalable vector register of the source multi-vector group, encoded as “Zn” times 2.

<Zn2>

Is the name of the second scalable vector register of the source multi-vector group, encoded as “Zn” times 2 plus 1.

<ZAd>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAd” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAd” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAd” field.

Assembler Symbols

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs1>

For the “8-bit” variant: is the first slice index offset, encoded as “off2” field times 4.

For the “16-bit” variant: is the first slice index offset, encoded as “o1” field times 4.

For the “32-bit” and “64-bit” variants: is the first slice index offset, with implicit value 0.

<offs4>

For the “8-bit” variant: is the fourth slice index offset, encoded as “off2” field times 4 plus 3.

For the “16-bit” variant: is the fourth slice index offset, encoded as “o1” field times 4 plus 3.

For the “32-bit” and “64-bit” variants: is the fourth slice index offset, with implicit value 3.

<Zn1>

Is the name of the first scalable vector register of the source multi-vector group, encoded as “Zn” times 4.

<Zn4>

Is the name of the fourth scalable vector register of the source multi-vector group, encoded as “Zn” times 4 plus 3.

<ZAd>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAd” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAd” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAd” field.

C9.2.183 MOVA (vector to array, two registers)

Move Z two-vector operand to two ZA single-vector groups

This instruction operates on two ZA single-vector groups.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The `vector group` symbol `VGx2` indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The `vector group` symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This instruction is used by the alias MOV (vector to array, two registers).

C9.2.185 MOVA (vector to tile, single)

Move Z vector to ZA tile slice

This instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination slice remain unmodified.

This instruction is used by the alias MOV (vector to tile, single).

It has encodings from 5 classes: 8-bit, 16-bit, 32-bit, 64-bit, and 128-bit

Assembler Symbols

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs>

For the “8-bit” variant: is the slice index offset, in the range 0 to 15, encoded in the “off4” field.

For the “16-bit” variant: is the slice index offset, in the range 0 to 7, encoded in the “off3” field.

For the “32-bit” variant: is the slice index offset, in the range 0 to 3, encoded in the “off2” field.

For the “64-bit” variant: is the slice index offset, in the range 0 to 1, encoded in the “o1” field.

For the “128-bit” variant: is the slice index offset, with implicit value 0.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<ZAd>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAd” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAd” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAd” field.

For the “128-bit” variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the “ZAd” field.

Alias Conditions

Alias	Is preferred when
MOV (vector to tile, single)	Unconditionally

Operation

```
CheckStreamingSVEAndZAEnabled();
let  VL : integer{} = CurrentVL();
let  PL : integer{} = VL DIV 8;
let dim : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = Z{}(n);
let index : bits(32) = X{}(s);
let slice : integer = (UInt(index) + offset) MOD dim;
var result : bits(VL) = ZAslice{}(d, esize, vertical, slice);

for e = 0 to dim-1 do
    let element : bits(esize) = operand[e*:esize];
    if ActivePredicateElement{PL}(mask, e, esize) then
        result[e*:esize] = element;
    end;
end;

ZAslice{VL}(d, esize, vertical, slice) = result;
```

C9.2.186 MOVAZ (tile to vector, two registers)

Move and zero ZA two-slice operand to Z two-vector operand

This instruction operates on a horizontal or vertical ZA two-slice operand within a ZA tile of the specified element size. The tile slices are zeroed after moving their contents to the destination vectors.

The first slice of the two-slice operand is selected by rounding down the sum of the slice index register and the immediate offset to the nearest lower multiple of 2, modulo the number of slices in the tile.

The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

It has encodings from 4 classes: 8-bit, 16-bit, 32-bit, and 64-bit

Assembler Symbols

<Zd1>

Is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 2.

<Zd2>

Is the name of the second scalable vector register of the destination multi-vector group, encoded as “Zd” times 2 plus 1.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs1>

For the “8-bit” variant: is the first slice index offset, encoded as “off3” field times 2.

For the “16-bit” variant: is the first slice index offset, encoded as “off2” field times 2.

For the “32-bit” variant: is the first slice index offset, encoded as “o1” field times 2.

For the “64-bit” variant: is the first slice index offset, with implicit value 0.

<offs2>

For the “8-bit” variant: is the second slice index offset, encoded as “off3” field times 2 plus 1.

For the “16-bit” variant: is the second slice index offset, encoded as “off2” field times 2 plus 1.

For the “32-bit” variant: is the second slice index offset, encoded as “o1” field times 2 plus 1.

For the “64-bit” variant: is the second slice index offset, with implicit value 1.

<ZAn>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAn” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAn” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAn” field.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
if nreg == 4 && esize == 64 && VL < 256 then EndOfDecode(Decode_UNDEF); end;
let slices : integer = VL DIV esize;
let index : bits(32) = X{}(s);
let slice : integer = ((UInt(index) - (UInt(index) MOD nreg)) + offset) MOD slices;

for r = 0 to nreg-1 do
    let result : bits(VL) = ZAslice{}(n, esize, vertical, slice + r);
    ZAslice{VL}(n, esize, vertical, slice + r) = Zeros{VL};
    Z{VL}(d + r) = result;
end;

Assembler Symbols

<Zd1>

Is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 4.

<Zd4>

Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as “Zd” times 4 plus 3.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs1>

For the “8-bit” variant: is the first slice index offset, encoded as “off2” field times 4.

For the “16-bit” variant: is the first slice index offset, encoded as “o1” field times 4.

For the “32-bit” and “64-bit” variants: is the first slice index offset, with implicit value 0.

<offs4>

For the “8-bit” variant: is the fourth slice index offset, encoded as “off2” field times 4 plus 3.

For the “16-bit” variant: is the fourth slice index offset, encoded as “o1” field times 4 plus 3.

For the “32-bit” and “64-bit” variants: is the fourth slice index offset, with implicit value 3.

<ZAn>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAn” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAn” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAn” field.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
if nreg == 4 && esize == 64 && VL < 256 then EndOfDecode(Decode_UNDEF); end;
let slices : integer = VL DIV esize;
let index : bits(32) = X{}(s);
let slice : integer = ((UInt(index) - (UInt(index) MOD nreg)) + offset) MOD slices;

for r = 0 to nreg-1 do
    let result : bits(VL) = ZAslice{}(n, esize, vertical, slice + r);
    ZAslice{VL}(n, esize, vertical, slice + r) = Zeros{VL};
    Z{VL}(d + r) = result;
end;
```

C9.2.188 MOVAZ (array to vector, two registers)

Move and zero two ZA single-vector groups to Z two-vector operand

This instruction operates on two ZA single-vector groups. The ZA single-vector groups are zeroed after moving their contents to the destination vectors.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The `vector group` symbol `VGx2` indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The `vector group` symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

C9.2.190 MOVAZ (tile to vector, single)

Move and zero ZA tile slice to Z vector

This instruction operates on a horizontal or vertical slice within a named ZA tile of the specified element size. The tile slice is zeroed after moving its contents to the destination vector.

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

This instruction is unpredicated.

It has encodings from 5 classes: 8-bit, 16-bit, 32-bit, 64-bit, and 128-bit

8-bit

let offset : integer = 0;
let esize : integer{} = 128;
let d : integer = UInt(Zd);
let vertical : boolean = V == '1';
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs>

For the “8-bit” variant: is the slice index offset, in the range 0 to 15, encoded in the “off4” field.

For the “16-bit” variant: is the slice index offset, in the range 0 to 7, encoded in the “off3” field.

For the “32-bit” variant: is the slice index offset, in the range 0 to 3, encoded in the “off2” field.

For the “64-bit” variant: is the slice index offset, in the range 0 to 1, encoded in the “o1” field.

For the “128-bit” variant: is the slice index offset, with implicit value 0.

<ZAn>

For the “16-bit” variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the “ZAn” field.

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the “ZAn” field.

For the “128-bit” variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the “ZAn” field.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let dim : integer = VL DIV esize;
let index : bits(32) = X{}(s);
let slice : integer = (UInt(index) + offset) MOD dim;
let operand : bits(VL) = ZAslice{}(n, esize, vertical, slice);
ZAslice{VL}(n, esize, vertical, slice) = Zeros{VL};
Z{VL}(d) = operand;
```

C9.2.193 MOVT (vector to table)

Move vector register to ZT0

This instruction copies the source vector register to ZT0 at the vector length offset specified by the immediate index. When the index is zero, the instruction writes zeros to the most significant (512-VL) bits of the ZT0 register. When the index is not zero, the unindexed portions of ZT0 remain unchanged.

This instruction is unpredicated.

C9.2.197 SDOT (2-way, multiple and indexed vector)

Multi-vector signed 16-bit integer dot product by indexed element to 32-bit integer

This instruction calculates the dot product of two signed 16-bit integer values held in each 32-bit element of the two or four first source vectors and two signed 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

For the “Two ZA single-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA single-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<index>

Is the immediate index of a pair of 16-bit elements within each 128-bit vector segment, in the range 0 to 3, encoded in the “i2” field.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV esize;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m);
    let operand3 : bits(VL) = ZAvector{}(vec);
    for e = 0 to elements-1 do
        var sum : bits(esize) = operand3[e*:esize];
```

C9.2.198 SDOT (2-way, multiple and single vector)

Multi-vector signed 16-bit integer dot product by vector to 32-bit integer

This instruction calculates the dot product of two signed 16-bit integer values held in each 32-bit element of the two or four first source vectors and two signed 16-bit integer values in the corresponding 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

C9.2.200 SDOT (4-way, multiple and indexed vector)

Multi-vector signed integer dot product by indexed element

This instruction calculates the dot product of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors of 32-bit elements, Two ZA single-vectors of 64-bit elements, Four ZA single-vectors of 32-bit elements, and Four ZA single-vectors of 64-bit elements

Assembler Symbols

<T>

Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

Is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn”.

<Tb>

Is the size specifier, encoded in “sz”:

sz	<Tb>
0	B
1	H

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” plus 1 modulo 32.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” plus 3 modulo 32.

C9.2.202 SDOT (4-way, multiple vectors)

Multi-vector signed integer dot product

This instruction calculates the dot product of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding 32-bit or 64-bit element of the two or four second source vectors. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

C9.2.206 SMIN (multiple and single vector)

Multi-vector signed minimum by vector

This instruction determines the signed minimum of elements of the second source vector and the corresponding elements of the two or four first source vectors and destructively places the results in the corresponding elements of the two or four first source vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2)

Assembler Symbols

<Zdn1>

For the “Two registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Zdn2>

Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<Zdn4>

Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
var results : array [[4]] of bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(dn+r);
    let operand2 : bits(VL) = Z{}(m);
    for e = 0 to elements-1 do
        let op1elt : bits(esize) = operand1[e*:esize];
        let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
        let op2elt : bits(esize) = operand2[e*:esize];
        let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
        let res : integer = Min(element1, element2);
        results[[r]][e*:esize] = res[esize-1:0];
    end;
end;

for r = 0 to nreg-1 do
    Z{VL}(dn+r) = results[[r]];
end;
```

C9.2.208 SMLAL (multiple and indexed vector)

Multi-vector signed 16-bit integer multiply-add by indexed element to 32-bit integer

This instruction multiplies each signed 16-bit element in the one, two, or four first source vectors by each signed 16-bit indexed element of the second source vector, widens each product to 32 bits, and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to 7.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

One ZA double-vector

```

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

Is the first vector select offset, encoded as “off2” field times 2.

<offs2>

Is the second vector select offset, encoded as “off2” field times 2 plus 1.

<Zn1>

For the “Two ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm1>

For the “Two ZA double-vectors” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 2.

For the “Four ZA double-vectors” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

<Zm4>

Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as “Zm” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
```

C9.2.211 SMLALL (multiple and indexed vector)

Multi-vector signed integer multiply-add long long by indexed element

This instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors by each signed 8-bit or 16-bit indexed element of the second source vector, widens each product to 32 bits or 64 bits, and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: One ZA quad-vector of 32-bit elements, One ZA quad-vector of 64-bit elements, Two ZA quad-vectors of 32-bit elements, Two ZA quad-vectors of 64-bit elements, Four ZA quad-vectors of 32-bit elements, and Four ZA quad-vectors of 64-bit elements

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

For the “One ZA quad-vector of 32-bit elements” and “One ZA quad-vector of 64-bit elements” variants: is the first vector select offset, encoded as “off2” field times 4.

For the “Four ZA quad-vectors of 32-bit elements”, “Four ZA quad-vectors of 64-bit elements”, “Two ZA quad-vectors of 32-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the first vector select offset, encoded as “o1” field times 4.

<offs4>

For the “One ZA quad-vector of 32-bit elements” and “One ZA quad-vector of 64-bit elements” variants: is the fourth vector select offset, encoded as “off2” field times 4 plus 3.

For the “Four ZA quad-vectors of 32-bit elements”, “Four ZA quad-vectors of 64-bit elements”, “Two ZA quad-vectors of 32-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the fourth vector select offset, encoded as “o1” field times 4 plus 3.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<index>

For the “Four ZA quad-vectors of 32-bit elements”, “One ZA quad-vector of 32-bit elements”, and “Two ZA quad-vectors of 32-bit elements” variants: is the element index, in the range 0 to 15, encoded in the “i4h:i4l” fields.

For the “Four ZA quad-vectors of 64-bit elements”, “One ZA quad-vector of 64-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

<Zn1>

For the “Two ZA quad-vectors of 32-bit elements” and “Two ZA quad-vectors of 64-bit elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA quad-vectors of 32-bit elements” and “Four ZA quad-vectors of 64-bit elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV esize;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 4);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m);
    for i = 0 to 3 do
        let operand3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let segmentbase : integer = e - (e MOD eltspersegment);
            let s : integer = 4 * segmentbase + index;
            let element1 : integer = SInt(operand1[(4 * e + i)*:(esize DIV 4)]);
            let element2 : integer = SInt(operand2[s*:(esize DIV 4)]);
            let product : bits(esize) = (element1 * element2)[esize-1:0];
            result[e*:esize] = operand3[e*:esize] + product;
        end;

Assembler Symbols

<T>

Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

Is the first vector select offset, encoded as “o1” field times 4.

<offs4>

Is the fourth vector select offset, encoded as “o1” field times 4 plus 3.

<Zn1>

For the “Two ZA quad-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA quad-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Tb>

Is the size specifier, encoded in “sz”:

sz	<Tb>
0	B
1	H

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zm1>

For the “Two ZA quad-vectors” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 2.

For the “Four ZA quad-vectors” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

<Zm4>

Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as “Zm” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 4);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m+r);
    for i = 0 to 3 do
        let operand3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let element1 : integer = SInt(operand1[(4 * e + i)*:(esize DIV 4)]);
            let element2 : integer = SInt(operand2[(4 * e + i)*:(esize DIV 4)]);
            let product : bits(esize) = (element1 * element2)[esize-1:0];
            result[e*:esize] = operand3[e*:esize] + product;
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;
```

C9.2.214 SMLSL (multiple and indexed vector)

Multi-vector signed 16-bit integer multiply-subtract by indexed element from 32-bit integer

This instruction multiplies each signed 16-bit element in the one, two, or four first source vectors by each signed 16-bit indexed element of the second source vector, widens each product to 32 bits, and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to 7.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

One ZA double-vector

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

For the “One ZA double-vector” variant: is the first vector select offset, encoded as “off3” field times 2.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the first vector select offset, encoded as “off2” field times 2.

<offs2>

For the “One ZA double-vector” variant: is the second vector select offset, encoded as “off3” field times 2 plus 1.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the second vector select offset, encoded as “off2” field times 2 plus 1.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<index>

Is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

<Zn1>

For the “Two ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;

C9.2.217 SMLSLL (multiple and indexed vector)

Multi-vector signed integer multiply-subtract long long by indexed element

This instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors by each signed 8-bit or 16-bit indexed element of the second source vector, widens each product to 32 bits or 64 bits, and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: One ZA quad-vector of 32-bit elements, One ZA quad-vector of 64-bit elements, Two ZA quad-vectors of 32-bit elements, Two ZA quad-vectors of 64-bit elements, Four ZA quad-vectors of 32-bit elements, and Four ZA quad-vectors of 64-bit elements

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

For the “One ZA quad-vector of 32-bit elements” and “One ZA quad-vector of 64-bit elements” variants: is the first vector select offset, encoded as “off2” field times 4.

For the “Four ZA quad-vectors of 32-bit elements”, “Four ZA quad-vectors of 64-bit elements”, “Two ZA quad-vectors of 32-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the first vector select offset, encoded as “o1” field times 4.

<offs4>

For the “One ZA quad-vector of 32-bit elements” and “One ZA quad-vector of 64-bit elements” variants: is the fourth vector select offset, encoded as “off2” field times 4 plus 3.

For the “Four ZA quad-vectors of 32-bit elements”, “Four ZA quad-vectors of 64-bit elements”, “Two ZA quad-vectors of 32-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the fourth vector select offset, encoded as “o1” field times 4 plus 3.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<index>

For the “Four ZA quad-vectors of 32-bit elements”, “One ZA quad-vector of 32-bit elements”, and “Two ZA quad-vectors of 32-bit elements” variants: is the element index, in the range 0 to 15, encoded in the “i4h:i4l” fields.

For the “Four ZA quad-vectors of 64-bit elements”, “One ZA quad-vector of 64-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

<Zn1>

For the “Two ZA quad-vectors of 32-bit elements” and “Two ZA quad-vectors of 64-bit elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA quad-vectors of 32-bit elements” and “Four ZA quad-vectors of 64-bit elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV esize;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 4);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m);
    for i = 0 to 3 do
        let operand3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let segmentbase : integer = e - (e MOD eltspersegment);
            let s : integer = 4 * segmentbase + index;
            let element1 : integer = SInt(operand1[(4 * e + i)*:(esize DIV 4)]);
            let element2 : integer = SInt(operand2[s*:(esize DIV 4)]);
            let product : bits(esize) = (element1 * element2)[esize-1:0];
            result[e*:esize] = operand3[e*:esize] - product;
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;
```

C9.2.220 SMOP4A (2-way)

Signed 16-bit integer quarter-tile sum of outer products to 32-bit integer, accumulating

This instruction generates four independent quarter-tile signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products are then destructively added to the 32-bit integer destination tile.

This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.221 SMOP4A (4-way)

Signed integer quarter-tile sum of outer products, accumulating

This instruction generates four independent quarter-tile signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively added to the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors, 32-bit, single vectors, 32-bit, multiple and single vectors, 32-bit, multiple vectors, 64-bit, single and multiple vectors, 64-bit, single vectors, 64-bit, multiple and single vectors, and 64-bit, multiple vectors

C9.2.222 SMOP4S (2-way)

Signed 16-bit integer quarter-tile sum of outer products to 32-bit integer, subtracting

This instruction generates four independent quarter-tile signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products are then destructively subtracted from the 32-bit integer destination tile.

This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.223 SMOP4S (4-way)

Signed integer quarter-tile sum of outer products, subtracting

This instruction generates four independent quarter-tile signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively subtracted from the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors, 32-bit, single vectors, 32-bit, multiple and single vectors, 32-bit, multiple vectors, 64-bit, single and multiple vectors, 64-bit, single vectors, 64-bit, multiple and single vectors, and 64-bit, multiple vectors

C9.2.224 SMOPA (2-way)

Signed 16-bit integer sum of outer products to 32-bit integer, accumulating

This instruction works with a 32-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds $SVL_S \times 2$ sub-matrix of signed 16-bit integer values, and the second source holds $2 \times SVL_S$ sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a $SVL_S \times 2$ sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a $2 \times SVL_S$ sub-matrix.

C9.2.225 SMOPA (4-way)

Signed integer sum of outer products, accumulating

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $SVL_S \times 4$ sub-matrix of signed 8-bit integer values, and the second source holds $4 \times SVL_S$ sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds $SVL_D \times 4$ sub-matrix of signed 16-bit integer values, and the second source holds $4 \times SVL_D$ sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer or $SVL_D \times SVL_D$ widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_D \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_D$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

C9.2.227 SMOPS (4-way)

Signed integer sum of outer products, subtracting

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $SVL_S \times 4$ sub-matrix of signed 8-bit integer values, and the second source holds $4 \times SVL_S$ sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds $SVL_D \times 4$ sub-matrix of signed 16-bit integer values, and the second source holds $4 \times SVL_D$ sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer or $SVL_D \times SVL_D$ widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_D \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_D$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

C9.2.238 SQRSHRN

Multi-vector signed saturating rounding shift right narrow by immediate to interleaved integer

This instruction shifts right by an immediate value the signed integer value in each element of the four source vectors, and places the four-way interleaved rounded results in the quarter-width destination elements. Each result element is saturated to the quarter-width N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. The immediate shift amount is an unsigned value in the range 1 to number of bits per source element.

This instruction is unpredicated.

C9.2.245 ST1B (scalar plus scalar, strided registers)

Contiguous store of bytes from multiple strided vectors (scalar index)

This instruction performs a contiguous store of bytes from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements are not written to memory.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2)

31	30	29	28	25	24	23	22	21	20	16	15	14	13	12	10	9	5	4	3	2	0
1	0	1	0 0 0 0		1	0	0	1	Rm		0	0	0	PNg		Rn		T	0	Zt	
												msz							N		

Encoding

```
ST1B  { <Zt1>.B, <Zt2>.B }, <PNg>, [<Xn|SP>, <Xm>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 2;
let tstride : integer = 8;
let t : integer = UInt(T::'0'::Zt);
let esize : integer{} = 8;
```

Four registers

(FEAT_SME2)

31	30	29	28	25	24	23	22	21	20	16	15	14	13	12	10	9	5	4	3	2	1	0
1	0	1	0 0 0 0		1	0	0	1	Rm		1	0	0	PNg		Rn		T	0	0	Zt	
												msz							N			

Encoding

```
ST1B  { <Zt1>.B, <Zt2>.B, <Zt3>.B, <Zt4>.B }, <PNg>, [<Xn|SP>, <Xm>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('1'::PNg);

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as “T:‘0’:Zt”.

For the “Four registers” variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as “T:‘00’:Zt”.

<Zt2>

For the “Two registers” variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as “T:‘1’:Zt”.

For the “Four registers” variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as “T:‘01’:Zt”.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the general-purpose offset register, encoded in the “Rm” field.

<Zt3>

Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as “T:‘10’:Zt”.

<Zt4>

Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as “T:‘11’:Zt”.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mbytes : integer{} = esize DIV 8;
var offset : bits(64);
var base : bits(64);
var addr : bits(64);
var src : bits(VL);
let pred : bits(PL) = P{}(g);
let mask : bits(PL * nreg) = CounterToPredicate{}(pred[15:0]);
let contiguous : boolean = TRUE;
let nontemporal : boolean = FALSE;
var transfer : integer = t;
let tagchecked : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescSVE(MemOp_STORE, nontemporal, contiguous,
                                                  tagchecked);

if !AnyActiveElement{PL*nreg}(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool(Unpredictable_CHECKSPNONEACTIVE) then
        CheckSPAlignment();
    end;
else
    if n == 31 then CheckSPAlignment(); end;
end;
```

C9.2.246 ST1B (scalar plus scalar, tile slice)

Contiguous store of bytes from 8-bit element ZA tile slice

This instruction performs a contiguous store of bytes from an 8-bit element ZA tile slice. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 8-bit elements in a vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset that is added to the base address. Inactive elements are not written to memory.

SME

(FEAT_SME)

31	30	29	28			25	24	23	22	21	20	16	15	14	13	12	10	9	5	4	3	0
1	1	1	0	0	0	0	0	0	0	1	Rm		V	Rs		Pg		Rn		0	off4

C9.2.252 ST1H (scalar plus scalar, tile slice)

Contiguous store of halfwords from 16-bit element ZA tile slice

This instruction performs a contiguous store of halfwords from a 16-bit element ZA tile slice. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 16-bit elements in a vector. The immediate offset is in the range 0 to 7. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset that is multiplied by 2 and added to the base address. Inactive elements are not written to memory.

C9.2.255 ST1W (scalar plus scalar, strided registers)

Contiguous store of words from multiple strided vectors (scalar index)

This instruction performs a contiguous store of words from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements are not written to memory.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2)

31	30	29	28	25	24	23	22	21	20	16	15	14	13	12	10	9	5	4	3	2	0
1	0	1	0 0 0 0		1	0	0	1	Rm		0	1	0	PNg		Rn		T	0	Zt	
												msz							N		

Encoding

```
ST1W  { <Zt1>.S, <Zt2>.S }, <PNg>, [<Xn|SP>, <Xm>, LSL #2]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 2;
let tstride : integer = 8;
let t : integer = UInt(T::'0'::Zt);
let esize : integer{} = 32;
```

Four registers

(FEAT_SME2)

31	30	29	28	25	24	23	22	21	20	16	15	14	13	12	10	9	5	4	3	2	1	0
1	0	1	0 0 0 0		1	0	0	1	Rm		1	1	0	PNg		Rn		T	0	0	Zt	
												msz							N			

Encoding

```
ST1W  { <Zt1>.S, <Zt2>.S, <Zt3>.S, <Zt4>.S }, <PNg>, [<Xn|SP>, <Xm>, LSL #2]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 4;
let tstride : integer = 4;
let t : integer = UInt(T::'00'::Zt);
let esize : integer{} = 32;

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as “T:‘0’:Zt”.

For the “Four registers” variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as “T:‘00’:Zt”.

<Zt2>

For the “Two registers” variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as “T:‘1’:Zt”.

For the “Four registers” variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as “T:‘01’:Zt”.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the general-purpose offset register, encoded in the “Rm” field.

<Zt3>

Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as “T:‘10’:Zt”.

<Zt4>

Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as “T:‘11’:Zt”.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mbytes : integer{} = esize DIV 8;
var offset : bits(64);
var base : bits(64);
var addr : bits(64);
var src : bits(VL);
let pred : bits(PL) = P{}(g);
let mask : bits(PL * nreg) = CounterToPredicate{}(pred[15:0]);
let contiguous : boolean = TRUE;
let nontemporal : boolean = FALSE;
var transfer : integer = t;
let tagchecked : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescSVE(MemOp_STORE, nontemporal, contiguous,
                                                  tagchecked);

if !AnyActiveElement{PL*nreg}(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool(Unpredictable_CHECKSPNONEACTIVE) then
        CheckSPAlignment();
    end;
else
    if n == 31 then CheckSPAlignment(); end;
end;
```

C9.2.256 ST1W (scalar plus scalar, tile slice)

Contiguous store of words from 32-bit element ZA tile slice

This instruction performs a contiguous store of words from a 32-bit element ZA tile slice. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 32-bit elements in a vector. The immediate offset is in the range 0 to 3. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset that is multiplied by 4 and added to the base address. Inactive elements are not written to memory.

SME

(FEAT_SME)

31	30 29	28 25	24	23 22	21	20 16	15	14 13	12 10	9 5	4	3 2	1 0
1	1 1	0 0 0 0	0	1 0	1	Rm	V	Rs	Pg	Rn	0	ZAt	off2
				msz									

Encoding

```
ST1W  { <ZAt><HV>.S[<Ws>, <offs>] }, <Pg>, [<Xn|SP>{, <Xm>, LSL #2}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('0'::Pg);
let s : integer = UInt('011'::Rs);
let t : integer = UInt(ZAt);
let offset : integer = UInt(off2);
let esize : integer{} = 32;
let vertical : boolean = V == '1';
```

Assembler Symbols

<ZAt>

Is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the “ZAt” field.

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded as “Rs” plus 12.

<offs>

Is the slice index offset, in the range 0 to 3, encoded in the “off2” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the “Rm” field.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let dim : integer = VL DIV esize;
var base : bits(64);
var addr : bits(64);

C9.2.257 STMOPA (2-way)

Signed 16-bit integer sparse sum of outer products to 32-bit integer, accumulating

This instruction generates signed integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 16-bit signed values from each overlapping 32-bit containers of the two $SVL_S \times 2$ sub-matrices in the first source vectors by the two 16-bit signed values from the corresponding 32-bit container of the $2 \times SVL_S$ sub-matrix in the second source vector. The two selected elements from each overlapping 32-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two $SVL_S \times 2$ sub-matrices. Each 32-bit container of the second source vector holds 2 elements of columns of a compressed $2 \times SVL_S$ sub-matrix.

The 2-in-4 16-bit signed values from overlapping 32-bit containers of the first source vectors are selected by 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 32-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

C9.2.258 STMOPA (4-way)

Signed 8-bit integer sparse sum of outer products to 32-bit integer, accumulating

This instruction generates signed integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit signed values from each overlapping 32-bit containers of the two $SVL_S \times 4$ sub-matrices in the first source vectors by the four 8-bit signed values from the corresponding 32-bit container of the $4 \times SVL_S$ sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two $SVL_S \times 4$ sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed $4 \times SVL_S$ sub-matrix.

The two sets of 2-in-4 8-bit signed values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

C9.2.259 STNT1B (scalar plus immediate, strided registers)

Contiguous store non-temporal of bytes from multiple strided vectors (immediate index)

This instruction performs a contiguous non-temporal store of bytes from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and immediate index that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2)

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as “T:‘0’:Zt”.

For the “Four registers” variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as “T:‘00’:Zt”.

<Zt2>

For the “Two registers” variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as “T:‘1’:Zt”.

For the “Four registers” variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as “T:‘01’:Zt”.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded as “imm4” times 2.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded as “imm4” times 4.

<Zt3>

Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as “T:‘10’:Zt”.

<Zt4>

Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as “T:‘11’:Zt”.

Operation

```
CheckStreamingSVEEnabled();

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded as “PNg” plus 8.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded as “imm4” times 2.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded as “imm4” times 4.

<Zt3>

Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as “T:‘10’:Zt”.

<Zt4>

Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as “T:‘11’:Zt”.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mbytes : integer{} = esize DIV 8;
var base : bits(64);
var addr : bits(64);
var src : bits(VL);
let pred : bits(PL) = P{}(g);
let mask : bits(PL * nreg) = CounterToPredicate{}(pred[15:0]);
let contiguous : boolean = TRUE;
```

C9.2.264 STNT1H (scalar plus scalar, strided registers)

Contiguous store non-temporal of halfwords from multiple strided vectors (scalar index)

This instruction performs a contiguous non-temporal store of halfwords from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

C9.2.267 STR (array vector)

Store ZA array vector

This instruction performs a contiguous store of bytes from a ZA array vector to the memory address generated by a 64-bit scalar base plus an optional immediate offset multiplied by the current vector length in bytes. The ZA array vector is selected by the sum of the vector select register and the same immediate offset, modulo the number of bytes in a Streaming SVE vector.

This instruction is unpredicated.

The store is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

C9.2.269 SUB (to array, array and multiple vectors)

Multi-vector subtract from ZA array vectors

This instruction destructively subtracts all elements of the two or four source vectors from the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

Assembler Symbols

<T>

Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zm1>

For the “Two ZA single-vectors” variant: is the name of the first scalable vector register of the source multi-vector group, encoded as “Zm” times 2.

For the “Four ZA single-vectors” variant: is the name of the first scalable vector register of the source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zm4>

Is the name of the fourth scalable vector register of the source multi-vector group, encoded as “Zm” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = ZAvector{}(vec);
    let operand2 : bits(VL) = Z{}(m+r);
    for e = 0 to elements-1 do
        let element1 : bits(esize) = operand1[e*:esize];
```

C9.2.272 SUDOT (4-way, multiple and indexed vector)

Multi-vector signed by unsigned 8-bit integer dot product by indexed elements to 32-bit integer

This instruction calculates the dot product of four signed 8-bit integer values held in each 32-bit element of the two or four first source vectors and four unsigned 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

let nreg : integer{} = 4;
```

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

Is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn”.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” plus 1 modulo 32.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” plus 3 modulo 32.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}((n+r) MOD 32);
    let operand2 : bits(VL) = Z{}(m);
    let operand3 : bits(VL) = ZAvector{}(vec);
    for e = 0 to elements-1 do
        var sum : bits(esize) = operand3[e*:esize];
        for i = 0 to 3 do
            let element1 : integer = SInt(operand1[(4 * e + i)*:(esize DIV 4)]);
            let element2 : integer = UInt(operand2[(4 * e + i)*:(esize DIV 4)]);
            sum = sum + element1 * element2;
        end;
        result[e*:esize] = sum;
    end;
    ZAvector{VL}(vec) = result;
    vec = vec + vstride;
end;
```

C9.2.274 SUMLALL (multiple and indexed vector)

Multi-vector signed by unsigned 8-bit integer multiply-add by indexed element to 32-bit integer

This instruction multiplies each signed 8-bit element in the one, two, or four first source vectors by each unsigned 8-bit indexed element of the second source vector, widens each product to 32 bits, and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The element index range is from 0 to one less than the number of elements per 128-bit segment.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA quad-vector, Two ZA quad-vectors, and Four ZA quad-vectors

C9.2.276 SUMOP4A

Signed by unsigned integer quarter-tile sum of outer products, accumulating

This instruction generates four independent quarter-tile signed by unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively added to the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors, 32-bit, single vectors, 32-bit, multiple and single vectors, 32-bit, multiple vectors, 64-bit, single and multiple vectors, 64-bit, single vectors, 64-bit, multiple and single vectors, and 64-bit, multiple vectors

Assembler Symbols

<ZAda>

For the “32-bit, multiple and single vectors”, “32-bit, multiple vectors”, “32-bit, single and multiple vectors”, and “32-bit, single vectors” variants: is the name of the ZA tile ZA0-ZA3, encoded in the “ZAda” field.

For the “64-bit, multiple and single vectors”, “64-bit, multiple vectors”, “64-bit, single and multiple vectors”, and “64-bit, single vectors” variants: is the name of the ZA tile ZA0-ZA7, encoded in the “ZAda” field.

<Zn>

Is the name of the first source scalable vector register, registers in the range Z0-Z15, encoded as “Zn” times 2.

<Zm1>

Is the name of the first scalable vector register of the second source multi-vector group, in the range Z16-Z31, encoded as “Zm” times 2 plus 16.

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, in the range Z16-Z31, encoded as “Zm” times 2 plus 17.

<Zm>

Is the name of the second source scalable vector register, registers in the range Z16-Z31, encoded as “Zm” times 2 plus 16.

<Zn1>

Is the name of the first scalable vector register of the first source multi-vector group, in the range Z0-Z15, encoded as “Zn” times 2.

C9.2.277 SUMOP4S

Signed by unsigned integer quarter-tile sum of outer products, subtracting

This instruction generates four independent quarter-tile signed by unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively subtracted from the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors, 32-bit, single vectors, 32-bit, multiple and single vectors, 32-bit, multiple vectors, 64-bit, single and multiple vectors, 64-bit, single vectors, 64-bit, multiple and single vectors, and 64-bit, multiple vectors

C9.2.278 SUMOPA (4-way)

Signed by unsigned integer sum of outer products, accumulating

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $SVL_S \times 4$ sub-matrix of signed 8-bit integer values, and the second source holds $4 \times SVL_S$ sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds $SVL_D \times 4$ sub-matrix of signed 16-bit integer values, and the second source holds $4 \times SVL_D$ sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer or $SVL_D \times SVL_D$ widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_D \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_D$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

C9.2.279 SUMOPS

Signed by unsigned integer sum of outer products, subtracting

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $SVL_S \times 4$ sub-matrix of signed 8-bit integer values, and the second source holds $4 \times SVL_S$ sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds $SVL_D \times 4$ sub-matrix of signed 16-bit integer values, and the second source holds $4 \times SVL_D$ sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer or $SVL_D \times SVL_D$ widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_D \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_D$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

Assembler Symbols

<Zd1>

For the “Two registers” variant: is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 4.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	D

<Zd2>

Is the name of the second scalable vector register of the destination multi-vector group, encoded as “Zd” times 2 plus 1.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

<Tb>

Is the size specifier, encoded in “size”:

size	<Tb>
00	RESERVED
01	B
10	H
11	S

<Zd4>

Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as “Zd” times 4 plus 3.

<Zn1>

Is the name of the first scalable vector register of the source multi-vector group, encoded as “Zn” times 2.

<Zn2>

Is the name of the second scalable vector register of the source multi-vector group, encoded as “Zn” times 2 plus 1.

C9.2.281 SUTMOPA

Signed by unsigned 8-bit integer sparse sum of outer products to 32-bit integer, accumulating

This instruction generates signed by unsigned integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit signed values from each overlapping 32-bit containers of the two $SVL_S \times 4$ sub-matrices in the first source vectors by the four 8-bit unsigned values from the corresponding 32-bit container of the $4 \times SVL_S$ sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two $SVL_S \times 4$ sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed $4 \times SVL_S$ sub-matrix.

The two sets of 2-in-4 8-bit signed values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

C9.2.282 SUVDOT

Multi-vector signed by unsigned 8-bit integer vertical dot product by indexed element to 32-bit integer

This instruction calculates the vertical dot product of the corresponding signed 8-bit elements from the four first source vectors and four unsigned 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.

The `vector group` symbol `VGx4` indicates that the ZA operand consists of four ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

C9.2.283 SVDOT (2-way)

Multi-vector signed 16-bit integer vertical dot product by indexed element to 32-bit integer

This instruction calculates the vertical dot product of the corresponding two signed 16-bit integer values held in the two first source vectors and two signed 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The `vector group` symbol `VGx2` indicates that the ZA operand consists of two ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

Is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<index>

Is the immediate index of a pair of 16-bit elements within each 128-bit vector segment, in the range 0 to 3, encoded in the “i2” field.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV 2;
let eltspersegment : integer = 128 DIV esize;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL);

for r = 0 to 1 do
    let operand3 : bits(VL) = ZAvector{}(vec);
    for e = 0 to elements-1 do
        let segmentbase : integer = e - (e MOD eltspersegment);
        let s : integer = segmentbase + index;
        var sum : bits(esize) = operand3[e*:esize];
        for i = 0 to 1 do
            let operand1 : bits(VL) = Z{}(n+i);
            let element1 : integer = SInt(operand1[(2 * e + r)*:(esize DIV 2)]);
            let element2 : integer = SInt(operand2[(2 * s + i)*:(esize DIV 2)]);
            sum = sum + element1 * element2;
        end;
        result[e*:esize] = sum;
    end;
    ZAvector{VL}(vec) = result;
    vec = vec + vstride;
end;
```

C9.2.284 SVDOT (4-way)

Multi-vector signed integer vertical dot product by indexed element

This instruction calculates the vertical dot product of the corresponding four signed 8-bit or 16-bit integer values held in the four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment.

The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.

The `vector group` symbol `VGx4` indicates that the ZA operand consists of four ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 8-bit to 32-bit and 16-bit to 64-bit

C9.2.287 UDOT (2-way, multiple and indexed vector)

Multi-vector unsigned 16-bit integer dot product by indexed element to 32-bit integer

This instruction calculates the dot product of two unsigned 16-bit integer values held in each 32-bit element of the two or four first source vectors and two unsigned 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

C9.2.289 UDOT (2-way, multiple vectors)

Multi-vector unsigned 16-bit integer dot product to 32-bit integer

This instruction calculates the dot product of two unsigned 16-bit integer values held in each 32-bit element of the two or four first source vectors and two unsigned 16-bit integer values in the corresponding 32-bit element of the two or four second source vectors. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

C9.2.290 UDOT (4-way, multiple and indexed vector)

Multi-vector unsigned integer dot product by indexed element

This instruction calculates the dot product of four unsigned 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four unsigned 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors of 32-bit elements, Two ZA single-vectors of 64-bit elements, Four ZA single-vectors of 32-bit elements, and Four ZA single-vectors of 64-bit elements

let esize : integer{} = 32 << UInt(sz);
let n : integer = UInt(Zn::'00');
let m : integer = UInt(Zm::'00');
let offset : integer = UInt(off3);
let nreg : integer{} = 4;
```

Assembler Symbols

<T>

Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

For the “Two ZA single-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA single-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Tb>

Is the size specifier, encoded in “sz”:

sz	<Tb>
0	B
1	H

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm1>

For the “Two ZA single-vectors” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 2.

For the “Four ZA single-vectors” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 4.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

<Zm4>

Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as “Zm” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m+r);
    let operand3 : bits(VL) = ZAvector{}(vec);
    for e = 0 to elements-1 do
        var sum : bits(esize) = operand3[e*:esize];
        for i = 0 to 3 do
            let element1 : integer = UInt(operand1[(4 * e + i)*:(esize DIV 4)]);
            let element2 : integer = UInt(operand2[(4 * e + i)*:(esize DIV 4)]);
            sum = sum + element1 * element2;
        end;
        result[e*:esize] = sum;
    end;
    ZAvector{VL}(vec) = result;
    vec = vec + vstride;
end;
```

C9.2.297 UMLAL (multiple and indexed vector)

Multi-vector unsigned 16-bit integer multiply-add by indexed element to 32-bit integer

This instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors by each unsigned 16-bit indexed element of the second source vector, widens each product to 32 bits, and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to 7.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

One ZA double-vector

```

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

For the “One ZA double-vector” variant: is the first vector select offset, encoded as “off3” field times 2.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the first vector select offset, encoded as “off2” field times 2.

<offs2>

For the “One ZA double-vector” variant: is the second vector select offset, encoded as “off3” field times 2 plus 1.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the second vector select offset, encoded as “off2” field times 2 plus 1.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<index>

Is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

<Zn1>

For the “Two ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV esize;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 2);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m);
    for i = 0 to 1 do
        let operand3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let segmentbase : integer = e - (e MOD eltspersegment);
            let s : integer = 2 * segmentbase + index;
            let element1 : integer = UInt(operand1[(2 * e + i)*:(esize DIV 2)]);
            let element2 : integer = UInt(operand2[s*:(esize DIV 2)]);
            let product : bits(esize) = (element1 * element2)[esize-1:0];
            result[e*:esize] = operand3[e*:esize] + product;
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;
```

C9.2.298 UMLAL (multiple and single vector)

Multi-vector unsigned 16-bit integer multiply-add by vector to 32-bit integer

This instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors by each unsigned 16-bit element in the second source vector, widens each product to 32 bits, and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

One ZA double-vector

C9.2.300 UMLALL (multiple and indexed vector)

Multi-vector unsigned integer multiply-add long long by indexed element

This instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors by each unsigned 8-bit or 16-bit indexed element of the second source vector, widens each product to 32 bits or 64 bits, and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: One ZA quad-vector of 32-bit elements, One ZA quad-vector of 64-bit elements, Two ZA quad-vectors of 32-bit elements, Two ZA quad-vectors of 64-bit elements, Four ZA quad-vectors of 32-bit elements, and Four ZA quad-vectors of 64-bit elements

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

For the “One ZA quad-vector of 32-bit elements” and “One ZA quad-vector of 64-bit elements” variants: is the first vector select offset, encoded as “off2” field times 4.

For the “Four ZA quad-vectors of 32-bit elements”, “Four ZA quad-vectors of 64-bit elements”, “Two ZA quad-vectors of 32-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the first vector select offset, encoded as “o1” field times 4.

<offs4>

For the “One ZA quad-vector of 32-bit elements” and “One ZA quad-vector of 64-bit elements” variants: is the fourth vector select offset, encoded as “off2” field times 4 plus 3.

For the “Four ZA quad-vectors of 32-bit elements”, “Four ZA quad-vectors of 64-bit elements”, “Two ZA quad-vectors of 32-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the fourth vector select offset, encoded as “o1” field times 4 plus 3.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<index>

For the “Four ZA quad-vectors of 32-bit elements”, “One ZA quad-vector of 32-bit elements”, and “Two ZA quad-vectors of 32-bit elements” variants: is the element index, in the range 0 to 15, encoded in the “i4h:i4l” fields.

For the “Four ZA quad-vectors of 64-bit elements”, “One ZA quad-vector of 64-bit elements”, and “Two ZA quad-vectors of 64-bit elements” variants: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

<Zn1>

For the “Two ZA quad-vectors of 32-bit elements” and “Two ZA quad-vectors of 64-bit elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA quad-vectors of 32-bit elements” and “Four ZA quad-vectors of 64-bit elements” variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV esize;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 4);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m);
    for i = 0 to 3 do
        let operand3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let segmentbase : integer = e - (e MOD eltspersegment);
            let s : integer = 4 * segmentbase + index;
            let element1 : integer = UInt(operand1[(4 * e + i)*:(esize DIV 4)]);
            let element2 : integer = UInt(operand2[s*:(esize DIV 4)]);
            let product : bits(esize) = (element1 * element2)[esize-1:0];
            result[e*:esize] = operand3[e*:esize] + product;
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;
```

C9.2.301 UMLALL (multiple and single vector)

Multi-vector unsigned integer multiply-add long long by vector

This instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors by each unsigned 8-bit or 16-bit element in the second source vector, widens each product to 32 bits or 64 bits, and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 3 classes: One ZA quad-vector, Two ZA quad-vectors, and Four ZA quad-vectors

C9.2.303 UMLSL (multiple and indexed vector)

Multi-vector unsigned 16-bit integer multiply-subtract by indexed element from 32-bit integer

This instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors by each unsigned 16-bit indexed element of the second source vector, widens each product to 32 bits, and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to 7.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

For the “One ZA double-vector” variant: is the first vector select offset, encoded as “off3” field times 2.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the first vector select offset, encoded as “off2” field times 2.

<offs2>

For the “One ZA double-vector” variant: is the second vector select offset, encoded as “off3” field times 2 plus 1.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the second vector select offset, encoded as “off2” field times 2 plus 1.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Zn1>

Is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn”.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” plus 1 modulo 32.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” plus 3 modulo 32.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 2);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}((n+r) MOD 32);
    let operand2 : bits(VL) = Z{}(m);
    for i = 0 to 1 do
        let operand3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let element1 : integer = UInt(operand1[(2 * e + i)*:(esize DIV 2)]);
            let element2 : integer = UInt(operand2[(2 * e + i)*:(esize DIV 2)]);
            let product : bits(esize) = (element1 * element2)[esize-1:0];
            result[e*:esize] = operand3[e*:esize] - product;
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;
```

C9.2.306 UMLSLL (multiple and indexed vector)

Multi-vector unsigned integer multiply-subtract long long by indexed element

This instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors by each unsigned 8-bit or 16-bit indexed element of the second source vector, widens each product to 32 bits or 64 bits, and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: One ZA quad-vector of 32-bit elements, One ZA quad-vector of 64-bit elements, Two ZA quad-vectors of 32-bit elements, Two ZA quad-vectors of 64-bit elements, Four ZA quad-vectors of 32-bit elements, and Four ZA quad-vectors of 64-bit elements

One ZA quad-vector of 32-bit elements

C9.2.308 UMLSLL (multiple vectors)

Multi-vector unsigned integer multiply-subtract long long

This instruction multiplies each unsigned 8-bit or 16-bit element in the two or four first source vectors by each unsigned 8-bit or 16-bit element in the one, two, or four second source vectors, widens each product to 32 bits or 64 bits, and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The quad-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: Two ZA quad-vectors and Four ZA quad-vectors

C9.2.309 UMOP4A (2-way)

Unsigned 16-bit integer quarter-tile sum of outer products to 32-bit integer, accumulating

This instruction generates four independent quarter-tile unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products are then destructively added to the 32-bit integer destination tile.

This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.310 UMOP4A (4-way)

Unsigned integer quarter-tile sum of outer products, accumulating

This instruction generates four independent quarter-tile unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively added to the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors, 32-bit, single vectors, 32-bit, multiple and single vectors, 32-bit, multiple vectors, 64-bit, single and multiple vectors, 64-bit, single vectors, 64-bit, multiple and single vectors, and 64-bit, multiple vectors

C9.2.311 UMOP4S (2-way)

Unsigned 16-bit integer quarter-tile sum of outer products to 32-bit integer, subtracting

This instruction generates four independent quarter-tile unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products are then destructively subtracted from the 32-bit integer destination tile.

This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.312 UMOP4S (4-way)

Unsigned integer quarter-tile sum of outer products, subtracting

This instruction generates four independent quarter-tile unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively subtracted from the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors, 32-bit, single vectors, 32-bit, multiple and single vectors, 32-bit, multiple vectors, 64-bit, single and multiple vectors, 64-bit, single vectors, 64-bit, multiple and single vectors, and 64-bit, multiple vectors

C9.2.313 UMOPA (2-way)

Unsigned 16-bit integer sum of outer products to 32-bit integer, accumulating

This instruction works with a 32-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds $SVL_S \times 2$ sub-matrix of unsigned 16-bit integer values, and the second source holds $2 \times SVL_S$ sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a $SVL_S \times 2$ sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a $2 \times SVL_S$ sub-matrix.

C9.2.314 UMOPA (4-way)

Unsigned integer sum of outer products, accumulating

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $SVL_S \times 4$ sub-matrix of unsigned 8-bit integer values, and the second source holds $4 \times SVL_S$ sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds $SVL_D \times 4$ sub-matrix of unsigned 16-bit integer values, and the second source holds $4 \times SVL_D$ sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer or $SVL_D \times SVL_D$ widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_D \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_D$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

C9.2.316 UMOPS (4-way)

Unsigned integer sum of outer products, subtracting

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $SVL_S \times 4$ sub-matrix of unsigned 8-bit integer values, and the second source holds $4 \times SVL_S$ sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds $SVL_D \times 4$ sub-matrix of unsigned 16-bit integer values, and the second source holds $4 \times SVL_D$ sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer or $SVL_D \times SVL_D$ widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_D \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_D$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

Assembler Symbols

<Zdn1>

For the “Two registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Zdn2>

Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<Zdn4>

Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
var results : array [[4]] of bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(dn+r);
    let operand2 : bits(VL) = Z{}(m);
    for e = 0 to elements-1 do
        let element : integer =  UInt(operand1[e*:esize]);
        var shift : integer = ShiftSat(SInt(operand2[e*:esize]), esize);
        var res : integer;
        if shift >= 0 then
            res = element << shift;
        else
            shift = -shift;
            res = (element + (1 << (shift - 1))) >> shift;
        end;
        results[[r]][e*:esize] = res[esize-1:0];
    end;
end;

for r = 0 to nreg-1 do
    Z{VL}(dn+r) = results[[r]];
end;
```

C9.2.324 URSHL (multiple vectors)

Multi-vector unsigned rounding shift left

This instruction shifts the unsigned elements of the two or four first source vectors by the corresponding elements of the two or four second source vectors, and destructively places the rounded results in the corresponding elements of the two or four first source vectors. A positive shift amount performs a left shift, otherwise a right shift by the negated shift amount is performed.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

C9.2.325 USDOT (4-way, multiple and indexed vector)

Multi-vector unsigned by signed 8-bit integer dot product by indexed element to 32-bit integer

This instruction calculates the dot product of four unsigned 8-bit integer values held in each 32-bit element of the two or four first source vectors and four signed 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

C9.2.328 USMLALL (multiple and indexed vector)

Multi-vector unsigned by signed 8-bit integer multiply-add by indexed element to 32-bit integer

This instruction multiplies each unsigned 8-bit element in the one, two, or four first source vectors by each signed 8-bit indexed element of the second source vector, widens each product to 32 bits, and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The element index range is from 0 to one less than the number of elements per 128-bit segment.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA quad-vector, Two ZA quad-vectors, and Four ZA quad-vectors

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded as “Rv” plus 8.

<offs1>

For the “One ZA quad-vector” variant: is the first vector select offset, encoded as “off2” field times 4.

For the “Four ZA quad-vectors” and “Two ZA quad-vectors” variants: is the first vector select offset, encoded as “o1” field times 4.

<offs4>

For the “One ZA quad-vector” variant: is the fourth vector select offset, encoded as “off2” field times 4 plus 3.

For the “Four ZA quad-vectors” and “Two ZA quad-vectors” variants: is the fourth vector select offset, encoded as “o1” field times 4 plus 3.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<index>

Is the element index, in the range 0 to 15, encoded in the “i4h:i4l” fields.

<Zn1>

For the “Two ZA quad-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA quad-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV esize;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 4);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(n+r);
    let operand2 : bits(VL) = Z{}(m);
    for i = 0 to 3 do
        let operand3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let segmentbase : integer = e - (e MOD eltspersegment);
            let s : integer = 4 * segmentbase + index;
            let element1 : integer = UInt(operand1[(4 * e + i)*:(esize DIV 4)]);
            let element2 : integer = SInt(operand2[s*:(esize DIV 4)]);
            let product : bits(esize) = (element1 * element2)[esize-1:0];
            result[e*:esize] = operand3[e*:esize] + product;
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;
```

C9.2.329 USMLALL (multiple and single vector)

Multi-vector unsigned by signed 8-bit integer multiply-add by vector to 32-bit integer

This instruction multiplies each unsigned 8-bit element in the one, two, or four first source vectors by each signed 8-bit element in the second source vector, widens each product to 32 bits, and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA quad-vector, Two ZA quad-vectors, and Four ZA quad-vectors

One ZA quad-vector

C9.2.331 USMOP4A

Unsigned by signed integer quarter-tile sum of outer products, accumulating

This instruction generates four independent quarter-tile unsigned by signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively added to the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors, 32-bit, single vectors, 32-bit, multiple and single vectors, 32-bit, multiple vectors, 64-bit, single and multiple vectors, 64-bit, single vectors, 64-bit, multiple and single vectors, and 64-bit, multiple vectors

C9.2.332 USMOP4S

Unsigned by signed integer quarter-tile sum of outer products, subtracting

This instruction generates four independent quarter-tile unsigned by signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively subtracted from the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors, 32-bit, single vectors, 32-bit, multiple and single vectors, 32-bit, multiple vectors, 64-bit, single and multiple vectors, 64-bit, single vectors, 64-bit, multiple and single vectors, and 64-bit, multiple vectors

C9.2.333 USMOPA (4-way)

Unsigned by signed integer sum of outer products, accumulating

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $SVL_S \times 4$ sub-matrix of unsigned 8-bit integer values, and the second source holds $4 \times SVL_S$ sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds $SVL_D \times 4$ sub-matrix of unsigned 16-bit integer values, and the second source holds $4 \times SVL_D$ sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer or $SVL_D \times SVL_D$ widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_D \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_D$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

C9.2.334 USMOPS

Unsigned by signed integer sum of outer products, subtracting

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

This instruction multiplies the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $SVL_S \times 4$ sub-matrix of unsigned 8-bit integer values, and the second source holds $4 \times SVL_S$ sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds $SVL_D \times 4$ sub-matrix of unsigned 16-bit integer values, and the second source holds $4 \times SVL_D$ sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer or $SVL_D \times SVL_D$ widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_S \times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_S$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $SVL_D \times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times SVL_D$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

C9.2.335 USTMOPA

Unsigned by signed 8-bit integer sparse sum of outer products to 32-bit integer, accumulating

This instruction generates unsigned by signed integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit unsigned values from each overlapping 32-bit containers of the two $SVL_S \times 4$ sub-matrices in the first source vectors by the four 8-bit signed values from the corresponding 32-bit container of the $4 \times SVL_S$ sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two $SVL_S \times 4$ sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed $4 \times SVL_S$ sub-matrix.

The two sets of 2-in-4 8-bit unsigned values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

C9.2.336 USVDOT

Multi-vector unsigned by signed 8-bit integer vertical dot product by indexed element to 32-bit integer

This instruction calculates the vertical dot product of corresponding unsigned 8-bit elements from the four first source vectors and four signed 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.

The `vector group` symbol `VGx4` indicates that the ZA operand consists of four ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

C9.2.337 UTMOPA (2-way)

Unsigned 16-bit integer sparse sum of outer products to 32-bit integer, accumulating

This instruction generates unsigned integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 16-bit unsigned values from each overlapping 32-bit containers of the two $SVL_S \times 2$ sub-matrices in the first source vectors by the two 16-bit unsigned values from the corresponding 32-bit container of the $2 \times SVL_S$ sub-matrix in the second source vector. The two selected elements from each overlapping 32-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two $SVL_S \times 2$ sub-matrices. Each 32-bit container of the second source vector holds 2 elements of columns of a compressed $2 \times SVL_S$ sub-matrix.

The 2-in-4 16-bit unsigned values from overlapping 32-bit containers of the first source vectors are selected by 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 32-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

C9.2.338 UTMOPA (4-way)

Unsigned 8-bit integer sparse sum of outer products to 32-bit integer, accumulating

This instruction generates unsigned integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit unsigned values from each overlapping 32-bit containers of the two $SVL_S \times 4$ sub-matrices in the first source vectors by the four 8-bit unsigned values from the corresponding 32-bit container of the $4 \times SVL_S$ sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two $SVL_S \times 4$ sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed $4 \times SVL_S$ sub-matrix.

The two sets of 2-in-4 8-bit unsigned values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

C9.2.340 UVDOT (2-way)

Multi-vector unsigned 16-bit integer vertical dot product by indexed element to 32-bit integer

This instruction calculates the vertical dot product of the corresponding two unsigned 16-bit integer values held in the two first source vectors and two unsigned 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The `vector group` symbol `VGx2` indicates that the ZA operand consists of two ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

C9.2.341 UVDOT (4-way)

Multi-vector unsigned integer vertical dot product by indexed element

This instruction calculates the vertical dot product of the corresponding four unsigned 8-bit or 16-bit integer values held in the four first source vectors and four unsigned 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index that selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment.

The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.

The `vector group` symbol `VGx4` indicates that the ZA operand consists of four ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 8-bit to 32-bit and 16-bit to 64-bit

8-bit to 32-bit

Assembler Symbols

<Zd1>

Is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 4.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Zd4>

Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as “Zd” times 4 plus 3.

<Zn1>

Is the name of the first scalable vector register of the source multi-vector group, encoded as “Zn” times 4.

<Zn4>

Is the name of the fourth scalable vector register of the source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
if VL < esize * 4 then EndOfDecode(Decode_UNDEF); end;
let quads : integer = VL DIV (esize * 4);
var result0 : bits(VL);
var result1 : bits(VL);
var result2 : bits(VL);
var result3 : bits(VL);

for r = 0 to 3 do
    let operand : bits(VL) = Z{}(n+r);
    let base : integer = r * quads;
    for q = 0 to quads-1 do
        result0[(base+q)*:esize] = operand[(4*q+0)*:esize];
        result1[(base+q)*:esize] = operand[(4*q+1)*:esize];
        result2[(base+q)*:esize] = operand[(4*q+2)*:esize];
        result3[(base+q)*:esize] = operand[(4*q+3)*:esize];
    end;
end;

Z{VL}(d+0) = result0;
Z{VL}(d+1) = result1;
Z{VL}(d+2) = result2;
Z{VL}(d+3) = result3;
```

C9.2.344 ZERO (single-vector)

Zero ZA single-vector groups

This instruction zeroes two or four ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

C9.2.347 ZERO (tiles)

Zero a list of 64-bit element ZA tiles

This instruction zeroes all bytes within each of the up to eight listed 64-bit element tiles named `ZA0.D` to `ZA7.D`, leaving the other 64-bit element tiles unmodified.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

For programmer convenience, an assembler must also accept the names of 32-bit, 16-bit, and 8-bit element tiles that are converted into the corresponding set of 64-bit element tiles.

In accordance with the architecturally defined mapping between different element size tiles:

- Zeroing the 8-bit element tile name `ZA0.B`, or the entire array name `ZA`, is equivalent to zeroing all eight 64-bit element tiles named `ZA0.D` to `ZA7.D`.
- Zeroing the 16-bit element tile name `ZA0.H` is equivalent to zeroing 64-bit element tiles named `ZA0.D`, `ZA2.D`, `ZA4.D`, and `ZA6.D`.
- Zeroing the 16-bit element tile name `ZA1.H` is equivalent to zeroing 64-bit element tiles named `ZA1.D`, `ZA3.D`, `ZA5.D`, and `ZA7.D`.
- Zeroing the 32-bit element tile name `ZA0.S` is equivalent to zeroing 64-bit element tiles named `ZA0.D` and `ZA4.D`.
- Zeroing the 32-bit element tile name `ZA1.S` is equivalent to zeroing 64-bit element tiles named `ZA1.D` and `ZA5.D`.
- Zeroing the 32-bit element tile name `ZA2.S` is equivalent to zeroing 64-bit element tiles named `ZA2.D` and `ZA6.D`.
- Zeroing the 32-bit element tile name `ZA3.S` is equivalent to zeroing 64-bit element tiles named `ZA3.D` and `ZA7.D`.

The preferred disassembly of this instruction uses the shortest list of tile names that represent the encoded immediate mask.

For example:

- An immediate that encodes 64-bit element tiles `ZA0.D`, `ZA1.D`, `ZA4.D`, and `ZA5.D` is disassembled as {`ZA0.S`, `ZA1.S`}.
- An immediate that encodes 64-bit element tiles `ZA0.D`, `ZA2.D`, `ZA4.D`, and `ZA6.D` is disassembled as {`ZA0.H`}.
- An all-ones immediate is disassembled as {`ZA`}.
- An all-zeros immediate is disassembled as an empty list { }.

C9.2.350 ZIP (two registers)

Interleave elements from two vectors

This instruction places the two-way interleaved elements from the first and second source vectors in the corresponding elements of the two destination vectors.

This instruction is unpredicated.

It has encodings from 2 classes: 8-bit to 64-bit elements and 128-bit element

8-bit to 64-bit elements

(FEAT_SME2)

31	30	29	28	25	24	23	22	21	20	16	15	13	12	10	9	5	4	1	0
1	1	0	0	0	0	1	size		1	Zm	1	1	0	1	0	0	Zn	Zd	0

op

Encoding

```
ZIP  { <Zd1>.<T>-<Zd2>.<T> }, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd::'0');
```

128-bit element

(FEAT_SME2)

31	30	29	28	25	24	23	22	21	20	16	15	13	12	10	9	5	4	1	0
1	1	0	0	0	0	1	0	0	1	Zm	1	1	0	1	0	1	Zn	Zd	0

op

Encoding

```
ZIP  { <Zd1>.Q-<Zd2>.Q }, <Zn>.Q, <Zm>.Q
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) then EndOfDecode(Decode_UNDEF); end;
if MaxImplementedSVL() < 256 then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 128;
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd::'0');

Assembler Symbols

<Zd1>

Is the name of the first scalable vector register of the destination multi-vector group, encoded as “Zd” times 2.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Zd2>

Is the name of the second scalable vector register of the destination multi-vector group, encoded as “Zd” times 2 plus 1.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
if VL < esize * 2 then EndOfDecode(Decode_UNDEF); end;
let pairs : integer = VL DIV (esize * 2);
let operand0 : bits(VL) = Z{}(n);
let operand1 : bits(VL) = Z{}(m);
var result : bits(VL);

for r = 0 to 1 do
    let base : integer = r * pairs;
    for p = 0 to pairs-1 do
        result[(2*p+0)*:esize] = operand0[(base+p)*:esize];
        result[(2*p+1)*:esize] = operand1[(base+p)*:esize];
    end;
    Z{VL}(d+r) = result;
end;
```

Part D
The AArch64 System Level Architecture

Chapter D1
The AArch64 System Level Programmers' Model

This chapter describes the AArch64 system level programmers' model. It contains the following sections:

- Exception levels
- Registers for instruction processing and exception handling
- System register locking
- Exceptions
- Process state, PSTATE
- Resets and power domains
- Mechanisms for entering a low-power state
- Self-hosted debug
- Event monitors
- Interprocessing
- Check Feature

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.1 Exception levels

R_{FYTFG} The architecture defines four *Exception levels*: EL0, EL1, EL2, and EL3.

R_{VPSDB} EL3 is the highest Exception level and EL0 the lowest. Therefore, EL3 is higher than EL2, EL2 is higher than EL1, and EL1 is higher than EL0.

R_{CCQWK} Unprivileged execution is any execution that occurs at EL0.

I_{WRRKQ} EL2 provides support for the virtualization of EL0 and EL1.

R_{NXCRB} A PE:
- Implements EL1 and EL0.
- Also implements EL3 and EL2 if FEAT_RME is implemented.

In a PE without FEAT_RME, all the following are true:
- Whether EL3 is implemented is IMPLEMENTATION DEFINED.
- Whether EL2 is implemented is IMPLEMENTATION DEFINED.
- Implementing a contiguous set of Exception levels is not required.

For which *Security state* each Exception level can be in, see Security states.
For which *Execution state* each Exception level is using, see Execution states.

R_{NZZNS} The current Exception level changes only when any of the following occur:
- Taking an exception.
- Returning from an exception.
- Processor reset.
- Exiting from Debug state.
- If in Debug state, executing a `DCPSx` instruction.
- If in Debug state, executing a `DRPS` instruction.

R_{XRQKF} The *target Exception level* is the Exception level to which an exception is taken.

R_{FFJBB} Each exception type has a target Exception level that is either:
- Implicit in the type of the exception.
- Defined by configuration bits in the System registers.

R_{TKYYF} An exception cannot be taken to EL0.

R_{QNTPB} An exception cannot cause entry to a lower Exception level.

D1.1.1 Execution state

R_{HTYJH} The architecture defines two Execution states. The AArch32 Execution state uses 32-bit processing. The AArch64 Execution state uses 64-bit processing.

I_{WKKGD} The AArch32 Execution state is compatible with Armv7-A operation.

R_{NKNVR} An Exception level is described as:
- *Using AArch64* when execution in that Exception level is in the AArch64 Execution state.
- *Using AArch32* when execution in that Exception level is in the AArch32 Execution state.

R_{VZTWD} The PE can only change Execution state at reset, or when changing Exception level.

R_{QNVJL} If an Exception level is using AArch32, then all lower Exception levels are using AArch32.

R_{BDMRT} If an Exception level is using AArch64, then all higher Exception levels are using AArch64.

R_{MWGKL} Interaction between the AArch64 and AArch32 Execution states is called *interprocessing*.

I_{KSMPY} In this chapter, the described behavior assumes the highest implemented Exception level is using AArch64.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.1.2 Security states

R_{WPBBJ} The architecture defines the following *Security states*:

- Secure state.
- Non-secure state.
- If FEAT_RME is implemented, also both of:
  - Realm state.
  - Root state.

I_{XKGPG} Execution in:

- Secure state cannot be observed or modified by an agent associated with any of:
  - Non-secure state.
  - Realm state.
- Realm state cannot be observed or modified by an agent associated with any of:
  - Non-secure state.
  - Secure state.
- Root state cannot be observed or modified by an agent associated with any other Security state.

R_{NRXJT} The architecture defines the following *Physical Address* (PA) spaces:

- Secure.
- Non-secure.
- If FEAT_RME is implemented, also the following:
  - Realm.
  - Root.
  - If FEAT_RME_GDI is implemented, also both of:
    - System Agent.
    - Non-secure Protected.

I_{RKGZF} Memory assigned to the:

- Secure physical address space cannot be read or modified by an agent associated with any of:
  - Non-secure state.
  - Realm state.
- Realm physical address space cannot be read or modified by an agent associated with any of:
  - Non-secure state.
  - Secure state.
- Root physical address space cannot be read or modified by an agent associated with any other Security state.

I_{YFMYJ} For details on the System Agent and Non-secure Protected PA spaces, see Granular Data Isolation.

R_{ZFPTR} EL3 is always in:

- Secure state in a PE without FEAT_RME.
- Root state in a PE with FEAT_RME.

I_{HGPBB} The Effective value of SCR_EL3.{NSE, NS} selects the Security state of EL2 and lower.

I_{FHKRH} The following table shows which Security states are implemented:

EL3 implemented	EL2 implemented	Implemented Security state/s
No	No	A single Security state, Secure or Non-secure, determined by the IMPLEMENTATION DEFINED choice to fix the Effective value of SCR_EL3.NS as either Secure or Non-secure.
No	Yes	
Yes	No	Secure and Non-secure.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL3 implemented	EL2 implemented	Implemented Security state/s
Yes	Yes	If FEAT_RME is: • Not implemented, then Secure and Non-secure. • Implemented, then Root, Realm, and Non-secure. Whether Secure state is implemented is IMPLEMENTATION DEFINED. If Secure state is implemented, FEAT_SEL2 is also implemented.

In a PE with FEAT_RME, software can discover whether Secure state is implemented by discovering whether FEAT_SEL2 is implemented from ID_AA64PFR0_EL1.SEL2.

R_{SGMFG} In a PE with FEAT_RME, EL2 and lower cannot be in Root state.

R_{DVTDD} EL2 can only be in Secure state if, in addition to the Effective value of SCR_EL3.{NSE, NS} selecting Secure state, both of the following are true:

- FEAT_SEL2 is implemented.
- The Effective value of SCR_EL3.EEL2 is `0b1`.

I_{ZZCQM} The state of SCR_EL3.NS, and SCR_EL3.NSE if FEAT_RME is implemented, can only change in EL3.

I_{YBGYV} Figure D1-1 illustrates the Security states in a PE with FEAT_RME.

Figure D1-1 Security states

Where:

- RMM is Realm Management Monitor.
- SPM is Secure Partition Manager.
- VM is Virtual Machine.

D1.1.3 Effect of not implementing an Exception level

R_{KFGRW} An exception cannot be taken to an unimplemented Exception level.

R_{HRDVX} Any configurable instruction control that defines an exception to an unimplemented Exception level does not cause that exception to the unimplemented Exception level. The Effective value of the configurable exception control is the value that does not cause an exception to that Exception level.

R_{WPVKJ} System calls made to an unimplemented Exception level from a lower Exception level are UNDEFINED.

R_{WPXJS} The translation regime associated with an unimplemented Exception level is not implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{WKQBG} Any exception return that targets an unimplemented Exception level is an illegal return.

R_{GTCCW} Every accessible register associated with an unimplemented Exception level is RES0 unless the register is associated with the Exception level only to provide the ability to transfer execution to a lower Exception level.

D1.1.3.1 Behavior when EL3 is not implemented

R_{BSNQL} If EL3 is not implemented, SCR_EL3.NS has a fixed Effective value that is IMPLEMENTATION DEFINED.

I_{BWVTM} An implementation can provide a configuration input that determines the Effective value of SCR_EL3.NS at reset.

R_{LBZCK} If EL3 is not implemented, and the Effective value of SCR_EL3.NS is 0, all of the following are true:

- The Effective value of MDCR_EL3.EPMAD is 1.
- The Effective value of MDCR_EL3.EDAD is 1.
- The Effective value of MDCR_EL3.SPME is 1.
- The Effective value of MDCR_EL3.NSPB is `0b01`.
- The Effective value of MDCR_EL3.SPD32 is `0b11`.
- The Effective value of MDCR_EL3.STE is 1.

R_{ZTWJS} If EL3 is not implemented, the Effective value of MDCR_EL3.STE is the inverse of the Effective value of SCR_EL3.NS.

R_{RDYPY} If all of the following are true, the Effective value of SCR_EL3.EEL2 is 1:

- EL3 is not implemented.
- EL2 is implemented.
- The Effective value of SCR_EL3.NS is 0.

D1.1.3.2 Behavior when EL2 is not implemented

R_{PQDWN} If EL2 is not implemented, all of the following are true:

- Virtual interrupts are disabled.
- The Effective value of CNTHCTL_EL2[1:0] is `0b11`.
- The Effective value of HCR_EL2.E2H is 0.
- The Effective value of HCR_EL2.TGE is 0.
- The Effective value of MDCR_EL2.HPMN is the value of PMCR_EL0.N.

D1.1.3.3 Behavior when EL2 is not implemented and EL3 is implemented

R_{RJFFP} If EL2 is not implemented and EL3 is implemented, all of the following are true:

- Except for any of the following registers, every accessible register associated with EL2 is RES0:
  - If EL1 can use AArch32 then the following registers are not RES0:
    - DACR32_EL2.
    - DBGVCR32_EL2.
    - FPEXC32_EL2.
    - IFSR32_EL2.
  - For VPIDR_EL2:
    - Reads return the value of MIDR_EL1.
    - Writes to VPIDR_EL2 are ignored.
  - For VMPIDR_EL2:
    - Reads return the value of MPIDR_EL1.
    - Writes to VMPIDR_EL2 are ignored.
- The Effective value of HCR_EL2.RW is the value of SCR_EL3.RW.
- SCR_EL3.HCE is RES0.
- The following Address translation and TLB invalidation instructions are UNDEFINED:
  - AT S1E2R.
  - AT S1E2W.

D1.1.3.4 Typical Exception level usage model

IWCCCB The architecture does not specify what software uses which Exception level. Such choices are outside the scope of the architecture. However, the following is a common usage model for the Exception levels:

Exception level	Usage
EL0	Applications.
EL1	OS kernel and associated functions that are typically described as privileged.
EL2	Hypervisor.
EL3	Monitor.

Non-Confidential

D1.2 Registers for instruction processing and exception handling

IBCVRH In the Arm architecture, registers are split into two main categories:

- Registers that provide system control or status reporting.
- Registers that are used in instruction processing, for example to accumulate a result, and in handling exceptions.

For more information, see AArch64 System Register Descriptions.

D1.2.1 The general-purpose registers

RJBKTZ The general-purpose register bank comprises the 31 general-purpose registers, R0-R30.

IRKTLT The general-purpose register bank is associated with instructions in the base instruction set.

RYDKHJ The general-purpose registers can be accessed as either of the following:

- 31 64-bit registers, X0-X30.
- 31 32-bit registers, W0-W30.

IPVGXY When a Warm reset is asserted, the general-purpose registers are reset to an architecturally UNKNOWN value.
For more information, see Register size and Registers in AArch64 Execution state.

D1.2.2 The stack pointer registers

RBBRKH If in AArch64 state, each implemented Exception level has a dedicated stack pointer register. The stack pointer registers are:

- SP_EL0.
- SP_EL1.
- If EL2 is implemented, SP_EL2.
- If EL3 is implemented, SP_EL3.

IYPMHQ When a Warm reset is asserted, the stack pointers are reset to an architecturally UNKNOWN value.
For more information, see Special purpose registers and PC alignment checking.

D1.2.2.1 Stack pointer register selection

RCNNQX The PE uses the following stack pointers:

- If executing at EL0, then the PE uses the EL0 stack pointer, SP_EL0.
- If executing at EL1, EL2, or EL3, then the PE uses the stack pointer determined by PSTATE.SP:
  - If PSTATE.SP is 0, then the PE uses the EL0 stack pointer, SP_EL0.
  - If PSTATE.SP is 1, then the PE uses the stack pointer for the current Exception level.

ICSFMY When an exception is taken, the stack pointer for the target Exception level is selected.

IVYNZY The selected stack pointer can be indicated by a suffix to the Exception level:

- The t suffix, referring to thread, indicates use of the SP_EL0 stack pointer.
- The h suffix, referring to handler, indicates use of the SP_ELx stack pointer.

IQZDYD The following are the AArch64 stack pointer options:

Exception level (EL)	Stack pointer (SP) option
EL0	SP_EL0
EL1	SP_EL1

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Exception level (EL)	Stack pointer (SP) option
EL2	SP_EL2
EL3	SP_EL3

D1.2.3 The SIMD and floating-point registers

R_{JSCYH} The SIMD and floating-point register bank comprises the 32 quadword (128-bit) SIMD and floating-point registers, V0-V31.

I_{LMMMW} The SIMD and floating-point register bank is used for floating-point, vector, and other SIMD-related scalar operations.

R_{LFCJZ} The SIMD and floating-point registers can be accessed as any of the following:

- 32 quadword (128-bit) registers, Q0-Q31.
- 32 doubleword (64-bit) registers, D0-D31.
- 32 word (32-bit) registers, S0-S31.
- 32 halfword (16-bit) registers, H0-H31.
- 32 byte (8-bit) registers, B0-B31.
- 128-bit vectors of elements.
- 64-bit vectors of elements.

I_{KFYJJ} When a Warm reset is asserted, the SIMD and floating-point registers are reset to an architecturally UNKNOWN value.
For more information, see Registers in AArch64 Execution state.

D1.2.4 Saved Program Status Registers

R_{PJSSD} In AArch64 state, each implemented Exception level to which an exception can be taken has a Saved Program Status Register (SPSR). The following are the SPSRs:

- For exceptions taken to EL1 using AArch64, SPSR_EL1.
- For exceptions taken to EL2 using AArch64, SPSR_EL2.
- For exceptions taken to EL3 using AArch64, SPSR_EL3.

I_{DVBPS} When a Warm reset is asserted, the SPSRs are reset to an architecturally UNKNOWN value.
For more information, see Process state, PSTATE.

D1.2.5 Exception Link Registers

R_{JQBYN} Exception Link Registers hold preferred exception return addresses.

R_{VCLNF} In AArch64 state, each implemented Exception level to which an exception can be taken has an Exception Link Register (ELR). The following are the ELRs:

- For exceptions taken to EL1, ELR_EL1.
- For exceptions taken to EL2, ELR_EL2.
- For exceptions taken to EL3, ELR_EL3.

I_{SHJSC} When a Warm reset is asserted, the ELRs are reset to an architecturally UNKNOWN value.
For more information, see Preferred exception return address.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.3 System register locking

R_{DJDVH} All statements in this section require FEAT_SRMASK.

Note

HCR_EL2.E2H is RES1 when FEAT_SRMASK is implemented.

I_{DFJZG} Software can program the mask registers shown in the following table to mask individual control fields of the corresponding System registers, as follows:

- The EL1 mask registers mask EL1 control fields from EL1 MSR writes.
- The EL2 mask registers mask EL2 control fields from EL2 MSR writes.

For example, if TCRMASK_EL1 is programmed to mask a TCR_EL1 control field, then EL1 MSR writes to TCR_EL1 do not update that masked field.

Table D1-4 System registers and their corresponding mask registers

System register	Mask register
ACTLR_EL1	ACTLRMASK_EL1
CPACR_EL1	CPACRMASK_EL1
SCTLR_EL1	SCTLRMASK_EL1
SCTLR2_EL1	SCTLR2MASK_EL1
TCR_EL1	TCRMASK_EL1
TCR2_EL1	TCR2MASK_EL1
ACTLR_EL2	ACTLRMASK_EL2
CPTR_EL2	CPTRMASK_EL2
SCTLR_EL2	SCTLRMASK_EL2
SCTLR2_EL2	SCTLR2MASK_EL2
TCR_EL2	TCRMASK_EL2
TCR2_EL2	TCR2MASK_EL2

Using the mask registers makes it possible, for example, for EL1 to frequently change specific EL1 control fields without always trapping the EL1 MSR System register writes to EL2.

R_{FHCYV} EL1 is permitted to program an EL1 mask register when it is zero. Otherwise, the write to the mask register is UNDEFINED unless it is trapped.

EL2 is permitted to program an EL2 mask register when it is zero. Otherwise, the write to the mask register is UNDEFINED.

I_{VGNST} An attempt to program a nonzero mask register is only guaranteed to be UNDEFINED if there has been a Context synchronization event since the write that set it to the nonzero value and before the new attempt to program it. This is because the check of whether it is nonzero is an indirect read of it.

I_{QTNLT} For each EL1 mask register:

- HFGRTR2_EL2 contains a fine-grained trap control for EL1 reads.
- HFGWTR2_EL2 contains a fine-grained trap control for EL1 writes.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.3.1 EL1 System register alias names

I_{QBPYD} For each of the EL1 System registers in Table D1-4, FEAT_SRMASK provides an *EL1 alias name*, <System_register>ALIAS_EL1. These are listed in System and Special-purpose register aliasing.

- EL1 software that is aware of the presence of the EL1 alias names can use them when it is also aware that fine-grained traps are trapping EL1 writes to EL1 System registers.

For each of the EL2 System registers in Table D1-4, FEAT_SRMASK does not provide an EL2 alias name.

- A kernel executing at EL2 is expected to use the EL1 alias names.

I_{CWCFN} The EL1 mask registers mask the EL1 alias names in addition to masking the corresponding EL1 System registers. For example, if TCRMASK_EL1 is programmed to mask a TCR_EL1 control field, then EL1 `MSR` writes to TCRALIAS_EL1 do not update that masked field.

R_{CSSSN} `MSR` and `MRS` accesses to the EL1 alias names are direct accesses to the corresponding EL1 System registers. However, without explicit synchronization, the accesses might be reordered relative to `MSR` and `MRS` accesses to the EL1 System registers.

I_{VPCLQ} The accessibility from EL1 to each EL1 alias name is the same as for the corresponding EL1 System register, except for the opcode, and that there is a separate fine-grained trap control for each of reads and writes for the EL1 alias name:

- HFGRTR2_EL2 contains the fine-grained trap control for EL1 reads.
- HFGWTR2_EL2 contains the fine-grained trap control for EL1 writes.

D1.3.2 EL12 alias names for mask registers

I_{HFLBB} Because HCR_EL2.E2H is RES1 when FEAT_SRMASK is implemented, FEAT_SRMASK provides an EL12 alias name for each EL1 mask register in Table D1-4, for use by EL2 hypervisor software. See System and Special-purpose register aliasing.

D1.3.3 Nested virtualization

I_{GFHTJ} `MSR` writes that are transformed to stores by FEAT_NV2 are not masked by the EL1 mask register configuration.

Non-Confidential

D1.4 Exceptions

D1.4.1 Exception entry terminology

D1.4.1.1 Taken, taken from, and taken to

RVDFHD When the PE responds to an exception, an exception is *taken*.

RFXGFX The PE state immediately before taking the exception is the state the exception is *taken from*.

RWTMVN The PE state immediately after taking the exception is the state the exception is *taken to*.

D1.4.1.2 Exception generating instructions

RQPPFN *Exception generating instructions* intentionally produce a precise exception in the instruction stream immediately after the exception generating instruction. They are:

- `HVC`.
- `SMC`.
- `SVC`.

D1.4.1.3 Synchronous and asynchronous exceptions

RFQHGR If all of the following apply, an exception is *synchronous*:

- The exception is generated as a result of direct execution or attempted execution of an instruction.
- The preferred exception return address has an architecturally defined relationship with the instruction that caused the exception.
- The exception is precise.

RPCXDH An exception is *asynchronous* if it is not synchronous.

RJPZPR Asynchronous exceptions taken to AArch64 state are also known as interrupts.

D1.4.1.4 Definition of a precise exception and imprecise exception

RTNVSL An exception is *precise* if on taking the exception, the PE state and the memory system state is consistent with the PE having executed all of the instructions up to but not including the point in the instruction stream where the exception was taken from, and none afterwards. However, for an instruction executing immediately at the point in the instruction stream that the exception was taken from, the definition of precise also permits any of the following:

- For synchronous Data Abort and Watchpoint exceptions that are taken to AArch64 state generated by an instruction that performs more than one single-copy atomic memory access, the values in registers or memory affected by the instruction can be UNKNOWN, if all of the following apply:
  - The accesses affecting those registers or memory locations do not, themselves, generate exceptions or debug events.
  - The registers are not involved in the calculation of the memory address used by the instruction.
- For synchronous Data Abort and Watchpoint exceptions that are generated from load or store instructions executed in AArch64 state, all the following can occur:
  - If the instruction was a load to either the base address register or the offset register, that register is restored to the original value, and any other destination registers become UNKNOWN.
  - If the instruction was a load that does not load the base address register or the offset register, then the destination registers become UNKNOWN.
  - If the instruction was an atomic that attempted both a load and a store, and the load was to the base address register, a source register or a compare register, that register is restored to the original value. Otherwise, that destination register becomes UNKNOWN.
- For implementations that include synchronous exception generation for floating-point exceptions, when a floating-point exception is taken, it is permitted that the cumulative floating-point exception bits are not restored.
- For a precise exception that is taken from AArch64 state during an instruction that performs more than one single-copy atomic memory access, the values in registers or memory affected by the instruction can be UNKNOWN, if all of the following apply:
  - The instruction is not `GCSSS2`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The accesses affecting those registers or memory locations do not, themselves, generate exceptions or debug events.
- The registers are not involved in the calculation of the memory address used by the instruction.

- For a synchronous exception or synchronous Debug state entry, generated by a Memory Copy and Memory Set instruction, and for an asynchronous exception or asynchronous Debug state entry part way through the execution of a Memory Copy and Memory Set instruction:
  - The values of PSTATE.{N, Z, C, V} are UNKNOWN on exception entry. The values held in SPSR_ELx.{N, Z, C, V} on exception entry, and DSPSR_EL0.{N, Z, C, V} on Debug state entry, are the initial values for the instruction.
  - All memory locations written by the pseudocode at the point at which the exception is taken are updated.
  - If the memory locations that are not written by the pseudocode at the point at which the exception is taken are within the set of locations to be read by the instruction if it is restarted with the X[n], X[d], and X[s] register values presented as part of taking the exception, then those memory locations are not updated.
  - For CPYF*T* and SET{G}*T* instructions, no memory locations that are not written by the pseudocode at the point at which the exception is taken are updated.
  - For Memory Copy and Memory Set instructions other than CPYF*T* and SET{G}*T*, any memory location that does not itself generate a synchronous exception on a write becomes UNKNOWN if all the following apply:
    - The memory location is within the set of locations to be written by the instruction if it is restarted with the X[n], X[d], and X[s] register values presented as part of taking the exception.
    - The memory location is not within the set of locations to be read by the instruction on that restart.
  - Only for a synchronous exception or synchronous Debug state entry, generated by a Memory Copy and Memory Set instruction:
    - On taking the exception, the X[n], X[d], and, as appropriate, X[s] register values hold a self-consistent set of values that correspond to the first element that was not copied or set, such that return to the instruction enables resumption of the memory copy or memory set. That first element does not need to be the element with a watchpoint, but can be an earlier element, including the first element.
    - If a memory location that generates a synchronous exception on a write is within the set of locations to be written by the instruction if it is restarted with the X[n], X[d], and X[s] register values presented as part of taking the exception, and if the memory location is not within the set of locations to be read by the instruction on that restart, then the memory location is unchanged.
    - For a synchronous exception, ELR_ELx points to the instruction that generated the exception.
    - For a synchronous Debug state entry, DLR_EL0 points to the instruction that generated the Debug state entry.
  - Only for an asynchronous exception or asynchronous Debug state entry part way through the execution of a Memory Copy and Memory Set instruction:
    - On taking the exception, the values of the registers that are updated by the instruction are presented as a self-consistent set of values that correspond to the first element that was not copied or set.

R_{ZNCXP} An exception is *imprecise* if it is not a precise exception.

R_{LSGJD} Except for SError exceptions, all exceptions taken to AArch64 state are precise. For each occurrence of an SError exception, whether the interrupt is precise or imprecise is IMPLEMENTATION DEFINED.

I_{ZNNNY} An asynchronous Data Abort exception generated by a load that causes an SError exception to be taken at some point later in the instruction stream than the load that generated the exception, is usually imprecise. The SError exception is usually imprecise because the data returned from the load is UNKNOWN, and so can have corrupted the state that is presented at the time that the exception is taken.

D1.4.1.5 Preferred exception return address

I_{LQPWH} The *preferred exception return address* is an address that software might return to after handling an exception in order to resume execution.

I_{HBQRX} The preferred exception return address is determined by the type of the exception.

R_{DPLYN} For an exception taken to an Exception level, ELx, using AArch64, the Exception Link Register for that Exception level, ELR_ELx, is set to the preferred exception return address.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{VBQMV} For asynchronous exceptions, the preferred exception return address is the address of the instruction following the instruction boundary at which the interrupt occurs.

R_{QYCWH} For synchronous exceptions other than exception generating instructions, the preferred exception return address is the address of the instruction that generates the exception.

R_{DKWPP} For an exception generating instruction that is executed, the preferred exception return address is the address of the instruction that follows the exception generating instruction.

R_{LBLBR} For an exception generating instruction that is trapped, disabled, or is UNDEFINED because the Exception level has insufficient privilege to execute the instruction, the preferred exception return address is the address of the exception generating instruction.

R_{XVMNH} When an exception is taken from an Exception level using AArch32 to an Exception level, ELx, using AArch64, ELR_ELx[63:32] are 0.

D1.4.1.6 Exception vectors

R_{FKKHH} When an exception is taken to an Exception level that is using AArch64, execution starts at the *exception vector*.

I_{QLHPV} The memory at the exception vector for an exception is expected to contain the handler code that corresponds to that exception category.

R_{BRCKV} The vector base address for an Exception level, ELx, is defined by the Vector Base Address Register, VBAR_ELx.

R_{PJKRC} Each exception category has an exception vector at a fixed offset from the vector base address.

I_{YCTHH} An exception taken to AArch64 is categorized for the purpose of assigning an exception vector based on the following information:

- Whether the exception is one of the following:
  - A synchronous exception, excluding synchronous External aborts.
  - A synchronous External abort.
  - An SError exception, including vSError and delegated SError exceptions.
  - An IRQ or vIRQ interrupt.
  - An FIQ or vFIQ interrupt.
- Information about the Exception level that the exception came from.
- Information about the SP in use.
- The state of the register file.

For information on synchronous exceptions, see Synchronous exception types. For information on asynchronous exceptions, see Asynchronous exception types.

R_{RYXCL} The following tables describe the offsets that are added to the vector base address to describe the exception vector:

Exception taken from	Offset for exception type		
	Synchronous exceptions, excluding External aborts	IRQ and vIRQ	FIQ and vFIQ
Current Exception level with SP_EL0.	0x000	0x080	0x100
Current Exception level with SP_ELx, x > 0.	0x200	0x280	0x300
Lower Exception level, where the implemented level immediately lower than the target level is using AArch64.	0x400	0x480	0x500
Lower Exception level, where the implemented level immediately lower than the target level is using AArch32.	0x600	0x680	0x700

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Exception taken from	Offset for exception type		
	Synchronous External aborts, EASE == 0	Synchronous External aborts, EASE == 1	SError, vSError, and delegated SError
Current Exception level with SP_EL0.	`0x000`	`0x180`	`0x180`
Current Exception level with SP_ELx, x > 0.	`0x200`	`0x380`	`0x380`
Lower Exception level, where the implemented level immediately lower than the target level is using AArch64.	`0x400`	`0x580`	`0x580`
Lower Exception level, where the implemented level immediately lower than the target level is using AArch32.	`0x600`	`0x780`	`0x780`

The applicable value of EASE is the following:

- For an exception taken to EL1, the Effective value of SCTLR2_EL1.EASE.
- For an exception taken to EL2, the Effective value of SCTLR2_EL2.EASE.
- For an exception taken to EL3, the Effective value of SCR_EL3.EASE.

I_{FSZTB} For the preceding tables, if EL3 is the target Exception level, the implemented Exception level immediately lower than EL3 is either:

- EL2, if EL2 is implemented and enabled for the Security state of the Exception level the exception was taken from.
- EL1, if EL2 is not implemented or not enabled for the Security state of the Exception level the exception was taken from.

D1.4.2 Exception entry

R_{DQXFW} When an exception is taken to an Exception level, ELx, that is using AArch64 state, all the following occur:

- Fields in SPSR_ELx are written according to their description in SPSR_ELx, based on the values in PSTATE immediately before the exception was taken.
- The preferred exception return address is written to ELR_ELx.
- The contents of PSTATE immediately after the exception is taken is as described in rule R_{WTXBY}.
- For synchronous exceptions and SError exceptions, exception syndrome information is written to ESR_ELx.
- Execution starts from the exception vector at the target Exception level.

R_{WTXBY} When an exception is taken to an Exception level, ELx, that is using AArch64 state, after recording the previous values in SPSR_ELx, the following PSTATE bits are set:

- PSTATE.EL is set to the target Exception level.
- All of PSTATE.{D, A, I, F, SP} are set to 1.
- PSTATE.{IL, nRW} are set to 0.
- PSTATE.SS is set according to the rules in AArch64 Self-hosted Debug.
- If FEAT_PAN is implemented, then for any of the following situations, PSTATE.PAN is set to 1:
  - The target Exception level is EL1 and SCTLR_EL1.SPAN is 0.
  - The target Exception level is EL2 using AArch64, the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, and SCTLR_EL2.SPAN is 0.
- If FEAT_PAN is implemented, the target Exception level is EL2 using AArch64, the Effective value of HCR_EL2.{E2H, TGE} is {1, 0}, and SCTLR_EL2.SPAN is 0, then it is IMPLEMENTATION SPECIFIC whether PSTATE.PAN is set to 1.
- If FEAT_UAO is implemented, then PSTATE.UAO is set to 0.
- If FEAT_BTI is implemented, then PSTATE.BTYPE is set to `0b00`.
- If FEAT_MTE is implemented, then PSTATE.TCO is set to 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_SSBS is implemented, then PSTATE.SSBS is set to the value of SCTLR_ELx.DSSBS.
- If FEAT_NMI is implemented, then PSTATE.ALLINT is set to the inverse value of SCTLR_ELx.SPINTMASK.
- If FEAT_EBEP, FEAT_SPE_EXC or FEAT_TRBE_EXC is implemented, then PSTATE.PM is set to 1.
- If FEAT_GCS is implemented, PSTATE.EXLOCK is updated based on the following situations:
  — On taking an exception to the same Exception level, PSTATE.EXLOCK is set to the Effective value of GCSCR_ELx.EXLOCKEN for the current Exception level.
  — On taking an exception to a higher Exception level, PSTATE.EXLOCK is set to 0.
- If FEAT_PAuth_LR is implemented, then PSTATE.PACM is set to 0.

R_{XKSNJ} If FEAT_UINJ is implemented, then when an exception is taken to an Exception level, ELx, that is using AArch64 state, PSTATE.UINJ is set to 0, and the resulting value stored in SPSR_ELx is 0.

I_{RFWPH} When an exception is taken to an Exception level that is using AArch64 state, the following PSTATE fields are unchanged:

- If FEAT_DIT is implemented, PSTATE.DIT.
- If FEAT_SME is implemented, PSTATE.{SM, ZA}.

I_{HLPGV} PSTATE.PACM is set to 0 when executing an `SVC`, `HVC`, or `SMC` instruction that is not trapped, disabled, or UNDEFINED, and the resulting value stored in SPSR_ELx.PACM is 0.

R_{SRXVW} If the Effective value of SCTLR_ELx.IESB is 1 at the target Exception level, an exception taken to AArch64 state is an error synchronization event.

R_{BBSRF} If SCTLR_ELx.EIS is 1, exception entry is a Context synchronization event. If SCTLR_ELx.EIS is 0, exception entry is not a Context synchronization event, but the indirect writes to ESR_ELx, FAR_ELx, SPSR_ELx, ELR_ELx, and HPFAR_EL2 due to exception entry are synchronized so that a direct read of the register after exception entry sees the indirectly written value caused by the exception entry.

I_{JFWCQ} For the purposes of the memory model, some exception entries are Instruction Fetch Barrier effects, regardless of the value of SCTLR_ELx.EIS. See Basic definitions for the list of exception entries.

I_{FZTLH} The ordering of error synchronization and context synchronization on exception entry is described in the pseudocode.

I_{WPBHV} Memory copy and memory set operations are guaranteed to function correctly only if the prologue, main, and epilogue Memory Copy and Memory Set instructions are executed in succession and are placed consecutively in memory. Failure to execute the three instructions in succession can result in the instructions causing exceptions. Software exception handlers are expected to require that the three instructions are placed consecutively in memory. If the three instructions are not placed consecutively in memory, exception returns to the wrong instructions might occur.

I_{LBHFM} There are additional behaviors for synchronous External aborts and SError exceptions. See also Taking error exceptions.

D1.4.2.1 Synchronous exception entry

R_{PMQBM} For any of the following synchronous exceptions taken from an Exception level using AArch64, if FEAT_BTI is implemented, then PSTATE.BTYPE is copied to SPSR_ELx.BTYPE and then PSTATE.BTYPE is set to 0:

- Software Step exception.
- PC Alignment Fault exception.
- Instruction Abort exception.
- Breakpoint exception.
- Address Matching Vector Catch exception.
- Illegal Execution state exception.
- Software Breakpoint exception.
- Branch Target exception.

When taking any other synchronous exception from an Exception level using AArch64, it is CONSTRAINED UNPREDICTABLE whether:

- SPSR_ELx.BTYPE is set to the value of PSTATE.BTYPE.
- SPSR_ELx.BTYPE is set to 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PSTATE.BTYPE is then set to 0.

I_{KVRPF} For synchronous exceptions that result in the exception handler emulating the instruction and returning to the following instruction, the handler typically completes by ensuring the state of the PE on returning from the exception is consistent with the emulated instruction having been executed. This usually includes ensuring the value of SPSR_ELx.BTYPE is consistent with the instruction being emulated having executed.

For `SVC`, `HVC`, and `SMC` instructions, when these instructions execute without being trapped, the value of SPSR_ELx already points to the following instruction. However SPSR_ELx.BTYPE is not guaranteed to be 0 and so might not be consistent with the `SVC`, `HVC`, or `SMC` instruction having executed. This might subsequently cause a Branch Target exception at the instruction after the `SVC`, `HVC`, or `SMC` instruction. This is unlikely to be encountered in real code since it requires the `SVC`, `HVC`, or `SMC` to be executed in a non-Guarded page with the instruction after the `SVC`, `HVC`, or `SMC` executed in a Guarded page.

R_{ZTSSH} For any of the following synchronous exception types, when an exception is taken to an Exception level, ELx, a *virtual address* (VA) that characterizes the exception is captured in FAR_ELx:

- An Instruction Abort exception.
- A Data Abort exception.
- A PC alignment fault exception.
- A Watchpoint exception.

For GPC exceptions, a VA that characterizes the exception is captured in FAR_EL3.

For synchronous External aborts that are not caused by translation table walks, it is CONSTRAINED UNPREDICTABLE whether the FAR_ELx contains a VA that characterizes the exception. The ESR_ELx.FnV bit in the ISS encoding for the External abort indicates the validity of the VA in FAR_ELx:

- If ESR_ELx.FnV in the ISS encoding for the External abort is 1, the VA in FAR_ELx is UNKNOWN.
- If ESR_ELx.FnV in the ISS encoding for the External abort is 0, the VA in FAR_ELx is valid.

For all other exceptions taken to ELx, FAR_ELx is UNKNOWN.

R_{JXPNL} When an SME load or store instruction, or an SVE contiguous vector load or store instruction, causes a Data Abort exception that sets ESR_ELx.ISV to 0:

- If the value written to FAR_ELx might not be the faulting VA, the PE sets ESR_ELx.FnP to 1 and sets FAR_ELx to any address within the naturally-aligned fault granule that contains the faulting VA. The naturally-aligned fault granule is as defined in the FAR_ELx register descriptions.
- Otherwise, the PE sets ESR_ELx.FnP to 0.

R_{FKLWR} For Instruction Abort or Data Abort exceptions caused by any of the following faults, when an exception is taken to EL2, an *intermediate physical address* (IPA) that characterizes the exception is captured in HPFAR_EL2:

- A Translation fault, Access Flag fault, or Address Size fault on a stage 2 translation not on a stage 1 translation table walk.
- A Translation fault, Access flag fault, Address Size fault, or Permission fault on stage 2 translation of an address accessed in a stage 1 translation table walk.
- A Granule Protection Fault (GPF) on an access for a stage 2 translation table.

For GPC exceptions due to a fault on an access for a stage 2 translation table walk, an IPA that characterizes the exception is captured in HPFAR_EL2.

For all other exceptions taken to EL2 using AArch64, HPFAR_EL2 is UNKNOWN.

R_{BFJJV} For GPC exceptions, a PA and physical address space that characterize the exception and a PA are captured in MFAR_EL3.

R_{TGQRC} For Instruction Abort or Data Abort exceptions caused by an External abort, when FEAT_PFAR is implemented:

- If all of the following apply, then ESR_ELx.PFV is set to 0:
  - The exception is taken to EL1.
  - EL2 is implemented and enabled in the current Security state.
  - The Effective value of HCR_EL2.VM is 1.
- Otherwise, ESR_ELx.PFV is set to an IMPLEMENTATION DEFINED value of 0 or 1.

For all other Instruction Abort and Data Abort exceptions, ESR_ELx.PFV is set to 0.

On taking an Instruction Abort or Data Abort exception:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If ESR_ELx.PFV is set to 1 by the PE, then a physical address space that characterizes the exception and a PA are captured in PFAR_ELx or MFAR_EL3 as applicable. The fault granule size is defined by D_{LVGRB}.
- If ESR_ELx.PFV is set to 0 by the PE, then the applicable PFAR_ELx or MFAR_EL3 register is set to an UNKNOWN value.

Note

PFAR_ELx never records the Intermediate Physical Address (IPA). PFAR_ELx might reveal a faulting physical addresses to a guest operating system if stage 2 translation is not being used and some other method is used to hide physical addresses from the guest (such as shadow page tables).

R_{DHLHF} For all exceptions other than Instruction Abort, Data Abort, and GPC exceptions, the applicable PFAR_ELx or MFAR_EL3 register is set to an UNKNOWN value.

R_{TGRZL} If an Instruction Abort or Breakpoint exception is generated part way through execution of a Memory Copy and Memory Set instruction, presentation of the exception state is as described in R_{TNVSL} for a synchronous exception or synchronous Debug state entry from a watchpoint, generated by a Memory Copy and Memory Set instruction.

R_{ZMSLS} For a CPY* Memory Copy instruction, if both the read and write generate the Data Abort or Watchpoint exception, it is CONSTRAINED UNPREDICTABLE whether the exception on the read or the exception on the write is presented. ESR_ELx.ISS.WnR is set to be consistent with whether the exception was on the read or the write.

D1.4.2.1.1 SVE MOVPRFX exception entry behavior

R_{RWVTR} When a `MOVPRFX` instruction pairs legally with another instruction and the execution of the pair generates a synchronous exception:

- If the generated exception is a Breakpoint Instruction exception from a prefixed `BRK` instruction then `MOVPRFX` updates the architectural state and ELR_ELx stores the address of `BRK` instruction.
- Otherwise, the return address that is stored in ELR_ELx is one of the following:
  - When the `MOVPRFX` instruction did not cause a change to the architectural state, the address of the `MOVPRFX` instruction is stored.
  - When the `MOVPRFX` instruction caused a change to the architectural state, the address of the prefixed instruction is stored.

R_{XRWVD} When a `MOVPRFX` instruction pairs legally with another instruction and the execution of the pair causes synchronous entry to Debug state:

- If the Debug state entry is due to a Halt Instruction debug event from a prefixed `HLT` instruction then `MOVPRFX` updates the architectural state and DLR_EL0 stores the address of `HLT` instruction.
- Otherwise, the return address that is stored in DLR_EL0 is one of the following:
  - When the `MOVPRFX` instruction did not cause a change to the architectural state, the address of the `MOVPRFX` instruction is stored.
  - When the `MOVPRFX` instruction caused a change to the architectural state, the address of the prefixed instruction is stored.

R_{TPRKM} When a `MOVPRFX` instruction pairs illegally with another instruction and execution of the pair generates a synchronous exception, the return address recorded in ELR_ELx is a CONSTRAINED UNPREDICTABLE choice one of the following:

- The address of the `MOVPRFX` instruction.
- The address of the prefixed instruction.

R_{JVNGC} When a `MOVPRFX` instruction pairs illegally with another instruction and execution of the pair causes entry to Debug state, the return address recorded in DLR_EL0 is a CONSTRAINED UNPREDICTABLE choice one of the following:

- The address of the `MOVPRFX` instruction.
- The address of the prefixed instruction.

R_{CRRPM} When a prefixed instruction generates an Instruction Abort due to an MMU fault or synchronous External abort and the `MOVPRFX` does not generate an Instruction Abort, then the address of the prefixed instruction is recorded in the appropriate FAR_ELx or HPFAR_EL2 register and the address of the `MOVPRFX` instruction is recorded in the appropriate ELR_ELx register.

R_{ZJYDX} When a prefixed instruction generates an Instruction Abort due to an MMU fault or synchronous External abort and the `MOVPRFX` also generates an Instruction Abort, then the address of the `MOVPRFX` instruction is recorded in the appropriate FAR_ELx or HPFAR_EL2 register and the appropriate ELR_ELx register.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.4.2.2 Asynchronous exception entry

R_{BWRCL} If FEAT_BTI is implemented, then when an asynchronous exception is taken from an Exception level using AArch64, PSTATE.BTYPE is copied to SPSR_ELx.BTYPE and then PSTATE.BTYPE is set to 0.

R_{JBKRW} If any of the following apply, when a physical SError exception is taken to AArch64 state, the pending state of the physical SError is cleared:

- FEAT_DoubleFault is implemented.
- If FEAT_RAS is implemented, and on taking the SError exception, the syndrome recorded in ESR_ELx indicates an SError other than IMPLEMENTATION DEFINED or uncategorized SError exception syndrome. See Taking error exceptions.

Otherwise, it is IMPLEMENTATION DEFINED whether the pending state of the physical SError is cleared. This IMPLEMENTATION DEFINED behavior might vary according to the type of the SError exception.

R_{SYZRH} When a virtual SError exception is taken to AArch64 state, HCR_EL2.VSE is set to 0.

R_{QXQQX} When a delegated SError exception is taken, SCR_EL3.DSE is set to 0.

R_{NPSDK} When FEAT_PFAR is implemented, on taking an SError exception to an Exception level using AArch64:

- If all of the following apply, ESR_ELx.PFV is set to 0:
  - The exception is taken to EL1.
  - EL2 is implemented and enabled in the current security state.
  - The Effective value of HCR_EL2.VM is 1.
- Otherwise, ESR_ELx.PFV is set to an IMPLEMENTATION DEFINED value of 0 or 1.

On taking an SError exception, if ESR_ELx.PFV is set to 1 by the PE then:

- An address within the same naturally-aligned fault granule as the faulting physical address is written to PFAR_ELx.PA or MFAR_EL3.PA as applicable. The fault granule size is defined by D_{LVGRB}.
- The faulting physical address space is written to PFAR_ELx.{NSE, NS} or MFAR_EL3.{NSE, NS} as applicable.

Note

PFAR_ELx never records the Intermediate Physical Address (IPA). PFAR_ELx might reveal a faulting physical addresses to a guest operating system if stage 2 translation is not being used and some other method is used to hide physical addresses from the guest (such as shadow page tables).

R_{YJTBL} On taking an SError exception, the following registers are UNKNOWN based on the ESR_ELx.PFV value:

- If ESR_EL1.PFV is set to 0, PFAR_EL1 is UNKNOWN.
- If ESR_EL2.PFV is set to 0, PFAR_EL2 is UNKNOWN.
- If ESR_EL3.PFV is set to 0, MFAR_EL3 is UNKNOWN.

R_{GZVBJ} An asynchronous exception or asynchronous Debug state entry part way through the execution of a Memory Copy and Memory Set instruction is permissible. For an asynchronous exception, ELR_ELx points to the instruction that the exception was taken on. For an asynchronous Debug state entry, DLR_EL0 points to the instruction that the Debug state entry was taken on.

R_{MNGMW} For an imprecise asynchronous exception part way through the execution of a Memory Copy and Memory Set instruction, the following are UNKNOWN:

- The state of the X[n], X[d], and X[s] registers.
- The state of memory that was being written to by the instruction.

D1.4.3 Exception return terminology

D1.4.3.1 Return, return from, return to

R_{MMSFW} An exception return is caused by the execution of an exception return instruction.

R_{JDJHH} The PE state immediately before an exception return instruction is executed is the state the exception *returns from*.

R_{HNVMN} The PE state immediately after the execution of an exception return instruction is the state the exception *returns to*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.4.4 Exception return

R_{SKNJF} In AArch64 state, the Exception return instructions are ERET, ERETAA, and ERETAB.

R_{PKJFB} The Exception return instructions are UNDEFINED in EL0.

R_{SVBYH} An exception return is either legal or illegal.

D1.4.4.1 Legal exception returns from AArch64 state

R_{BWCFK} On a legal exception return from an Exception level, ELx, all of the following occur:

- If SCTLR_ELx.IESB is 1, and the Exception return instruction does not generate an exception, the PE inserts an error synchronization event before the Exception return instruction.
- Fields in PSTATE that have a corresponding field in SPSR_ELx are written according to their description in SPSR_ELx.
- The PC is set to the value in ELR_ELx.
- If returning to an Exception level using AArch32 state, all the following apply:
  - If SPSR_ELx.T is 0, ELR_ELx[1:0] are treated as being 0 for setting the PC.
  - If SPSR_ELx.T is 1, ELR_ELx[0] is treated as being 0 for setting the PC.
- The contents of PSTATE are set to the values held in SPSR_ELx.
- If FEAT_PAuth_LR is implemented and any of the following apply, PSTATE.PACM is set to 0:
  - The trivial implementation of PSTATE.PACM is used.
  - The effects of PACM instructions are disabled at the target Exception level.
- If the PSTATE.IL bit copied from SPSR_ELx is 1 and the target Exception level for the return is using AArch32 state, the PSTATE.{IT, T} bits are determined by an IMPLEMENTATION DEFINED choice of one of the following:
  - Set to 0.
  - For returns initiated by an Exception return instruction or DRPS instruction, copied from SPSR_ELx.
  - For debug exits, copied from DSPSR_EL0.

  The IMPLEMENTATION DEFINED choice might vary dynamically within the implementation. Software must regard the value as being an UNKNOWN choice between the two values.
- The Event Register for the PE executing the Exception return instruction is set.
- The local Exclusives monitor for the PE executing the Exception return instruction is cleared. It is IMPLEMENTATION DEFINED whether clearing the local Exclusives monitor also clears the global Exclusives monitor.
- After the PC is set to the value held in ELR_ELx and the contents of PSTATE are set to the values held in SPSR_ELx, ELR_ELx and SPSR_ELx become UNKNOWN.
- If the exception return is from EL2, to EL0 in AArch64 state when HCR_EL2.TGE is 0, ELR_EL1 and SPSR_EL1 become UNKNOWN.
- If the Effective value of SCTLR_ELx.EOS is 1, the exception return is a Context synchronization event.
- If the Effective value of SCTLR_ELx.EOS is 0, the exception return is not a Context synchronization event.

D1.4.4.2 Illegal exception returns from AArch64 state

R_{TYTWB} If in AArch64 state, any of the following situations can cause an illegal exception return:

- A return is made to an Exception level higher than the current Exception level.
- A return is made to an Exception level that is not implemented.
- If FEAT_RME is implemented, then if SCR_EL3.{NSE, NS} is {1, 0}, an exception return from EL3 to a lower Exception level.
- If all of the following are true, and a return is made to EL1:
  - EL2 is implemented and enabled in the current Security state
  - HCR_EL2.TGE is 1.
- If all of the following are true, and a return is made to EL2:
  - EL3 is implemented.
  - SCR_EL3.NS is 0.
  - FEAT_SEL2 is not implemented.
- If all of the following are true, and a return is made to EL2:
  - EL3 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - SCR_EL3.NS is 0.
  - FEAT_SEL2 is implemented.
  - SCR_EL3.EEL2 is 0.
- A return where the saved PSTATE.M[4] is 0 and at least one of the following is true:
  - M[1] is 1.
  - M[3:0] are `0b0001`.
  - The Exception level being returned to is using AArch32 state, as determined by SCR_EL3.RW, HCR_EL2.RW, or as configured from reset.
- A return where the saved PSTATE.M[4] bit is 1, indicating a return to AArch32 state, and at least one of the following are true:
  - AArch32 state is not supported at any Exception level.
  - The M field value is not a valid AArch32 state PE mode.
  - The Exception level being returned to is using AArch64 state, as determined by SCR_EL3.RW, HCR_EL2.RW, or as configured from reset.
- If the Effective value of GCSCR_ELx.EXLOCKEN is 1 and PSTATE.EXLOCK is 0, the execution of an exception return instruction to return to the current Exception level ELx.

R_{VWJHB} On an illegal exception return from an Exception level, ELx, all of the following occur:

- If SCTLR_ELx.IESB is 1, the PE inserts an error synchronization event before the Exception return instruction.
- The PC is set to the value in ELR_ELx.
  If the saved PSTATE.M[4] bit is 1, for illegal exception returns to AArch32 state, all of the following are true:
  - The PC bits[31:2] are set to the value in ELR_ELx.
  - The PC bits[63:32, 1:0] are UNKNOWN.
- PSTATE.IL is set to 1.
- PSTATE.{EL, nRW, SP} are unchanged.
- PSTATE.{N, Z, C, V, D, A, I, F} are set to the associated values in SPSR_ELx.
- PSTATE.SS is handled as if the return is a legal exception return.
- If PSTATE.nRW is 1, indicating a return to AArch32 state, then the following PSTATE bits are also set:
  - PSTATE.{Q, IT, GE, E} are set to the associated values in SPSR_ELx.
  - It is CONSTRAINED UNPREDICTABLE whether PSTATE.T is 0 or set to the contents of SPSR_ELx.
- If FEAT_PAN is implemented, then PSTATE.PAN is set to the associated value in SPSR_ELx.
- All of the following are UNKNOWN:
  - If FEAT_UAO is implemented, then PSTATE.UAO.
  - If FEAT_DIT is implemented, then PSTATE.DIT.
  - If FEAT_MTE is implemented, then PSTATE.TCO.
  - If FEAT_SSBS is implemented, then PSTATE.SSBS.
  - If FEAT_BTI is implemented, then PSTATE.BTYPE.
  - If FEAT_PAuth_LR is implemented, then PSTATE.PACM.
- If FEAT_NMI is implemented, then PSTATE.ALLINT is set to the associated value in SPSR_ELx.
- If FEAT_EBEP, FEAT_SPE_EXC or FEAT_TRBE_EXC is implemented, then PSTATE.PM is set to the associated value in SPSR_ELx.
- If FEAT_GCS is implemented, then PSTATE.EXLOCK is unchanged.
- If FEAT_UINJ is implemented, then PSTATE.UINJ is set to 0.
- The Event Register for the PE executing the Exception return instruction is set.
- The local Exclusives monitor for the PE executing the Exception return instruction is cleared. It is IMPLEMENTATION DEFINED whether clearing the local Exclusives monitor also clears the global Exclusives monitor.
- After the PC has been set to the value held in ELR_ELx and the contents of PSTATE have been set to the value held in SPSR_ELx, the ELR_ELx and SPSR_ELx become UNKNOWN.
- If the Effective value of SCTLR_ELx.EOS is 1, the exception return is a Context synchronization event.
- If the Effective value of SCTLR_ELx.EOS is 0, the exception return is not a Context synchronization event.

D1.4.5 Synchronous exception types

R_{BZGXV} All of the following are synchronous exceptions:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Any exception generated by attempting to execute an instruction that is UNDEFINED, including:
  - Attempts to execute instructions at an inappropriate Exception level.
  - Attempts to execute instructions when they are disabled.
  - Attempts to execute instruction bit patterns that are not allocated.
  - Any attempt to execute any instruction when PSTATE.UINJ is 1. See Undefined Instruction exceptions injected by PSTATE.UINJ.
- Any exception caused by attempts to execute an instruction when the value of PSTATE.IL is 1. These are called Illegal Execution State exceptions.
- Any exception caused by the use of a misaligned SP. These are called SP Alignment Fault exceptions.
- Any exception caused by attempting to execute an instruction with a misaligned PC. These are called PC Alignment Fault exceptions.
- If FEAT_BTI is implemented, execution is inside a guarded memory region, and PSTATE.BTYPE does not equal 0, then any exception caused by executing an instruction that is not compatible with the current value of PSTATE.BTYPE. These are called Branch Target exceptions.
- Any exception caused by a pointer authentication instruction authentication failure. These are called PAC Fail exceptions.
- Any exception caused by the exception generating instructions SVC, HVC, or SMC. These are respectively called Supervisor Call (SVC) exceptions, Hypervisor Call (HVC) exceptions, or Secure Monitor Call (SMC) exceptions.
- Traps on attempts to execute instructions that the System registers define as instructions that are trapped to a higher Exception level. These are called Trap exceptions.
- Any exception caused by Instruction Aborts that were generated by the memory address translation system that was associated with attempts to execute instructions from areas of memory that generate faults. These are called Instruction Abort exceptions.
- Any exception caused by Data Aborts that were generated by the memory address translation system that are associated with attempts to read or write memory that generate faults. These are called Data Abort exceptions.
- Any exception caused by Data Aborts because of a misaligned address. These are called Data Abort exceptions.
- If FEAT_MTE2 is implemented, any exception caused by a Data Abort as a result of a Tag Check Fault. These are called Data Abort exceptions.
- If FEAT_RME is implemented, any exception that results from a *Granule Protection Check* (GPC) fault. Depending on the cause of the exception, the GPC fault type, and the value of the routing control SCR_EL3.GPF, these are called:
  - GPC exceptions.
  - Data Abort exceptions.
  - Instruction Abort exceptions.
- Memory Copy exceptions and Memory Set exceptions. For more information, see Memory Copy and Memory Set exceptions.
- Guarded Control Stack exceptions. For more information, see Guarded Control Stack exceptions.
- All of the debug exceptions:
  - Breakpoint Instruction exceptions.
  - Breakpoint exceptions.
  - Watchpoint exceptions.
  - Vector Catch exceptions.
  - Software Step exceptions.
- In an implementation that supports the trapping of floating-point exceptions, any exception caused by trapped floating-point exceptions. These are called Trapped Floating-point exceptions.
- An IMPLEMENTATION DEFINED set of exceptions caused by External aborts.

I_{XRFSY} The architecture permits, but does not require, synchronous or asynchronous handling of External aborts. However, some situations specified by the architecture must be handled synchronously. For more information, see Taking error exceptions.

D1.4.5.1 Taking synchronous exceptions from EL0

R_{DPLSC} If EL2 is using AArch64 and the Effective value of HCR_EL2.TGE is 1, when any of the following exceptions are taken from EL0, they are taken to EL2, unless routed to a higher Exception level. If EL2 is using AArch64 and the Effective value of HCR_EL2.TGE is 0, when any of the following exceptions are taken from EL0, they are taken to EL1, unless routed to a higher Exception level:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Stage 1 Data Abort.
- Stage 1 Instruction Abort.
- PC Alignment fault.
- SP Alignment fault.
- Tag Check fault.
- Branch Target exception.
- Illegal Execution State exception.
- Trapped Floating-point exception.
- Supervisor Call.
- Undefined Instruction exception.
- PAC Fail exception.
- WFE trap.
- WFI trap.
- Advanced SIMD and floating-point Access trap.
- SVE Access trap.
- SME Access traps.
- SME Illegal Instruction exceptions.
- Synchronous External aborts.
- Memory Copy and Memory Set exceptions.
- PMU exceptions.
- Guarded Control Stack exceptions.

If EL2 is using AArch64 and either HCR_EL2.TGE is 1 or MDCR_EL2.TDE is 1, when any of the following debug exceptions are taken from EL0, they are taken to EL2. If EL2 is using AArch64 and both HCR_EL2.TGE is 0 and MDCR_EL2.TDE is 0, when any of the following debug exceptions are taken from EL0, they are taken to EL1:

- Breakpoint exception.
- Software Breakpoint exception.
- Software Step exception.
- Watchpoint exception.

If EL2 is using AArch64 and either HCR_EL2.TGE is 1 or MDCR_EL2.TDE is 1, when a Vector Catch exception is taken from EL0, it is taken to EL2. If EL2 is using AArch64 and both HCR_EL2.TGE is 0 and MDCR_EL2.TDE is 0, a Vector Catch exception cannot be taken.

R_{JNBTN} For an exception that is taken from EL0 to EL2 because the value of HCR_EL2.TGE is 1:

- If the exception would have been reported in ESR_EL1 using any EC value other than `0x07`, then the EC value and corresponding ISS encoding that would have been used to report the exception in ESR_EL1 are used to report the exception in ESR_EL2.
- If the exception would have been reported in ESR_EL1 using the EC value `0x07`, then the EC value `0x00` and ISS encoding value `0x00` are reported in ESR_EL2.

D1.4.5.2 Exception levels for taking a synchronous External abort

R_{QDLHN} If all of the following are true, then a synchronous External abort is taken to EL3 using AArch64:

- EL3 is implemented and using AArch64.
- Any of the following are true:
  - SCR_EL3.EA is 1 and the exception is taken from EL2, EL1, or EL0.
  - The exception is taken from EL3.

Otherwise, if all of the following are true, then a synchronous External abort exception is taken to EL2:

- EL2 is implemented and enabled in the current Security state.
- The exception is taken from EL1 or EL0.
- Any of the following are true:
  - The Effective value of HCR_EL2.TEA or HCR2.TEA is 1.
  - The exception was generated by an External abort on a stage 2 translation table walk.
  - The exception was generated by an External abort on a System register access converted to a memory access by FEAT_NV2. This can only occur at EL1.
  - The Effective value of HCR_EL2.TGE or HCR.TGE is 1. This can only occur at EL0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise, if FEAT_DoubleFault2 is implemented and all of the following are true, then a synchronous External abort exception is taken to EL2:

- EL2 is implemented, enabled in the current Security state, and using AArch64.
- The Effective value of HCRX_EL2.TMEA is 1.
- PSTATE.A is 1.
- The exception is taken from EL1.

Otherwise, if FEAT_DoubleFault2 is implemented and all of the following are true, then a synchronous External abort exception is taken to EL3:

- EL3 is implemented and using AArch64.
- The Effective value of SCR_EL3.TMEA is 1.
- PSTATE.A is 1.
- The exception is taken from EL1 or EL2.

Otherwise, all of the following apply:

- A synchronous External abort exception taken from EL2 is taken to EL2.
- When EL1 is using AArch64, synchronous External abort exception taken from EL1 or EL0 is taken to EL1 using AArch64.

I_{MBJFW} The terms used in the tables in I_{NDBHM} have the following meanings:

SCR_EL3 The Effective value of a field in SCR_EL3.

HCR If EL2 is using AArch32, this is the Effective value of a field in HCR or HCR2. If EL2 is using AArch64, this is the Effective value of a field in HCR_EL2.

HCRX_EL2 The Effective value of a field in HCRX_EL2.

PSTATE The Effective value of a field in PSTATE.

EA The Effective value of SCR_EL3.EA. If EL3 is not implemented, the Effective value of SCR_EL3.EA is 0.

TMEA The Effective value of SCR_EL3.TMEA or HCRX_EL2.TMEA.

If FEAT_DoubleFault2 is not implemented, the Effective values of SCR_EL3.TMEA and HCRX_EL2.TMEA are 0.

If EL2 is not implemented or EL2 is disabled in the current Security state, the Effective value of SCR_EL3.HXEn is 0, or EL2 is using AArch32, then the Effective value of HCRX_EL2.TMEA is 0.

TGE The Effective value of HCR.TGE. If EL2 is not implemented, or if EL2 is disabled in the current Security state, then the Effective value of HCR.TGE is 0.

A The Effective value of PSTATE.A.

EL1 The exception is taken to EL1.
If EL1 is using AArch32, then the exception is taken to the AArch32 Abort mode.

EL2 The exception is taken to EL2.
If EL2 is using AArch32, then the exception is taken to the AArch32 Hyp mode.

EL3 The exception is taken to EL3 using AArch64.

n/a Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

I_{NDBHM} The following table summarizes the destination Exception level for a synchronous External abort exception taken from ELx, and all of the following applies:

- SCR_EL3.{NS, EEL2} are not shown. I_{MBJFW} describes Effective values involving Security states.
- The error was generated by a stage 1 fault on an access that is not a System register access. See R_{QDLHN} for details of other cases.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SCR_EL3		HCR		HCRX_EL2	PSTATE	Exception taken from

0b1	X	0b0	X	X	X	EL3	EL3	EL3	EL3
0b1	X	0b1	X	X	X	EL3	n/a	EL3	EL3

D1.4.5.3 Granule Protection Check faults

IYRNGX If FEAT_RME is implemented, then when GPCCR_EL3.GPC is 1, *Granule Protection Checks* (GPCs) on accesses to Physical Address (PA) space are enabled and might result in *GPC faults*.

RPYTGX GPC faults are reported as synchronous exceptions:

GPC fault	Synchronous exception type
Granule Protection Fault (GPF) at EL3	Instruction Abort exception or Data Abort exception
GPF at EL2, EL1, or EL0 when SCR_EL3.GPF is 0	Instruction Abort exception or Data Abort exception
GPF at EL2, EL1, or EL0 when SCR_EL3.GPF is 1	GPC exception
Granule Protection Table (GPT) walk faults	GPC exception
GPT address size faults	GPC exception
Synchronous External abort on GPT fetch	GPC exception

RFXMGJ GPC exceptions are taken to EL3.
Instruction Abort exceptions and Data Abort exceptions resulting from GPFs at:

- EL3 are taken to EL3.
- EL2 are taken to EL2.
- EL1 and EL0 are taken to:
  - EL2 when the GPF is on an access for a stage 2 translation table, including for a hardware update of stage 2 tables.
  - Otherwise:
    - EL1 when HCR_EL2.{TGE, GPF} is {0, 0}.
    - EL2 when HCR_EL2.{TGE, GPF} is not {0, 0}.

IXWVCY For GPFs at EL2, EL1, or EL0 when SCR_EL3.GPF is 1, EL3 firmware can choose to delegate the resulting GPC exception to a lower Exception level, as an Instruction Abort exception or Data Abort exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{JXSRX} When the PE is in Debug state and EDSCR.SDD is 1, SCR_EL3.GPF is treated as 0, and the following GPC faults are treated as a GPF for the purposes of causing an exception:

- GPT walk faults.
- GPT address size faults.
- Synchronous External abort on GPT fetch.

I_{ZTKNY} GPC exceptions due to a synchronous External abort on GPT fetch are subject to SCR_EL3.EASE.

I_{YJLPJ} All GPC faults are reported with a priority consistent with the GPC being performed on any access to PA space. That is, for each existing synchronous External abort, GPC faults are reported with immediately higher priority than the corresponding synchronous External abort for that access. See MMU fault prioritization from a single address translation stage.

I_{YHXKR} When GPCCR_EL3.GPCP is 1, the PE can omit GPCs on fetches of translation table entries that are Table descriptors for stage 2 translation table walks, for a performance optimization. Enabling this optimization is dependent on the security model of the system.

R_{RWGJH} If GPCCR_EL3.GPCP is 1 and the PE omits a GPC when fetching a translation table entry that is a Table descriptor for a stage 2 translation table walk, then when the entry is processed:

- If the entry is not a Table descriptor, the PE must complete a GPC on the address of the entry before the translation completes. This is permitted to occur concurrently with a GPC on the entry content, as long as the priority order for fault reporting is maintained.
- Arm strongly recommends that the PE perform a GPC on the address of the entry if the entry generates a fault that would report syndrome information from that entry. If the GPC results in a GPC fault, the fault is reported as though GPCCR_EL3.GPCP is 0.

I_{ZDKBX} When a load or store instruction results in accesses to two granules, the access to each granule is subject to a GPC.

R_{GVSNZ} If an instruction that stores to memory generates a GPC fault, the value of each memory location that instruction attempted to store to is either:

- Unchanged if access to the location triggered the GPC fault.
- UNKNOWN for any location for which access did not trigger a fault or debug event.

I_{RFMWD} A GPC fault might occur at any point in the translation process that requires access to a PA. For example, to perform a store at EL1, a PE performs:

- A stage 1 translation for the VA.
- Stage 2 translations for:
  - The output IPA from the stage 1 translation.
  - The IPA of each stage 1 descriptor.
- GPCs for all of:
  - The PA that the VA translates to.
  - The PA of each stage 1 descriptor.
  - The PA of each stage 2 descriptor.

D1.4.5.4 SVE synchronous memory faults

I_{YLCFS} In this section, the term *Memory fault* refers to the detection of an erroneous condition or debug event as a result of performing a data memory access for an SVE load or store instruction.

R_{SKNTR} When an SVE load or store instruction results in a data memory access, the detection of any of the following conditions is considered to be a *Memory fault*:

- MMU fault.
- Alignment fault, excluding the SP alignment fault.
- Synchronous External abort, including synchronous parity error or ECC error.
- Watchpoint debug event.
- When FEAT_MTE2 is implemented, a synchronous Tag Check Fault.

For more information, see Memory aborts.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{LDTYT} The detection or generation of a *Memory fault* by an SVE load or store instruction may or may not cause a synchronous Data Abort or Watchpoint exception to be taken.

R_{LVCNH} Unless otherwise specified in this section, SVE vector load and store instructions that detect a *Memory fault* cause a Data Abort or Watchpoint exception to be taken, as described in SVE Data Abort and Watchpoint exceptions.

R_{FPVTT} A *Memory fault* detected for a memory location that can only be accessed by an *Inactive element* of a predicated SVE vector load or store instruction is ignored and does not cause a Data Abort or Watchpoint exception to be taken by that instruction.

D1.4.5.4.1 SVE Data Abort and Watchpoint exceptions

R_{KJPTS} Unless otherwise specified in this section, a Data Abort and Watchpoint exception caused by an SVE load or store instruction follows the behaviors described in Definition of a precise exception and imprecise exception, Exception entry, and Prioritization of Synchronous exceptions taken to AArch64 state.

I_{DGSNC} SVE load and store instructions can generate a sequence of single-copy atomic memory accesses that might not be completed due to a *Memory fault* causing a Data Abort or Watchpoint exception to be taken during the memory access sequence.

R_{ZKBRX} When the execution of an SVE load or store instruction detects multiple *Memory faults* caused by different single-copy atomic memory accesses, the *Memory faults* are not prioritized by the architecture.

I_{MSVYK} When an SVE load or store instruction that has not been architecturally executed is restarted after an exception return, any memory locations that it accessed before taking the exception might be accessed again. Therefore, SVE load or store instructions might perform multiple accesses to memory locations that do not cause a *Memory fault* but which are sensitive to the number of accesses, or have been modified between the accesses.

R_{ZXNXT} When execution of an SVE load instruction causes a Data Abort or Watchpoint exception to be taken and the destination is not a vector register that is also used as a base or index register by the instruction, then all elements of the destination register become UNKNOWN.

R_{SNJQR} When execution of an SVE load instruction causes a Data Abort or Watchpoint exception to be taken and the destination is a vector register that is also used as a base or index register by the instruction, then all elements of the destination vector register are restored to their original value prior to execution of the load instruction.

R_{DWYCY} When execution of an SVE predicated vector store instruction causes a Data Abort or Watchpoint exception to be taken, one or more of the following occurs:

- Memory locations that are associated with *Active elements* and which do not generate a *Memory fault* become UNKNOWN.
- Memory locations that are associated with *Active elements* and which generate a *Memory fault* are unchanged.
- Memory locations that are only associated with *Inactive elements* are unchanged.

D1.4.5.4.2 SVE First-fault and Non-fault loads

I_{JZBGW} When a memory access performed for the *First active element* of an SVE First-fault vector load instruction detects a *Memory fault*, this causes a synchronous exception to be taken as described in SVE Data Abort and Watchpoint exceptions.

I_{DXBNG} When a memory access performed for the *First active element* of an SVE First-fault vector load instruction does not detect a *Memory fault*, the other elements are handled in the same way as the elements of an SVE Non-fault vector load instruction.

R_{JKGYJ} A Data Abort or Watchpoint exception is not generated when a *Memory fault* is detected by a memory access performed for any of the following elements:

- Any *Active element* of an SVE Non-fault vector load.
- Any *Active element* of an SVE First-fault vector load except for the *First active element*.

R_{MNKNV} The PE can choose to suppress a memory access performed for any of the following elements:

- Any *Active element* of an SVE Non-fault vector load.
- Any *Active element* of an SVE First-fault vector load except for the *First active element*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{YFTRN} When a memory access performed for any of the following elements detects a *Memory fault*, an asynchronous Tag check fault, or is suppressed for any other reason, the FFR predicate elements starting from that element number, up to and including the highest-numbered element, are set to FALSE:

- Any *Active element* of an SVE Non-fault vector load.
- Any *Active element* of an SVE First-fault vector load except for the *First active element*.

Note

An asynchronous Tag check fault setting elements in FFR to FALSE is required to be synchronous with respect to the instruction stream as per R_{XXMMP}.

I_{BMQVT} An FFR predicate element is never set to TRUE by an SVE vector load, therefore the fault indications are cumulative.

I_{BXNTL} A memory access performed for the First active element of an SVE First-fault vector load instruction is not precisely equivalent to the memory access for an Active element of a regular SVE predicated vector load instruction. When the initial value of the FFR element corresponding to the First active element is FALSE, then even if an access is performed for that element and does not detect a *Memory fault*, the content of the corresponding destination vector element is still CONSTRAINED UNPREDICTABLE, as described in rule R_{NGFTJ}.

R_{NGFTJ} After an SVE Non-fault vector load or First-fault vector load is executed, each destination vector element contains one of the values listed in the following table:

Table D1-9 Contents of destination vector element after an SVE Non-fault vector load or First-fault vector load

Corresponding FFR element	Vector element status	Content of destination vector element
FALSE	Active	Each byte of the element contains an independently CONSTRAINED UNPREDICTABLE choice of one of the following: • 0. • The previous value of that byte in the destination vector register. • If and only if all of the following apply, the value read from memory: — The memory access for that byte was not an access to any type of Device memory, or for a First-fault vector load was an access to Device memory inside the 64-byte window of the First active element. See Device memory for more information. — The memory access for that byte does not return information that cannot be accessed at the current or a lower level of privilege.
FALSE	Inactive	A CONSTRAINED UNPREDICTABLE choice of: • 0. • The previous value of that vector element.
TRUE	Active	The value read from memory.
TRUE	Inactive	0.

R_{WCHSR} In Table D1-9, watchpoints and MTE Tag check faults are not a mechanism for preventing access to memory.

D1.4.5.5 Undefined Instruction exceptions injected by PSTATE.UINJ

R_{NKNRG} If FEAT_UINJ is implemented, then any attempt to execute any instruction when PSTATE.UINJ is 1 causes an Undefined Instruction exception with ESR_ELx.EC `0b000000`.

I_{HPGHL} Software can set SPSR_ELx.UINJ to 1, and on exception return that value is copied to PSTATE.UINJ. Then, when the PE attempts to execute the next instruction, an Undefined Instruction exception occurs.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.4.5.6 Prioritization of Synchronous exceptions taken to AArch64 state

RZFGJP The following list shows the priorities for synchronous exceptions taken to an Exception level using AArch64. The highest priority is 1. The AArch64 priority numbers correlate with the equivalent AArch32 and Debug prioritization lists.

Priority	Synchronous exception type
1	Reset Catch debug event. See Reset Catch debug events.
2	Exception Catch debug event if it has a priority of 2. See Exception Catch debug event.
3	Halting Step debug event. See Halting Step debug events.
4	Software Step exception. See Software Step exceptions.
5	Exception Catch debug event if it has a priority of 5. See Exception Catch debug event.
6	PC alignment fault exception. See PC alignment checking.
7	Illegal Execution state exceptions. It is IMPLEMENTATION DEFINED whether this is prioritized here or at 12. See Illegal exception returns from AArch64 state.
8	Instruction Abort exceptions, including exceptions generated by an MMU fault for the translation of an instruction fetch, that are not covered by priorities 9 or 11. If FEAT_RME is implemented, this includes GPC exceptions and Granule Protection Faults. See MMU fault prioritization from a single address translation stage.
9	If prioritized here, Instruction Abort exceptions due to Synchronous External abort, not on translation table walk or hardware update of translation table.
10	Breakpoint exceptions, or AArch32 Address Matching Vector Catch exceptions. See Breakpoint exceptions and Vector Catch exceptions.
11	The exceptions listed for priority 9, if they are prioritized as 11.
12	Illegal Execution state exceptions. It is IMPLEMENTATION DEFINED whether this is prioritized here or at 7. See Illegal exception returns from AArch64 state.
13	If FEAT_UINJ is implemented, an Undefined Instruction exception caused by an attempt to execute an instruction when PSTATE.UINJ is 1.
14	Software Breakpoint exceptions, caused by execution of a Breakpoint instruction.
15	Branch Target exception. See PSTATE.BTYPE.
16	EXLOCK Exception. See Guarded Control Stack exceptions.
17	Exceptions taken to EL3 due to the MPAM3_EL3.TRAPLOWER trap control.
18	Exceptions taken to EL3 due to the MPAMBW3_EL3.nTRAPLOWER trap control.
19	Exceptions taken from EL1 to EL2 because of the configuration of one of the following: • HSTR_EL2.Tn. • HCR_EL2.TIDCP. • If FEAT_NV is implemented, the Effective value of HCR_EL2.{NV1, NV}. Exceptions taken from EL0 to EL1 or EL2 because of the configuration of the following: • If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP. Exceptions taken from EL0 to EL2 because of the configuration of the following: • If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Priority	Synchronous exception type
20	Exceptions that occur as a result of attempting to execute an instruction that is UNDEFINED for one or more of the following reasons: • Attempting to execute a `UDF` instruction. • Attempting to execute an unallocated instruction encoding, including an encoding for an instruction that is not implemented in the PE implementation. • Attempting to execute an instruction that is defined to never be accessible at the current Exception level and Security state, regardless of any enables or traps. • Debug state execution of an instruction encoding that is not accessible in Debug state. • Non-debug state execution of an instruction encoding that is not accessible in Non-debug state. • Attempting to execute an `HVC` instruction, when `HVC` instructions are disabled by SCR_EL3.HCE or HCR_EL2.HCD. • Attempting to execute an `MSR` or `MRS` instruction to SP_EL0, when SPSel.SP is 0. • Attempting to execute an `MSR` or `MRS` instruction using an _EL12 register name, when the Effective value of HCR_EL2.E2H is 0. • If FEAT_FGT and FEAT_PMUv3 are implemented, attempting to execute an `MSR` or `MRS` instruction in AArch64 state, or an `MCR` or `MRC` instruction in AArch32 state, that accesses a register associated with an unimplemented PMU event counter. • If FEAT_SRMASK is implemented, attempting to execute an `MSR` write access to any of the following: — An EL1 mask register from EL1, when the EL1 mask register is nonzero and the access is not trapped. — An EL2 mask register from EL2, when the EL2 mask register is nonzero. • Attempting to execute an `HLT` instruction, when `HLT` instructions are disabled by EDSCR.HDE or halting is prohibited. • Attempting to execute an SVE instruction that is UNDEFINED because the *Maximum implemented SVE vector length* in both Streaming SVE mode, and Non-streaming SVE mode, is less than the minimum required vector length for that instruction. See Maximum implemented SVE vector lengths. • Attempting to execute an SME instruction that is UNDEFINED because the *Maximum implemented Streaming SVE vector length* is less than the minimum required vector length for that instruction. See Maximum implemented SVE vector lengths. • Attempting to execute an SVE `MOVPRFX` instruction with an immediately following instruction that the `MOVPRFX` cannot predictably prefix, when the choice of resulting behavior is for either instruction to generate an Undefined Instruction exception. See Move prefix.

Priority	Synchronous exception type
20 cont'd	• If in Debug state: — Attempting to execute a `DCPS1` instruction in Non-secure EL0 HCR_EL2.TGE is 1. — Attempting to execute a `DCPS2` instruction in EL1 or EL0, when EL2 is disabled in the current Security state or is not implemented. — Attempting to execute a `DCPS3` instruction, when EDSCR.SDD is 1 or EL3 is not implemented. — Attempting to execute in EL2, EL1, or EL0 an instruction that is configured by EL3 control registers to trap to EL3, when EDSCR.SDD is 1. It is IMPLEMENTATION DEFINED whether this type of exception is prioritized at this level or has the priority of the original trap exception. • If in AArch32 state: — If SCTLR_EL1.ITD is 1, attempting to execute an instruction in an IT block. — If SCTLR_EL1.SED is 1, attempting to execute a `SETEND` instructions. — If SCTLR_EL1.CP15BEN is 0, attempting to execute a `CP15DMB`, `CP15DSB`, or `CP15ISB` barrier instruction. • Attempting to execute an instruction that is UNDEFINED because all of the following apply: — EL0 is using AArch32. — EL1 is using AArch64. — Programming FPCR.{Stride, Len} to nonzero values is supported. — One or more of FPCR.{Stride, Len} is nonzero.
21	If FEAT_SME or FEAT_SVE is implemented, an exception taken to EL1, or to EL2 if HCR_EL2.TGE is 1, due to one of the following trap controls: • CPACR_EL1.SMEN or CPACR_EL1.ZEN.
22	If all of the following apply, any exception that is generated by a configurable trap or enable: • The exception is not already covered by priorities 4-21. • The exception is taken to EL1, or, if HCR_EL2.TGE is 1, is taken to EL2.
23	As the result of one of the following configuration controls, an exception taken from EL0 to EL2: • When the exception is taken to AArch64 state: — HSTR_EL2.T*n*. — HCR_EL2.TIDCP. • When the exception is taken to AArch32 state: — HSTR.T*n*. — HCR.TIDCP.
24	If FEAT_SME or FEAT_SVE is implemented, an exception taken to EL2 due to one of the following trap controls: • CPTR_EL2.SMEN or CPTR_EL2.ZEN, when the Effective value of HCR_EL2.E2H is 1. • CPTR_EL2.TSM or CPTR_EL2.TZ, when the Effective value of HCR_EL2.E2H is 0.

Priority	Synchronous exception type
25	As the result of one of the following configuration controls, an exception taken to EL2: • When the exception is taken to AArch64 state: controls in CPTR_EL2, other than those controls covered in priority 24. • When the exception is taken to AArch32 state: controls in HCPTR.
26	As the result of a configuration control in one of the following registers, an exception taken to EL2: • When the exception is taken to AArch64 state: — HCR_EL2: Other than a setting made in the {TIDCP, NV} fields, and MRS/MSR instruction using an _EL12 register name when the Effective value of HCR_EL2.E2H is 0. — CNTHCTL_EL2: Any setting. — MDCR_EL2: Any setting. Any of the following fine-grained traps: — HAFGRTR_EL2. — HDFGRTR_EL2. — HDFGRTR2_EL2. — HDFGWTR_EL2. — HDFGWTR2_EL2. — HFGITR_EL2. — HFGITR2_EL2. — HFGRTR_EL2. — HFGRTR2_EL2. — HFGWTR_EL2. — HFGWTR2_EL2. When the exception is taken to AArch32 state: — HCR: Other than the TIDCP bit. — CNTHCTL: Any setting. — HDCR: Any setting.
27	Other than an exception defined by priorities 4-26 inclusive, any exception that is the result of a configurable access to instructions, where the exception is taken to EL2.
28	An exception caused by the SMC instruction being UNDEFINED because SCR_EL3.SMD is 1.
29	An exception caused by any of the following Exception generating instructions: • `HVC`. • `SMC`. • `SVC`. For AArch64 State, see Branches, Exception generating, and System instructions.
30	If FEAT_SME or FEAT_SVE is implemented, an exception taken to EL3 due to one of the following trap controls: • CPTR_EL3.ESM or CPTR_EL3.EZ.
31	An exception taken to EL3 as the result of configuration controls in CPTR_EL3, other than those controls covered in priority 30. It is IMPLEMENTATION DEFINED whether the exception is prioritized as an UNDEFINED instruction or has the priority of the original Trap exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Priority	Synchronous exception type
32	Exceptions Trapped to EL3 from Secure EL1 using AArch32.
33	An Exception taken to EL3 from EL0, EL1, or EL2 as a result of configuration controls in MDCR_EL3. It is IMPLEMENTATION DEFINED whether the exception is prioritized as an UNDEFINED instruction or has the priority of the original Trap exception.
34	Other than an exception defined by priorities 4-33, inclusive, any exception taken to EL3 because of a configurable access to an instruction. If an exception generated by a configurable instruction control is treated as UNDEFINED as a result of EDSCR.SDD configuration, then it is IMPLEMENTATION DEFINED whether the exception is prioritized as an UNDEFINED instruction or has the priority of the original Trap exception.
35	*SME illegal instruction exceptions* due to attempting to execute an SME instruction when PSTATE.SM is 0, or attempting to execute certain Advanced SIMD or SVE instructions when PSTATE.SM is 1. See Streaming SVE mode.
36	SME illegal instruction exceptions due to attempting to access *ZA storage* or the *ZT0 register* when PSTATE.ZA is 0. See ZA storage and SME2 ZT0 register.
37	SME illegal instruction exceptions due to attempting to access the ZT0 register when an SMCR_ELx.EZT0 control is 0. See SME2 ZT0 register and SME traps and exceptions.
38	An exception as a result of attempting to execute an SVE or SME instruction that is UNDEFINED because the Effective SVE vector length is less than the minimum required vector length for that instruction. See also Configurable SVE vector lengths.
39	When FEAT_FPAC is implemented, a PAC Fail exception. See Faulting on pointer authentication.
40	When SIMD & Floating Point is implemented, any trapped floating-point exception. See Floating-point exceptions and exception traps.
41	This priority number is used by debug events.
42	An SP alignment fault. See SP alignment checking.
43	When FEAT_MOPS is implemented, Memory Copy and Memory Set exceptions caused by the CPY* or SET* instruction algorithm option of the implementation that an exception is taken from being different from the algorithm option of the implementation that is returned to. See Memory Copy and Memory Set exceptions.
44	When FEAT_MOPS is implemented, Memory Copy and Memory Set exceptions that are not defined by priority 43. See Memory Copy and Memory Set exceptions.
For priorities 45, 46, 47, 48 or 49: when an instruction results in more than one single-copy atomic memory access, the architecture will not prioritize the individual Synchronous exceptions generated as the result of the multiple memory accesses. When FEAT_GCS is implemented, a stricter requirement is defined for the `GCSSS2` instruction in R_{XTZVS}.	
45	In descending priority order: a) Data Abort exceptions on translation table walks and translation table entry updates. b) GPC Exceptions on translation table walks and translation table entry updates, if FEAT_RME is implemented. c) Data Abort exceptions due to synchronous External aborts on translation table walks and translation table entry updates. d) Data Abort exceptions arising from an MMU fault not on a translation table walk, that are not covered by priorities 46 or 48. See also: • MMU fault prioritization from a single address translation stage. • External aborts.

D1.4.5.7 Trapping of floating-point exceptions

R_{TSQFJ} Execution of a floating-point instruction, or execution of an Advanced SIMD or SVE instruction that performs floating-point operations, can generate an exceptional condition, called a floating-point exception.

R_{BBSGN} For each of the following floating-point exceptions, it is IMPLEMENTATION DEFINED whether an implementation includes synchronous exception generation:

- Input Denormal.
- Inexact.
- Underflow.
- Overflow.
- Divide by Zero.
- Invalid Operation.

I_{YRVSW} The architecture does not support asynchronous reporting of floating-point exceptions. If an implementation does not support synchronous exception generation from a floating-point exception, then that synchronous exception is never generated and all statements on when that synchronous exception is generated do not apply.

I_{KJTLV} For any of the implemented floating-point exceptions listed in R_{BBSGN}, FPCR provides control bits to enable synchronous exception generation.

R_{VJFJR} The Exception level that a Trapped Floating-point exception is taken to is defined as follows:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

R_{TRWMV} If an implementation includes synchronous exception generation for floating-point exceptions in AArch64 state, when the execution of separate operations in separate SIMD or SVE elements causes multiple floating-point exceptions, the ESR_ELx reports only the exceptions associated with one element that the instruction uses. The architecture does not specify which element is reported.

R_{VJNYH} When a floating-point exception is trapped, all of the following apply:

- When the trapped floating-point exception is taken, it is IMPLEMENTATION DEFINED whether the FPSR is restored to the value of the FPSR immediately before the instruction that generated the trapped floating-point exception.When the trapped floating-point exception is taken, if the FPSR is not restored, it is CONSTRAINED UNPREDICTABLE which untrapped floating-point exceptions, if any, are indicated by the corresponding FPSR cumulative floating-point exception bits having the value 1.
- In ESR_ELx at the target Exception level, all of the following apply:
  - The highest priority trapped floating-point exception has a floating-point exception trapped bit set to 1.
  - If any other untrapped floating-point exceptions are generated by the same operation, each untrapped exception has a floating-point exception trapped bit set to 0. This applies to both higher priority and lower priority untrapped floating-point exceptions.
  - If any lower priority trapped floating-point exceptions are generated by the same operation, for each exception, it is CONSTRAINED UNPREDICTABLE whether the floating-point exception trapped bit is set to 1.

R_{FTPRW} For trapped floating-point exceptions from Advanced SIMD or SVE instructions, the architecture does not define the floating-point exception prioritization between different elements of the instruction.

D1.4.5.8 Memory Copy and Memory Set exceptions

I_{TPJXM} If an exception is taken during the execution of Memory Copy and Memory Set instructions, and execution of these instructions restarts on a physical hardware PE implementation that is different from where the exception was taken from, then a Memory Copy or Memory Set exception can be generated.

R_{JQZHK} For CPYE*, CPYFE*, CPYFM*, and CPYM* instructions, if the instruction algorithm option indicated by the value of PSTATE.C is different from the PSTATE.C value of the implementation, then a Memory Copy exception is generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{XQQXB} For SETE*, SETGE*, SETGM*, and SETM* instructions, if the instruction algorithm option indicated by the value of PSTATE.C is different from the PSTATE.C value of the implementation, then a Memory Set exception is generated.

R_{PHLLT} For CPYE*, CPYFE*, CPYFM*, and CPYM* instructions, if the instruction alignment and size requirements of the implementation that an exception is taken from are different from the alignment and size requirements of the implementation that is returned to, then a Memory Copy exception is generated.

R_{BKCPW} For SETE*, SETGE*, SETGM*, and SETM* instructions, if the instruction alignment and size requirements of the implementation that an exception is taken from are different from the alignment and size requirements of the implementation that is returned to, then a Memory Set exception is generated.

I_{QJFTK} The Memory Copy and Memory Set exceptions that are caused by alignment and size requirement differences can be avoided if the following apply:

- The CPYFP*, CPYP*, SETGP*, or SETP* instruction is executed before the appropriate CPYFM*, CPYM*, SETGM*, or SETM* on the same implementation.
- The CPYFM*, CPYM*, SETGM*, or SETM* instruction is executed before the appropriate CPYFE*, CPYE*, SETGE*, or SETE* on the same implementation.

I_{LNTYW} The generic return routine for Memory Copy and Memory Set exceptions is to adjust the register arguments to be consistent with performing a new memory copy or memory set, and then to return to the CPYFP*, CPYP*, SETGP*, or SETP* instruction to restart the memory copy or memory set.

I_{TTVQX} The generic return routine for Memory Copy and Memory Set exceptions can be used by relying on the Memory Copy and Memory Set instructions being placed consecutively in memory - prologue, then main, and then epilogue.

I_{CNTMJ} The generic return routine for Memory Copy exceptions is shown in the following pseudocode:

```
if FormatOption == 0b00 || FormatOption == 0b11 then
   //format is from option B
   if SPSR_ELx.N=='1' then
      //backward copy
      DestReg = DestReg - SizeReg;
      SrcReg = SrcReg - SizeReg;
else // format is from option A;
   if SizeReg<63>=='1' then
      // forward copy
      DestReg = DestReg + SizeReg;
      SrcReg = SrcReg + SizeReg;
      SizeReg = -1*SizeReg;
if FromEpilogue then
      ReturnAddress = ELR_ELx - 8;
else
      ReturnAddress = ELR_ELx - 4;
```

I_{MWFQH} The generic return routine for Memory Set exceptions is shown in the following pseudocode:

```
if FormatOption == 0b01 || FormatOption == 0b10 then
   // format is from Option A
   // forward set
   DestReg = DestReg + SizeReg;
   SizeReg = -1*SizeReg;
if FromEpilogue then
   ReturnAddress = ELR_ELx - 8;
else
   ReturnAddress = ELR_ELx - 4;
```

I_{PRXVQ} The information in SPSR_ELx.C (or, equivalently, the ESR_ELx.ISS.FormatOption field), SPSR_ELx.N, and the sign of the value in the Xn register is sufficient to determine the current format of the Xd, Xs, and Xn registers, and perform any required reformatting, before restarting the memory copy or memory set. However, it is not required to use FEAT_MOPS instructions and the memory copy or memory set could alternatively be restarted using a software implementation.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{ZHRJP} The Exception levels that Memory Copy and Memory Set exceptions are taken to are as follows:

- From EL0, to EL1 if HCR_EL2.TGE is 0. Otherwise, they are taken to EL2.
- From EL1, to either EL1 or EL2, depending on the value of HCRX_EL2.MCE2.
- From EL2 or EL3, to the same Exception level.

I_{NXHPS} The HCRX_EL2.MCE2 control bit allows Memory Copy and Memory Set exceptions to be handled in a system where Memory Copy and Memory Set instructions might be used at EL1 at times when taking an exception to EL1 is not acceptable. This is necessary only if there is a possibility of the migration of EL1 code between different physical hardware PE implementations when EL1 is not tolerant of taking an exception.

I_{ZWLQV} Arm expects that software running at EL1 will only enable EL0 use of the Memory Copy and Memory Set instructions with SCTLR_EL1.MSCEn if it implements the generic return routine for Memory Copy and Memory Set exceptions.

D1.4.6 Asynchronous exception types

R_{ZNTKG} The Arm architecture Exception model distinguishes the following classes of asynchronous exceptions:

- Physical Interrupts
- Virtual Interrupts
- PMU exceptions, see Exception-based event profiling.

There are the following types of physical interrupt:

- SError (also described as a System Error)
- IRQ
- FIQ

There are the following types of virtual interrupt:

- vSError (also described as a Virtual System Error)
- Delegated SError
- vIRQ
- vFIQ

R_{SLLMN} IRQ, FIQ, vIRQ, and vFIQ interrupts are precise asynchronous exceptions.

R_{GGWMZ} If FEAT_NMI is implemented, then IRQ, FIQ, vIRQ, and vFIQ interrupts can have Superpriority as an additional attribute.

I_{PYQBL} When SCTLR_ELx.NMI is 0, the attribute of Superpriority has no effect on interrupts taken to ELx.
See also:

- Physical interrupt masking.
- Virtual asynchronous exception masking.

R_{PBKNX} The mechanism by which Superpriority is assigned is IMPLEMENTATION DEFINED.

R_{DXHJZ} Each physical interrupt type can be assigned a target Exception level of EL1, EL2, or EL3.

I_{VMWYT} ISR_EL1 shows the pending status of the physical interrupts, the physical SError exception, the virtual interrupts, and the virtual and delegated SError exceptions, as follows:

- When read from EL1:
  - The pending status of whichever virtual interrupts are enabled, and of the virtual SError exception if enabled. If the virtual SError exception is not enabled and the delegated SError exception is enabled, the pending status of the delegated SError exception.
- When read from EL2:
  - The pending status of the delegated SError exception, if the delegated SError exception is enabled.

Otherwise, when read from EL1, EL2, or EL3, the pending status of the physical interrupts, and of the physical SError exception.

I_{RWYFW} An implementation might support other mechanisms for signaling a virtual interrupt.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{WRGNC} The following Profiling exceptions can also be asynchronous exceptions:

- PMU Profiling exceptions. See Exception-based event profiling.
- TRBE Profiling exceptions. See Trace buffer management.
- SPE Profiling exceptions. See Profiling Buffer management.

I_{XHCGZ} The mechanism by which physical interrupts are signaled to the PE are IMPLEMENTATION DEFINED and might be either edge-triggered or level-sensitive. A common implementation choice is that the IRQ and FIQ interrupts are level-sensitive, and this is supported by the Generic Interrupt Controller (GIC).

I_{YSKZH} The physical SError exception is often used, amongst other things, for communicating External aborts from the memory system that are to be taken asynchronously. For more information, see PE error handling.

R_{KTWMT} For an External abort generated by the memory system that is taken asynchronously using the SError exception, the SError exception always behaves as an edge-triggered interrupt. For any other sources of SError exceptions, it is IMPLEMENTATION DEFINED whether they are edge-triggered or level-sensitive.

R_{HSFRC} When taking the SError exception to an Exception level using AArch64, ESR_ELx at the target Exception level is updated to describe the SError exception.

If FEAT_RAS is implemented, then:

- When taking a vSError exception to an Exception level using AArch64, ESR_ELx at the target Exception level is updated with exception syndrome information from VSESR_EL2.
- If FEAT_E3DSE is implemented, then when taking a delegated SError exception, ESR_ELx at the target Exception level is updated with exception syndrome information from VSESR_EL3.

R_{RKDNV} When taking an IRQ, vIRQ, FIQ or vFIQ interrupt to an Exception level using AArch64, ESR_ELx at the target Exception level is not updated.

D1.4.6.1 Virtual asynchronous exceptions

R_{MLLVN} Each virtual interrupt type can be independently enabled from EL2. If a virtual interrupt type is enabled from EL2, the target Exception level for the corresponding physical interrupt is not EL1.

R_{RTLGR} Pending vIRQ and vFIQ interrupts can be assigned Superpriority by using controls in HCRX_EL2.

R_{BCXJB} If HCR_EL2.TGE is 0, then setting an HCR_EL2.{FMO, IMO} routing control bit to 1 enables the corresponding virtual interrupt.

If HCR_EL2.TGE is 1, then virtual interrupts are disabled.

R_{CDCKC} If HCR_EL2.TGE is 0, then setting the Effective value of either the HCR_EL2.AMO or HCRX_EL2.TMEA routing control bit to 1 enables the virtual SError exception.

If HCR_EL2.TGE is 1, then virtual SError exceptions are disabled.

R_{NVFXB} If a virtual asynchronous exception type is enabled, that type of interrupt can be generated by any one of the following:

- Execution at EL0 or EL1 if the corresponding virtual interrupt pending bit, HCR_EL2.{VSE, VI, VF}, is 1.
- For a vIRQ or a vFIQ, by an IMPLEMENTATION DEFINED mechanism. This might be a signal from an interrupt controller.

R_{SDVLM} If a virtual interrupt is disabled, the virtual interrupt cannot be taken.

I_{NJPHG} The following table describes the bits that enable virtual interrupts, the bits that cause virtual asynchronous exceptions to be pending in HCR_EL2, and the bits that enable signaling of pending virtual interrupts with Superpriority in HCRX_EL2:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Virtual asynchronous exception type	Enable control	Cause a virtual asynchronous exception to be pending	Pending virtual interrupt has Superpriority
vSError	HCR_EL2.AMO or HCRX_EL2.TMEA	HCR_EL2.VSE	n/a
vIRQ	HCR_EL2.IMO	HCR_EL2.VI	HCRX_EL2.VINMI
vFIQ	HCR_EL2.FMO	HCR_EL2.VF	HCRX_EL2.VFNMI

R_{MZWNH} When taking a vIRQ or a vFIQ interrupt, the corresponding virtual interrupt pending bit in HCR_EL2 retains its state.

I_{QVCWH} If the virtual interrupt pending bits are used, the vIRQ or vFIQ exception handler must cause software executing at EL2 or EL3 to set their corresponding virtual interrupt pending bits to 0.

I_{YPRNB} When taking a vSError exception, HCR_EL2.VSE is cleared to 0.

I_{LFSXS} A virtual SError is never taken to EL2 or EL3, regardless of the values of HCRX_EL2.TMEA and SCR_EL3.TMEA.

D1.4.6.2 Delegated SErrors

I_{NVRSW} If FEAT_E3DSE is implemented, *delegated SError exceptions* are defined by SCR_EL3.EnDSE, SCR_EL3.DSE, VSESR_EL3, and VDISR_EL3.

R_{TNWJT} If the Effective value of SCR_EL3.{EA, TMEA} is not {0, 0}, then setting the Effective value of the SCR_EL3.EnDSE control bit to 1 enables the delegated SError exception.
If the Effective value of SCR_EL3.{EA, TMEA} is {0, 0}, or the Effective value of SCR_EL3.EnDSE is 0, then delegated SError exceptions are disabled.

R_{WLQXL} If delegated SError exceptions are enabled, then setting SCR_EL3.DSE to 1 pends a delegated SError exception while executing at EL0, EL1, or EL2 .

R_{RWMSM} If the delegated SError exception is disabled, the delegated SError exception cannot be taken.

I_{QKSJR} When taking a delegated SError exception, SCR_EL3.DSE is cleared to 0.

I_{LVWLF} A delegated SError is never taken to EL3, regardless of the value of SCR_EL3.TMEA.

D1.4.6.3 Establishing the target Exception level of an asynchronous exception

R_{QZPXL} The R_{NMMXK} table uses the following terms:

Term	Meaning
SCR_EL3	The Effective value of a field in SCR_EL3.
NS	If FEAT_RME is implemented, then if Secure state is not implemented, the Effective value of SCR_EL3.NS is 1.
EEL2	If EL3 is not implemented, the Effective value of SCR_EL3.EEL2 is 1.
IRQ FIQ	If EL3 is not implemented, the Effective value of these fields is 0.
RW	If EL3 is not implemented, the Effective value of SCR_EL3.RW is 1.
HCR	If EL2 is using AArch32, this is the Effective value of a field in HCR. If EL2 is using AArch64, this is the Effective value of a field in HCR_EL2.
TGE	If EL2 is not implemented, the Effective value of HCR.TGE or HCR_EL2.TGE is 0.
IMO FMO	If EL2 is not implemented, the Effective value of these fields is 0.
E2H	If EL2 is not implemented, the Effective value of HCR.E2H or HCR_EL2.E2H is 0.
RW	If EL2 is not implemented, the Effective value of HCR_EL2.RW is the same as the Effective value of SCR_EL3.RW.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Term	Meaning
EL1	The exception is taken to EL1 using AArch64.
EL2	The exception is taken to EL2 using AArch64.
EL3	The exception is taken to EL3 using AArch64.
C	The interrupt is not taken and remains pending, regardless of the PSTATE.{I, F, ALLINT} interrupt masks.
IRQ, FIQ	The exception is taken to the AArch32 IRQ mode or the AArch32 FIQ mode accordingly.
Hyp	The exception is taken to AArch32 Hyp mode.
n/a	Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

R_{NMMXK} The following table describes the routing of physical FIQ and IRQ interrupts if the highest implemented Exception level is using AArch64 and either EDSCR.INTdis is `0b00` or invasive debug is disabled.

Table D1-13 FIQ and IRQ interrupt exception targets

SCR_EL3				HCR				Target when taken from			
NS	EEL2	IRQ FIQ	RW	TGE	IMO FMO	E2H	RW	EL0	EL1	EL2	EL3
0	0	0	0	x	x	x	x	IRQ, FIQ	IRQ, FIQ	n/a	C
0	0	0	1	x	x	x	x	EL1	EL1	n/a	C
0	0	1	x	x	x	x	x	EL3	EL3	n/a	EL3
0	1	0	x	0	0	0	0	IRQ, FIQ	IRQ, FIQ	C	C
0	1	0	x	0	0	0	1	EL1	EL1	C	C
0	1	0	x	0	0	1	x	EL1	EL1	C	C
0	1	0	x	0	1	x	x	EL2	EL2	EL2	C
0	1	0	x	1	x	x	x	EL2	n/a	EL2	C
0	1	1	x	0	x	x	x	EL3	EL3	EL3	EL3
0	1	1	x	1	x	x	x	EL3	n/a	EL3	EL3

R_{ZZYHK} The R_{MGNFZ} and R_{VRBFW} tables use the following terms:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Term	Meaning
SCR_EL3	The Effective value of a field in SCR_EL3.
EA	If EL3 is not implemented, the Effective value of SCR_EL3.EA is 0.
TMEA	If FEAT_DoubleFault2 is not implemented, the Effective value of SCR_EL3.TMEA is 0.
NMEA	If FEAT_DoubleFault is not implemented, the Effective value of SCR_EL3.NMEA is 0.
HCR_EL2	The Effective value of a field in HCR_EL2.
HCR	The Effective value of a field in HCR.
TGE	If EL2 is not implemented, or if EL2 is disabled in the current Security state, then the Effective value of HCR_EL2.TGE or HCR.TGE is 0.
E2H	If EL2 is not implemented, or if EL2 is disabled in the current Security state, the Effective value of HCR_EL2.E2H is 0.
AMO	If EL2 is not implemented, or if EL2 is disabled in the current Security state, the Effective value of HCR_EL2.AMO or HCR.AMO is 0.
SCTLR2_EL2	The Effective value of a field in SCTLR2_EL2.
NMEA	If FEAT_DoubleFault2 is not implemented, the Effective value of SCTLR2_EL2.NMEA is 0. If EL2 is not implemented or EL2 is disabled in the current Security state, or if the Effective value of SCR_EL3.SCTLR2En is 0, then the Effective value of SCTLR2_EL2.NMEA is 0.
HCRX_EL2	The Effective value of a field in HCRX_EL2.
TMEA	If FEAT_DoubleFault2 is not implemented, the Effective value of HCRX_EL2.TMEA is 0. If EL2 is not implemented or EL2 is disabled in the current Security state, or the Effective value of SCR_EL3.HXEn is 0, then the Effective value of HCRX_EL2.TMEA is 0.
SCTLR2_EL1	The Effective value of a field in SCTLR2_EL1.
NMEA	If FEAT_DoubleFault2 is not implemented, the Effective value of SCTLR2_EL1.NMEA is 0. If the Effective value of HCRX_EL2.SCTLR2En is 0 or the Effective value of SCR_EL3.SCTLR2En is 0, then the Effective value of SCTLR2_EL1.NMEA is 0.
PSTATE	The value of a field in PSTATE.
A	The value of PSTATE.A.
EL1	The exception is taken to EL1. If EL1 is using AArch32, then the exception is taken to Abort mode.
EL2	The exception is taken to EL2 using AArch64.
EL3	The exception is taken to EL3 using AArch64.
C	The interrupt is not taken and remains pending, regardless of the PSTATE.A mask.
Abt	The exception is taken to the AArch32 Abort mode.
Hyp	The exception is taken to AArch32 Hyp mode.
n/a	Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

R_{MGNFZ} The following tables describe the routing of SError exceptions taken from ELx.

All of the following apply to these tables:

- SCR_EL3.{NS, EEL2} are not shown because R_{ZZYHK} describes Effective values involving Security states.
- Either EDSCR.INTdis is `0b00` or invasive debug is disabled.

D1.4.6.3.1 Establishing the target Exception level of a delegated SError exception

R_{VRBFW} The following table describes the routing of delegated SError exceptions taken from ELx. See R_{ZZYHK} for the terms used.

All of the following apply to this table:

- SCR_EL3.{NS, EEL2} are not shown because R_{ZZYHK} describes Effective values involving Security states.
- Either EDSCR.INTdis is `0b00` or invasive debug is disabled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D1-17 Delegated SError exception target when EL2 is using AArch64, in an implementation that includes FEAT_E3DSE

HCR_EL2		HCRX_EL2	PSTATE	Taken from		
TGE	AMO	TMEA	A	EL0	EL1	EL2
0b0	0b0	0b0	X	EL1	EL1	C
0b0	0b0	0b1	0b0	EL1	EL1	C
0b0	0b0	0b1	0b1	EL2	EL2	C
0b0	0b1	X	X	EL2	EL2	EL2
0b1	X	X	X	EL2	n/a	EL2

D1.4.6.4 Asynchronous exception masking

R_{HDMYQ} An interrupt can be masked. A masked interrupt is not taken and remains pending.

R_{PVHHQ} Whether an interrupt is masked is determined by all of the following:

- The PSTATE.{A, I, F, ALLINT, SP} bits.
- The value of AllIntMask, as described in R_{XZPDT}.
- Whether an IRQ or FIQ interrupt has Superpriority.
- The implemented Exception levels.
- The configuration of the Hypervisor Configuration Registers.
- For an SError, whether the exception is non-maskable.
- The configuration of the Secure Configuration Register.

R_{LMWZH} If in AArch64 state and the target Exception level of an interrupt is lower than the current Exception level, the interrupt is masked.

R_{XZPDT} If FEAT_NMI is implemented and SCTLR_ELx.NMI is 1, all of the following apply:

- The AllIntMask variable is created and is defined as follows:
  `AllIntMask == PSTATE.ALLINT || (PSTATE.SP && SCTLR_ELx.SPINTMASK)`
- When AllIntMask is 1 and execution is at ELx, an IRQ or FIQ interrupt that is targeted to ELx is masked regardless of Superpriority.
- When AllIntMask is 0 and execution is at ELx:
  - An IRQ or FIQ interrupt with Superpriority that is targeted to ELx is not masked by PSTATE.I or PSTATE.F, respectively.
  - An IRQ or FIQ interrupt without Superpriority that is targeted to ELx is masked by PSTATE.I or PSTATE.F, respectively, in the same way as when the Effective value of SCTLR_ELx.NMI is 0.

I_{BXXWT} AllIntMask does not affect the masking or routing of interrupts to a higher Exception level.

R_{SFMGZ} If FEAT_NMI is not implemented or SCTLR_ELx.NMI is 0, the Effective value of AllIntMask is 0.

D1.4.6.4.1 Physical interrupt masking

R_{MHWBP} If the target Exception level of a physical IRQ interrupt is the current Exception level, ELx, the following controls determine whether the interrupt is masked:

PSTATE.I	SCTLR_ELx.NMI	AllIntMask	IRQ	IRQ with Superpriority
0	0	x	Not masked	Not masked
0	1	0	Not masked	Not masked
0	1	1	Masked	Masked

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PSTATE.I	SCTLR_ELx.NMI	AllIntMask	IRQ	IRQ with Superpriority
1	0	x	Masked	Masked
1	1	0	Masked	Not masked
1	1	1	Masked	Masked

R_{GFXKY} If the target Exception level of a physical FIQ interrupt is the current Exception level, ELx, the following controls determine whether the interrupt is masked:

PSTATE.F	SCTLR_ELx.NMI	AllIntMask	FIQ	FIQ with Superpriority
0	0	x	Not masked	Not masked
0	1	0	Not masked	Not masked
0	1	1	Masked	Masked
1	0	x	Masked	Masked
1	1	0	Masked	Not masked
1	1	1	Masked	Masked

PSTATE.F	FIQ
0	Not masked
1	Masked

R_{GCTZC} If the target Exception level of a physical SError is the current Exception level, the PSTATE.A control determines whether the interrupt is masked.

However, if the target Exception level is the current Exception level, and if any of the following are true, the PSTATE.A control is ignored, and the exception is taken:

- The target Exception level is EL3, FEAT_DoubleFault is implemented and the Effective value of SCR_EL3.NMEA is 1.
- The target Exception level is EL2, FEAT_DoubleFault2 is implemented and the Effective value of SCTLR2_EL2.NMEA is 1.
- The target Exception level is EL1, FEAT_DoubleFault2 is implemented and the Effective value of SCTLR2_EL1.NMEA is 1.

R_{XBYXL} If the target Exception level of a physical interrupt is higher than the current Exception level, all of the following apply:

- If the target Exception level is EL3, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
- If the target Exception level is EL2 and any of the following are true, the interrupt cannot be masked by the PSTATE.{A, I, F} bits.
  - The Effective value of HCR_EL2.E2H is 0.
  - The Effective value of HCR_EL2.TGE is 0.
- If the target Exception level is EL2 and all of the following are true, the interrupt can be masked by the PSTATE.{A, I, F} bits:
  - The Effective value of HCR_EL2.E2H is 1.
  - The Effective value of HCR_EL2.TGE is 1.
  - The interrupt does not have Superpriority or SCTLR_EL2.NMI is 0.
- If the target Exception level is EL1 and the interrupt does not have Superpriority or SCTLR_EL1.NMI is 0, the interrupt can be masked by the PSTATE.{A, I, F} bits.

I_{KDYCN} The ability to execute in EL0 with interrupts taken to EL1 masked is required by some user level driver code.

Non-Confidential

R_{HPRNX} The R_{SXLWJ} table uses the following terms:

Term	Meaning
SCR_EL3	The Effective value of a field in SCR_EL3.
NS	If FEAT_RME is implemented, then if Secure state is not implemented, the Effective value of SCR_EL3.NS is 1.
EEL2	If EL3 is not implemented, the Effective value of SCR_EL3.EEL2 is 1. If FEAT_SEL2 is not implemented, the Effective value of SCR_EL3.EEL2 is 0.
IRQ FIQ	If EL3 is not implemented, then the Effective value of these fields is 0.
RW	If EL3 is not implemented, the Effective value of SCR_EL3.RW is 1.
HCR	If EL2 is using AArch32, this is the Effective value of a field in HCR. If EL2 is using AArch64, this is the Effective value of a field in HCR_EL2.
TGE	If EL2 is not implemented, the Effective value of HCR.TGE or HCR_EL2.TGE is 0.
E2H	If EL2 is not implemented, the Effective value of HCR.E2H or HCR_EL2.E2H is 0.
IMO FMO	If EL2 is not implemented, the Effective value of these fields is 0.
A	When the interrupt is pending, it is taken regardless of the value of the PSTATE.{A, I, F, ALLINT} interrupt masks.
B	When the interrupt is pending, it might be subject to masking, as defined in R_{MHWBP} or R_{GFXKY}. If the interrupt is masked, it is not taken. If the interrupt is not masked, it is taken.
C	When the interrupt is pending, it is not taken, regardless of the value of the PSTATE.{A, I, F, ALLINT} interrupt masks.
n/a	Not applicable. The PE cannot be executing at this Exception level for the specified state of HCR and SCR_EL3.

R_{SXLWJ} The following table describes the target and masking of physical FIQ and IRQ interrupts, if the highest implemented Exception level is using AArch64.

Table D1-22 FIQ and IRQ interrupt exception targets and masking

SCR_EL3				HCR			Effect of the interrupt mask when executing at:			
NS	EEL2	IRQ FIQ	RW	TGE	E2H	IMO FMO	EL0	EL1	EL2	EL3
0	0	0	x	x	x	x	B	B	n/a	C
0	0	1	x	x	x	x	A	A	n/a	B

SCR_EL3				HCR			Effect of the interrupt mask when executing at:			
NS	EEL2	IRQ FIQ	RW	TGE	E2H	IMO FMO	EL0	EL1	EL2	EL3
1	x	0	1	1	0	x	A	n/a	B	C
1	x	0	1	1	1	x	B	n/a	B	C
1	x	1	x	0	x	x	A	A	A	B
1	x	1	x	1	x	x	A	n/a	A	B

R_{ZSRWR} The R_{JFKMF} tables use the following terms:

Term	Meaning
SCR_EL3	The Effective value of a field in SCR_EL3.
EA	If EL3 is not implemented, the Effective value of SCR_EL3.EA is 0.
TMEA	If FEAT_DoubleFault2 is not implemented, the Effective value of SCR_EL3.TMEA is 0.
NMEA	If FEAT_DoubleFault is not implemented, the Effective value of SCR_EL3.NMEA is 0.
HCR_EL2	The Effective value of a field in HCR_EL2.
HCR	The Effective value of a field in HCR.
TGE	If EL2 is not implemented or EL2 is disabled in the current Security state, then the Effective value of HCR_EL2.TGE or HCR.TGE is 0.
E2H	If EL2 is not implemented or EL2 is disabled in the current Security state, then the Effective value of HCR_EL2.E2H is 0.
AMO	If EL2 is not implemented or EL2 is disabled in the current Security state, then the Effective value of HCR_EL2.AMO or HCR.AMO is 0.
SCTLR2_EL2	The Effective value of a field in SCTLR2_EL2.
NMEA	If FEAT_DoubleFault2 is not implemented, the Effective value of SCTLR2_EL2.NMEA is 0. If EL2 is not implemented or EL2 is disabled in the current Security state, or if the Effective value of SCR_EL3.SCTLR2En is 0, then the Effective value of SCTLR2_EL2.NMEA is 0.
HCRX_EL2	The Effective value of a field in HCRX_EL2.
TMEA	If FEAT_DoubleFault2 is not implemented, the Effective value of HCRX_EL2.TMEA is 0. If EL2 is not implemented or EL2 is disabled in the current Security state, or the Effective value of SCR_EL3.HXEn is 0, then the Effective value of HCRX_EL2.TMEA is 0.
SCTLR2_EL1	The Effective value of a field in SCTLR2_EL1.
NMEA	If FEAT_DoubleFault2 is not implemented, the Effective value of SCTLR2_EL1.NMEA is 0. If the Effective value of HCRX_EL2.SCTLR2En is 0 or the Effective value of SCR_EL3.SCTLR2En is 0, then the Effective value of SCTLR2_EL1.NMEA is 0.
A	When the exception is pending, it is taken regardless of the value of the PSTATE.A mask.
B	When the exception is pending, it might be subject to masking, as defined in R_{GCTZC}. If the interrupt is masked, it is not taken. If the interrupt is not masked, it is taken.
C	The exception is not taken and remains pending, regardless of the PSTATE.A mask.
n/a	Not applicable. The field does not exist in the register in this configuration or the Exception level is not accessible in this configuration.

R_{JFKMF} The following tables describe the masking of SError exceptions.

All of the following apply to these tables:

- SCR_EL3.{NS, EEL2} are not shown because R_{ZSRWR} describes Effective values involving Security states.
- Either EDSCR.INTdis is `0b00` or invasive debug is disabled.

Table D1-25 SError exception masking when EL2 is using AArch32

SCR_EL3		HCR		Effect of the interrupt mask when executing at		
EA	TMEA	TGE	AMO	EL0	EL1	EL2
0b0	0b0	0b0	0b0	B	B	B
0b0	0b0	0b0	0b1	A	A	B
0b0	0b0	0b1	X	A	n/a	B
0b0	0b1	0b0	X	A	A	A
0b0	0b1	0b1	X	A	n/a	A
0b1	X	0b0	X	A	A	A
0b1	X	0b1	X	A	n/a	A

D1.4.6.4.2 Virtual asynchronous exception masking

R_{SNLJH} The following controls determine whether a virtual IRQ interrupt is masked:

PSTATE.I	SCTLR_EL1.NMI	PSTATE.EL	AllIntMask	vIRQ	vIRQ with Superpriority
0	0	xx	x	Not Masked	Not Masked
0	1	EL0	x	Not Masked	Not Masked
0	1	EL1	0	Not Masked	Not Masked
0	1	EL1	1	Masked	Masked
1	0	xx	x	Masked	Masked
1	1	EL0	x	Masked	Not Masked
1	1	EL1	0	Masked	Not Masked
1	1	EL1	1	Masked	Masked

R_{XSPSG} The following controls determine whether a virtual FIQ interrupt is masked:

PSTATE.F	SCTLR_EL1.NMI	PSTATE.EL	AllIntMask	vFIQ	vFIQ with Superpriority
0	0	xx	x	Not Masked	Not Masked
0	1	EL0	x	Not Masked	Not Masked
0	1	EL1	0	Not Masked	Not Masked
0	1	EL1	1	Masked	Masked
1	0	xx	x	Masked	Masked
1	1	EL0	x	Masked	Not Masked
1	1	EL1	0	Masked	Not Masked
1	1	EL1	1	Masked	Masked

R_{GYGBD} Virtual asynchronous exceptions can only be taken from EL0 or EL1 and can only be taken to EL1. If EL2 is not enabled in the current Security state, all types of virtual asynchronous exceptions are always masked. If executing at EL2 or EL3, all types of virtual asynchronous exceptions are always masked.

R_{MMYBS} The following controls determine whether a virtual SError interrupt is masked:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PSTATE.A	PSTATE.EL	vSError
0	xx	Not Masked
1	xx	Masked

I_{BNCCH} The ability to execute at EL0 with virtual interrupts taken to EL1 masked is required by some user level driver code.

R_{WVZVM} The R_{BKHXL} table uses the following terms:

Term	Meaning
SCR_EL3	The Effective value of a field in SCR_EL3.
EEL2	If EL3 is not implemented, the Effective value of SCR_EL3.EEL2 is 1.
NS	If FEAT_RME is implemented, then if Secure state is not implemented, the Effective value of SCR_EL3.NS is 1.
EA IRQ FIQ	If EL3 is not implemented, the Effective value of these fields is 0.
HCR	If EL2 is using AArch32, this is the Effective value of a field in HCR. If EL2 is using AArch64, this is the Effective value of a field in HCR_EL2.
E2H	If EL2 is using AArch32, the Effective value of HCR.E2H is 0.
TGE	If EL2 is not implemented, the Effective value of HCR.TGE or HCR_EL2.TGE is 0.
AMO IMO FMO	If EL2 is not implemented, the Effective value of these fields is 0.
B	When the interrupt is pending, it might be subject to masking, as defined in R_{SNLJH}, R_{XSPSG}, and R_{MMYBS}. If the interrupt is masked, it is not taken. If the interrupt is not masked, it is taken.
C	When the interrupt is pending, it is not taken, regardless of the value of the PSTATE.{A, I, F, ALLINT, SP, PM} interrupt masks.
n/a	Not applicable. The PE cannot be executing at this Exception level for the specified state of HCR and SCR_EL3.

R_{BKHXL} The following table describes the masking of virtual interrupts when the highest implemented Exception level is using AArch64:

SCR_EL3			HCR			Effect of the interrupt mask when executing at:			
EEL2	NS	EA IRQ FIQ	E2H	TGE	AMO IMO FMO	EL0	EL1	EL2	EL3
0	0	x	x	x	x	C	C	n/a	C
1	0	x	x	0	0	C	C	C	C
1	0	x	x	0	1	B	B	C	C
1	0	x	x	1	x	C	n/a	C	C
x	1	x	x	0	0	C	C	C	C
x	1	x	x	0	1	B	B	C	C
x	1	x	x	1	x	C	n/a	C	C

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.4.6.4.3 Delegated SError exception masking

R_{ZZXBJ} The R_{LPCYB} table uses the following terms:

Term	Meaning
HCR_EL2	The Effective value of a field in HCR_EL2.
TGE	If EL2 is not implemented, or EL2 is disabled in the current Security state, then the Effective value of HCR_EL2.TGE is 0.
E2H	If FEAT_VHE is implemented and FEAT_E2H0 is not implemented, then the effective value of HCR_EL2.E2H is 1. Otherwise, if FEAT_VHE is not implemented, or EL2 is not implemented, or EL2 is disabled in the current Security state, then the Effective value of HCR_EL2.E2H is 0.
AMO	If EL2 is not implemented, or EL2 is disabled in the current Security state, then the Effective value of HCR_EL2.AMO is 0.
HCRX_EL2	The Effective value of a field in HCRX_EL2.
TMEA	If FEAT_DoubleFault2 is not implemented, EL2 is not implemented, EL2 is disabled in the current Security state, or the Effective value of SCR_EL3.HXEn is 0, then the Effective value of HCRX_EL2.TMEA is 0.
A	When the exception is pending, it is taken regardless of the value of the PSTATE.A mask. However, the target Exception level of the exception might depend on the value of PSTATE.A. See R_{VRBFW}.
B	When the exception is pending, it might be subject to masking. If PSTATE.A is 1, then the exception is masked and is not taken. If PSTATE.A is 0, then the exception is not masked and is taken.
C	The error exception is not taken and remains pending, regardless of the value of the PSTATE.A mask.
n/a	Not applicable. The Exception level is not present in this configuration.

R_{LPCYB} The following table describes the masking of delegated SError exceptions.
All of the following apply to this table:

- SCR_EL3.{NS, EEL2} are not shown because R_{ZZXBJ} describes Effective values involving Security states.
- Either EDSCR.INTdis is `0b00` or invasive debug is disabled.

Table D1-32 Delegated SError exception masking in an implementation that includes FEAT_E3DSE

HCR_EL2			HCRX_EL2	Effect of the interrupt mask when executing at:		
TGE	E2H	AMO	TMEA	EL0	EL1	EL2
0b0	X	0b0	0b0	B	B	C
0b0	X	0b0	0b1	A	A	C
0b0	X	0b1	X	A	A	B
0b1	0b0	X	X	A	n/a	B
0b1	0b1	X	X	B	n/a	B

D1.4.6.5 Prioritization of asynchronous exceptions

R_{BKHSW} The virtual SError exception injected using HCR_EL2.VSE has priority over the delegated SError exception injected using SCR_EL3.DSE. Otherwise, the prioritization of physical asynchronous exceptions and virtual asynchronous exceptions is IMPLEMENTATION DEFINED.

R_{RBZYL} For all of the following Context synchronization events, if an asynchronous exception is pending before the Context synchronization event, and the asynchronous exception remains pending and is not masked after the Context synchronization event, then the asynchronous exception is taken before the first instruction after the Context synchronization event:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Execution of an ISB instruction.
- If FEAT_ExS is not implemented, exception entry.
- If FEAT_ExS is implemented and the appropriate SCTLR_ELx.EIS bit is 1, exception entry.
- If FEAT_ExS is not implemented, exception return.
- If FEAT_ExS is implemented and the appropriate SCTLR_ELx.EOS bit is 1, exception exit.
- Exit from Debug state.

If the first instruction after the Context synchronization event generates a synchronous exception, the architecture does not define whether the PE takes the asynchronous exception or the synchronous exception first.

I_{RDBWJ} A RAS error synchronization event defines additional requirements for taking an SError exception. See Error synchronization event.

R_{QVRHH} Other than the behaviors described in R_{RBZYL}, an unmasked, pending asynchronous exception must be taken in finite time.

R_{ZQPLL} If an unmasked asynchronous exception was pending but is changed to not pending before it is taken, it is CONSTRAINED UNPREDICTABLE whether or not the asynchronous exception is taken. If the asynchronous exception is taken, it is taken before the first Context synchronization event after the asynchronous exception was changed to be not pending.

D1.4.6.6 Taking an asynchronous exception during a multi-access load or store

R_{ZBFSL} If in AArch64 state, asynchronous exceptions can be taken during a sequence of memory accesses caused by a single load or store instruction. This is true regardless of the memory type being accessed.

In this situation, the behavior is consistent with the requirements described in R_{TNVSL} in Definition of a precise exception and imprecise exception.

D1.4.6.7 Taking an asynchronous exception during an SVE instruction

R_{TFLTX} Permitting SVE instructions to be interrupted by asynchronous exceptions is IMPLEMENTATION DEFINED.

R_{WFMZK} When returning from an asynchronous exception, an interrupted SVE instruction is restarted and cannot resume at the point the instruction was interrupted.

I_{QRQJP} For Data Aborts taken asynchronously, see Definition of a precise exception and imprecise exception.

D1.4.7 UNDEFINED instructions

R_{ZLJDF} An instruction which is UNDEFINED generates a synchronous exception for that instruction unless there is a higher priority exception generated for that instruction.

R_{SXYZB} The Exception level that the synchronous Undefined Instruction exception is taken to is defined as follows:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

D1.4.8 Configurable instruction controls

R_{QMWPZ} *Configurable instruction controls* are control bits held in System registers that determine whether attempting to execute an instruction generates a synchronous exception at the point in the instruction stream of that instruction, and the instruction is not executed.

I_{ZSSHJ} Configurable instruction controls might be referred to by any of the following names:

- Instruction enables.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Instruction disables.
- Trap controls.

The definitions of each type overlap, and in some cases is historical. Describing a register control field as an instruction enable, an instruction disable, or a trap control, gives no indication of how an exception that is generated as a consequence of the value of that field is handled or reported. Each configurable instruction control defines how the exception that is generated as a consequence of the configurable instruction control is handled or reported.

R_{VWWGJ} An exception can only be generated as a result of a configurable instruction control if all the following apply:

- The instruction generating the exception does not also generate a higher priority exception.
- The instruction generating the exception is not UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state in which the instruction is executed.

R_{JTXTF} It is UNPREDICTABLE / CONSTRAINED UNPREDICTABLE whether configurable instruction controls generate an exception when the instruction is UNPREDICTABLE or CONSTRAINED UNPREDICTABLE in the PE state in which the instruction is executed, with all of the following constraints:

- If the instruction description explicitly states that the configurable instruction control is applied with higher priority than the CONSTRAINED UNPREDICTABLE behavior, then the configurable instruction control generates an exception.
- The CONSTRAINED UNPREDICTABLE behaviors cannot lead to any behavior that is prohibited by the general definition of UNPREDICTABLE.

I_{BJBMF} UNPREDICTABLE and CONSTRAINED UNPREDICTABLE instructions can generate exceptions as a result of configurable instruction controls, but the architecture does not require them to do so.

Note: Many CONSTRAINED UNPREDICTABLE behaviors for instructions include an allowance that the CONSTRAINED UNPREDICTABLE instruction behaves the same way as a closely related instruction that is not CONSTRAINED UNPREDICTABLE. In those cases, the instruction enable, disable, or trap control that causes an exception on the closely related instruction will cause the same exception on the CONSTRAINED UNPREDICTABLE instruction.

I_{TFGPW} An implementation might provide more controls, in IMPLEMENTATION DEFINED registers, to provide control of trapping of IMPLEMENTATION DEFINED features.

R_{QQLHG} When a configurable instruction control causes an exception, the exception is taken and the instruction is not executed, and therefore all the following are true:

- The preferred exception return address of the exception is the instruction that generates the exception.
- There are no changes to the registers accessed by the instruction, including as a result of side-effects of a register access.

R_{SZCKN} When a configurable instruction control causes a conditional instruction to generate an exception in AArch32 state, it is IMPLEMENTATION DEFINED whether the exception applies to conditional AArch32 instructions that fail their condition code check.

D1.4.8.1 EL0 and EL1 configurable instruction controls

I_{TJPQP} The following EL0 and EL1 System registers contain configurable instruction controls:

Register name	Register description
AMUSERENR_EL0	Activity Monitors User Enable Register
CPACR_EL1	Architectural Feature Access Control Register
MDSCR_EL1	Monitor System Debug Control Register
PMUSERENR_EL0	Performance Monitors User Enable Register
SCTLR_EL1	System Control Register (EL1)
TCR_EL1	Translation Control Register (EL1)

R_{KYYYZ} An exception caused by configurable instruction controls in EL1 can be taken from either AArch64 state or AArch32 state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.4.8.2 EL2 configurable instruction controls

I_{FFLBF} The following EL2 System registers contain configurable instruction controls:

Register name	Register description
CPTR_EL2	Architectural Feature Trap Register, EL2
HAFGRTR_EL2	Hypervisor Activity Monitors Fine-Grained Read Trap Register
HCR_EL2	Hypervisor Configuration Register
HCRX_EL2	Extended Hypervisor Configuration Register
HDFGRTR_EL2	Hypervisor Debug Fine-Grained Read Trap Register
HDFGRTR2_EL2	Hypervisor Debug Fine-Grained Read Trap Register 2
HDFGWTR_EL2	Hypervisor Debug Fine-Grained Write Trap Register
HDFGWTR2_EL2	Hypervisor Debug Fine-Grained Write Trap Register 2
HFGITR_EL2	Hypervisor Fine-Grained Instruction Trap Register
HFGITR2_EL2	Hypervisor Fine-Grained Instruction Trap Register 2
HFGRTR_EL2	Hypervisor Fine-Grained Read Trap Register
HFGRTR2_EL2	Hypervisor Fine-Grained Read Trap Register 2
HFGWTR_EL2	Hypervisor Fine-Grained Write Trap Register
HFGWTR2_EL2	Hypervisor Fine-Grained Write Trap Register 2
HSTR_EL2	Hypervisor System Trap Register
MDCR_EL2	Monitor Debug Configuration Register, EL2
SCTLR_EL2	System Control Register, EL2
TCR_EL2	Translation Control Register, EL2

R_{JZJRG} An exception caused by configurable instruction controls in EL2 can be taken from either AArch64 state or AArch32 state.

R_{SNLNY} EL2 configurable instruction controls are ignored in Secure state if Secure EL2 is not implemented or not enabled.

D1.4.8.3 EL3 configurable instruction controls

R_{LTKXZ} The following EL3 System registers contain configurable instruction controls:

Register name	Register description
CPTR_EL3	Architectural Feature Trap Register, EL3
FGWTE3_EL3	Fine-Grained Write Traps EL3
MDCR_EL3	Monitor Debug Configuration Register, EL3
SCTLR_EL3	System Control Register, EL3
SCR_EL3	Secure Configuration Register
TCR_EL3	Translation Control Register, EL3

R_{NMCCJ} An exception caused by configurable instruction controls in EL3 can be taken from either AArch64 state or AArch32 state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.4.9 Exception generating instructions

IYRYNQ The exception generating instructions are commonly called system calls and refer to the instructions that generate any of the following synchronous exception types:

- Supervisor Call exception.
- Hypervisor Call exception.
- Secure Monitor Call exception.

RBRCQB A Supervisor Call is generated by executing an `SVC` instruction.

RTNSNV A Supervisor Call exception is taken to the following Exception levels:

- If executing at EL0:
  - If the Effective value of HCR_EL2.TGE is 0, the exception is taken to EL1.
  - If the Effective value of HCR_EL2.TGE is 1, the exception is taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

INCTDB A Supervisor Call enables software executing at EL0 to make a call to an operating system or other software executing at EL1.

RLLLGJ If EL2 is implemented and the `HVC` instruction is not UNDEFINED, a Hypervisor Call is generated by executing an `HVC` instruction.

RRWKMY A Hypervisor Call exception is taken to the following Exception levels:

- If EL2 is implemented and enabled in the current Security state, when taken from EL1, the exception is taken to EL2.
- When taken from EL2, the exception is taken to EL2.
- When taken from EL3, the exception is taken to EL3.

RZVTPR If any of the following is true, the `HVC` instruction is UNDEFINED:

- The PE is executing at EL0.
- If EL2 is not enabled in the current Security state, and the PE is executing at EL1.
- The Effective value of SCR_EL3.HCE is 0.
- EL2 is not implemented.

RNDGTC If EL3 is implemented and the `SMC` instruction is not UNDEFINED or trapped, a Secure Monitor Call is generated by executing an `SMC` instruction. A Secure Monitor Call is a synchronous exception that is taken to EL3.

RHMXQS If any of the following are true, the `SMC` instruction is UNDEFINED:

- The PE is executing at EL0.
- EL3 is not implemented and the `SMC` instruction is not trapped to EL2 by HCR_EL2.TSC.
- SCR_EL3.SMD is 1 and the `SMC` instruction is not trapped to EL2 by HCR_EL2.TSC.

D1.4.10 Program Counter and stack pointer alignment

D1.4.10.1 PC alignment checking

RQCCWG If bits [1:0] of the PC are not `0b00`, there is a misaligned PC.

RSJLDM The execution of an instruction with a misaligned PC generates a synchronous PC Alignment exception on that instruction.

RJKZZX A PC Alignment exception is taken to the following Exception levels:

- If executing at EL0:
  - If HCR_EL2.TGE is 0, the exception is taken to EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— If HCR_EL2.TGE is 1, the exception is taken to EL2.

- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

R_{MVTQT} When a PC Alignment Fault exception is taken to an Exception level, ELx, using AArch64, the ELR_ELx and the FAR_ELx both hold the entire PC in its misaligned form.

I_{VFXPV} A misalignment of the PC is an indication of a serious error, for example software corruption of an address.

D1.4.10.2 SP alignment checking

R_{RDMXG} When the SP is used as the base address of a calculation, regardless of any offset applied by the instruction, if bits [3:0] of the SP are not `0b0000`, there is a misaligned SP.

R_{TFVSM} If SP alignment checking is enabled, then the execution of a load or store using the SP with a misaligned SP generates a synchronous SP Alignment exception on that load or store.

R_{JQXVP} PRFM instructions that use the SP do not perform stack alignment checking.

R_{STDYJ} The following bits enable SP alignment checking at each Exception level when that Exception level is using AArch64.

- If the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, SCTLR_EL2.SA0 controls EL0. Otherwise, SCTLR_EL1.SA0 controls EL0.
- SCTLR_EL1.SA controls EL1.
- SCTLR_EL2.SA controls EL2.
- SCTLR_EL3.SA controls EL3.

R_{NCGYQ} An SP Alignment exception is taken to the following Exception levels:

- If executing at EL0:
  — If HCR_EL2.TGE is 0, the exception is taken to EL1
  — If HCR_EL2.TGE is 1, the exception it taken to EL2.
- If executing at EL1, the exception is taken to EL1.
- If executing at EL2, the exception is taken to EL2.
- If executing at EL3, the exception is taken to EL3.

R_{DLDVL} If SP alignment checking is enabled and an SVE predicated load or store instruction with any *Active elements* uses the current SP as the base address, then the SP register is checked for 16-byte alignment.

R_{FNCJX} If SP alignment checking is enabled and an SVE predicated load or store instruction with no *Active elements* uses the current SP as the base address, then it is CONSTRAINED UNPREDICTABLE whether the SP register is checked for 16-byte alignment.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.5 Process state, PSTATE

RSPCZF Process state, or PSTATE, is an abstraction of process state information.

ILPKMT All Arm instruction sets provide instructions that operate on elements of PSTATE.

IKXKMY PSTATE includes all of the following:

- Fields that are meaningful only in AArch32 state.
- Fields that are meaningful only in AArch64 state.
- Fields that are meaningful in both Execution states.

IZHGST PSTATE is defined in pseudocode as the PSTATE structure.

D1.5.1 PSTATE fields that are meaningful in AArch64 state

ILLLXL PSTATE fields that are meaningful in AArch64 state are grouped into the following categories:

- Condition flags.
- Execution state controls.
- Exception mask bits.
- Access control bits.
- Timing control bits.
- Speculation control bits.

RPCDTX The following PSTATE bits are meaningful in AArch64 state:

PSTATE field name	PSTATE field group	Required implemented feature	Value when a Warm reset is asserted	Additional details
N, Negative condition flag	Condition flags	-	-	-
Z, Zero condition flag	Condition flags	-	-	-
C, Carry condition flag	Condition flags	-	-	-
V, Overflow condition flag	Condition flags	-	-	-
SS, Software Step bit	Execution state controls	-	0	-
IL, Illegal Execution state bit	Execution state controls	-	0	-
nRW, Current Execution state bit	Execution state controls	-	0	If the current Execution state is AArch64, the PSTATE.nRW bit is 0.
EL, Current Exception level field	Execution state controls	-	When a Warm reset is asserted into an Exception level using AArch64, the PSTATE.EL field holds the encoding for the highest implemented Exception level.	-
SP, Stack pointer register selection bit	Execution state controls	-	1	-
D, Debug exception mask bit	Exception mask bits	-	1	-
A, I, F Asynchronous exception mask bits	Exception mask bits	-	1	-

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PSTATE field name	PSTATE field group	Required implemented feature	Value when a Warm reset is asserted	Additional details
ALLINT, All interrupt mask bit	Exception mask bits	FEAT_NMI	-	-
PAN, Privileged Access Never state bit	Access control bits	FEAT_PAN	-	-
UAO, User Access Override bit	Access control bits	FEAT_UAO	-	-
TCO, Tag Check Override bit	Access control bits	FEAT_MTE	-	-
BTYPE, Branch target identification bit	Access control bits	FEAT_BTI	-	-
DIT, Data Independent Timing bit	Timing control bits	FEAT_DIT	0	-
SSBS, Speculative Store Bypass Safe bit	Speculation control bits	FEAT_SSBS	IMPLEMENTATION DEFINED	-
PM, PMU exception mask	Exception mask bits	FEAT_EBEP	-	-
EXLOCK, GCS exception state lock	Access control bits	FEAT_GCS	0	-
SM, Enables Streaming SVE mode	Execution state controls	FEAT_SME	0	-
ZA, Enables SME ZA storage	Access control bits	FEAT_SME	0	-
PACM. PACM instruction executed	Execution state controls	FEAT_PAuth_LR	0	-
UINJ, Inject Undefined Instruction exception	Execution state controls	FEAT_UINJ	0	-

D1.5.1.1 Accessing PSTATE fields

R_{LYGBS} In AArch64 state, PSTATE fields are accessed using Special-purpose registers that are directly read using the MRS (register) instructions, and directly written using the MSR (register) instructions.

R_{DGPCL} If in AArch64 state, the following Special-purpose registers can access the PSTATE fields that hold AArch64 state:

Special-purpose register	PSTATE fields
NZCV	N, Z, C, V
DAIF	D, A, I, F
CurrentEL	EL
SPSel	SP
PAN	PAN
UAO	UAO
DIT	DIT
SSBS	SSBS
TCO	TCO
ALLINT	ALLINT
PM	PM
SVCR	SM, ZA

All other PSTATE fields do not have direct read and write access.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{BRSMZ} Software can use the MSR (immediate) instructions to directly write to PSTATE.{D, A, I, F, SP, PAN, UAO, DIT, SSBS, TCO, ALLINT, PM, SM, ZA}.

R_{LDXKJ} The following PSTATE fields can be accessed at EL0:

- PSTATE.{N, Z, C, V, SSBS, DIT, TCO, SM, ZA}.
- If SCTLR_EL1.UMA is 1, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, PSTATE.{D, A, I, F}.
- PSTATE.{SM, ZA} access instructions can be executed at EL0 or higher.
- All other PSTATE access instructions can be executed at EL1 or higher and are UNDEFINED at EL0.

R_{HXYGT} Writes to the PSTATE fields have side-effects on various aspects of the PE operation. For side-effects caused by writes to a PSTATE field, all of the following are true:

- The side-effect is guaranteed not to be visible to earlier instructions in the Execution stream.
- The side-effect is guaranteed to be visible to later instructions in the Execution stream.

Other side-effects might occur but are not guaranteed.

D1.6 Resets and power domains

I_{DQXXZ} The PE logic is split into a Debug power domain and a Core power domain. Cold and Warm resets, reset elements in the Core power domain. An External debug reset can reset the Debug power domain. Other resets might be implemented.

D1.6.1 Power domains and reset domains

R_{JMTZY} The architecture defines the following power domains:

- The Core power domain.
- The Debug power domain.
- The system counter power domain.
- If trace is implemented, a power domain for the Trace Unit.
- If FEAT_RAS is implemented, there may be one or more IMPLEMENTATION DEFINED error recovery power domains. The relationship between these power domains and other power domains is IMPLEMENTATION DEFINED. For error records associated with the PE, this is the same as the Core power domain.
- If FEAT_AMUv1 is implemented, the AMU power domain.
- For *MPAM Memory System Components* (MSC), a power domain for each MSC.

I_{QBPTS} The power domains are described as logical because the architecture does not require two physical power domains.

R_{PDMKB} It is IMPLEMENTATION DEFINED whether each power domain powers up and powers down separately or together.

R_{ZDVQQ} The Core power domain contains:

- Non-debug registers and logic.
- Self-hosted debug registers and logic.
- Shared debug registers and logic.
- Some external debug registers and logic.

R_{GTVLN} The Debug power domain contains:

- The interface between the PE and the external debugger.
- Some external debug registers.

R_{MLXWM} If an external debugger is connected to the PE, the Debug power domain is powered up.

I_{KTSWK} For more information on access permissions for the external debug interface registers, see Access permissions for the External debug interface registers or the individual register descriptions.

D1.6.2 Reset types

I_{HDQLB} The architecture defines the following resets:

- Warm reset.
- Cold reset.
- External Debug reset.
- Trace unit reset. See Resetting the trace unit.
- Timer reset.
- If FEAT_RAS is implemented, there may be one or more IMPLEMENTATION DEFINED error recovery resets. The relationship between this reset and other resets is IMPLEMENTATION DEFINED. For error records associated with the PE, the error recovery reset is the same as Warm reset.
- If the FEAT_AMUv1 is implemented, AMU reset.
- For *MPAM Memory System Components* (MSC), a reset for each MSC.

I_{FMTCY} Other resets are IMPLEMENTATION DEFINED and can be mapped onto the architecturally-defined resets.

R_{PXXYQ} Mechanisms to assert resets, other than RMR_ELx, are IMPLEMENTATION DEFINED. One such mechanism is EDPRCR.CWRR. Any reset-asserting mechanism that software can command, including hardware mechanisms directly exposed to software, must only be accessible at the highest Exception level.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{HLDGD} When a Cold reset is asserted, for each register in the Core power domain, the reset sets the register to its architecturally-defined reset value.

R_{PJXVL} When a Warm reset is asserted, registers and logic in the Core power domain that are affected by the Warm reset are reset to their architecturally-defined reset value. Registers and logic that are only reset by a Cold reset are unaffected by a Warm reset.

R_{NBKHK} When an External Debug reset is asserted, the External Debug reset domain is reset and affected registers are set to their architecturally-defined External debug reset values. The Cold reset domain is unaffected.

R_{RKSZM} When a Cold reset is asserted, a Warm reset is asserted.

I_{VBZBW} Every register field that has storage belongs to exactly one reset domain. Each System register field definition defines the reset domain and the reset value.

I_{MWTXK} If RMR_ELx is implemented, writing 1 to RMR_ELx.RR requests a Warm reset.

R_{SGXSW} Writing 1 to RMR_ELx.RR is only a request for a Warm reset. The reset is not guaranteed to occur unless the following code sequence is executed:

```
; In addition, interrupts and debug requests for this PE should be disabled
; in the system before running this sequence to ensure the WFI suspends execution,
        MOV Wy, #3          ; for AArch64, #2 for AArch32; y is any register
        DSB                 ; ensure all stores etc are complete
        MSR RMR_ELx, Wy     ; request the reset
        ISB                 ; synchronize change to the RMR
Loop
        WFI                 ; enter a quiescent state
        B Loop
```

R_{DDTVZ} It is IMPLEMENTATION DEFINED whether a Warm reset can be asserted without using RMR_ELx.

I_{LWNDC} Arm recommends that a Warm reset can be asserted independently of a Cold reset.

I_{QLZGF} A Warm reset allows debugging across a reset of the PE logic in the Core power domain.

R_{SKGMH} It is IMPLEMENTATION DEFINED whether an External Debug reset and a Cold reset can be asserted independently.

I_{WTJYS} Arm recommends that when separate Core and Debug power domains are implemented, the External Debug reset and Cold reset can be asserted independently.

D1.6.3 Reset behavior

I_{TWYCF} Immediately after a reset, much of the PE state is architecturally UNKNOWN. However, some of the PE state is defined, see the individual register descriptions for more information. The state that is reset to known values is sufficient to permit predictable initial execution at the highest Exception level, such that this execution is then capable of initializing the remaining state of the system where necessary before use.

R_{JYLQV} When a Cold or Warm reset is asserted, all of the following occur:

- The PE enters the highest implemented Exception level.
- The stack pointer for the highest implemented Exception level, SP_ELx, is selected.

R_{ZBHGJ} When a Cold or Warm reset is deasserted, execution starts at an IMPLEMENTATION DEFINED address, anywhere in the *Physical Address* (PA) range. The RVBAR associated with the highest implemented Exception level RVBAR_EL1, RVBAR_EL2, or RVBAR_EL3, holds the address at which the PE starts execution.

I_{QSCPY} When a Cold or Warm reset is deasserted, the IMPLEMENTATION DEFINED address from which the PE starts execution is typically set either by a hardwired configuration of the PE or by configuration input signals.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{RRJLM} When a Warm reset is asserted, all of the following are architecturally UNKNOWN:

- All general-purpose, SVE, SIMD, and floating-point registers.
- The global exclusive monitor for the PE.
- The local exclusive monitor for the PE.
- System and Special-purpose registers with a reset value of architecturally UNKNOWN.

I_{KWHDG} When a Cold or Warm reset is asserted, PSTATE.{SS, IL, nRW, EL, SP, D, A, I, F, DIT, EXLOCK, ZA, SM, PACM, UINJ} fields are set to known values.

R_{BGSHC} When a Cold or Warm reset is asserted, the TLBs and caches are in an IMPLEMENTATION DEFINED state.

R_{XNNNH} When a Cold or Warm reset has been asserted and before the memory management system is enabled, the TLBs, caches or both might need to be invalidated by IMPLEMENTATION DEFINED invalidation sequences.

R_{TZHFZ} When a Cold or Warm reset has been asserted and before Normal memory accesses are permitted to be Cacheable, the TLBs, caches or both might need to be invalidated by IMPLEMENTATION DEFINED invalidation sequences.

R_{KMCGN} If IMPLEMENTATION DEFINED resets are implemented, each IMPLEMENTATION DEFINED reset can treat the cache and TLB state differently.

R_{TJGFQ} If IMPLEMENTATION DEFINED resets are implemented, for each IMPLEMENTATION DEFINED reset, the TLBs, caches, or both might require a different IMPLEMENTATION DEFINED invalidation sequence.

I_{PHDMZ} The IMPLEMENTATION DEFINED invalidation sequence might be a NOP.

D1.6.3.1 External debug access to registers in reset

R_{VFMKQ} If External Debug reset is asserted, for each register that can be accessed by the external debug interface, a register access by the external debug interface has one of the following IMPLEMENTATION DEFINED results:

- The external debug interface can access the register, and the access result is IMPLEMENTATION DEFINED.
- The external debug interface cannot access the register.

I_{QHHMQ} If either a Cold or Warm reset is asserted, accesses of registers or register fields might be direct accesses or indirect side-effects of an access.

R_{YKRBF} If either a Cold or Warm reset is asserted, external debug interface accesses of a register or register field have the following effects:

Access	Register or register field reset behavior	Effect on register or register field
Write	Reset by the reset signal	Set to CONSTRAINED UNPREDICTABLE choice of the reset value or the value written.
Write	Not reset by the reset signal	Set to the value written.
Read	Reset by the reset signal	Returns an UNKNOWN value.
Read	Not reset by the reset signal	Returns the value of the register or register field.

Non-Confidential

D1.7 Mechanisms for entering a low-power state

I_{RTNZD} The architecture provides the following mechanisms that software can use to indicate that the PE can enter low-power state:

- Wait for Event.
- Wait for Interrupt.

D1.7.1 Wait for Event

I_{ZZQGW} The Wait for Event mechanism behavior depends on the interaction of all of the following:

- The Event Register for the PE. See The Event Register.
- The Wait for Event (WFE) or Wait for Event with Timeout (WFET) instruction. See The Wait for Event and Wait for Event with Timeout instructions.
- WFE wakeup events. See WFE wakeup events in AArch64 state.
- The Send Event instructions, SEV and SEVL, that can cause WFE wakeup events. See The Send Event instructions.

R_{TJTFC} The architecture does not define the exact nature of the low-power state entered by WFE or WFET, except that when a WFE or WFET instruction is executed, memory coherency and architectural state are not lost.

I_{WBMQQ} The Wait for Event mechanism is associated with suspending execution on a PE for power saving, therefore Arm recommends that the Event Register is set infrequently. Software must only use the setting of the Event Register as a hint, and must not assume that any particular message is sent as a result of the setting of the Event Register.

D1.7.1.1 The Event Register

R_{PVKKP} The Event Register is a single bit register for each PE.

I_{TZVVM} The event register is a conceptual register and cannot be explicitly accessed.

I_{PDJMB} If the Event Register is 1, then an event has occurred since the register was last cleared and the event might require some action by the PE.

R_{RJYVC} When the PE executes a WFE or WFET instruction, all of the following apply:

- If the Event Register is 0, then the PE can enter the low-power state.
- If the Event Register is 1, then all of the following apply:
  - The PE does not suspend operation.
  - The Event Register is cleared to 0.
  - The WFE or WFET instruction completes immediately.

R_{DDGLZ} The reset value of the Event Register is UNKNOWN.

R_{XRZRK} The Event Register for a PE is set by any of the following:

- A Send Event instruction, SEV, executed by any PE in the system.
- A Send Event Local instruction, SEVL, executed by the PE.
- An exception return.
- The clearing of the global monitor for the PE.
- An event from a Generic Timer event stream, see Event streams.
- An event sent by some IMPLEMENTATION DEFINED mechanism.

I_{PJZBB} The Event Register is cleared only by a Wait for Event (WFE) instruction or a Wait for Event with Timeout (WFET) instruction.

I_{ZXJPD} Software cannot read or write the value of the Event Register directly.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.7.1.2 The Wait for Event and Wait for Event with Timeout instructions

R_{QRXWZ} If FEAT_WFxT is implemented, the Wait for Event with Timeout (WFET) instruction is implemented

R_{CSKPF} If the Event Register is 0, when a WFE or WFET instruction is executed, the PE can suspend execution and enter a low-power state.

R_{GZZQM} If the PE enters a low-power state, the PE remains in the lower-power state until one of the following occurs:

- The PE detects a WFE wakeup event.
- An IMPLEMENTATION DEFINED wake event that is architecturally permitted to occur at any time.
- A reset is asserted.

I_{QGHTM} The architecture permits all of the following:

- The PE is permitted to leave the low-power state for any reason.
- The PE is permitted to treat WFE as a NOP, but this is not recommended for lowest power operation.

R_{SLQVQ} If the PE is in a low-power state, when the PE detects a WFE wakeup event, or earlier if the implementation chooses, the WFE or WFET instruction completes. If the wakeup event sets the Event Register, when execution is restarted, the state of the Event Register is IMPLEMENTATION DEFINED.

I_{DRSJV} Software using the Wait for Event mechanism must tolerate spurious wakeup events, including multiple wakeup events.

D1.7.1.3 Trapping of WFE and WFET

I_{KMHTB} The WFE and WFET instructions are available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 can be configured to trap to a higher Exception level.

R_{JWKTL} If FEAT_TWED is implemented, then all of the following apply:

- A delay before taking a WFE or WFET trap can be configured.
- If a delay before taking a WFE or WFET trap is configured, then the delay does not affect the priority of the traps.

I_{RDYQK} For example, if execution is subject to a trap at EL1 because SCTLR_EL1.nTWE is 0 and HCR_EL2.TWE is 1, the only trap that will be taken is a trap to EL1, even if the delay at EL1 is longer than the delay at EL2.

D1.7.1.4 WFE wakeup events in AArch64 state

I_{RJRLR} In this section, AllIntMask refers to the value described in R_{XZPDT}.

I_{LRPVP} If a WFE or WFET instruction puts a PE into low-power state, a WFE wakeup event received by the PE causes that PE to exit low-power state.

R_{KBMFC} All of the following are WFE wakeup events:

- The execution of an SEV instruction on any PE in a multiprocessor system.
- Any physical SError exception, physical IRQ interrupt, or physical FIQ interrupt received by the PE that is not disabled by EDSCR.INTdis and either of the following is true:
  - The interrupt is marked as A in the tables in Asynchronous exception masking, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
  - The interrupt is marked as B in the tables in Asynchronous exception masking and any of the following are true:
    - The value of the corresponding PSTATE.{A, I, F} mask bit is 0.
    - AllIntMask is 0 and the IRQ or FIQ interrupt has Superpriority.
      See R_{MHWBP} and R_{GFXKY}.
- If all of the following apply, any virtual SError exception, virtual IRQ interrupt, or virtual FIQ interrupt received by the PE:
  - The PE is executing at EL1 or EL0.
  - The interrupt is not disabled by EDSCR.INTdis.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— The interrupt or exception is marked as B in the table in Virtual asynchronous exception masking and any of the following are true:
  — The value of the corresponding PSTATE.{A, I, F} mask bit is 0.
  — AllIntMask is 0 and the vIRQ or vFIQ interrupt has Superpriority. See R_{SNLJH} and R_{XSPSG}.

- If all the following apply, any delegated SError exception received by the PE:
  — The PE is executing at EL2, EL1, or EL0.
  — The exception is not disabled by EDSCR.INTdis.
  — Either of the following is true:
    — The exception is marked as A in the table in Delegated SError exception masking.
    — The exception is marked as B in the table in Delegated SError exception masking and PSTATE.A is 0.
- If halting is allowed, an asynchronous External Debug Request debug event. For the definition of halting, see Halting allowed and halting prohibited and External Debug Request debug event.
- An event sent by the timer event stream for the PE. See Event streams.
- An event caused by the clearing of the global monitor for the PE.
- An event sent by some IMPLEMENTATION DEFINED mechanism.
- When FEAT_WFxT is implemented, for `WFET` instructions, a *local timeout event* caused by the virtual count threshold value, expressed in CNTVCT_EL0, being equaled or exceeded.

I_{FRZZX} Not all of the wakeup events in R_{KBMFC} set the Event Register.

D1.7.1.5 The Send Event instructions

R_{DQRMZ} The Send Event instructions are:

- `SEV`, Send Event: Causes an event to be signaled to all PEs in a multiprocessor system.
- `SEVL`, Send Event Local: Causes an event to be signaled locally without requiring the event to be signaled to other PEs in a multiprocessor system.

I_{FVQBK} An `SEVL` instruction might signal an event to other PEs by an IMPLEMENTATION DEFINED mechanism, but it is not required to do so.

R_{HTDFW} The mechanism that signals an event to other PEs is IMPLEMENTATION DEFINED.

R_{RLHHM} When an event is signaled by an `SEV` instruction, the ordering of the event with respect to the completion of memory accesses by instructions before the SEV instruction is not guaranteed.

I_{DVZXD} Arm recommends that software includes a `DSB` instruction before any `SEV` instruction. `DSB` instruction ensures that no instructions, including any SEV instructions, that appear in program order after the `DSB` instruction, can execute until the `DSB` instruction has completed. See Data Synchronization Barrier.

I_{QJDQV} The `SEVL` instruction appears to execute in program order relative to any subsequent WFE or WFET instruction executed on the same PE.

I_{HWHBP} The behavior in I_{QJDQV} applies without the need for any explicit insertion of barrier instructions.

D1.7.2 Wait for Interrupt mechanism

I_{LMJGQ} A PE can use the Wait for Interrupt mechanism to enter a low-power state.

R_{JHZBN} When FEAT_WFxT is implemented, the Wait for Interrupt with Timeout (WFIT) instruction is implemented.

R_{DBXLJ} Software can use the Wait for Interrupt (WFI) and Wait for Interrupt with Timeout (WFIT) instructions to cause the PE to enter a low-power state.

R_{HSPJD} If a Wait for Interrupt (WFI) and Wait for Interrupt with Timeout (WFIT) instructions causes the PE to enter a low-power state, the PE remains in that low-power state until any of the following occur:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The PE detects a WFI wakeup event.
- An IMPLEMENTATION DEFINED wake event that is architecturally permitted to occur at any time.
- A reset is asserted.

I_{MFLXH} The architecture permits all of the following:

- The PE is permitted to leave the low-power state for any reason.
- The PE is permitted to treat WFI as a NOP, but this is not recommended for lowest power operation.

R_{MRVLC} When the PE leaves a low-power state that was entered because of a WFI or WFIT instruction, the WFI or WFIT instruction completes.

R_{HJPJY} Except for all or the following, the architecture does not define the exact nature of the low-power state:

- When a WFI or WFIT instruction is executed, the architecture requires that memory coherency is not lost.
- If the system is configured such that the WFI or WFIT instruction can be completed, then the architecture requires that the architectural state is not lost.

I_{WWYXS} In some implementations, based on the configuration of system specific registers, WFI can be used as part of a powerdown sequence where no interrupts will cause WFI wakeup events, and restoration of power involves resetting of the PE. In those cases, the WFI is permitted to cause a loss of architectural state, as it is assumed that this state will have been saved by software as part of the powerdown sequence before the WFI.

I_{CHMWP} The WFI and WFIT instructions are available at all Exception levels. Attempts to enter a low-power state made by software executing at EL0, EL1, or EL2 can be configured to trap to a higher Exception level.

D1.7.2.1 WFI wakeup events

I_{CYKVZ} In this section, AllIntMask refers to the value described in R_{XZPDT}.

R_{VRLPB} All of the following are WFI wakeup events:

- Any physical SError exception, physical IRQ interrupt, or physical FIQ interrupt received by the PE that is marked as A or B in the tables in Asynchronous exception masking, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
- If the PE is executing at EL1 or EL0, any virtual SError exception, virtual IRQ interrupt, or virtual FIQ interrupt received by the PE, that is marked as B in the tables in Virtual asynchronous exception masking, regardless of the value of the corresponding PSTATE.{A, I, F} mask bit.
- If the PE is executing at EL2, EL1, or EL0, any delegated SError exception received by the PE that is marked as A or B in the table in Delegated SError exception masking, regardless of the value of PSTATE.A.
- If halting is allowed, an asynchronous External Debug Request debug event. For the definition of halting, see Halting allowed and halting prohibited and External Debug Request debug event.
- An event sent by an IMPLEMENTATION DEFINED mechanism.
- When FEAT_WFxT is implemented, for `WFIT` instructions, a *local timeout event* caused by the virtual count threshold value, expressed in CNTVCT_EL0, being equaled or exceeded.

R_{NLVGY} WFI wakeup events are never disabled by EDSCR.INTdis, and are never masked by the PSTATE.{A, I, F} mask bits, or by the state of AllIntMask. If wakeup is invoked by an interrupt that is disabled or masked, the interrupt is not taken.

I_{VCDGW} Because debug events are WFI wakeup events, Arm recommends that Wait for Interrupt is used as part of an idle loop rather than waiting for a single specific interrupt event to occur and then moving forward. This ensures that the intervention of debug while waiting does not significantly change the function of the program being debugged.

I_{FXRXC} If the PE is in WFx state when a PMU Capture event occurs, it must wake-up to service the request. Arm recommends the Capture event is not treated as an IMPLEMENTATION DEFINED WFx wake-up event and the PE returns to standby after. See PMU snapshots.

I_{ZQWXZ} The architecture does not require the WFI mechanism to drain down any pending memory activity before suspending execution, and software must not rely on the WFI mechanism operating in this way.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.7.3 Pending Profiling exceptions

I_{WNMSV} A pending asynchronous Profiling exception is not required to be a WFE wakeup event or WFI wakeup event.

Arm recommends that a pending unmasked asynchronous Profiling exception is treated as an IMPLEMENTATION DEFINED wakeup event, to allow timely processing of the profiling event. For example, if other telemetry data needs to be collected by software from the system. However, if a Profiling exception becomes pending as the PE enters a low-power WFx state, then the PE might not have registered the pending Profiling exception before entering the WFx state.

A similar condition applies when using PMU, SPE, or TRBE interrupts, because the PE has to have asserted the interrupt request to the interrupt controller before entering the WFx state for it to be a wakeup event. This is due to IMPLEMENTATION SPECIFIC timings that determine whether a profiling event causes a WFx wakeup or prevents the PE from entering the WFx state.

I_{VPTQY} In I_{WNMSV}, pending means that, if the Profiling exception were unmasked, a Profiling exception would be taken by a simple sequential execution of the program before the execution of the next instruction.

D1.7.4 Using WFI to indicate an idle state on bus interfaces

R_{TZPSV} When all of the following are true, the IMPLEMENTATION DEFINED mechanism for entering powerdown state can be completed:

- The IMPLEMENTATION DEFINED mechanism forces quiescence on a PE.
- The IMPLEMENTATION DEFINED mechanism prevents any possible WFI wakeup events.

R_{VWDWJ} The mechanism for entering powerdown state is IMPLEMENTATION DEFINED.

I_{FFGGG} Although the mechanism for entering powerdown state is IMPLEMENTATION DEFINED, the WFI and WFE mechanisms are often used to enter powerdown state.

R_{RMBKR} If a WFI powerdown mechanism is implemented, when a WFI or WFIT instruction is executed, the PE completes all current operations and any associated bus activity also completes. When all current PE operations and associated bus activity are complete, the PE can signal to an external power controller that there is no ongoing bus activity.

R_{CLTZY} After a WFI instruction is executed and all currently executing instructions and related bus activity has completed, the PE is waiting for an interrupt and is in *idle state*. If in idle state, the PE can process memory-mapped or external debug interface accesses to debug registers.

I_{CYBLG} The indication of idle state to the system normally only applies to the non-debug functional interfaces used by the PE, not the debug interfaces.

R_{DHHKY} If OSDLR_EL1.DLK is 1, the PE does not signal the idle state to the control logic unless it can also guarantee that the debug interface is idle. For more information about the OS Double Lock, see Debug behavior when the OS Double Lock is locked.

I_{WRZGC} In a PE that implements separate Core and Debug power domains, the debug interface referred to in this section is the interface between the Core and Debug power domains, since the signal to the power controller indicates that the Core power domain is idle. For more information about the power domains, see Power domains and debug.

I_{RFLDH} The exact nature of the debug interface is IMPLEMENTATION DEFINED, but the use of Wait for Interrupt as the only architecturally-defined mechanism that completely suspends execution makes it suitable as the preferred powerdown entry mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.8 Self-hosted debug

I_{MJGPY} The architecture supports both of the following:

Self-hosted debug

The PE itself hosts a debugger. The debugger programs the PE to generate debug exceptions. Debug exceptions are accommodated in the Arm Exception model.

External debug

The PE is controlled by an external debugger. The debugger programs the PE to generate debug events, that cause the PE to enter Debug state. In Debug state, the PE is halted.

D1.8.1 Debug exceptions

I_{PWPHY} If a debugger has programmed the PE to generate Debug exceptions, the Debug exceptions occur during normal program flow.

I_{DSWBH} For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger might enable one or more debug exceptions.

I_{BXVCF} The debug exceptions are all of the following:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

I_{VYKHK} The PE can only generate a particular debug exception if all of the following are true:

- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state. Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.
- A debugger has enabled that particular debug exception. All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls.

I_{GRWSG} Breakpoints and watchpoints can cause entry to Debug state instead of causing debug exceptions. See About External Debug.

D1.8.2 The PSTATE debug mask bit, D

R_{DYRLS} The debug exception mask bit, PSTATE.D, can mask Watchpoint, Breakpoint, and Software Step exceptions if the target Exception level is the current Exception level.

R_{RDYDM} If in AArch64 state and the target Exception level of a debug exception is lower than the current Exception level, the debug exception is masked.

R_{JWZFQ} If the target Exception level is higher than the current Exception level, debug exceptions are not masked by PSTATE.D.

R_{KCHGM} If PSTATE.D is 1 and the PE is already handling an exception in AArch64 state, the Watchpoint, Breakpoint, and Software Step exceptions are masked.

I_{LVYYH} If an exception is already being handled, masking prevents software from generating another instance of an exception and prevents recursive entry into the exception handler and loss of return state.

R_{NCHXS} Masking debug interrupts with PSTATE.D prevents the generation of new debug exceptions, therefore, any masked debug exceptions are not taken if PSTATE.D is later set to 0.

I_{VSTYD} The behavior described in R_{NCHXS} differs from the behavior for interrupts, where the PSTATE.{A, I, F} mask prevents the interrupt from being taken, but instead the interrupt remains pending.

I_{KWFMZ} When an exception is taken, PSTATE.D is set to 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.9 Event monitors

IYVDTB The architecture supports the following non-invasive architectural components that allow for event monitoring:

Performance Monitors

The Performance Monitors have a wide feature set, flexible selection of counted events, and are read/write in operation.

Activity Monitors

The Activity Monitors have a narrow feature set, limited selection of counted events, and are read-only in operation.

D1.9.1 The Performance Monitors Extension

IZSPVV The System registers provide access to a Performance Monitoring Unit (PMU), defined as the OPTIONAL Performance Monitors Extension to the architecture, a non-invasive debug resource that provides information about the operation of the PE.

The PMU provides:

- A 64-bit cycle counter.
- An IMPLEMENTATION DEFINED number of event counters. If FEAT_PMUv3p5 is implemented, the event counters are 64-bit unsigned counters, otherwise the event counters are 32-bit event counters.Each event counter can be configured to count occurrences of a specified event. The events that can be counted are:
  - Architectural and microarchitectural events that are likely to be consistent across many microarchitectures. The PMU architecture uses event numbers to identify an event, and the PMU specification defines which event number must be used for each of these architectural and microarchitectural events.
  - IMPLEMENTATION SPECIFIC events. The PMU specification reserves event numbers for IMPLEMENTATION SPECIFIC events.
- An OPTIONAL 64-bit instructions counter.

For more information, see The Performance Monitors Extension.

D1.9.2 The Activity Monitors Extension

IPCKDC If the OPTIONAL Activity Monitors Extension is implemented, the System registers provide access to controls and counters for the Activity Monitors Unit (AMU).

For more information, see The Activity Monitors Extension.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.10 Interprocessing

R_{FKKJY} Moving between the AArch64 and AArch32 Execution states is called *interprocessing*.

R_{NKBQL} The Execution state can only change on a change of Exception level.

I_{WNJBK} Therefore, Execution state can change only on taking an exception to a higher Exception level or returning from an exception to a lower Exception level. For an exception that is taken to the same Exception level or is returning from the same Exception level, the Execution state cannot change.

R_{GLNVF} When taking an exception to a higher Exception level, the Execution state is one of the following:

- Unchanged.
- Changed from AArch32 state to AArch64 state.

R_{KTCXV} When returning from an exception to a lower Exception level, the Execution state is one of the following:

- Unchanged.
- Changed from AArch64 state to AArch32 state.

D1.10.1 Register mappings between AArch32 state and AArch64 state

I_{XVDJR} Register mappings between AArch32 state and AArch64 state describe the following:

- For exceptions taken from AArch32 state to AArch64 state, where the AArch32 register content is found.
- For exception returns from AArch64 state to AArch32 state, how the AArch32 register content is derived.

R_{PCCLL} The AArch32 state register contents occupy the bottom 32 bits of the AArch64 state registers.

R_{CTBNQ} If in AArch32 state, the upper 32 bits of AArch64 state registers are inaccessible and are ignored.

R_{GMLYF} For bits[63:32] of AArch64 registers that are not mapped to AArch32 registers, the unmapped bits are unchanged by AArch32 state execution.

D1.10.1.1 Mapping of the general-purpose registers between the Execution states

I_{PYKVS} The following table shows the mappings of general-purpose registers between Execution states:

AArch32 register	AArch64 register
R0	X0
R1	X1
R2	X2
R3	X3
R4	X4
R5	X5
R6	X6
R7	X7
R8_usr	X8
R9_usr	X9
R10_usr	X10
R11_usr	X11
R12_usr	X12

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AArch32 register	AArch64 register
SP_usr	X13
LR_usr	X14
SP_hyp	X15
LR_irq	X16
SP_irq	X17
LR_svc	X18
SP_svc	X19
LR_abt	X20
SP_abt	X21
LR_und	X22
SP_und	X23
R8_fiq	X24
R9_fiq	X25
R10_fiq	X26
R11_fiq	X27
R12_fiq	X28
SP_fiq	X29
LR_fiq	X30

I_{JCWRB} For some exceptions, the exception syndrome given in the ESR_ELx identifies one or more register numbers from the issued instruction that generated the exception. If one of these exceptions is taken from an Exception level using AArch32, the register numbers give the AArch64 view of the register.

I_{VSFBC} For example, if an exception is taken from AArch32 Abort mode and the faulting instruction specified R14, the ESR_ELx.ISS field would report this using the EC value `0b10100`, because register X20 provides the AArch64 view of LR_abt, which is the copy of R14 used in Abort mode.

D1.10.1.2 Mapping of the SIMD and floating-point registers between the Execution states

I_{DPNRF} The following table shows the mappings of SIMD and floating-point registers between the Execution states:

AArch64 register	AArch32 register
V0	Q0
V1	Q1
V2	Q2
.	.
.	.
.	.
V15	Q15

R_{TJJVC} The AArch64 state registers V16-V31 are not accessible from AArch32 state.

I_{VTZXL} The mapping between the V, D, and S registers in AArch64 state is not the same as the mapping between the Q, D, and S registers in AArch32 state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{VSTPQ} In AArch64 state, there are:

- 32 128-bit V registers, V0-V31.
- 32 64-bit D registers, D0-D31.
- 32 32-bit S registers, S0-S31.

R_{WJGSQ} A smaller register occupies the least significant bytes of the corresponding larger register.

I_{FFHKC} The following graphic shows the mapping of V, D, and S registers in AArch64 state:

R_{DHVZF} In AArch32 state, there are:

- 16 128-bit Q registers, Q0-Q15.
- 32 64-bit D registers, D0-D31.
- 32 32-bit S registers, S0-S31.

R_{BPYPZ} Smaller registers are packed into larger registers.

I_{YHYWN} The following graphic shows the mapping of Q, D and S registers in AArch32 state:

R_{GXGJK} In AArch32 state:

- There are no S registers that correspond to Q8-Q15.
- D16-D31 pack into Q8-Q15.

I_{MKXYB} If software executing in AArch64 state interprets D or S registers from AArch32 state, the software must unpack the D or S registers from the V registers before it uses them. For example, the following diagram shows the mapping of the AArch32 S0-S31 registers through the AArch32 D and Q registers into the AArch64 V, D and S registers:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.10.1.3 Mapping of the System registers between the Execution states

I_{MPMNZ} For a full list of mappings of writable AArch64 System registers to the AArch32 System registers, see Table K14-5.

R_{BQSMK} The relationship between the AArch64 System registers and the AArch32 System registers is architecturally defined.

R_{LPDQL} Modifications made to AArch32 System registers affect only the parts of the AArch64 state registers that are mapped to the AArch32 System registers.

I_{HTCVH} Supervisory code, such as a hypervisor, executing in AArch64 state, can save, restore, and interpret the System registers belonging to a lower Exception level that is using AArch32.

I_{LYHXS} In some cases, two AArch32 System registers are packed into a single AArch64 System register.

R_{QXNZN} If EL3 is implemented and is using AArch32, some System registers are banked between Secure and Non-secure states. In this type of banking, there is an instance of the register in Secure state and another instance of the register in Non-secure state.

R_{TVZJS} If any of the following are true, banking between Secure and Non-secure states is not supported:

- EL3 is not implemented.
- EL3 is implemented and is using AArch64.

I_{JRZXQ} If EL3 is implemented and is using AArch64, the same, non-banked, registers are accessed in the following state:

- Secure EL1 with EL1 using AArch32.
- Non-secure EL1 with EL1 using AArch32.

I_{HSRHJ} If EL3 is implemented and is using AArch64, it is not possible to architecturally determine whether an AArch64 register is mapped onto the Secure or the Non-secure instance of corresponding AArch32 register.

R_{MCZCY} If EL3 is implemented and is using AArch64, the interrupt asserted by the AArch64 CNTP_* timer is the same interrupt that is asserted by the Non-secure AArch32 CNTP_* timer when EL3 is using AArch32.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IJSZYM Although not required, Arm expects that implementations map many of the AArch64 registers for use by EL3 to the Secure instances of the banked AArch32 registers, and map many of the AArch64 registers for use by EL1 to the Non-secure instances of the banked AArch32 registers. However, if EL2 and EL3 are implemented and both support use of AArch32, this mapping is not possible for the following registers:

- IFAR - This is because when EL3 is using AArch32, HIFAR is an alias of the Secure IFAR.
- DFAR - This is because when EL3 is using AArch32, HDFAR is an alias of the Secure DFAR.

IBYYWR There are some AArch32 System registers that are only used in AArch32 state and do not have an equivalent AArch64 System register. However, there are AArch64 registers that can access, from a higher Exception level, the AArch32 registers that do not have an AArch64 state equivalent.

IVGXRB For a full list of AArch64 registers that access AArch32 System registers with no AArch64 equivalent, see Table K14-6.

IWRKYQ For a full list AArch64 registers that allow access to the AArch32 ID registers from AArch64 state, see Table K14-7.

D1.10.1.4 State of the general-purpose registers on taking an exception to AArch64 state

D1.10.1.4.1 If the general-purpose register was accessible from AArch32 state

RWWJWP When an exception is taken from AArch32 state to AArch64 state and the general- purpose register was accessible from AArch32 state, the upper 32 bits have one of the following IMPLEMENTATION DEFINED values and might vary dynamically within an implementation:

- The upper 32 bits retain the value that the same architectural register held before any AArch32 execution.
- The upper 32 bits are set to zero.

The IMPLEMENTATION DEFINED behavior applies regardless of whether any execution occurred at the Exception level that was using AArch32.

ITKQYW For example, the IMPLEMENTATION DEFINED behavior described in RWWJWP applies even if AArch32 state was entered by an exception return from AArch64 state, and another exception was immediately taken to AArch64 state without any instruction execution in AArch32 state.

IQFBYM When an exception is taken from AArch32 state to AArch64 state, software must regard the value of the upper 32 bits as a CONSTRAINED UNPREDICTABLE choice between the two values described in RWWJWP.

D1.10.1.4.2 If the general-purpose register was not accessible from AArch32 state

RRHRQX If all of the following apply, when an exception is taken from AArch32 state to AArch64 state, the X15 register is treated as if it is accessible and therefore the upper 32 bits of X15 might either be set to zero or retain their previous value:

- The target Exception level is EL3.
- EL2 is not implemented or EL1 is in Secure state.
- SCR_EL3.RW is 0.

Otherwise, when an exception is taken from AArch32 state to AArch64 state, for a general-purpose register that was not accessible from AArch32 state, the register retains the value it had before any AArch32 execution.

D1.10.1.4.3 Determining the upper 32 bits of AArch64 registers on taking an exception from AArch32 state

RZJBSH Whether a general-purpose register has its upper 32 bits set to zero or retained on taking an exception from AArch32 to AArch64 is affected by all of the following:

- The AArch64 state target Exception level.
- The values of both:
  - SCR_EL3.RW.
  - HCR_EL2.RW or HCR.RW, where HCR.RW is a notional bit that is RES 0.

RDGVGF The following table shows which general-purpose registers can have their upper 32 bits set to zero on taking an exception from AArch32 state to AArch64 state. In this table, a dash (-) indicates that the RW values are not valid for the targeted Exception level.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SCR_EL3.RW	HCR_EL2.RW or HCR.RW	Registers when the target Exception level is:		
		EL3	EL2	EL1
0	0	X0-X30	-	-
0	1	Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.		
1	0	X0-X14, X16-X30	X0-X14, X16-X30	-
1	1	X0-X14	X0-X14	X0-X14

R_{WKWVT} If EL2 is not implemented, or the SCR_EL3.NS or SCR.NS bits prevent its use, the registers that can have their upper 32 bits set to zero on taking an exception from AArch32 state to AArch64 state are the same as when HCR_EL2.RW has the same value as SCR_EL3.RW.

R_{WPVQR} The following table shows which general-purpose registers can retain their upper 32 bits on taking an exception from AArch32 state to AArch64 state. In this table, a dash (-) indicates that the RW values are not valid for the target Exception level.

SCR_EL3.RW	HCR_EL2.RW or HCR.RW	Registers when the target Exception level is:		
		EL3	EL2	EL1
0	0	None	-	-
0	1	Not valid because the RW bit values would imply that EL2 is AArch32 and EL1 is AArch64.		
1	0	X15	X15	-
1	1	X15-X30	X15-X30	X15-X30

R_{LGSLY} If EL2 is not implemented, or SCR_EL3.NS prevents its use, the registers that can have their upper 32 bits retained on taking an exception to AArch64 state from AArch32 state are the same as when HCR_EL2.RW has the same value as SCR_EL3.RW.

D1.10.1.5 SPSR, ELR, and AArch64 SP relationships on changing Execution state

I_{PSRRS} The following table shows SPSR and ELR registers that are architecturally mapped between AArch32 state and AArch64 state:

AArch32 register	AArch64 register
SPSR_svc	SPSR_EL1
SPSR_hyp	SPSR_EL2
ELR_hyp	ELR_EL2

R_{CHHXX} When an exception is taken from an Exception level using AArch32 to EL3 using AArch64 and EL2 has been using AArch32 state, the upper 32 bits of ELR_EL2 have one of the following IMPLEMENTATION DEFINED values:

- The upper 32 bits retain the value that the same architectural register held before any AArch32 execution.
- The upper 32 bits are set to zero.

R_{WFDMR} The following AArch32 registers are used only during execution in AArch32 state. However, they retain their state if there is execution at EL1 and EL1 is using AArch64 state.

- SPSR_abt.
- SPSR_und.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- SPSR_irq.
- SPSR_fiq.

I_{TBFWN} For the purposes of context switching, the registers in R_{WFDMR} are accessible during execution in AArch64 state at Exception levels higher than EL1.

I_{WRPZP} If EL1 does not support execution in AArch32 state, the registers in R_{WFDMR} are RES0.

R_{MBVJZ} If an exception is taken from an Exception level using AArch32 to an Exception level using AArch64, the AArch64 stack pointers and Exception Link Registers associated with an Exception level that are not accessible during AArch32 execution at the Exception level from which the exception was taken, retain the state that they had before AArch32 execution. This applies to the following registers:

- SP_EL0.
- SP_EL1.
- SP_EL2.
- ELR_EL1.

D1.10.1.6 PSTATE.SM and PSTATE.ZA behaviors on changing Execution state

R_{SWQGH} The values of PSTATE.{SM, ZA} do not change when any of the following occurs:

- An exception return from AArch64 to AArch32 Execution state.
- An exception taken from AArch32 to AArch64 Execution state.

R_{GXKNK} In AArch32 state, the Effective value of PSTATE.SM is 0.

I_{MWQNV} When PSTATE.SM is 1, a change in Execution state from AArch64 to AArch32, or from AArch32 to AArch64, causes all implemented bits of the SVE registers (including SIMD&FP registers) and the FPSR to be reset to a fixed value.

I_{WYKRM} The value of PSTATE.ZA does not change in AArch32 Execution state. Therefore, a transition between AArch64 and AArch32 Execution state when PSTATE.ZA is 1 has no effect on the contents of ZA storage, or the ZT0 register when FEAT_SME2 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D1.11 Check Feature

IFCDFK FEAT_CHK provides CHKFEAT with the following properties:

- CHKFEAT is allocated from the Hint instruction space, to allow it to be used on any PE, regardless of whether FEAT_CHK is implemented.
- CHKFEAT takes a value as an input where one or more bits of the input value is set to 1 to test whether the requested feature is enabled, and if the feature is enabled the relevant bit is cleared to 0. Otherwise, the bit is unchanged.
- When FEAT_CHK is not implemented, the input value is unchanged, indicating the requested feature is not enabled.
- CHKFEAT returns the state of GCSEnabled().

ICZRRH For the encoding allocation for CHKFEAT, see op0 == 0b00, architectural hints, barriers and CLREX, and PSTATE access.

IQMQXS Since the CHKFEAT instruction is in the Hint instruction encoding space, it is effectively implemented on all PEs that support AArch64. However, the CHKFEAT instruction only returns a result value that is different from the input value when any of the features that are identified by the CHKFEAT are implemented.

RVXBTN An example of how CHKFEAT can be used in an implementation independent manner is shown below.

Example D1-1 Example code for using CHKFEAT

```
    MOV X16, #0x1           ; X16 has bit [0] set to select GCS
    CHKFEAT X16             ; Updates X16 with the status of GCS
    TBNZ X16, #0, skipgcs   ; Skip over GCS code if GCS is not enabled

    ...                     ; GCS related code

skipgcs:
```

Chapter D2
AArch64 Self-hosted Debug

When the PE is using self-hosted debug, it generates *debug exceptions*. This chapter describes the AArch64 self-hosted debug Exception model. It is organized as follows:

- About self-hosted debug
- Routing debug exceptions
- The debug exception enable controls
- The effect of powerdown on debug exceptions
- Summary of the routing and enabling of debug exceptions
- Pseudocode description of debug exceptions
- Breakpoint Instruction exceptions
- Breakpoint exceptions
- Watchpoint exceptions
- Vector Catch exceptions
- Software Step exceptions
- Synchronization and debug exceptions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.1 About self-hosted debug

Self-hosted debug supports debugging through the generation and handling of *debug exceptions*, which are taken using the Exception model described in The AArch64 System Level Programmers' Model. This section introduces some terms that are used in describing self-hosted debug, and then introduces the debug exceptions. See:

- Definition of a debugger in the context of self-hosted debug.
- Context ID and Process ID.
- About debug exceptions.

D2.1.1 Definition of a debugger in the context of self-hosted debug

Within this chapter, *debugger* means that part of an operating system, or higher level of system software, that handles debug exceptions and programs the Debug System registers. An operating system with rich application environments might provide debug services that support a debugger user interface executing at EL0. From the architectural perspective, the debug services are the debugger.

D2.1.2 Context ID and Process ID

A CONTEXTIDR_ELx identifies the current *Context ID*, which is used by:

- The debug logic, for breakpoint and watchpoint matching.
- Implemented trace logic, to identify the current process.

In AArch64 state, the CONTEXTIDR_ELx has a single field, PROCID, that is defined as the *Process Identifier* (Process ID). Therefore, in AArch64 state, the Context ID and Process ID are identical.

D2.1.3 About debug exceptions

Debug exceptions occur during normal program flow if a debugger has programmed the PE to generate them. For example, a software developer might use a debugger contained in an operating system to debug an application. To do this, the debugger enables one or more debug exceptions. The debug exceptions that can be generated in stage 1 of an AArch64 translation regime are:

- Breakpoint Instruction exceptions.
- Breakpoint exceptions, generated by hardware breakpoints.
- Watchpoint exceptions, generated by hardware watchpoints.
- Software Step exceptions.

In addition, debug exceptions generated in an AArch32 translation regime might be routed to EL2 using AArch64. See Routing debug exceptions. AArch32 Self-hosted Debug describes the debug exceptions that can be generated in an AArch32 translation regime.

Vector Catch exceptions are exceptions that cannot be generated in an AArch64 translation regime but can be generated in stage 1 of an AArch32 translation regime and routed to EL2 using AArch64. Vector Catch exceptions describes the behavior for this case.

Other than Breakpoint Instruction exceptions, the PE can generate a particular debug exception only if all of the following are true:

- The OS Lock is unlocked.
- `DoubleLockStatus()` == FALSE.
- Debug exceptions are not disabled from the current Exception level and Security state.
  See Enabling debug exceptions from the current Exception level and Security state.
- A debugger has not disabled that particular debug exception.
  All of the debug exceptions except for Breakpoint Instruction exceptions have an enable control contained in the MDSCR_EL1. See The debug exception enable controls.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Breakpoint Instruction exceptions are always enabled.

Note

If *halting is allowed* and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause entry to Debug state instead of causing debug exceptions. In Debug state, the PE is halted.
For the definition of halting is allowed, see Halting allowed and halting prohibited.

The following list summarizes each of the debug exceptions:

Breakpoint Instruction exceptions

Breakpoint instructions generate these. Breakpoint instructions are instructions that software developers can use to cause exceptions at particular points in the program flow.

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. Whenever one of these is committed for execution, the PE takes a Breakpoint Instruction exception.

Breakpoint Instruction exceptions cannot be masked. The PE takes Breakpoint Instruction exceptions regardless of both of the following:

- The current Exception level.
- The current Security state.

For more information, see Breakpoint Instruction exceptions.

Breakpoint exceptions

The architecture provides 2-64 hardware breakpoints. These can be programmed to generate Breakpoint exceptions based on one or more of particular instruction addresses, accesses to any address in an instruction address range, or particular PE contexts.

For example, a software developer might program a hardware breakpoint to generate a Breakpoint exception whenever the instruction with address `0x1000` is committed for execution.

The architecture supports the following types of hardware breakpoint for use in stage 1 of an AArch64 translation regime:

- Address.
  - Comparisons are made with the virtual address of each instruction in the program flow.
- Context:
  - Context ID Match. Matches with the Context ID held in the CONTEXTIDR_EL1, and if FEAT_VHE is implemented, CONTEXTIDR_EL2.
  - VMID Match. Matches with the VMID value held in the VTTBR_EL2.
  - Context ID and VMID Match. Matches with both the Context ID and the VMID value.

An Address breakpoint can link to a context-matching breakpoint, so that the Address breakpoint generates a Breakpoint exception only if the PE is in a particular context when the address match occurs.

A breakpoint generates a Breakpoint exception whenever an instruction that causes a match is committed for execution.

If halting is allowed and EDSCR.HDE is 1, hardware breakpoints cause entry to Debug state. That is, they halt the PE. See Debug State.

Otherwise:

- If debug exceptions are enabled, hardware breakpoints cause Breakpoint exceptions.
- If debug exceptions are disabled, hardware breakpoints are ignored.

For more information, see Breakpoint exceptions.

Watchpoint exceptions

The architecture provides 2-64 hardware watchpoints. These can be programmed to generate Watchpoint exceptions based on accesses to particular data addresses, or based on accesses to any address in a data address range.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For example, a software developer might program a hardware watchpoint to generate a Watchpoint exception on an access to any address in the data address range `0x1000 - 0x101F`.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is a Context matching breakpoint with linking enabled. In this case, the watchpoint generates a Watchpoint exception only if the PE is in a particular context when the data address match occurs.

A hardware watchpoint can link to a hardware breakpoint if the hardware breakpoint is an address breakpoint with linking enabled. In this case, the watchpoint generates a Watchpoint exception only if the address of the instruction making the access matches the breakpoint.

The smallest data address size that a watchpoint can be programmed to match on is a byte. A single watchpoint can be programmed to match on one or more bytes.

A watchpoint generates a Watchpoint exception whenever an instruction that initiates an access that causes a match is committed for execution.

If halting is allowed and EDSCR.HDE is 1, hardware watchpoints cause entry to Debug state. That is, they halt the PE. See Debug State.

Otherwise:

- If debug exceptions are enabled, hardware watchpoints cause Watchpoint exceptions.
- If debug exceptions are disabled, hardware watchpoints are ignored.

For more information, see Watchpoint exceptions.

Vector Catch exceptions

These are not generated in an AArch64 translation regime. They can be generated only in an AArch32 translation regime. See Vector Catch exceptions.

Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can debug software executing at a lower Exception level, by making it single-step instructions.

After the software being debugged has single-stepped an instruction, the PE takes a Software Step exception.

Software step can be used only by a debugger executing in an Exception level that is using AArch64. However, the instruction stepped might be executed in either Execution state, and therefore Software Step exceptions can be taken from either Execution state.

If debug exceptions are enabled, Software Step exceptions can be generated.

If debug exceptions are disabled, software step is inactive.

For more information, see Software Step exceptions.

Table D2-1 summarizes PE behavior and shows the location of the pseudocode for each of the debug exceptions.

Table D2-1 PE behavior and pseudocode for each of the debug exceptions

Debug exception	PE behavior if debug exceptions are:		Pseudocode
	Enabled	Disabled	
Breakpoint Instruction exceptions	Takes the exception	Takes the exception	Pseudocode description of Breakpoint Instruction exceptions
Breakpoint exceptions	Takes the exception[a]	Ignored	Pseudocode description of Breakpoint exceptions taken from an AArch64 stage 1 translation regime

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Debug exception	PE behavior if debug exceptions are:		Pseudocode
	Enabled	Disabled	
Watchpoint exceptions	Takes the exception[a]	Ignored	Pseudocode description of Watchpoint exceptions taken from AArch64 state
Vector Catch exceptions	Takes the exception	Ignored	Pseudocode description of Vector Catch exceptions
Software Step exceptions	Takes the exception	Not applicable[b]	Pseudocode description of Software Step exceptions

a. If halting is allowed and EDSCR.HDE is 1, hardware breakpoints and watchpoints cause the PE to enter Debug state instead of causing debug exceptions. See Debug State.

b. Software Step is inactive if debug exceptions are disabled. No Software Step exceptions can be generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.2 Routing debug exceptions

Debug exceptions are routed to the *debug target Exception level*, EL_D, according to the following controls:

- HCR_EL2.TGE.
- MDCR_EL2.TDE.
- The Security state when the exception is taken.
- The Exception level where the exception is taken.

This means that, for all debug exceptions, EL_D is either EL1 or EL2.

Note

If EL2 is not implemented, the Effective value of HCR_EL2.TGE is 0 and the Effective value of MDCR_EL2.TDE is 0. Throughout this section, references to the values of these fields are to the Effective values of the fields.

The routing of debug exceptions is as follows:

Debug exceptions taken when EL2 is implemented and enabled in the current Security state

The routing of debug exceptions taken depends on the values of MDCR_EL2.TDE and HCR_EL2.TGE:

If the Effective value of {MDCR_EL2.TDE, HCR_EL2.TGE} is not {0, 0}

Debug exceptions are routed to EL2, EL_D is EL2.

Otherwise

Debug exceptions behave as follows:

- Debug exceptions taken from EL1 and EL0 are routed to EL1. EL_D is EL1.
- Breakpoint Instruction exceptions taken from EL2 are routed to EL2.
- All other debug exceptions are disabled from EL2 using AArch64.

When EL3 is implemented

Breakpoint Instruction exceptions taken from EL3 are routed to EL3.

All other debug exceptions are disabled from EL3 using AArch64.

Otherwise

Debug exceptions are routed to EL1. EL_D is EL1.

This means that, for all debug exceptions, the *debug target Exception level*, EL_D, is either EL1 or EL2.

Table D2-2, Table D2-3, and Table D2-4 show the routing of debug exceptions. In these tables:

NSE Means the Effective value of SCR_EL3.NSE. If FEAT_RME is not implemented, this is 0.

NS Means the Effective value of SCR_EL3.NS. If Secure state is not implemented, this is 1.

EEL2 Means the Effective value of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.

TDE or TGE Means the logical OR of the Effective value of MDCR_EL2.TDE and the Effective value of HCR_EL2.TGE.

(EL*x*) Means EL_D is EL*x*. However:

- All debug exceptions other than Breakpoint Instruction exceptions are disabled from this Exception level.
- Breakpoint Instruction exceptions taken when executing in this Exception level are routed to the same Exception level. This may not be the same as the EL_D Exception level.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL*x* Means EL_D is EL*x*.

Table D2-2 Routing when both EL3 and EL2 are implemented

NSE	NS	EEL2	TDE or TGE	EL_D when executing in:			
				EL0	EL1	EL2	EL3

Non-Confidential

D2.3 The debug exception enable controls

The enable controls for each debug exception are as follows:

Breakpoint Instruction exceptions

None. Breakpoint Instruction exceptions are always enabled.

Breakpoint exceptions

MDSCR_EL1.MDE, plus an enable control for each breakpoint, DBGBCR<n>_EL1.E.

If more than 16 breakpoints are implemented, then extended breakpoint and watchpoint enable controls are implemented for the additional breakpoints, MDCR_EL3.EBWE, MDCR_EL2.EBWE, MDSCR_EL1.EMBWE, and EDSCR2.EHBWE.

Watchpoint exceptions

MDSCR_EL1.MDE, plus an enable control for each watchpoint, DBGWCR<n>_EL1.E.

If more than 16 watchpoints are implemented, then extended breakpoint and watchpoint enable controls are implemented for the additional watchpoints, MDCR_EL3.EBWE, MDCR_EL2.EBWE, MDSCR_EL1.EMBWE, and EDSCR2.EHBWE.

Vector Catch exceptions

MDSCR_EL1.MDE.

Software Step exceptions

MDSCR_EL1.SS.

In addition, for all debug exceptions other than Breakpoint Instruction exceptions, software must configure the controls that enable debug exceptions from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state.

The PE cannot take a debug exception if debug exceptions are disabled from either the current Exception level or the current Security state.

Breakpoint Instruction exceptions are always enabled from the current Exception level and Security state.

D2.3.1 Enabling debug exceptions from the current Exception level and Security state

Debug exceptions are enabled from the current Exception level, where EL_D is the Exception level defined in Routing debug exceptions, as follows:

- When executing at any Exception level that is higher than EL_D:
  - Breakpoint Instruction exceptions are enabled.
  - All other debug exceptions are disabled.
- When executing at EL_D:
  - Breakpoint Instruction exceptions are enabled.
  - All other debug exceptions are disabled if either of the following is true:
    - The Local (kernel) Debug Enable bit, MDSCR_EL1.KDE, is 0.
    - The Debug exception mask bit, PSTATE.D, is 1.

  This means that a debugger must explicitly enable these debug exceptions from EL_D by setting MDSCR_EL1.KDE to 1 and PSTATE.D to 0.
- When executing at EL1, EL_D is EL2, and FEAT_NV2 is implemented:
  - Watchpoint debug exceptions generated by a System register access converted to a memory access because the Effective value of HCR_EL2.NV2 is 1 are disabled if MDSCR_EL1.KDE is 0 and enabled if MDSCR_EL1.KDE is 1. The value of PSTATE.D is ignored.
  - All other debug exceptions are enabled.
- Otherwise all debug exceptions are enabled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D2-5 shows when debug exceptions are enabled from the current Security state.

If EL3 and Secure state are implemented, software executing at EL3 can set the *Secure Debug Disable* bit, MDCR_EL3.SDD, to 1 to disable all debug exceptions taken from AArch64 Secure state other than Breakpoint Instruction exceptions.

The A-profile architecture does not support disabling debug exceptions in Non-secure state and, if FEAT_RME is implemented, Realm state.

Table D2-5 Whether debug exceptions are enabled from the current Security state

Current Security state	Breakpoint Instruction exceptions	All other debug exceptions
Non-secure	Enabled	Enabled
Secure	Enabled	Disabled if the Effective value of MDCR_EL3.SDD is 1. Otherwise enabled.
Realm	Enabled	Enabled
Root	Enabled	Disabled

If EL3 is not implemented and the implementation is a Secure state only implementation, or Secure state is not implemented, then the Effective value of MDCR_EL3.SDD is 0.

D2.3.2 Pseudocode description of enabling debug exceptions

`AArch64_GenerateDebugException()` determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the current Exception level and Security state.

`AArch64_GenerateDebugExceptionsFrom()` determines whether debug exceptions other than Breakpoint Instruction exceptions are enabled from the specified Exception level and Security state.

These functions are described in A-profile Architecture Pseudocode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.4 The effect of powerdown on debug exceptions

Debug OS Save and Restore sequences describes the *powerdown save routine* and the *restore routine*.

When executing either routine, software must use the OS Lock to disable generation of all of the following:

- Breakpoint exceptions.
- Watchpoint exceptions.
- Vector Catch exceptions.
- Software Step exceptions.

This is because the generation of these exceptions depends on the state of the debug registers, and the state of the debug registers might be lost over these routines.

If the OS Lock is unlocked, and `DoubleLockStatus()` == FALSE, debug exceptions other than Breakpoint Instruction exceptions are enabled.

If OS Lock is locked, or if `DoubleLockStatus()` ==TRUE, debug exceptions other than Breakpoint Instruction exceptions are disabled.

Breakpoint Instruction exceptions are enabled regardless of the state of the OS Lock and the OS Double Lock.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.5 Summary of the routing and enabling of debug exceptions

Behavior is as follows:

Breakpoint Instruction exceptions

These are always enabled, regardless of the current Exception level and Security state. A Breakpoint Instruction exception taken from EL3 is always routed to EL3. A Breakpoint Instruction exception taken from EL2 is routed to EL2. A Breakpoint Instruction exception taken from EL0 or EL1 is always routed to EL_D.

All other debug exceptions

Table D2-6 shows the valid combinations of MDCR_EL3.SDD, MDCR_EL2.TDE, MDSCR_EL1.KDE, and PSTATE.D, and for each combination shows where these exceptions are enabled from and where they are taken to. The table does not include the case when executing at EL1, EL_D is EL2, and FEAT_NV2 is implemented that is described in Enabling debug exceptions from the current Exception level and Security state.

In the table:

Lock Means the value of (OSLSR_EL1.OSLK == '1' || `DoubleLockStatus()`).

NSE Means the Effective value of SCR_EL3.NSE. If FEAT_RME is not implemented, this is 0.

NS Means the Effective value of SCR_EL3.NS. If Secure state is not implemented, this is 1.

SDD Means the Effective value of MDCR_EL3.SDD. See Disabling debug exceptions from Secure state.

EEL2 Means the Effective value of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.

TGE Means the Effective value of HCR_EL2.TGE. If EL2 is not implemented, the PE behaves as if this is 0.

TDE Means the Effective value of MDCR_EL2.TDE. If EL2 is not implemented, the PE behaves as if this is 0.

KDE Means the value of MDSCR_EL1.KDE.

D Means the value of PSTATE.D.

n/a Means not applicable. The PE cannot be executing at this Exception level.

- Means that debug exceptions are disabled from that Exception level.

Table D2-6 Routing of Breakpoint, Watchpoint, Software Step, and Vector Catch exceptions

D2.6 Pseudocode description of debug exceptions

The `AArch64_Abort()` function processes `FaultRecord` objects, as described in Abort exceptions, and generates a debug exception.

Some functions called by `AArch64_Abort()` are:

- `AArch64_BreakpointException()`.
- `AArch64_WatchpointException()`.
- `AArch64_VectorCatchException()`.
- `AArch64_InstructionAbort()`.
- `AArch64_DataAbort()`.

These functions are defined in A-profile Architecture Pseudocode.

D2.7 Breakpoint Instruction exceptions

This section describes Breakpoint Instruction exceptions in an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing one of the following:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.
- At EL0 using AArch32 when FEAT_VHE is implemented, EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

For software executing in an Exception level that is using AArch64, a Breakpoint Instruction exception results from the execution of an A64 `BRK` instruction. Within the AArch64 EL1&0 or EL2&0 translation regime, executing a T32 or A32 `BKPT` instruction at EL0 using AArch32 generates a Breakpoint Instruction exception.

For more information about the T32 and A32 `BKPT` instructions, see:

- Breakpoint instruction in the T32 and A32 instruction sets.
- BKPT instructions as the first instruction in an IT block.

The following subsections describe Breakpoint Instruction exceptions in an AArch64 translation regime:

- About Breakpoint Instruction exceptions.
- Breakpoint instructions.
- Exception syndrome information and preferred return address.
- Pseudocode description of Breakpoint Instruction exceptions.

D2.7.1 About Breakpoint Instruction exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint.*
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint Instruction exceptions, which this section describes, are software breakpoints. Breakpoint exceptions describes hardware breakpoints.

There is no enable control for Breakpoint Instruction exceptions. They are always enabled, and cannot be masked.

A Breakpoint Instruction exception is generated whenever a breakpoint instruction is committed for execution, regardless of all of the following:

- The current Exception level.
- The current Security state.
- Whether the *debug target Exception level*, EL_D, is using AArch64 or AArch32.

Note

Debuggers using breakpoint instructions must be aware of the rules for concurrent modification and execution of instructions. See Concurrent modification and execution of instructions.

D2.7.2 Breakpoint instructions

The breakpoint instruction in the A64 instruction set is `BRK #<immediate>`. It is unconditional.

For details of the instruction encoding, see BRK.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The breakpoint instruction in the T32 and A32 instruction sets is `BKPT #<immediate>`.

For more information about the T32 and A32 breakpoint instruction, see Breakpoint instruction in the T32 and A32 instruction sets.

D2.7.3 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address.

D2.7.3.1 Exception syndrome information

On taking a Breakpoint Instruction exception, the PE records information about the exception in the *Exception Syndrome Register* (ESR) at the Exception level the exception is taken to in ESR_ELx

Note

Breakpoint Instruction exceptions are the only debug exception that can be taken to EL3 using AArch64.

Table D2-7 shows the information that the PE records.

Table D2-7 Information recorded in the ESR_ELx

ESR_ELx field	Information recorded in ESR_EL1, ESR_EL2, or ESR_EL3.
Exception Class, EC	Whether the breakpoint instruction was executed in AArch64 state or AArch32 state. The PE sets this to: • `0x3C` for an A64 `BRK` instruction. • `0x38` for an A32 or T32 `BKPT` instruction.
Instruction Length, IL	The PE sets this to: • 0 for a 16-bit T32 `BKPT` instruction. • 1 for an A64 `BRK` instruction, or an A32 `BKPT` instruction.
Instruction Specific Syndrome, ISS	**ISS[24:16]** RES0. **ISS[15:0]** The PE copies the instruction Comment field value into here, zero extended as necessary.

Note

- If debug exceptions are routed to EL2, it is the exception that is routed, not the instruction that is trapped. Therefore, if a Breakpoint Instruction exception is routed to EL2, ESR_EL2.EC is set to the same value as if the exception was taken to EL1.
- For information about how debug exceptions can be routed to EL2, see Routing debug exceptions.

D2.7.3.2 Preferred return address

The preferred return address is the address of the breakpoint instruction, not the next instruction. This is different to the behavior of other exception-generating instructions, like `SVC`.

D2.7.4 Pseudocode description of Breakpoint Instruction exceptions

`AArch64_SoftwareBreakpoint()` generates a Breakpoint Instruction exception that is taken to AArch64 state.

This function is defined in A-profile Architecture Pseudocode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.8 Breakpoint exceptions

This section describes Breakpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing one of the following:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.
- At EL0 using AArch32 when FEAT_VHE is implemented, EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} == {1, 1}.

This section contains the following subsections:

- About Breakpoint exceptions.
- Breakpoint types and linking of breakpoints.
- Execution conditions for which a breakpoint generates Breakpoint exceptions.
- Breakpoint instruction address comparisons.
- Breakpoint context comparisons.
- Breakpoint usage constraints.
- Preferred return address.
- Pseudocode description of Breakpoint exceptions taken from an AArch64 stage 1 translation regime.

D2.8.1 About Breakpoint exceptions

A *breakpoint* is an event that results from the execution of an instruction, which is based on either:

- The instruction address, the PE context, or both. This type of breakpoint is called a *hardware breakpoint.*
- The instruction itself. That is, the instruction is a *breakpoint instruction*. These can be included in the program that the PE executes. This type of breakpoint is called a *software breakpoint*.

Breakpoint exceptions are generated by *Breakpoint debug events*. Breakpoint debug events are generated by hardware breakpoints. Software breakpoints are described in Breakpoint Instruction exceptions.

An implementation can include between 2-64 hardware breakpoints.

If AArch32 is supported at EL1 or FEAT_Debugv8p9 is not implemented, then the PE does not implement more than 16 breakpoints.

When more than 16 breakpoints are implemented, the number of breakpoints is identified to software by ID_AA64DFR1_EL1.BRPs and EDDFR1.BRPs. Otherwise ID_AA64DFR0_EL1.BRPs shows how many are implemented.

To use an implemented hardware breakpoint, a debugger programs the following registers for the breakpoint:

- The *Breakpoint Control Register*, DBGBCR<n>_EL1. This contains controls for the breakpoint, for example an enable control.
- The *Breakpoint Value Register*, DBGBVR<n>_EL1. This holds the value used for breakpoint matching, which is one of:
  - An instruction virtual address.
  - A Context ID.
  - A VMID value.
  - A concatenation of both a Context ID value and a VMID value.
  - If FEAT_VHE is implemented, a concatenation of two Context ID values.

These registers are numbered, so that:

- DBGBCR0_EL1 and DBGBVR0_EL1 are for breakpoint number zero.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- DBGBCR1_EL1 and DBGBVR1_EL1 are for breakpoint number one.
- . . .
- DBGBCR<n-1>_EL1 and DBGBVR<n-1>_EL1 are for breakpoint number (n-1).

A debugger can link a breakpoint that is programmed with an address and a breakpoint that is programmed with anything other than an address together, so that a Breakpoint debug event is generated only if both breakpoints match.

For each instruction in the program flow, all of the breakpoints are tested. When a breakpoint is tested, it generates a Breakpoint debug event if all of the following are true:

- The breakpoint is enabled. That is, the Effective value of DBGBCR<n>_EL1.E is 1.
- The conditions specified in the DBGBCR<n>_EL1 are met.
- The comparison with the value held in the DBGBVR<n>_EL1 is successful.
- If the breakpoint is linked to another breakpoint, the comparisons made by that other breakpoint are also successful.
- The instruction is committed for execution.

The address of each instruction is compared against the DBGBVR<n>_EL1 values of all Address matching breakpoints with linking disabled that can generate a breakpoint match at the current Exception level in the current Security state, possibly after the application of a breakpoint mask, and:

- The Boolean equality comparison results of all the address match breakpoints are OR'd together to generate a first result.
- The Boolean inequality comparison results of all the address mismatch breakpoints are AND'd together to generate a second result.

Note

Because ranges have power-of-two sizes and are aligned, it is not possible to configure strictly overlapping pairs of ranges. Only non-overlapping or subsets can be selected.

The resulting address match is:

- False, if there are no such breakpoints.
- The first result, if all such breakpoints are address match breakpoints.
- The second result, if all such breakpoints are address mismatch breakpoints.
- The logical-AND of the first result and the second result, if there is a mix of address match and address mismatch breakpoints.

This address match result is OR'd with the Boolean results of all Context matching breakpoints with linking disabled that are enabled and can generate a breakpoint match at the current Exception level in the current Security state. The breakpoint generates the Breakpoint debug event regardless of the following:

- Whether the instruction passes its Condition code check.
- The instruction type.

Note

This does not apply to breakpoints with linking enabled. A breakpoint with linking enabled only delivers its result to the breakpoint(s) and/or watchpoint(s) linked to it, if any.

If halting is allowed and EDSCR.HDE is 1, Breakpoint debug events cause entry to Debug state.

Otherwise, if debug exceptions are:

- Enabled, Breakpoint debug events generate Breakpoint exceptions.
- Disabled, Breakpoint debug events are ignored.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The remainder of this Breakpoint exceptions section, including all subsections, describes breakpoints as generating Breakpoint exceptions.
However, the behavior described also applies if breakpoints are causing entry to Debug state.

Example D2-1 shows an example of setting an address match breakpoint and an address mismatch breakpoint, and the conditions that cause a breakpoint exception.

Example D2-1 Breakpoint address match and breakpoint address mismatch

Two breakpoints are programmed as follows:

- Breakpoint 0 is programmed with:
  - DBGBCR0_EL1.{BT2, BT} = *Address match breakpoint*.
  - DBGBCR0_EL1.MASK = M_0, where $M_0 > 2$.
  - DBGBVR0_EL1 = A_0, where A_0 is aligned to 2^{M_0}.

  This means that breakpoint 0 will match an instruction address B if it is within a range, as follows:
  $B \in \{A_0, A_0 + 4, \ldots (A_0 + 2^{M_0} - 4)\}$
  $\Rightarrow (A_0 \leq B) \wedge (B < A_0 + 2^{M_0})$
- Breakpoint 1 is programmed with:
  - DBGBCR1_EL1.{BT2, BT} = *Address mismatch breakpoint*.
  - DBGBCR1_EL1.MASK = M_1, where $M_1 > 2$.
  - DBGBVR1_EL1 = A_1, where A1 is aligned to 2^{M_1}.

  This means that breakpoint 1 will match an instruction address B if it is outside of a range, as follows:
  $B \notin \{A_1, A_1 + 4, \ldots (A_1 + 2^{M_1} - 4)\}$
  $\Rightarrow (B < A_1) \vee (B \geq A_1 + 2^{M_1})$
- Such that $\{A_1, A_1 + 4, \ldots (A_1 + 2^{M_1} - 4)\} \subset \{A_0, A_0 + 4, \ldots (A_0 + 2^{M_0} - 4)\}$.
- Both breakpoints match at the current Exception level in the current Security state.

Then the combination of these two breakpoints will only generate a breakpoint for an instruction address B if it is both within the first range and outside of the second range, as follows:

$B \in \{A_0, A_0 + 4, \ldots (A_0 + 2^{M_0} - 1)\} \wedge B \notin \{A_1, A_1 + 4, \ldots (A_1 + 2^{M_1} - 4)\}$

$\Rightarrow B \in \{A_0, A_0 + 4, \ldots (A_1 - 4), (A_1 + 2^{M_1}), (A_1 + 2^{M_1} + 4), \ldots (A_0 + 2^{M_0} - 4)\}$

$\Rightarrow ((A_0 \leq B) \wedge (B < A_1)) \vee ((B \geq A_1 + 2^{M_1}) \wedge (B < A_0 + 2^{M_0}))$

The debug exception enable controls describes the enable controls for Breakpoint debug events.

D2.8.2 Accessing breakpoint System registers

R_{MLTYN} When any of the following are true, the Effective value of MDSELR_EL1.BANK is zero:

- Executing at EL3 and MDCR_EL3.EBWE is 0.
- Executing at EL2 and the Effective value of MDCR_EL2.EBWE is 0.
- Executing at EL1 and the Effective value of MDSCR_EL1.EMBWE is 0.

R_{JGQGB} If all of the following are true, MDSELR_EL1 is RES0:

- FEAT_Debugv8p9 is implemented.
- 16 or fewer breakpoints are implemented.
- 16 or fewer watchpoints are implemented.

R_{KSCWV} The MRS and MSR System register names for accessing breakpoint control registers DBGBCR<n>_EL1 and breakpoint value registers DBGBVR<n>_EL1 are mapped to physical registers as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The register names DBGBCR0_EL1 through DBGBCR15_EL1 are mapped to the physical registers DBGBCR<BANK×16+0>_EL1 through DBGBCR<BANK×16+15>_EL1.
- The register names DBGBVR0_EL1 through DBGBVR15_EL1 are mapped to the physical registers DBGBVR<BANK×16+0>_EL1 through DBGBVR<BANK×16+15>_EL1.

IHMNFZ MSR and MRS instructions using the breakpoint System register names in RKSCWV make indirect reads of MDSELR_EL1.BANK. This means that direct writes to MDSELR_EL1.BANK must be explicitly synchronized before a direct read or direct write using any of these System register names.

D2.8.3 Breakpoint types and linking of breakpoints

Each implemented breakpoint is one of the following:

- A *context-aware* breakpoint. This is a breakpoint that can be programmed to generate a Breakpoint exception on any one of the following:
  - An instruction address match or mismatch.
  - A Context ID match, with the value held in CONTEXTIDR_EL1 or the value held in CONTEXTIDR_EL2.
  - A VMID match, with the VMID value held in VTTBR_EL2.
  - Both a Context ID match and a VMID match.
- A breakpoint that is not *context-aware*. These can only be programmed to generate a Breakpoint exception on an instruction address match.

If more than 16 *context-aware* breakpoints are implemented, the number of *context-aware* breakpoints is identified to software by ID_AA64DFR1_EL1.CTX_CMPs and EDDFR1.CTX_CMPs. Otherwise ID_AA64DFR0_EL1.CTX_CMPs indicates how many are implemented.

At least one breakpoint must be *context-aware*.

If 16 or fewer breakpoints are implemented, the highest numbered are *context-aware*.

If more than 16 breakpoints are implemented:

- If 16 or fewer are *context-aware*, these are the highest numbered breakpoints up to breakpoint number 15.
- Otherwise, *context-aware* breakpoints are numbered consecutively beginning at breakpoint number 0.

Any breakpoint that is programmed to generate a Breakpoint exception on an instruction address match is categorized as an *Address breakpoint*. Breakpoints that are programmed to match on anything else are categorized as *Context breakpoints*.

When a debugger programs a breakpoint to be an Address or a Context breakpoint, it must also program that breakpoint so that it is either:

- Used in isolation. In this case, the breakpoint is called an *Unlinked breakpoint*.
- Linked to another Context matching breakpoint. In this case, the breakpoint is called a *Linked breakpoint*.
- Enabled for linking from another breakpoint or watchpoint. In this case, the breakpoint has *Linking enabled* and does not generate debug events in isolation.

By linking an Address breakpoint and a Context breakpoint together, the debugger can create a breakpoint pair that generates a Breakpoint exception only if the PE is in a particular context when an instruction address match occurs. This is shown in Example D2-2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D2-2 Linking an Address breakpoint and a Context breakpoint

For example, a debugger might:

1. Program breakpoint number one to be a *Linked Address Match breakpoint*.
2. Program breakpoint number five to be a *Context matching breakpoint with linking enabled*.
3. Link these two breakpoints together. A Breakpoint exception is generated only if both the instruction address matches and the Context ID matches.

The *Breakpoint Type* fields for a breakpoint, DBGBCR<n>_EL1.{BT2, BT}, control the breakpoint type and whether the breakpoint is enabled for linking.

If AArch32 state is implemented, Address breakpoints can be programmed to generate Breakpoint exceptions on addresses that are halfword-aligned but not word-aligned. This makes it possible to breakpoint on T32 instructions. See Specifying the halfword-aligned address that an Address breakpoint matches on.

D2.8.3.1 Rules for linking breakpoints

The rules for breakpoint linking are as follows:

- Only Linked Address breakpoint types can be linked.
- Any type of Linked Address breakpoint can link to any type of Context matching breakpoint with linking enabled.

  The *Linked Breakpoint Number* field, DBGBCR<n>_EL1.{LBNX, LBN}, for the Linked Address breakpoint specifies the particular Context matching breakpoint that the Linked Address breakpoint links to, and:

  — The {LBNX, LBN} fields are ignored if the breakpoint is not a Linked Address breakpoint.

  — DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} for the Linked Address breakpoint define the execution conditions that the breakpoint pair generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions.

  — DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} for the Context matching breakpoint with linking enabled are ignored.
- Linked Address breakpoints cannot link to watchpoints. The {LBNX, LBN} fields always specify a breakpoint.
- If a Linked Address breakpoint links to a breakpoint that is not *context-aware* or does not have linking enabled, the behavior of the Linked Address breakpoint is CONSTRAINED UNPREDICTABLE. See Other usage constraints for Address breakpoints.

A single Context matching breakpoint with linking enabled might be linked to by all, or any combination of, the following:

- Multiple Linked Address breakpoints.
- Multiple Linked watchpoints.

If FEAT_ABLE is implemented, a single Address matching breakpoint with linking enabled might be linked to by multiple Linked watchpoints.

Note

If FEAT_NV2 is implemented, the hypervisor must use the `{0b0, 0b1101}`, CONTEXTIDR_EL2 Match breakpoint with linking enabled type to guarantee a linked match, see Interaction with self-hosted and External debug.

If no linked breakpoints and no linked watchpoints link to a breakpoint programmed with linking enabled, then the breakpoint does not generate any Breakpoint exceptions or debug events.

Figure D2-1 shows an example of permitted breakpoint and watchpoint linking.

Non-Confidential

Figure D2-1 The role of linking in Breakpoint and Watchpoint exception generation

In Figure D2-1, each Linked Address breakpoint can generate a Breakpoint exception only if the comparisons made by both it, and the breakpoint that it links to, are successful. Similarly, each Linked watchpoint can only generate a Watchpoint exception if the comparisons made by both it, and the breakpoint that it links to, are successful.

D2.8.3.2 Breakpoint types defined by DBGBCR<n>_EL1.{BT2, BT}

If FEAT_ABLE is not implemented then the Effective value of DBGBCR<n>_EL1.BT2 is 0.

The following lists provides more detail about each breakpoint type:

`{0b0, 0b0000}`, **Unlinked Address Match breakpoint**

Generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful address match, as described in Breakpoint instruction address comparisons.

DBGBCR<n>_EL1.{LBNX, LBN} for this breakpoint are ignored.

`{0b0, 0b0001}`, **Linked Address Match breakpoint**

Generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} for this breakpoint. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A successful address match defined by this breakpoint, as described in Breakpoint instruction address comparisons.
- A successful context match defined by the Context breakpoint with linking enabled that this breakpoint links to.

DBGBCR<n>_EL1.{LBNX, LBN} for this breakpoint selects the Context breakpoint with linking enabled that this breakpoint links to.

`{0b0, 0b0010}`, **Context ID Match breakpoint**

{BT2, BT} == `{0b0, 0b0010}` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons.

The value of DBGBVR<n>_EL1.ContextID is compared with the current Context ID.

CONTEXTIDR_EL2 holds the current Context ID when all of:

- The implementation includes FEAT_VHE.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and the Effective value of HCR_EL2.E2H is 1.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.

Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

DBGBCR<n>_EL1.{LBNX, LBN, BAS} for this breakpoint are ignored

`{0b0, 0b0011}`, **Context ID Match breakpoint with linking enabled**

{BT2, BT} == `{0b0, 0b0011}` is a reserved value if the breakpoint is not a context-aware breakpoint.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.

The value of DBGBVR<n>_EL1.ContextID is compared with the current Context ID.

CONTEXTIDR_EL2 holds the current Context ID when all of:

- The implementation includes FEAT_VHE.
- EL2 is implemented and enabled in the current Security state.
- EL2 using AArch64 and the Effective value of HCR_EL2.E2H is 1.
- The PE is executing at EL0 and HCR_EL2.TGE is 1, or the PE is executing at EL2.

Otherwise, CONTEXTIDR_EL1 holds the current Context ID.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`{0b0, 0b0100}`, **Unlinked Address Mismatch breakpoint**

{BT2, BT} == `{0b0, 0b0100}` is a reserved value unless one of the following applies:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- FEAT_BWE is implemented.
- EL1 is using AArch32.

In stage 1 of an AArch64 translation regime, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful address mismatch, as described in Breakpoint instruction address comparisons.

DBGBCR<n>_EL1.{LBNX, LBN} for this breakpoint is ignored.

`0b0100`, Unlinked Address Mismatch breakpoint describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

`{0b0, 0b0101}`, **Linked Address Mismatch breakpoint**

{BT2, BT} == {`0b0`, `0b0101`} is a reserved value unless one of the following applies:

- FEAT_BWE is implemented.
- EL1 is using AArch32.

In stage 1 of an AArch64 translation regime, generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates Breakpoint exceptions for. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful address mismatch defined by this breakpoint, as described in Breakpoint instruction address comparisons.
- A successful context match defined by the Context matching breakpoint that this breakpoint links to.

DBGBCR<n>_EL1.{LBNX, LBN} for this breakpoint selects the Context matching breakpoint that this breakpoint links to.

`0b0101`, Linked Address Mismatch breakpoint describes the behavior of Address Mismatch breakpoints in stage 1 of an AArch32 translation regime.

`{0b0, 0b0110}`, **CONTEXTIDR_EL1 Match breakpoint**

{BT2, BT} == {`0b0`, `0b0110`} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include FEAT_VHE.

In an implementation that includes FEAT_VHE, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

Note

The operation of this breakpoint does not depend on the Effective value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBNX, LBN, BAS} for this breakpoint are ignored.

`{0b0, 0b0111}`, **CONTEXTIDR_EL1 Match breakpoint with linking enabled**

{BT2, BT} == {`0b0`, `0b0111`} is a reserved value if either:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The breakpoint is not a context-aware breakpoint.
- The implementation does not include FEAT_VHE.

In an implementation that includes FEAT_VHE, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.

The Context ID check is made against the value in CONTEXTIDR_EL1. The value of DBGBVR<n>_EL1.ContextID is compared with the Context ID value held in CONTEXTIDR_EL1.

Note

The operation of this breakpoint does not depend on the Effective value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`{0b0, 0b1000}`, **VMID Match breakpoint**

{BT2, BT} == {`0b0`, `0b1000`} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful VMID match, as described in Breakpoint context comparisons.

DBGBCR<n>_EL1.{LBNX, LBN, BAS} for this breakpoint are ignored.

`{0b0, 0b1001}`, **VMID Match breakpoint with linking enabled**

{BT2, BT} == {`0b0`, `0b1001`} is a reserved value if either:

- The breakpoint is not a context-matching breakpoint.
- EL2 is not implemented.

For context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address Match breakpoint that links to this breakpoint. See Breakpoint instruction address comparisons.
  - A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— A successful VMID match defined by this breakpoint, as described in Breakpoint context comparisons.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`{0b0, 0b1010}`, **Context ID and VMID Match breakpoint**

{BT2, BT} == {`0b0`, `0b1010`} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on all of the following:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions that the breakpoint generates a Breakpoint exception for. See Execution conditions for which a breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons.
- A successful VMID match.

The value of DBGBVR<n>_EL1.ContextID is compared with CONTEXTIDR_EL1.

Breakpoint context comparisons describes the requirements for a successful Context ID match and a successful VMID match.

DBGBCR<n>_EL1.{LBNX, LBN, BAS} for this breakpoint are ignored.

`{0b0, 0b1011}`, **Context ID and VMID Match breakpoint with linking enabled**

{BT2, BT} == {`0b0`, `0b1011`} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- EL2 is not implemented.

When EL2 is implemented, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on all of the following:
  - — A successful instruction address match, defined by a Linked Address breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.
  - — A successful VMID match defined by this breakpoint.
- Generation of a Watchpoint exception depends on all of the following:
  - — A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - — A successful Context ID match defined by this breakpoint, as described in Breakpoint context comparisons.
  - — A successful VMID match defined by this breakpoint.

The value of DBGBVR<n>_EL1.ContextID is compared with CONTEXTIDR_EL1.

Breakpoint context comparisons describes the requirements for a successful Context ID match and a successful VMID match by this breakpoint.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`{0b0, 0b1100}`, **CONTEXTIDR_EL2 Match breakpoint**

{BT2, BT} == {`0b0`, `0b1100`} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

Note

The operation of this breakpoint does not depend on the Effective value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBNX, LBN, BAS} for this breakpoint are ignored.

`{0b0, 0b1101}`**, CONTEXTIDR_EL2 Match breakpoint with linking enabled**

{BT2, BT} == {`0b0`, `0b1101`} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, either:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful CONTEXTIDR_EL2 match, as described in Breakpoint context comparisons.

The Context ID check is made against the value in CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1 is compared with the Context ID value held in CONTEXTIDR_EL2.

Note

The operation of this breakpoint does not depend on the Effective value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`{0b0, 0b1110}`**, Full Context ID Match breakpoint**

{BT2, BT} == {`0b0`, `0b1110`} is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, generation of a Breakpoint exception depends on both:

- DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC}. These define the execution conditions for which the breakpoint generates Breakpoint exceptions.
- A successful Context ID match, as described in Breakpoint context comparisons.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1[31:0] is compared with the Context ID value

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

held in CONTEXTIDR_EL1, and the value of DBGBVR<n>_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

Note

The operation of this breakpoint does not depend on the Effective value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBNX, LBN, BAS} for this breakpoint are ignored.

`{0b0, 0b1111}`, **Full Context ID Match breakpoint with linking enabled**

{BT2, BT} == `{0b0, 0b1111}` is a reserved value if either:

- The breakpoint is not a context-aware breakpoint.
- FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, which means the implementation does not include CONTEXTIDR_EL2.

In an implementation in which FEAT_VHE is implemented or FEAT_Debugv8p2 is implemented, for context-aware breakpoints, one of the following applies:

- If no Linked breakpoints or Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Breakpoint exception depends on both:
  - A successful instruction address match, defined by a Linked Address match breakpoint that links to this breakpoint, see Breakpoint instruction address comparisons.
  - A successful Context ID match, as described in Breakpoint context comparisons.
- Generation of a Watchpoint exception depends on both:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful Context ID match, as described in Breakpoint context comparisons.

The Context ID check is made against the values in both CONTEXTIDR_EL1 and CONTEXTIDR_EL2. The value of DBGBVR<n>_EL1[31:0] is compared with the Context ID value held in CONTEXTIDR_EL1, and the value of DBGBVR<n>_EL1[63:32] is compared with the Context ID value held in CONTEXTIDR_EL2. Both comparisons must match for the Context ID check.

Note

The operation of this breakpoint does not depend on the Effective value of HCR_EL2.E2H.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, BAS, PMC} for this breakpoint are ignored.

`{0b1, 0b0000}`, **Unlinked Address Match breakpoint with linking enabled**

{BT2, BT} == `{0b1, 0b0000}` is a reserved value if the breakpoint does not support being configured as an address matching breakpoint with linking enabled.

Otherwise, one of the following applies:

- If no Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Watchpoint exception by an instruction depends on the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful instruction address match, as described in Breakpoint instruction address comparisons.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, PMC} for this breakpoint are ignored.

`{0b1, 0b0001}`, **Linked Address Match breakpoint with linking enabled**

{BT2, BT} == `{0b1, 0b0001}` is a reserved value if the breakpoint does not support being configured as an address matching breakpoint with linking enabled.

Otherwise, one of the following applies:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If no Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Watchpoint exception by an instruction depends on the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful instruction address match defined by this breakpoint, as described in Breakpoint instruction address comparisons.
  - A successful context match defined by the Context matching breakpoint with linking enabled that this breakpoint links to.

DBGBCR<n>_EL1.{LBNX, LBN} for this breakpoint selects the Context matching breakpoint with linking enabled that this breakpoint links to.

DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} for this breakpoint are ignored.

`{0b1, 0b0100}`**, Unlinked Address Mismatch breakpoint with linking enabled**

{BT2, BT} == {`0b1`, `0b0100`} is a reserved value if one of the following applies:

- The breakpoint does not support being configured as an address matching breakpoint with linking enabled.
- FEAT_BWE is not implemented.

Otherwise, one of the following applies:

- If no Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Watchpoint exception by an instruction depends on the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful instruction address match, as described in Breakpoint instruction address comparisons.

DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, PMC} for this breakpoint are ignored.

`{0b1, 0b0101}`**, Linked Address Mismatch breakpoint with linking enabled**

{BT2, BT} == {`0b1`, `0b0101`} is a reserved value if one of the following applies:

- The breakpoint does not support being configured as an address matching breakpoint with linking enabled.
- FEAT_BWE is implemented.

Otherwise, one of the following applies:

- If no Linked watchpoints link to this breakpoint, then the breakpoint does not generate any debug exceptions.
- Generation of a Watchpoint exception by an instruction depends on the following:
  - A successful data address match, defined by a Linked watchpoint that links to this breakpoint, see Watchpoint data address comparisons.
  - A successful instruction address match defined by this breakpoint, as described in Breakpoint instruction address comparisons.
  - A successful context match defined by the Context matching breakpoint with linking enabled that this breakpoint links to.

DBGBCR<n>_EL1.{LBNX, LBN} for this breakpoint selects the Context matching breakpoint that this breakpoint links to.

DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} for this breakpoint are ignored.

Note

See Reserved DBGBCR<n>_EL1.{BT2, BT} values for the behavior of breakpoints programmed with reserved {BT2, BT} values.

D2.8.4 Execution conditions for which a breakpoint generates Breakpoint exceptions

Each breakpoint can be programmed so that it generates Breakpoint exceptions only for certain execution conditions. For example, a breakpoint might be programmed to generate Breakpoint exceptions only when the PE is executing at EL0 in Secure state.

DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} defines the execution conditions the breakpoint generates Breakpoint exceptions for, as follows:

Security State Control Extension, SSCE, and Security State Control, SSC

SSCE and SSC control whether the breakpoint generates Breakpoint exceptions in only one Security state or in multiple Security states.

Note

This is determined by the Security state of the PE, not from the physical address space attribute returned by the translation of the virtual address on which the breakpoint is set.

Higher Mode Control, HMC, and Privileged Mode Control, PMC

HMC and PMC together control which Exception levels the breakpoint generates Breakpoint exceptions in.

Table D2-8 shows the valid combinations of the values of HMC, SSCE, SSC, and PMC, and for each combination shows which Exception levels breakpoints generate Breakpoint exceptions in.

In the table:

NS Non-secure state.

S Secure state.

RL In implementations that include FEAT_RME, Realm state.

RT In implementations that include FEAT_RME, Root state.

Y or - Means that a breakpoint programmed with the values of HMC, SSCE, SSC, and PMC shown in that row:

- **Y** Can generate Breakpoint exceptions in that Exception level and Security state.
- **-** Cannot generate Breakpoint exceptions in that Exception level and Security state.

Table D2-8 Summary of breakpoint HMC, SSCE, SSC, and PMC encodings

HMC	SSCE	SSC	PMC	Security states	EL3[a]	EL2	EL1	EL0
0	0	00	01	RL, S, NS	-	-	Y	-

1	0	11	01		-	Y	Y	-
1	0	11	11		-	Y	Y	Y
1	1	01	00	RL	-	Y	-	-
1	1	01	01		-	Y	Y	-
1	1	01	11		-	Y	Y	Y

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSCE, SSC, and PMC are relevant only if breakpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSCE, SSC, and PMC that generate Breakpoint exceptions at EL3 using AArch64.

b. If FEAT_RME is implemented, this combination specifies Root state. Otherwise, Secure state.

All combinations of HMC, SSCE, SSC, and PMC that Table D2-8 does not show are reserved. A combination in Table D2-8 might be reserved if an Exception level or Security state is not implemented. For information about which combinations of HMC, SSCE, SSC, and PMC are reserved if an Exception level or Security state is not implemented, see Reserved DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} values.

D2.8.5 Breakpoint instruction address comparisons

In this subsection, the term `AddrTop` represents the most significant bit of a virtual address used by breakpoint data address comparisons. `AddrTop` is:

- 55, if address tagging is used for the address. See Address tagging.
- 63, otherwise.

Note

When stage 1 translation is enabled, in AArch64 state, the virtual address size is determined by the configured input address size for the stage 1 translation. Software can configure a smaller address width for a virtual address, see Input address size configuration. Attempting to translate an address that is larger than the configured input address size generates a Translation fault.
When stage 1 translation is disabled, using an address that is larger than the implemented PA size generates an Address size fault. The implemented PA size is IMPLEMENTATION DEFINED, as described in Implemented physical address size. These faults have a higher priority than breakpoints.

An address comparison is successful if bits [`AddrTop`:2] of the current instruction virtual address are equal to DBGBVR<n>_EL1[`AddrTop`:2].

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

DBGBVR<n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits. DBGBVR<n>_EL1[1:0] are RES0 and are ignored.

If EL1 is using AArch64 and EL0 is using AArch32, T32 and A32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the instruction addresses are zero-extended before comparison with the breakpoint.

D2.8.5.1 Specifying the halfword-aligned address that an Address breakpoint matches on

For Address Match breakpoints, if the implementation supports AArch32 state, a debugger must program the *Byte Address Selection* field, DBGBCR<n>_EL1.BAS.

Table D2-9 Programmable BAS values

BAS	Match instruction at	Constraint for debuggers
`0b0011`	DBGBVR<n>_EL1	Use for T32 instructions.
`0b1100`	DBGBVR<n>_EL1 + 2	Use for T32 instructions.
`0b1111`	DBGBVR<n>_EL1	Use for A64 and A32 instructions.

If the implementation is an AArch64-only implementation, all instructions are word-aligned and DBGBCR<n>_EL1.BAS is RES1.

Figure D2-2 shows a summary of when Address Match breakpoints programmed with particular BAS values generate Breakpoint exceptions. The figure contains four parts:

- A column showing the row number, on the left.
- An instruction set and instruction size table.
- A location of instruction figure.
- A BAS field values table, on the right.

To use the figure, read across the rows. For example, row 7 shows that a breakpoint with DBGBCR<n>_EL1.BAS programmed as either `0b0011` or `0b1111` generates Breakpoint exceptions for A64 instructions. A64 instructions are always at word-aligned addresses.

Note

To breakpoint on an A64 instruction, Arm recommends that the debugger programs DBGBCR<n>_EL1.BAS as `0b1111`.

In the figure:

Yes Means that the breakpoint generates a Breakpoint exception.

No Means that the breakpoint does not generate a Breakpoint exception.

UNP Means that is it CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception. See Other usage constraints for Address breakpoints.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

	Instruction set	Size	Location of instruction[a]								BAS[3:0]		
			-2	-1	0	+1	+2	+3	+4	+5	0b0011	0b1100	0b1111
Row 1	T32	16-bit			■	■					Yes	No	Yes
Row 2		16-bit					■	■			No	Yes	UNP
Row 3	T32	32-bit	■	■	■	■					UNP	No	UNP
Row 4		32-bit			■	■	■	■			Yes	UNP	Yes
Row 5		32-bit					■	■	■	■	No	Yes	UNP
Row 6	A32	32-bit			■	■	■	■			Yes	UNP	Yes
Row 7	A64	32-bit			■	■	■	■			Yes	UNP	Yes

a. 0 means the word-aligned address held in the DBGBVR<n>_EL1[maxAddressSize:2]:00.
The other locations are as follows:
- -2 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) - 2).
- -1 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) - 1).
- ...
- ...
- +5 means ((DBGBVR<n>_EL1[maxAddressSize:2]:00) + 5).

The solid areas show the location of the instruction.

Figure D2-2 Summary of BAS field meanings for Address Match breakpoints

D2.8.5.2 Address Mismatch breakpoints

If FEAT_BWE is not implemented, then mismatch breakpoints do not generate a breakpoint match in AArch64 state.

If FEAT_BWE is implemented, then mismatch breakpoints can generate a breakpoint match in AArch64 state and this can cause entry to Debug state.

The behavior of an address mismatch breakpoint is the same as for an address match breakpoint, except that the result is inverted such that only addresses other than the specified address, or addresses outside of the range of addresses, generate a breakpoint match.

Other breakpoint conditions specified by DBGBCR<n>_EL1 are not inverted.

D2.8.5.3 Programming a breakpoint range with eight or more bytes

A debugger can use the DBGBCR<n>_EL1.MASK field to program a single breakpoint with an instruction address range if all of the following are true:

- It is a size that is:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.
- It starts at an address that is aligned to the size.

If *m* least significant address bits are masked, the breakpoint generates a Breakpoint exception on all of the following:

- Address DBGBCR<n>_EL1[`AddrTop`:*m*]:000...
- Address DBGBCR<n>_EL1[`AddrTop`:*m*]:111...
- Any address between these two addresses.

For example, if the four least significant address bits are masked, Breakpoint exceptions are generated for all addresses between DBGBCR<n>_EL1[`AddrTop`:4]:0000 and DBGBCR<n>_EL1[`AddrTop`:4]:1111, including these addresses.

When masking address bits, a debugger must both:

- Program DBGBCR<n>_EL1.BAS to be `0b1111`. See Programming dependencies of the BAS and MASK fields.
- In DBGBVR<n>_EL1, set the masked address bits to zero. See Other usage constraints.

D2.8.6 Breakpoint context comparisons

The breakpoint type defined by DBGBCR<n>_EL1.BT determines what context comparison is required, if any. Table D2-10 shows the BT values that require a comparison, and the match required for the comparison to be successful.

Table D2-10 Breakpoint Context ID and VMID comparison tests

DBGBCR<n>.BT	Test required for successful context comparison
0b001x	• When FEAT_VHE is implemented, EL2 is using AArch64, the Effective value of HCR_EL2.E2H is 1, and either the PE is executing at EL0 with HCR_EL2.TGE set to 1, or the PE is executing at EL2, CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID value. • Otherwise, CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value.
0b011x	CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value.
0b100x	VTTBR_EL2.VMID must match the DBGBVR<n>_EL1.VMID value.
0b101x	CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value and VTTBR_EL2.VMID must match the DBGBVR<n>_EL1.VMID value.
0b110x	CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID2 value, DBGBVR<n>_EL1[63:32].
0b111x	Both: • CONTEXTIDR_EL1 must match the DBGBVR<n>_EL1.ContextID value, DBGBVR<n>_EL1[31:0]. • CONTEXTIDR_EL2 must match the DBGBVR<n>_EL1.ContextID2 value, DBGBVR<n>_EL1[63:32].

No Context ID or VMID comparison is required for other valid DBGBCR.BT values.

Context breakpoints do not generate Breakpoint exceptions when any of:

- The comparison uses the value of CONTEXTIDR_EL1 and any of:
  - The PE is executing at EL3 using AArch64.
  - The PE is executing at EL2.
  - FEAT_VHE is implemented, EL2 is using AArch64, EL2 is enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.
- The comparison uses the value of CONTEXTIDR_EL2 and any of:
  - Neither FEAT_VHE is implemented, nor FEAT_Debugv8p2 is implemented.
  - The PE is in Secure state, and either FEAT_SEL2 is not implemented, or Secure EL2 is disabled.
  - The PE is executing at EL3.
  - EL2 is using AArch32.
  - EL2 is not implemented.
- The comparison uses the current VMID value and any of:
  - EL2 is not implemented.
  - The PE is in Secure state, and either FEAT_SEL2 is not implemented, or Secure EL2 is disabled.
  - The PE is executing at EL2.
  - The PE is executing at EL3.
  - FEAT_VHE is implemented, EL2 is using AArch64, EL2 is enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

Note

- For all Context breakpoints, DBGBCR<n>_EL1.BAS is RES1 and is ignored.
- For Context matching breakpoints with linking enabled, DBGBCR<n>_EL1.{LBNX, LBN, SSCE, SSC, HMC, PMC} are RES0 and are ignored.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.8.7 Breakpoint usage constraints

See the following sections:

- Reserved DBGBCR<n>_EL1.{BT2, BT} values.
- Reserved DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} values.
- Programming dependencies of the BAS and MASK fields.
- Reserved DBGBCR<n>_EL1.BAS values.
- Usage constraints on DBGBCR<n>_EL1.{LBNX, LBN} values.
- Reserved DBGWCR<n>_EL1.MASK values.
- Other usage constraints for Address breakpoints.
- Other usage constraints for Context breakpoints.

D2.8.7.1 Reserved DBGBCR<n>_EL1.{BT2, BT} values

Table D2-11 shows when particular DBGBCR<n>_EL1.BT values are reserved.

Table D2-11 Reserved BT values when the Effective value of DBGBCR<n>_EL1.BT2 is 0

BT value	Breakpoint type	Reserved
`0b001x`	Context ID Match	If the breakpoint is not *context-aware*.
`0b010x`	Address Mismatch	If FEAT_BWE is not implemented and one of the following: • In stage 1 of an AArch64 translation regime. • EDSCR.HDE is 1 and halting is allowed.
`0b011x`	CONTEXTIDR_EL1 Match	If FEAT_VHE is not implemented, or the breakpoint is not *context-aware*.
`0b100x`	VMID Match	If EL2 is not implemented, or the breakpoint is not *context-aware*.
`0b101x`	Context ID and VMID Match	If EL2 is not implemented, or the breakpoint is not *context-aware*.
`0b110x`	CONTEXTIDR_EL2 Match	If FEAT_VHE is not implemented and FEAT_Debugv8p2 is not implemented, or if the breakpoint is not *context-aware*.
`0b111x`	Full Context ID Match	

If FEAT_ABLE is implemented and BT2 is 1, all values of BT other than `0b0x0x` are reserved.

If a breakpoint is programmed with one of these reserved {BT2, BT} values:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a {BT2, BT} value that is not reserved, other than for a direct or external read of DBGBCR<n>_EL1.
- For a direct or external read of DBGBCR<n>_EL1, if the reserved {BT2, BT} value:
  - Has no function for any execution conditions, the value read back is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the {BT2, BT} value so that the breakpoint functions for the other execution conditions.

The behavior of breakpoints with reserved {BT2, BT} values might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.8.7.2 Reserved DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} values

Table D2-12 shows when particular combinations of the Effective value of DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} are reserved in stage 1 of an AArch64 translation regime.

When FEAT_RME is not implemented, DBGBCR<n>_EL1.SSCE is RES0, and its Effective value is 0.

Table D2-12 Reserved HMC, SSCE, SSC, and PMC combinations

Condition	Reserved combinations of the Effective value of HMC, SSCE, SSC, and PMC
Secure state is not implemented.	Any combination when HMC is 0, the Effective value of SSCE is 0, and SSC is `0b10`.
FEAT_RME and Secure state are not implemented.	Any combination when HMC is 0 and SSC is `0b01`, and the combination when HMC is 1, SSC is `0b10`, and PMC is `0b00`.
EL3 is not implemented and EL2 is implemented.	Any combination when SSC is either `0b01` or `0b10`.
Both EL3 and EL2 are not implemented.	Any combination when either HMC is 1 or SSC is not `0b00`.
EL2 is not implemented.	The combination when HMC is 1, SSC is `0b11`, and PMC is `0b00`.
Secure EL2 is not implemented.	Any combination when SSC is `0b11`, except the combination when HMC is 1, the Effective value of SSCE is 0, SSC is `0b11`, and PMC is `0b00`.
EL3 is not implemented or Secure EL2 is not implemented.	The combination when HMC is 1, the Effective value of SSCE is 0, SSC is `0b01`, and PMC is `0b00`.
Always.	Combinations not included in Table D2-8.

For all breakpoints except Context matching breakpoints with linking enabled, if a breakpoint is programmed with one of these reserved combinations:

- If the reserved combination has a function for other execution conditions:
  - The breakpoint must behave as if it is disabled.
  - A direct or external read of DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} returns the values written. This means that software can save and restore the combination so that the breakpoint can function for the other execution conditions.
- If the reserved combination does not have a function for other execution conditions:
  - It must behave either as if it is programmed with a combination that is not reserved or as if it is disabled.
  - A direct or external read of DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} returns UNKNOWN values.

If the breakpoint is a Context matching breakpoint with linking enabled, then:

- The values of HMC, SSCE, SSC, and PMC are ignored.
- A direct or external read of DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} returns UNKNOWN values.

The behavior of breakpoints with reserved combinations of HMC, SSCE, SSC, and PMC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

D2.8.7.3 Programming dependencies of the BAS and MASK fields

When programming a breakpoint, a debugger must use either:

- The MASK field, to program the breakpoint with an address range that can be eight bytes to 2GB.
- The BAS field. Table D2-9 gives the valid values of the DBGBCR<n>_EL1.BAS field .

If the debugger uses the:

- MASK field, it must program BAS to be `0b1111`, so that all bytes in the doubleword or word are selected.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- BAS field, it must program MASK to be `0b00000`, so that the MASK field does not indicate any address ranges.

If any of the following apply, then it is CONSTRAINED UNPREDICTABLE whether or not a Breakpoint exception is generated:

- DBGBCR<n>_EL1.MASK is programmed with a reserved value.
- DBGBCR<n>_EL1.MASK is a valid nonzero value and any of the following apply:
  - DBGBCR<n>_EL1.BAS is not `0b1111`, and AArch32 is supported at EL0.
  - DBGBVR<n>_EL1[(MASK-1):0] is nonzero.
  - DBGBCR<n>_EL1.{BT2, BT} is {`0b0`, `0b0x1x`} or {`0b0`, `0b1xxx`}, indicating a Context matching breakpoint.
- DBGBCR<n>_EL1.MASK is zero, DBGBCR<n>_EL1.{BT2, BT} is {`0b0`, `0b010x`}, indicating an address mismatch breakpoint without linking enabled, and AArch32 is not supported at EL1.

Breakpoint <n> does not match in AArch64 state. A stand-alone mismatch of a single address is not supported in AArch64 state.

When any of these conditions apply, the PE behaves as if one of the following applies:

- DBGBCR<n>_EL1.MASK has been programmed with a defined value, which might be `0b00000` (no mask), other than for a direct read of DBGBCR<n>_EL1.
- The breakpoint is disabled.

The UNPREDICTABLE behavior is constrained to the generation of Breakpoint and Watchpoint exceptions and debug events.

D2.8.7.4 Reserved DBGBCR<n>_EL1.BAS values

In an AArch64-only implementation, DBGBCR<n>_EL1.BAS for all breakpoints is RES1.

Otherwise:

For all Context breakpoints

DBGBCR<n>_EL1.BAS is RES1 and is ignored.

For all Address breakpoints

Table D2-9 gives the valid values of the DBGBCR<n>_EL1.BAS field.

If a breakpoint is programmed with a reserved BAS value:

- The breakpoint must behave as if it is either:
  - Disabled.
  - Programmed with a BAS value that is not reserved, other than for a direct or external read of DBGBCR<n>_EL1.
- A direct or external read of DBGBCR<n>_EL1.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

D2.8.7.5 Usage constraints on DBGBCR<n>_EL1.{LBNX, LBN} values

For Linked Address breakpoints

A Linked Address breakpoint must link to a *context-aware* breakpoint. For a Linked Address breakpoint, any DBGBCR<n>_EL1.{LBNX, LBN} value that is not for a *context-aware* breakpoint is reserved.

If a Linked Address breakpoint links to a breakpoint that is not implemented, or that is not *context-aware*, then reads of DBGBCR<n>_EL1.{LBNX, LBN} return an UNKNOWN value and behavior is CONSTRAINED UNPREDICTABLE. The Linked Address breakpoint behaves as if it is either:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Disabled.
- Linked to an UNKNOWN *context-aware* breakpoint.

If a Linked Address breakpoint links to a breakpoint that is implemented and that is *context-aware*, but that is either not enabled or not programmed as a Context matching breakpoint with linking enabled, it behaves as if it is disabled.

For all other breakpoint types

DBGBCR<n>_EL1.{LBNX, LBN} reads UNKNOWN and its value is ignored.

D2.8.7.6 Other usage constraints for Address breakpoints

For all Address breakpoints

- DBGBVR<n>_EL1[1:0] are RES0 and are ignored.
- If the implementation supports AArch32 state:
  - For 32-bit instructions, if a breakpoint matches on the address of the second halfword but not the address of the first halfword, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception.
  - If DBGBCR<n>.BAS is `0b1111`, it is CONSTRAINED UNPREDICTABLE whether the breakpoint generates a Breakpoint exception for a T32 instruction starting at address ((DBGBVR<n>[48:2]:00) + 2). For T32 instructions, Arm recommends that the debugger programs the BAS field with either `0b0011` or `0b1100`.

D2.8.7.7 Other usage constraints for Context breakpoints

For all Context breakpoints

Any bits of DBGBVR<n>_EL1 that are not used to specify Context ID or VMID are RES0 and are ignored.

For breakpoints with linking enabled

If no Linked Address breakpoints or Linked watchpoints link to a breakpoint with linking enabled, the breakpoint with linking enabled does not generate any Breakpoint exceptions.

D2.8.8 Preferred return address

The preferred return address of a Breakpoint exception is the address of the instruction that was not executed because the PE took the Breakpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.8.9 Pseudocode description of Breakpoint exceptions taken from an AArch64 stage 1 translation regime

`AArch64_BreakpointValueMatch()` tests the value in DBGBVR<n>_EL1.

`AArch64_StateMatch()` tests the values in DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} and, if the breakpoint links to a breakpoint with linking enabled, also tests the Context matching breakpoint.

`AArch64_BreakpointMatch()` tests a single breakpoint against the current instruction PC, combining state match and value match, and returns the breakpoint type and match info.

`AArch64_CheckBreakpoint()` evaluates all implemented instruction breakpoints for the current instruction and, if there is a match, causes the PE to enter Debug state or generate a Breakpoint exception.

`AArch64_BreakpointException()` is called to generate a Breakpoint exception.

These functions are defined in A-profile Architecture Pseudocode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.9 Watchpoint exceptions

This section describes Watchpoint exceptions in stage 1 of an AArch64 translation regime.

The PE is using an AArch64 translation regime when it is executing one of the following:

- In an Exception level that is using AArch64.
- At EL0 using AArch32 when EL1 is using AArch64.
- At EL0 using AArch32 when FEAT_VHE is implemented, EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

This section contains the following subsections:

- About Watchpoint exceptions.
- Watchpoint types and linking of watchpoints.
- Execution conditions for which a watchpoint generates Watchpoint exceptions.
- Watchpoint data address comparisons.
- Watchpoint behavior for certain instruction classes.
- Watchpoint usage constraints.
- Exception syndrome information, fault address information, and preferred return address.
- Pseudocode description of Watchpoint exceptions taken from AArch64 state.

D2.9.1 About Watchpoint exceptions

A *watchpoint* is an event that results from the execution of an instruction, based on a data address. Watchpoints are also known as *data breakpoints*.

A watchpoint operates as follows:

1. A debugger programs the watchpoint with a data address, or a data address range.
2. The watchpoint generates a *Watchpoint debug event* on an access to the address, or any address in the address range.

A watchpoint never generates a Watchpoint debug event on an instruction fetch.

An implementation can include between 2-64 watchpoints. In an implementation, ID_AA64DFR0_EL1.WRPs and EDDFR1.WRPs show how many are implemented.

If AArch32 is supported at EL1 or FEAT_Debugv8p9 is not implemented, then the PE does not implement more than 16 watchpoints.

To use an implemented watchpoint, a debugger programs the following registers for the watchpoint:

- The *Watchpoint Control Register*, DBGWCR<n>_EL1. This contains controls for the watchpoint, for example an enable control.
- The *Watchpoint Value Register*, DBGWVR<n>_EL1. This holds the data virtual address used for watchpoint matching.

These registers are numbered, so that:

- DBGWCR0_EL1 and DBGWVR0_EL1 are for watchpoint number zero.
- DBGWCR1_EL1 and DBGWVR1_EL1 are for watchpoint number one.
- . . .
- DBGWCR<n-1>_EL1 and DBGWVR<n-1>_EL1 are for watchpoint number (n-1).

A watchpoint can:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Be programmed to generate Watchpoint debug events on read accesses only, on write accesses only, or on both types of access.
- Link to a *Context matching breakpoint with linking enabled*, so that a Watchpoint debug event is generated only if the PE is in a particular context when the address match occurs.
- If FEAT_ABLE is implemented, link to an *Address matching breakpoint with linking enabled* so that a Watchpoint debug event is generated only if the address of the instruction that made the matching access was executed from a specific address or from a specified range of addresses.

  The Address matching breakpoint with linking enabled can also be linked to a Context matching breakpoint with linking enabled.
- If FEAT_BWE2 is implemented, link to an *Address mismatch breakpoint* so that a Watchpoint debug event is generated only if the address of the instruction that made the access was executed from an address that was not selected. See Watchpoint data address comparisons.
- Be programmed as an address match watchpoint or an address mismatch watchpoint. See Watchpoint data address comparisons.

A single watchpoint can be programmed to match or mismatch on one or more address bytes. A watchpoint generates a Watchpoint debug event on an access to any byte that it is watching. The number of bytes a watchpoint is watching is either:

- One to eight bytes, provided that these bytes are contiguous and that they are all in the same naturally-aligned doubleword. A debugger uses the *Byte Address Select* field, DBGWCR<n>_EL1.BAS, to select the bytes. See Programming a watchpoint range with eight bytes or fewer.
- Eight bytes to 2GB, provided that both of the following are true:
  - The number of bytes is a power-of-two.
  - The range starts at an address that is aligned to the range size.

  A debugger uses the *MASK* field, DBGWCR<n>_EL1.MASK, to program a watchpoint with eight bytes to 2GB. See Programming a watchpoint range with eight or more bytes.

A debugger must use either the BAS field or the MASK field. If it uses both, whether the watchpoint generates Watchpoint debug events is CONSTRAINED UNPREDICTABLE. See Programming dependencies of the BAS and MASK fields.

For each memory access, all of the watchpoints are tested. When a watchpoint is tested, it generates a Watchpoint debug event if all of the following are true:

- The conditions specified in the DBGWCR<n>_EL1 are met. This includes all of the following:
  - The watchpoint is enabled. See DBGWCR<n>_EL1.E.
  - The type of the access. That is, whether the access is a load, a store, or both. See DBGWCR<n>_EL1.LST.
  - The Security state, Exception level, and privilege of the access. See Execution conditions for which a watchpoint generates Watchpoint exceptions.
  - If the watchpoint links to a breakpoint with linking enabled, the comparison or comparisons made by the breakpoint. See Rules for linking watchpoints.

  Together, these define the *context* of the data access that the watchpoint matches.
- The comparison with the address held in the DBGWVR<n>_EL1 is successful. See Watchpoint data address comparisons.
- The instruction that initiates the memory access is committed for execution.
- The instruction that initiates the memory access passes its Condition code check.
- If the access is due to a System register access instruction executed at EL1 and transformed into a memory access by the mechanism described in Enhanced support for nested virtualization and one of the following is true:
  - EDSCR.HDE is set to 1 and halting is allowed.
  - Debug exceptions are enabled at EL2. For more information, see Enabling debug exceptions from the current Exception level and Security state.

If multiple watchpoints can generate a Watchpoint debug event for an access, then, for all watchpoints that are enabled and match the context of the data access:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Boolean equality comparison results of all the address match watchpoints are OR'd together to generate a first result.
- The Boolean inequality comparison results of all the address mismatch watchpoints are AND'd together to generate a second result.

A watchpoint debug event is generated if any of the following apply:

- The first result is true and all enabled watchpoints are address match watchpoints.
- The second result is true and all enabled watchpoints are address mismatch watchpoints.
- Both the first and second results are true, and both address match watchpoints and address mismatch watchpoints are enabled.

The pseudocode function `AArch64_CheckWatchpoint()` describes the details for combining the results of individual watchpoints to determine the final result of watchpoint match.

If halting is allowed and EDSCR.HDE is 1, Watchpoint debug events cause entry to Debug state. Otherwise, if debug exceptions are:

- Enabled, Watchpoint debug events generate Watchpoint exceptions.
- Disabled, Watchpoint debug events are ignored.

Note

The remainder of this Watchpoint Exceptions section, including all subsections, describes watchpoints as generating Watchpoint exceptions.
However, unless specified otherwise, the behavior described also applies if watchpoints are causing entry to Debug state.

The debug exception enable controls describes the enable controls for Watchpoint debug events.

D2.9.2 Accessing watchpoint System registers

R_{MLRFY} The rules in Accessing breakpoint System registers that apply to MDSELR_EL1.BANK when accessing breakpoint registers also apply to watchpoint registers. See R_{MLTYN}, R_{JGQGB}, and I_{HMNFZ}.

R_{YKKCH} The `MRS` and `MSR` System register names for accessing breakpoint control registers DBGWCR<n>_EL1 and breakpoint value registers DBGWVR<n>_EL1 are mapped to physical registers as follows:

- The register names DBGWCR0_EL1 through DBGWCR15_EL1 are mapped to the physical registers DBGWCR<BANK×16+0>_EL1 through DBGWCR<BANK×16+15>_EL1.
- The register names DBGWVR0_EL1 through DBGWVR15_EL1 are mapped to the physical registers DBGWVR<BANK×16+0>_EL1 through DBGWVR<BANK×16+15>_EL1.

I_{XMTTT} `MSR` and `MRS` instructions using the watchpoint System register names in R_{YKKCH} make indirect reads of MDSELR_EL1.BANK. This means that direct writes to MDSELR_EL1.BANK must be explicitly synchronized before a direct read or direct write using any of these System register names.

D2.9.3 Watchpoint types and linking of watchpoints

When a debugger programs a watchpoint, it must program that watchpoint so that:

- It is either:
  - Used in isolation. In this case, the watchpoint is called an *Unlinked watchpoint*.
  - Linked to a breakpoint with linking enabled. In this case, the watchpoint is called a *Linked watchpoint*.
- And is either:
  - An address match watchpoint.
  - An address mismatch watchpoint.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When a Linked watchpoint links to an Address matching breakpoint with linking enabled, the Linked watchpoint generates a Watchpoint exception only if the address of the instruction that made the matching access was executed from a specific address or in range of addresses.

When a Linked watchpoint links to a Context matching breakpoint with linking enabled, or a Linked watchpoint links to a Linked Address matching breakpoint with linking enabled that links to a Context matching breakpoint with linking enabled, the Linked watchpoint generates a Watchpoint exception only if the PE is in a particular context when the data address match occurs.

Example D2-3 Linking a watchpoint and an Address matching breakpoint

For example, a debugger might:

1. Program watchpoint number one with a data address.
2. Program breakpoint number five to be a *Linked VMID Match breakpoint*.
3. Link the watchpoint and the breakpoint together. A Watchpoint exception is generated only if both the data address matches and the VMID matches.

D2.9.3.1 Rules for linking watchpoints

The rules for watchpoint linking are as follows:

- Only Linked watchpoints can be linked.
- A Linked watchpoint can be linked to any breakpoint with linking enabled.
- A Linked watchpoint can link to any type of breakpoint with linking enabled. The *Linked Breakpoint Number* field, DBGWCR<n>_EL1.{LBNX, LBN}, for the Linked watchpoint specifies the particular breakpoint that the Linked watchpoint links to, and:
  - DBGWCR<n>_EL1.{SSCE, SSC, HMC, PAC} for the Linked watchpoint defines the execution conditions that the watchpoint generates Watchpoint exceptions for. See Execution conditions for which a watchpoint generates Watchpoint exceptions.
  - DBGBCR<n>_EL1.{SSCE, SSC, HMC, PMC} for the breakpoint with linking enabled are ignored.
- A Linked watchpoint cannot link to another watchpoint. The {LBNX, LBN} fields always specify a breakpoint.
- If any of the following apply, then the behavior of the Linked watchpoint is CONSTRAINED UNPREDICTABLE:
  - The Linked watchpoint is linked to a breakpoint that does not support linking.
  - FEAT_ABLE is not implemented and the Linked watchpoint is linked to a breakpoint that is not context aware.
  - FEAT_ABLE is not implemented and the Linked watchpoint is linked to an Address matching breakpoint.
  - The Linked watchpoint is linked to an unimplemented breakpoint.
  - The Linked watchpoint or Linked breakpoint is linked to a breakpoint that does not have linking enabled.

  See Watchpoint usage constraints.
- If the access is due to a System register access instruction executed at EL1 and transformed into a memory access by the mechanism described in Enhanced support for nested virtualization, and the watchpoint is linked to a Context matching breakpoint with linking enabled, or a Linked Address matching breakpoint with linking enabled that is linked to a Context matching breakpoint with linking enabled, then it is CONSTRAINED UNPREDICTABLE whether there is a watchpoint match.
- Multiple Linked watchpoints can link to a single breakpoint with linking enabled.

  Note

  Multiple Address breakpoints can also link to a single breakpoint with linking enabled. Breakpoint exceptions describes breakpoints.

- If an instruction address generates a breakpoint match for more than one enabled Address matching breakpoint with linking enabled, then it is CONSTRAINED UNPREDICTABLE whether Watchpoint exceptions and debug events are generated.

Figure D2-1 shows an example of permitted watchpoint linking.

D2.9.4 Execution conditions for which a watchpoint generates Watchpoint exceptions

Each watchpoint can be programmed so that it generates Watchpoint exceptions only for certain execution conditions. For example, a watchpoint might be programmed to generate Watchpoint exceptions only for Non-secure EL2 accesses.

DBGWCR<n>_EL1.{SSCE, SSC, HMC, PAC} define the execution conditions a watchpoint generates Watchpoint exceptions for, as follows:

Security State Control Extension, SSCE, and Security State Control, SSC

SSCE and SSC control whether the watchpoint generates Watchpoint exceptions in only one Security state or in multiple Security states.

Note

This is determined by the Security state of the PE, not from the physical address space attribute returned by the translation of the virtual address on which the watchpoint is set.

Higher Mode Control, HMC, and Privileged Access Control, PAC

HMC and PAC together control which Exception levels and privilege levels the watchpoint generates Watchpoint exceptions in.

The PAC control relates to the privilege of the memory access and the Exception level at which the access was made:

- Unprivileged memory accesses generated by unprivileged memory access instructions are treated as unprivileged EL0 accesses.
- System register accesses executed at EL1 and transformed into a memory access by the mechanism described in Enhanced support for nested virtualization are treated as EL2 accesses.

Example D2-4

PAC condition for generating a Watchpoint exception

This means that, if the PE executes an unprivileged memory access instruction at EL1, any resulting Explicit Memory Effect that is unprivileged triggers a watchpoint only if both:

- PAC is programmed to a value that generates watchpoints on EL0 accesses.
- All other conditions for generating the watchpoint are met.

Example A64 unprivileged memory access instructions are `LDTR` and `STTR`.

Table D2-13 shows the valid combinations of HMC, SSCE, SSC, and PAC, and for each combination shows which Exception levels watchpoints generate Watchpoint exceptions in.

In the table:

NS Non-secure state.

S Secure state.

RL In implementations that include FEAT_RME, Realm state.

RT In implementations that include FEAT_RME, Root state.

Y or - Means that a watchpoint programmed with the values of HMC, SSCE, SSC, and PAC shown in that row:

- **Y** Can generate Watchpoint exceptions in that Exception level and Security state.
- **-** Cannot generate Watchpoint exceptions in that Exception level and Security state.

1	1	01	01		-	Y	Y	-
1	1	01	11		-	Y	Y	Y

a. Debug exceptions are not generated at EL3 using AArch64. This means that these combinations of HMC, SSCE, SSC, and PAC are relevant only if watchpoints cause entry to Debug state. Self-hosted debuggers must avoid combinations of HMC, SSCE, SSC, and PAC that generate Watchpoint exceptions at EL3 using AArch64.

b. If FEAT_RME is implemented, this combination specifies Root state. Otherwise, Secure state.

All combinations of HMC, SSCE, SSC, and PAC that Table D2-13 does not show are reserved. A combination in Table D2-13 might be reserved if an Exception level or Security state is not implemented. For information about which combinations of HMC, SSCE, SSC and PAC are reserved if an Exception level or Security state are not implemented or enabled, see Reserved DBGWCR<n>_EL1.{SSCE, SSC, HMC, PAC} values.

D2.9.5 Watchpoint data address comparisons

In this subsection, the term `AddrTop` represents the most significant bit of a virtual address used by watchpoint data address comparisons. `AddrTop` is:

- 55, if address tagging is used for the address. See Address tagging.
- 63, otherwise.

Note

When stage 1 translation is enabled, in AArch64 state, the virtual address size is determined by the configured input address size for the stage 1 translation. Software can configure a smaller address width for a virtual address. See Input address size configuration. Attempting to translate an address that is larger than the configured input address size generates a Translation fault.
When stage 1 translation is disabled, using an address that is larger than the implemented PA size generates an Address size fault. The implemented PA size is IMPLEMENTATION DEFINED, as described in Implemented physical address size. These faults have a higher priority than watchpoints.

Bits [`AddrTop`:2] of the data address are compared with DBGWVR<n>_EL1[`AddrTop`:2], taking into account all of the following:

- The size of the access. See Size of the data access.
- The bytes selected by DBGWVR<n>_EL1.BAS. See Programming a watchpoint range with eight bytes or fewer.
- Any address ranges indicated by DBGWVR<n>_EL1.MASK. See Programming a watchpoint range with eight or more bytes.

The comparison is successful if any of following are true:

- The watchpoint is an address match watchpoint, and the two values being compared match.
- The watchpoint is an address mismatch watchpoint, and the two values being compared do not match.

If EL1 is using AArch64 and EL0 is using AArch32, AArch32 instructions can be executed in stage 1 of an AArch64 translation regime. In this case, the 32-bit data address is zero-extended before comparison with the watchpoint.

Note

- DBGWVR<n>_EL1 is a 64-bit register. The most significant bits of this register are sign-extension bits.
- DBGWVR<n>_EL1[1:0] are RES0 and are ignored.

D2.9.5.1 Size of the data access

Because watchpoints can be programmed to generate Watchpoint exceptions on individual bytes, the size of each data access must be taken into account. The address of every byte in a data access is compared, and:

- In the case of an address match watchpoint, the watchpoint generates a Watchpoint exception if any byte address matches. See Example D2-5.
- In the case of an address mismatch watchpoint, the watchpoint generates a Watchpoint exception if any byte address does not match. See Example D2-6.

Example D2-5

1. A debugger programs an address match watchpoint to generate Watchpoint exceptions only when the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint generates a Watchpoint exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D2-6

1. A debugger programs an address mismatch watchpoint to generate Watchpoint exceptions when any address other than the byte at address `0x1009` is accessed.
2. The PE accesses the unaligned doubleword starting at address `0x1003`.

In this scenario, the watchpoint generates a Watchpoint exception.

The size of data accesses initiated by `DC ZVA` instructions is the DC ZVA block size that DCZID_EL0.BS defines.

The size of data accesses initiated by `DC IVAC` instructions is an IMPLEMENTATION DEFINED size that is both:

- From the inclusive range between:
  - The size that CTR_EL0.DminLine defines.
  - 2KB.
- A power-of-two.

For both of these instructions:

- The lowest address accessed by the instruction is the address supplied to the instruction, rounded down to the nearest multiple of the access size initiated by that instruction.
- The highest address accessed is (size - 1) bytes above the lowest address accessed.

See also Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions.

D2.9.5.2 Programming a watchpoint range with eight bytes or fewer

The Byte Address Select field, DBGWCR<n>_EL1.BAS, selects bytes in the doubleword starting at the address contained in DBGWVR<n>_EL1.

If the address programmed into the DBGWVR<n>_EL1 is:

- Doubleword-aligned:
  - All eight bits of DBGWCR<n>_EL1.BAS are used.
- Word-aligned but not doubleword-aligned:
  - Only DBGWCR<n>_EL1.BAS[3:0] are used. In this case, DBGWCR<n>_EL1.BAS[7:4] are RES0.

An address match watchpoint generates a Watchpoint exception when an access accesses any byte address that DBGWCR<n>_EL1.BAS selects. An address mismatch watchpoint generates a Watchpoint exception when an access accesses any byte address that DBGWCR<n>_EL1.BAS does not select.

Table D2-14 Supported BAS values when the DBGWVR<n>_EL1 address alignment is doubleword

BAS value	Description
BAS[0] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`000` selected.
BAS[1] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`001` selected.
BAS[2] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`010` selected.
BAS[3] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`011` selected.
BAS[4] == 1	Byte at address DBGWVR<n>_EL1[`AddrTop`:3]:`100` selected.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BAS value	Description
BAS[5] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:3]:101 selected.
BAS[6] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:3]:110 selected.
BAS[7] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:3]:111 selected.

Table D2-15 Supported BAS values when the DBGWVR<n>_EL1 address alignment is word

BAS value[a]	Description
BAS[0] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:2]:00 selected.
BAS[1] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:2]:01 selected.
BAS[2] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:2]:10 selected.
BAS[3] == 1	Byte at address DBGWVR<n>_EL1[AddrTop:2]:11 selected.

a. DBGWCR<n>_EL1.BAS[7:4] are RES0.

If the BAS field selects more than one byte, the bytes it selects must be contiguous. For watchpoint behavior when its BAS field selects non-contiguous bytes, see Other usage constraints.

When programming the BAS field with anything other than 0b11111111, a debugger must program DBGWCR<n>_EL1.MASK to 0b00000. See Programming dependencies of the BAS and MASK fields.

A watchpoint generates a Watchpoint exception whenever a watched byte is accessed, even if:

- The access size is smaller or larger than the address region being watched.
- The access is misaligned, and the base address of the access is not in the doubleword or word of memory addressed by the DBGWVR<n>_EL1[AddrTop:3]. See Example D2-5.

Example D2-7

The following are some example configurations of the BAS field:

- To program an address match watchpoint to generate a Watchpoint exception on the byte at address 0x1003, program:
  - DBGWVR<n>_EL1 with 0x1000.
  - DBGWCR<n>_EL1.BAS to be 0b00001000.
- To program an address match watchpoint to generate a Watchpoint exception on the bytes at addresses 0x2003, 0x2004 and 0x2005, program:
  - DBGWVR<n>_EL1 with 0x2000.
  - DBGWCR<n>_EL1.BAS to be 0b00111000.
- If the address programmed into the DBGWVR<n>_EL1 is doubleword-aligned:
  - To generate a Watchpoint exception when any byte in the word starting at the doubleword-aligned address is accessed, program DBGWCR<n>_EL1.BAS to be 0b00001111.
  - To generate a Watchpoint exception when any byte in the word starting at address DBGWVR<n>_EL1[31:3]:100 is accessed, program DBGWCR<n>_EL1.BAS to be 0b11110000.

Note

Arm deprecates programming a DBGWVR<n>_EL1 with an address that is not doubleword-aligned.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.9.5.3 Programming a watchpoint range with eight or more bytes

A debugger can use the *MASK* field, DBGWCR<n>_EL1.MASK, to program a single watchpoint with a data address range. The range must meet all of the following criteria:

- It is a size that is:
  - A power-of-two.
  - A minimum of eight bytes.
  - A maximum of 2GB.
- It starts at an address that is aligned to the size.

The MASK field specifies the number of least significant data address bits that must be masked. Up to 31 least significant bits can be masked.

If *m* least significant address bits are masked, an address match watchpoint generates a Watchpoint exception on all of the following:

- Address DBGWVR<n>_EL1[`AddrTop`:*m*]:000. . .0.
- Address DBGWVR<n>_EL1[`AddrTop`:*m*]:111. . .1.
- Any address between these two addresses.

An address mismatch breakpoint generates a Watchpoint exception for any address outside of the range.

Example D2-8

If the four least significant address bits are masked, Watchpoint exceptions are generated for all addresses between DBGWVR<n>_EL1[`AddrTop`:4]:0000 and DBGWVR<n>_EL1[`AddrTop`:4]:1111, including these addresses.

When masking address bits, a debugger must both:

- Program DBGWCR<n>_EL1.BAS to be `0b11111111`. See Programming dependencies of the BAS and MASK fields.
- In the DBGWVR<n>_EL1, set the masked address bits to 0. For watchpoint behavior when any of the masked address bits are not 0, see Other usage constraints.

D2.9.6 Watchpoint behavior for certain instruction classes

Under normal operating conditions, the following do not generate Watchpoint exceptions:

- Instruction cache maintenance instructions.
- Address translation instructions.
- TLB maintenance instructions.
- Prefetch memory instructions.
- All data cache maintenance instructions except `DC IVAC`.

Note

Despite their mnemonics, the DC ZVA, DC GVA, and DC GZVA instructions are not data cache maintenance instructions.

However, the debug architecture allows for IMPLEMENTATION DEFINED controls, such as those in ACTLR registers, to enable watchpoints on an IMPLEMENTATION DEFINED subset of these instructions. Whether a watchpoint treats the instruction as a load or a store, and the access size of instruction cache, address translation, and TLB operations are IMPLEMENTATION DEFINED.

The access size of the IMPLEMENTATION DEFINED instruction cache, address translation, and TLB operations which generate Watchpoint exceptions are IMPLEMENTATION DEFINED.

See also the following subsections:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Watchpoint behavior on accesses by Store-Exclusive instructions.
- Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions.
- Watchpoint behavior on accesses by SVE and SME instructions.
- Watchpoint behavior on accesses by Allocation tag load and store instructions.

D2.9.6.1 Watchpoint behavior on accesses by Store-Exclusive instructions

If a watchpoint matches on a data access caused by a Store-Exclusive instruction, then:

- If the store fails because an Exclusives monitor does not permit it, it is IMPLEMENTATION DEFINED whether the watchpoint generates a Watchpoint exception.
- Otherwise, the watchpoint generates a Watchpoint exception.

D2.9.6.2 Watchpoint behavior on accesses by the DC IVAC instruction and the DC ZVA, DC GVA, and DC GZVA instructions

`DC ZVA`, `DC GVA` and `DC GZVA` operations can generate Watchpoint exceptions.

If DC IVAC is not treated as a `NOP`, it can generate Watchpoint exceptions.

`DC IVAC`, `DC ZVA`, `DC GZVA` and `DC GVA` operations are treated as data stores by DBGWCR<n>_EL1.LSC.

Note

For the size of data accesses performed by the `DC IVAC` instruction and the `DC ZVA` instruction, see Watchpoint data address comparisons. The size of all data accesses must be considered because watchpoints can be programmed to match on individual bytes.

D2.9.6.3 Watchpoint behavior on accesses by SVE and SME instructions

R_{ZRWTZ} For SVE predicated vector load or store instructions which are not First-fault vector loads or Non-fault vector loads, when the instruction performs a non-speculative single-copy atomic access matching a configured watchpoint due to an *Active element*, a Watchpoint exception is generated.

R_{GLRCD} For SVE predicated non-contiguous vector load or store instructions, if the instruction performs an access due to an *Inactive element*, a Watchpoint exception is not generated.

R_{DYGMS} For SVE Non-fault vector load instructions, when the instruction performs an access, a Watchpoint exception is not generated other than as permitted by R_{LVLYV}.

R_{LKKQG} For SVE Non-fault vector load instructions, when the instruction performs a non-speculative single-copy atomic access matching a configured watchpoint due to an *Active element*, the access is reported in the FFR.

R_{TLSCX} For SVE First-fault vector load instructions, when the instruction performs a non-speculative single-copy atomic access matching a configured watchpoint due to the *First active element*, a *Watchpoint event* is generated.

R_{XBBLW} For SVE First-fault vector load instructions, when the instruction performs a non-speculative single-copy atomic access matching a configured watchpoint due to an *Active element* that is not the *First active element*, a Watchpoint exception is not generated and the access is reported in the FFR.

I_{CKZFP} Watchpoints are not a mechanism for preventing access to memory.

I_{ZHXGG} For SVE Non-fault and First-fault vector load instructions that do not generate a Watchpoint exception, an access that matches a configured watchpoint can return the data and set the appropriate FFR elements to FALSE.

D_{TDYYR} A *relaxed watchpoint access* is a memory access or set of contiguous memory accesses generated by any of:

- SIMD&FP load/store instruction when the PE is in Streaming SVE mode.
- SVE contiguous vector load/store instruction.
- SME load/store instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

RLVLYV If all the following are true for a *relaxed watchpoint access*, then it is CONSTRAINED UNPREDICTABLE whether or not a watchpoint is triggered:

- The watchpoint matches a range where the lowest accessed address is rounded down to the nearest multiple of 16 bytes and the highest accessed address is rounded up to the nearest multiple of 16 bytes minus 1.
- The watchpoint does not match the range of the original access or set of contiguous accesses.
- Either the watchpoint generates a Watchpoint exception, or FEAT_EDHSR is implemented.

IYVSFL If a Watchpoint exception is triggered by a match on a rounded access address range that would not have been triggered by the original access address range, then this may report a false-positive match. The debugger should attempt to detect and step over false-positive matches. The architecture does not permit missed, or false-negative matches.

D2.9.6.4 Watchpoint behavior on accesses by Allocation tag load and store instructions

If FEAT_MTE is implemented, an instruction that loads or stores an Allocation Tag is considered a load or store to each location in the associated Tag Granule for the purpose of triggering Watchpoint exceptions.

D2.9.7 Watchpoint usage constraints

See the following:

- Reserved DBGBCR<n>_EL1.{BT2, BT} values when using Watchpoints.
- Reserved DBGWCR<n>_EL1.{SSCE, SSC, HMC, PAC} values.
- Usage constraints on DBGWCR<n>_EL1.{LBNX, LBN} values.
- Programming dependencies of the BAS and MASK fields.
- Reserved DBGWCR<n>_EL1.BAS values.
- Reserved DBGWCR<n>_EL1.MASK values.
- Other usage constraints.

D2.9.7.1 Reserved DBGBCR<n>_EL1.{BT2, BT} values when using Watchpoints

It is CONSTRAINED UNPREDICTABLE whether Watchpoint exceptions and debug events are generated if DBGBCR<n>_EL1.{BT2, BT} is a reserved value. See Reserved DBGBCR<n>_EL1.{BT2, BT} values .

D2.9.7.2 Reserved DBGWCR<n>_EL1.{SSCE, SSC, HMC, PAC} values

Table D2-16 shows when particular combinations of the Effective value of DBGWCR<n>_EL1.{SSCE, SSC, HMC, PAC} are reserved.

When FEAT_RME is not implemented, DBGWCR<n>_EL1.SSCE is RES0, and its Effective value is 0.

Table D2-16 Reserved SSCE, SSC, HMC, and PAC combinations

Condition	Reserved combinations of the Effective value of HMC, SSCE, SSC, and PAC
Secure state is not implemented.	Any combination when HMC is 0, the Effective value of SSCE is 0, and SSC is `0b10`.
FEAT_RME and Secure state are not implemented.	Any combination when HMC is 0 and SSC is `0b01`, and the combination when HMC is 1, SSC is `0b10`, and PAC is `0b00`.
EL3 is not implemented and EL2 is implemented.	Any combination when SSC is either `0b01` or `0b10`.
Both EL3 and EL2 are not implemented.	Any combination when either HMC is 1 or SSC is not `0b00`.
EL2 is not implemented.	The combination when HMC is 1, SSC is `0b11`, and PAC is `0b00`.
Secure EL2 is not implemented.	Any combination when SSC is `0b11`, except the combination when HMC is 1, the Effective value of SSCE is 0, SSC is `0b11`, and PAC is `0b00`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Condition	Reserved combinations of the Effective value of HMC, SSCE, SSC, and PAC
EL3 is not implemented or Secure EL2 is not implemented.	The combination when HMC is 1, the Effective value of SSCE is 0, SSC is `0b01` and PAC is `0b00`.
Always.	Combinations not included in Table D2-13.

If a watchpoint is programmed with one of these reserved combinations:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with a combination that is not reserved, other than for a direct or external read of DBGWCR<n>_EL1.
- For a direct or external read of DBGWCR<n>_EL1, if the reserved combination:
  - Has no function for any execution conditions, the value read back for each of SSCE, SSC, HMC, and PAC is UNKNOWN.
  - Has a function for execution conditions other than the current execution conditions, the value read back is the value written. This permits software to save and restore the combination so that the watchpoint functions for the other execution conditions.

The behavior of watchpoints with reserved combinations of SSCE, SSC, HMC, and PAC might change in future revisions of the architecture. For this reason, software must not rely on the behavior described here.

D2.9.7.3 Usage constraints on DBGWCR<n>_EL1.{LBNX, LBN} values

For Linked Watchpoints

If any of the following are true for a Linked watchpoint <n>, then direct reads of DBGWCR<n>_EL1.{LBNX, LBN} return an UNKNOWN value and it is CONSTRAINED UNPREDICTABLE whether Watchpoint exceptions and debug events are generated:

- The Linked watchpoint is linked to an unimplemented breakpoint.
- The Linked watchpoint is linked to a breakpoint which does not support linking.
- FEAT_ABLE is not implemented and the Linked watchpoint is linked to a breakpoint which is not context aware.

Otherwise, if any of the following are true for a Linked watchpoint <n>, then the Linked watchpoint behaves as if it is disabled:

- The Linked watchpoint is linked to an enabled breakpoint that does not have linking enabled.
- FEAT_ABLE is not implemented and the Linked watchpoint is linked to an enabled Address matching breakpoint.
- The Linked watchpoint is linked to a disabled breakpoint.

It is CONSTRAINED UNPREDICTABLE whether Watchpoint exceptions and debug events are generated if an instruction address generates a breakpoint match for more than one enabled Address matching breakpoint with linking enabled.

For Unlinked Watchpoints For Unlinked watchpoints, DBGWCR<n>_EL1.{LBNX, LBN} reads UNKNOWN and its value is ignored.

D2.9.7.4 Programming dependencies of the BAS and MASK fields

When programming a watchpoint, a debugger must use either:

- The MASK field, to program the watchpoint with an address range that can be eight bytes to 2GB.
- The BAS field, to select which bytes in the doubleword or word starting at the address contained in the DBGWVR<n>_EL1 the watchpoint must generate Watchpoint exceptions for.

If the debugger uses the:

- MASK field, it must program BAS to be `0b11111111`, so that all bytes in the doubleword or word are selected.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- BAS field, it must program MASK to be `0b00000`, so that the MASK field does not indicate any address ranges.

If an enabled watchpoint has a MASK field that is nonzero and a BAS field that is not set to `0b11111111`, then for each byte in the address range, it is CONSTRAINED UNPREDICTABLE whether or not a Watchpoint exception is generated.

D2.9.7.5 Reserved DBGWCR<n>_EL1.BAS values

The BAS field must be programmed with a value `Zeros(8-n-m):Ones(n):Zeros(m)`, where:

- `n` is a nonzero positive integer less-than-or-equal-to 8.
- `m` is a positive integer less-than 8. `m` is permitted to be zero.
- `n+m` is less-than-or-equal-to 8.
- If DBGWVR<n>_EL1[2] is 1, then `n+m` is less-than-or-equal-to 4.

All other values are reserved.

Note

`Zeros{0}()` is an empty bitstring.

If DBGWVR<n>_EL1[2] is 1, DBGWCR<n>_EL1.BAS[7:4] are RES0.

If a watchpoint is programmed with a reserved BAS value:

- It is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception for each byte in the doubleword or word of memory addressed by the DBGWVR<n>_EL1.
- A direct or external read of DBGWCR<n>_EL1.BAS returns an UNKNOWN value.

Software must not rely on these properties as the behavior of reserved values might change in a future revision of the architecture.

D2.9.7.6 Reserved DBGWCR<n>_EL1.MASK values

If a watchpoint is programmed with a reserved MASK value:

- The watchpoint must behave as if it is either:
  - Disabled.
  - Programmed with an UNKNOWN value that is not reserved, that might be `0b00000`, other than for a direct or external read of DBGWCR<n>_EL1.
- A direct or external read of DBGWCR<n>_EL1.MASK returns an UNKNOWN value.

D2.9.7.7 Other usage constraints

For all watchpoints:

- DBGWVR<n>_EL1[1:0] are RES0 and are ignored.
- If DBGWCR<n>_EL1.MASK is nonzero, and any masked bits of DBGWVR<n>_EL1 are not 0, it is CONSTRAINED UNPREDICTABLE whether the watchpoint generates a Watchpoint exception when the unmasked bits match.
- A watchpoint never generates any Watchpoint exceptions if DBGWCR<n>_EL1.LSC is `0b00`.

D2.9.8 Exception syndrome information, fault address information, and preferred return address

On taking a Watchpoint exception or entering Debug state for a Watchpoint debug event, the PE records the following:

- Information about the debug event or exception in a *syndrome register*. No information is recorded if the watchpoint causes the PE to enter Debug state and FEAT_EDHSR is not implemented.
- An address that the debugger can use to determine the memory location that caused the watchpoint, in a *Fault Address Register*. No address is recorded if the PE sets the FnV bit in the syndrome register to 1, as described in Fault address information.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The syndrome register and fault address register used are one of the following:

- For a Watchpoint exception taken to EL1, ESR_EL1 and FAR_EL1.
- For a Watchpoint exception taken to EL2, ESR_EL2 and FAR_EL2.
- For a Watchpoint debug event that causes entry to Debug state, EDHSR, if implemented, and EDWAR.

In cases where one instruction triggers multiple watchpoints, only one address is recorded.

See ISS encoding for an exception from a Watchpoint exception for more information.

Note

Watchpoint exceptions cannot be taken to EL3 using AArch64.

This section uses the following terms:

D_{RCTWV} **Naturally-aligned block of memory**

Means:

- A power-of-two size.
- No larger than the `DC ZVA` block size defined by the DCZID_EL0.BS field, if ESR_ELx.FnP or EDHSR.FnP is 0.
- No larger than the smallest implemented translation granule if ESR_ELx.FnP or EDHSR.FnP is 1.
- Contains a watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint, or a watchpointed address in the address range permitted by R_{LVLYV} in Watchpoint behavior on accesses by SVE and SME instructions.

The size of the naturally-aligned block of memory is IMPLEMENTATION DEFINED. There is no architectural means of discovering the size.

D_{WNGCC} **Watchpointed address**

Is defined as follows:

- If all watchpoints are address match watchpoints, then a watchpointed address is any address for which at least one of the address match watchpoints generates a watchpoint match.
- If all watchpoints are address mismatch watchpoints, then a watchpointed address is any address for which all address mismatch watchpoints generate a watchpoint match.
- Otherwise, a watchpointed address is any address for which at least one of the address match watchpoints generates a watchpoint match and all address mismatch watchpoints generate a watchpoint match.

For more information, see the subsections that follow. These are:

- Exception syndrome information.
- Fault address information.
- Preferred return address.

D2.9.8.1 Exception syndrome information

R_{SQDKJ} If an instruction generates a watchpoint match where the watchpointed data address or data address range is not accessed by the instruction, the PE:

- Sets ESR_ELx.WPF to 1, on taking a Watchpoint exception generated by the watchpoint match.
- If FEAT_EDHSR is implemented, sets EDHSR.WPF to 1, on entering Debug state on a Watchpoint debug event generated by the watchpoint match.

Otherwise, ESR_ELx.WPF or EDHSR.WPF is set to an IMPLEMENTATION DEFINED choice of 0 or 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D2-9

When R_{LVLYV} in Watchpoint behavior on accesses by SVE and SME instructions applies, a *relaxed watchpoint access* might generate a watchpoint match for a data address or data address range that the instruction does not access. Arm strongly recommends that ESR_ELx.WPF or EDHSR.WPF is set to 0 for all other cases.

R_{KSSHC} If a watchpoint matches an access that is due to a *relaxed watchpoint access*, then the PE:

- Sets ESR_ELx.FnV to an IMPLEMENTATION DEFINED value, 0 or 1, on taking a Watchpoint exception generated by the watchpoint match.
- If FEAT_EDHSR is implemented, sets EDHSR.FnV to an IMPLEMENTATION DEFINED value, 0 or 1, on entering Debug state on a Watchpoint debug event generated by the watchpoint match.

Otherwise, ESR_ELx.FnV or EDHSR.FnV is set to 0.

R_{RLWSF} When the PE sets ESR_ELx.FnV to 0 on taking a Watchpoint exception generated by a watchpoint match:

- If the lowest watchpointed address that is higher than or equal to the address recorded in FAR_ELx might not have been accessed by the instruction, other than as permitted by R_{LVLYV}, the PE sets ESR_ELx.FnP to 1.
- Otherwise, the PE sets ESR_ELx.FnP to 0.

R_{CJWYX} When FEAT_EDHSR is implemented and the PE sets EDHSR.FnV to 0 on entering Debug state on a Watchpoint debug event generated by a watchpoint match:

- If the lowest watchpointed address that is higher than or equal to the address recorded in EDWAR might not have been accessed by the instruction, other than as permitted by R_{LVLYV}, the PE sets EDHSR.FnP to 1.
- Otherwise the PE sets EDHSR.FnP to 0.

R_{TLMWP} When FEAT_Debugv8p2 is implemented and FEAT_Debugv8p9 is not implemented, the PE behavior on taking a Watchpoint exception is as follows:

- If the PE sets ESR_ELx.FnV to 1 or ESR_ELx.FnP to 1, then the PE sets ESR_ELx.WPTV to 1.
- If the address recorded in FAR_ELx is not within a naturally-aligned block of memory, then the PE sets ESR_ELx.WPTV to 1.
- Otherwise, the PE sets ESR_ELx.WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

R_{RLFQK} When FEAT_Debugv8p2 is implemented and FEAT_Debugv8p9 is not implemented, the PE behavior on entering Debug state on a Watchpoint debug event is as follows:

- If FEAT_EDHSR is implemented and the PE sets EDHSR.FnV to 1 or EDHSR.FnP to 1, then the PE sets EDHSR.WPTV to 1.
- If the address recorded in EDWAR is not within a naturally-aligned block of memory, where the naturally-aligned block of memory is defined by D_{RCTWV}, then the PE sets EDHSR.WPTV to 1.
- Otherwise, if FEAT_EDHSR is implemented, then the PE sets EDHSR.WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

R_{WVSZS} When FEAT_Debugv8p9 is implemented, on a watchpoint match the PE:

- Sets ESR_ELx.WPTV to 1 on taking a Watchpoint exception generated by the watchpoint match.
- Sets EDHSR.WPTV to 1 on entering Debug state on a Watchpoint debug event generated by the watchpoint match.

R_{PVYNL} On a watchpoint match generated by watchpoint <*n*>:

- If the PE sets ESR_ELx.WPTV to 1 on taking a Watchpoint exception generated by the watchpoint match, then ESR_ELx.WPT is set to <*n*>.
- If FEAT_EDHSR is implemented and the PE sets EDHSR.WPTV to 1 on entering Debug state on a Watchpoint debug event generated by the watchpoint match, then EDHSR.WPT is set to <*n*>.
- Otherwise, ESR_ELx.WPT or EDHSR.WPT is UNKNOWN.

R_{XQBQN} When an instruction generates multiple watchpoint matches and the PE sets ESR_ELx.WPTV to 1 on taking a Watchpoint exception generated by the watchpoint match, or FEAT_EDHSR is implemented and the PE sets EDHSR.WPTV to 1 on entering Debug state on a Watchpoint debug event generated by the watchpoint match, then the value <n> reported in ESR_ELx.WPT or EDHSR.WPT, is defined as follows:

- If all the matching watchpoints are address match watchpoints or all the matching watchpoints are address mismatch watchpoints, then <n> is any watchpoint that generates a watchpoint match.
- Otherwise, <n> is any address match watchpoint that generates a watchpoint match.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.9.8.2 Fault address information

D2.9.8.2.1 Address recorded for Watchpoint exceptions generated by Memory Copy and Memory Set instructions

R_{FMRLD} If FEAT_MOPS is implemented, when a watchpoint is triggered by a Memory Copy or Memory Set instruction, the address recorded in FAR_ELx or EDWAR is all of:

- If the watchpoint is triggered by a write made by a Memory Copy or Memory Set instruction, in the inclusive range between:
  - The lowest address written to by the instruction that triggered the watchpoint.
  - The highest watchpointed address written to by the instruction that triggered the watchpoint.
- If the watchpoint is triggered by a read made by a Memory Copy instruction, in the inclusive range between:
  - The lowest address read from by the instruction that triggered the watchpoint.
  - The highest watchpointed address read from by the instruction that triggered the watchpoint.
- If the watchpoint generates an entry to Debug state and FEAT_EDHSR is not implemented, within a naturally-aligned block of memory.
- Within the current translation granule of the watchpointed address.

D2.9.8.2.2 Address recorded for Watchpoint exceptions generated by zeroing and data cache maintenance instructions

R_{GBDMM} For a watchpoint triggered by a DC ZVA, DC GVA, DC GZVA, or STZGM instruction, or a Data Cache maintenance operation, the address recorded in FAR_ELx or EDWAR is both:

- Any address accessed by the instruction.
- Within a naturally-aligned block of memory.

Note

Despite their mnemonics, the DC ZVA, DC GVA, and DC GZVA instructions are not data cache maintenance instructions.

D2.9.8.2.3 Address recorded for Watchpoint exceptions generated by SVE and SME instructions

R_{GVKYZ} For a watchpoint triggered by an SVE contiguous load/store instruction or by an SME load/store instruction, the address recorded in FAR_ELx or EDWAR is both:

- In the inclusive range between:
  - The lowest address accessed by the vector instruction that triggered the watchpoint, or the lowest rounded address as permitted by R_{LVLYV} in Watchpoint behavior on accesses by SVE and SME instructions.
  - The highest watchpointed address accessed by the vector instruction that triggered the watchpoint, or the highest rounded address as permitted by R_{LVLYV}.
- If either the watchpoint generates an entry to Debug state and FEAT_EDHSR is not implemented, or FEAT_Debugv8p2 is not implemented, then the range is further restricted such that:
  - The range includes a watchpointed address.
  - The range does not include any Inactive elements.

  Otherwise, the range might include Inactive elements that have not been accessed by the instruction. See R_{RLWSF} and R_{CJWYX}. However, other than as permitted by R_{LVLYV}, the watchpoint was triggered by an Active element.
- Within a naturally-aligned block of memory.

D2.9.8.2.4 Address recorded for Watchpoint exceptions generated by other instructions

The address recorded by other instructions must be both:

- From the inclusive range between:
  - The lowest address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.
  - The highest watchpointed address accessed by the memory access or set of contiguous memory accesses that triggered the watchpoint.
- Within a naturally-aligned block of memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D2-10 Address recorded for a watchpoint programmed on `0x8019`

A debugger programs a watchpoint to generate a Watchpoint exception on any access to the byte `0x8019`.

An A32 load multiple instruction then loads nine registers starting from address `0x8004` upwards. This triggers the watchpoint.

If the `DC ZVA` block size is:

- 32 bytes, the address that the PE records must be between `0x8004` and `0x8019` inclusive.
- 16 bytes, the address that the PE records must be between `0x8010` and `0x8019` inclusive.

D2.9.8.3 Preferred return address

The preferred return address of a Watchpoint exception is the address of the instruction that was not executed because the PE took the Watchpoint exception instead.

This means that the preferred return address is the address of the instruction that caused the exception.

D2.9.9 Pseudocode description of Watchpoint exceptions taken from AArch64 state

`AArch64_WatchpointByteMatch()` tests an individual byte accessed by an operation.

`AArch64_StateMatch()` tests the values in DBGWCR<n>_EL1.{HMC, SSCE, SSC, PAC}, and if the watchpoint links to a breakpoint with linking enabled, also tests the breakpoint that the watchpoint links to.

`AArch64_WatchpointMatch()` tests the value in DBGWVR<n>_EL1.

`AArch64_CheckWatchpoint()` generates a `FaultRecord` that `AArch64_Abort()` raises a Watchpoint exception for if all of the following are true:

- MDSCR_EL1.MDE is 1.
- Debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state.
- All of the conditions required for Watchpoint exception generation are met. See About Watchpoint exceptions.

Note

`AArch64_CheckWatchpoint()` might halt the PE and cause it to enter Debug state. External debug uses Debug state.

`AArch64_WatchpointException()` is called to generate a Watchpoint exception.

These functions are defined in Pseudocode for AArch64 operation.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.10 Vector Catch exceptions

Vector Catch exceptions are not generated in AArch64 translation regimes.

Note

This means that they are never taken to EL1 using AArch64 and are supported only if at least EL1 using AArch32 is supported.

A debugger that is executing in EL2 using AArch64 can route Vector Catch exceptions to EL2 using AArch64. See Routing debug exceptions.

`AArch64_VectorCatchException()` is called to generate a Vector Catch exception.

Vector Catch exceptions describes Vector Catch exceptions.

D2.11 Software Step exceptions

The following subsections describe Software Step exceptions:

- About Software Step exceptions.
- Rules for setting MDSCR_EL1.SS to 1.
- The software step state machine.
- Entering the active-not-pending state.
- Behavior in the active-not-pending state.
- Entering the active-pending state.
- Behavior in the active-pending state.
- Stepping T32 IT instructions.
- Exception syndrome information and preferred return address.
- Additional considerations.
- Pseudocode description of Software Step exceptions.

D2.11.1 About Software Step exceptions

Software step is a resource that a debugger can use to make the PE single-step instructions.

For example, by using software step, debugger software executing at a higher Exception level can single-step instructions at a lower Exception level.

Operation is as follows:

1. A debugger:
   a. Enables software step by setting MDSCR_EL1.SS to 1. See The debug exception enable controls.
   b. Executes an exception return instruction, to branch to the instruction to be single-stepped in the software being debugged.
   c. Optionally configures the MDSTEPOP_EL1 register. See Behavior in the active-not-pending state.
2. The PE then:
   a. Executes the instruction to be single-stepped.
   b. Takes a Software Step exception on the next instruction, returning control to the debugger.

However, another exception might be generated during this process. This exception is one of the following:

- A synchronous exception that is generated by the instruction being stepped.
- An asynchronous exception taken before or during the instruction being stepped, to the extent permitted by the definition of a precise exception, without completing execution of the instruction being stepped.
- An asynchronous exception that is taken after completing execution of the instruction being stepped.

The PE can take a Software Step exception only if debug exceptions are enabled from the current Exception level and Security state. See Enabling debug exceptions from the current Exception level and Security state.

A state machine describes the behavior of software step, shown in The software step state machine.

Throughout this Software Step exceptions section, including in all subsections, EL_D means the Exception level that Software Step exceptions are targeting. Routing debug exceptions defines EL_D as the *debug target Exception level*.

D2.11.2 Rules for setting MDSCR_EL1.SS to 1

Debugger software must be executing in an Exception level and Security state that debug exceptions are disabled from when it sets MDSCR_EL1.SS to 1.

The Exception level that hosts the debugger software must be using AArch64.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.11.3 The software step state machine

In Figure D2-3:

- The OS Lock is unlocked and `DoubleLockStatus()` == FALSE.
- The PE is not in Secure state with MDCR_EL3.SDD set to 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Execution is at either:

- An Exception level that is higher than EL^D.
- EL^D with (PSTATE.D == 1 || MDSCR_EL1.KDE == 0).

This is termed *execution in a debugger or above*.

To make the PE single-step an instruction, the debugger:

1. Sets SPSR_ELx.SS to 1.
2. Programs the ELR_ELx to point to the instruction to be stepped and optionally programs MDSTEPOP_EL1.
3. Executes an Exception return instruction.

Execution is in the software being debugged, at either:

- An Exception level that is lower than EL^D.
- EL^D with (PSTATE.D == 0 && MDSCR_EL1.KDE == 1).

Execution is in the software being debugged, at either:

- An Exception level that is lower than EL^D.
- EL^D with (PSTATE.D == 0 && MDSCR_EL1.KDE == 1).

A Software Step exception is pending.

Execution has returned to the debugger.

a. The step is the PE either:
   - Taking an exception to an Exception level that debug exceptions are disabled from.
   - If execution is at EL^D with MDSCR_EL1.KDE == 1, executing an instruction that sets PSTATE.D to 1.

   Software step is inactive when debug exceptions are disabled from the current Exception level, and debug exceptions are disabled from EL^D when PSTATE.D is 1.

b. The step is the PE either:
   - Executing the instruction to be stepped without taking an exception.
   - Taking an exception to an Exception level that debug exceptions are enabled from. The Exception level might be using AArch64 or AArch32.

c. Or, if execution is at EL^D with MDSCR_EL1.KDE == 1, by software setting PSTATE.D to 0.

Figure D2-3 Software step state machine

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For a description of when debug exceptions are enabled or disabled from an Exception level, see Enabling debug exceptions from the current Exception level and Security state.

For more information about how a step is completed, see Behavior in the active-not-pending state.

The software step states are:

Inactive

Software step is inactive. It cannot generate any Software Step exceptions or affect PE execution. Software step is inactive whenever any of the following are true:

- MDSCR_EL1.SS is 0.
- EL_D is using AArch32.
- Debug exceptions are disabled from the current Exception level or Security state.

Active-not-pending

None of the conditions mentioned in Inactive are true, therefore software step is active.

The instruction to be stepped is usually the instruction in memory at the address specified by the PC. However, when FEAT_STEP2 is implemented, the instruction to be stepped might be specified in MDSTEPOP_EL1.

Active-pending

None of the conditions mentioned in Inactive are true, therefore software step is active.

A Software Step exception is pending on the current instruction.

Whenever software step is active, whether the state machine is in the active-not-pending state or the active-pending state depends on PSTATE.SS. Table D2-17 shows this.

Table D2-17 State machine states

EL_D using:	Debug exception enable status in the current Exception level and Security state	MDSCR_EL1.SS	PSTATE.SS	State machine state
AArch32	X	X	X	Inactive
AArch64	Disabled	X	X	Inactive
AArch64	Enabled	0	X	Inactive
AArch64	Enabled	1	1	Active-not-pending
AArch64	Enabled	1	0	Active-pending

D2.11.4 Entering the active-not-pending state

Software step can only enter the active-not-pending state from the inactive state.

Software step:

- Enters the active-not-pending state when an Exception return instruction writes 1 to PSTATE.SS, by copying from SPSR_ELx.SS when it restores PSTATE.
- Might enter the active-not-pending state on exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 1. See Exiting Debug state.

An Exception return instruction only copies 1 from SPSR_ELx.SS to PSTATE.SS if all of the following are true:

- MDSCR_EL1.SS is 1.
- EL_D is using AArch64.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Debug exceptions are disabled from the current Exception level.
- Debug exceptions are enabled from the Exception level that the Exception return instruction targets.

Otherwise, Exception return instructions set PSTATE.SS to 0, regardless of the value of SPSR_ELx.SS.

Table D2-18 shows this. In the table:

Lock Means the value of (OSLSR_EL1.OSLK == '1' || `DoubleLockStatus()`).

NS Means the Effective value of SCR_EL3.NS.

SDD Means the Effective value of MDCR_EL3.SDD. See Disabling debug exceptions from Secure state.

EEL2 Means the Effective value of SCR_EL3.EEL2. If FEAT_SEL2 is not implemented, this is 0.

TGE Means the value of HCR_EL2.TGE. If EL2 is not implemented, the PE behaves as if this is 0.

TDE Means the Effective value of MDCR_EL2.TDE. See Routing debug exceptions.

EL1 is using The Execution state when the EL_D is EL1.

EL2 is using The Execution state when the EL_D is EL2.

Table D2-18 Value an Exception return instruction writes to PSTATE.SS

MDSCR_EL1.SS	Lock	NS	SDD	EEL2	TGE	TDE	EL1 is using	EL2 is using	Value an Exception return instruction writes to PSTATE.SS
0	X	X	X	X	X	X	X	X	0
1	TRUE	X	X	X	X	X	X	X	0
	FALSE	0	1	X	X	X	X	X	0
			0	0	X	X	AArch32	n/a	0
							AArch64	n/a	See Table D2-19
				1	0	0	AArch32	n/a	0
							AArch64	AArch64	See Table D2-19
						1	AArch32	AArch32	0
							X	AArch64	See Table D2-20
					1	X	n/a	AArch32	0
							n/a	AArch64	See Table D2-20
		1	X	X	0	0	AArch32	n/a	0
							AArch64	AArch64	See Table D2-19
						1	AArch32	AArch32	0
							X	AArch64	See Table D2-20
					1	X	n/a	AArch32	0
							n/a	AArch64	See Table D2-20

For:

- If EL_D is EL1 using AArch64, Table D2-19 shows the value an Exception return instruction writes to PSTATE.SS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If EL_D is EL2 using AArch64, Table D2-20 shows the value an Exception return instruction writes to PSTATE.SS.

In both tables:

From EL Means the Exception level at which the PE executes the Exception return instruction.

Target EL Is the target Exception level of the Exception return instruction.

Note

If the Exception return instruction is an illegal exception return, the target Exception level of the Exception return instruction is the current Exception level. See Illegal exception returns from AArch64 state.

KDE Is MDSCR_EL1.KDE. See Enabling debug exceptions from the current Exception level and Security state

Table D2-19 Value an Exception return instruction writes to PSTATE.SS if ELD is EL1 using AArch64

From EL	Target EL	KDE	PSTATE.D	SPSR_ELx.D	Software step enable status at: From EL	Software step enable status at: Target EL	Value an Exception return instruction writes to PSTATE.SS
EL3	EL3	X	X	X	Disabled	Disabled	0
	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL3.SS
	EL0	X	X	X	Disabled	Enabled	SPSR_EL3.SS
EL2	EL2	X	X	X	Disabled	Disabled	0
	EL1	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL2.SS
	EL0	X	X	X	Disabled	Enabled	SPSR_EL2.SS
EL1	EL1	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled[a]	-[b]	0
			1	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL1.SS
	EL0	0	X	X	Disabled	Enabled	SPSR_EL1.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL1.SS

a. Because MDSCR_EL1.SS == 1, it means that the Exception return instruction is itself being stepped.

b. Depends on SPSR_EL1.D.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D2-20 Value an Exception return instruction writes to PSTATE.SS if ELD is EL2 using AArch64

From EL	Target EL	KDE	PSTATE.D	SPSR_ELx.D	Software step enable status at: From EL	Software step enable status at: Target EL	Value an Exception return instruction writes to PSTATE.SS
EL3	EL3	X	X	X	Disabled	Disabled	0
	EL2	0	X	X	Disabled	Disabled	0
		1	X	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL3.SS
	EL1	X	X	X	Disabled	Enabled	SPSR_EL3.SS
	EL0	X	X	X	Disabled	Enabled	SPSR_EL3.SS
EL2	EL2	0	X	X	Disabled	Disabled	0
		1	0	X	Enabled[a]	-[b]	0
			1	1	Disabled	Disabled	0
				0	Disabled	Enabled	SPSR_EL2.SS
	EL1	0	X	X	Disabled	Enabled	SPSR_EL2.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL2.SS
	EL0	0	X	X	Disabled	Enabled	SPSR_EL2.SS
		1	0	X	Enabled[a]	Enabled	0
			1	X	Disabled	Enabled	SPSR_EL2.SS
EL1	EL1	X	X	X	Enabled[a]	Enabled	0
	EL0	X	X	X	Enabled[a]	Enabled	0

a. Because MDSCR_EL1.SS == 1, it means that the Exception return instruction is itself being stepped.

b. Depends on SPSR_EL2.D.

Note

No AArch32 instruction can set PSTATE.SS to 1.

D2.11.5 Behavior in the active-not-pending state

In this state, the PE does one of the following:

- Executes the instruction to be stepped and either:
  - Completes it without taking a synchronous exception.
  - Takes a synchronous exception if the instruction generates one.
- Takes an asynchronous exception without completing execution of the instruction.
- Enters Debug state because of a *Halting debug event*.

The instruction to be stepped is usually the instruction in memory at the address specified by the PC.

However, when FEAT_STEP2 is implemented, the instruction to be stepped might be specified in MDSTEPOP_EL1. See Software Step behavior when FEAT_STEP2 is implemented.

If the PE executes the instruction without taking any exceptions, then the PE sets PSTATE.SS to 0, meaning that after the instruction has been executed:

- If the instruction has disabled debug by setting PSTATE.D to 1 then software step advances to the inactive state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the instruction disables software step by a direct write to a System register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS, then software step might advance to the inactive state. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine.
- Otherwise, software step advances to the active-pending state. See Behavior in the active-pending state.

If the PE takes either a synchronous or an asynchronous exception, behavior is as described in one of the following:

- If the PE takes an exception to an Exception level that is using AArch64.
- If the PE takes an exception to an Exception level that is using AArch32.

If the PE enters Debug state because of a Halting debug event, behavior is as described in Entering Debug state and Software Step.

D2.11.5.1 If the PE takes an exception to an Exception level that is using AArch64

As part of exception entry, the PE does all of the following:

- Sets SPSR_ELx.SS to 0 or 1, depending on the exception. See Table D2-21.
- It is IMPLEMENTATION SPECIFIC whether SPSR_ELx.SS is set to 0 or 1 when an SError exception is taken to ELx without completing execution of the instruction.
- Sets PSTATE.SS to 0. This causes software step to enter either the active-pending state or the inactive state, depending on whether debug exceptions are enabled or disabled from the Exception level that the exception is taken to:

  Enabled Software step enters the active-pending state.

  Disabled Software step enters the inactive state.

  In either case, on taking the exception, a step is complete.
- Sets PSTATE.D to 1.

Table D2-21 Categorization of exceptions, for setting SPSR_ELx.SS to 0 or 1

Exception description	Exceptions	SPSR_ELx.SS
Exceptions whose preferred return address is for the instruction that follows the instruction to be stepped.	Supervisor Call (`SVC`) exceptions. Hypervisor Call (`HVC`) exceptions. Secure Monitor Call (`SMC`) exceptions.	0
Exceptions whose preferred return address is the address of the instruction to be stepped.	All other synchronous exceptions, and asynchronous exceptions that are taken before the instruction to be stepped.	1

Note

If an `SMC` instruction executed at Non-secure EL1 is trapped to EL2 because HCR_EL2.TSC is 1, the exception is a Trap exception, not a Secure Monitor Call exception, and so SPSR_ELx.SS is set to 1, not 0.

D2.11.5.2 If the PE takes an exception to an Exception level that is using AArch32

This can happen only when all of the following is true:

- EL2 is implemented and is using AArch64, and the Effective value of MDCR_EL2.TDE is 1. Because MDCR_EL2.TDE is 1, EL_D is EL2.
- The exception is taken to EL1 using AArch32.

As part of exception entry, the PE sets PSTATE.SS to 0. This causes software step to enter the active-pending state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- Software step always enters the active-pending state because the exception is taken to an Exception level that debug exceptions are enabled from, EL1. Debug exceptions are enabled from EL1 because EL_D is EL2, and debug exceptions are always enabled from Exception levels that are lower than EL_D.
- AArch32 SPSRs have no SS bit.

D2.11.5.3 Software Step behavior when FEAT_STEP2 is implemented

R_{VTLLV} When FEAT_STEP2 is implemented, executing from MDSTEPOP_EL1 is enabled when all of the following are true:

- The PE is in AArch64 state.
- Software Step is in the active-not-pending state.
- MDSCR_EL1.EnSTEPOP is 1.
- Either EL3 is not implemented or MDCR_EL3.EnSTEPOP is 1.
- Any of the following apply:
  - EL2 is not implemented.
  - EL2 is disabled in the current Security state.
  - MDCR_EL2.EnSTEPOP is 1.

Otherwise, executing from MDSTEPOP_EL1 is disabled.

I_{WTPKX} The pseudocode function `SoftwareStepOpEnabled()` returns TRUE when executing from MDSTEPOP_EL1 is enabled and FALSE otherwise.

I_{SFGGB} When executing from MDSTEPOP_EL1 is disabled, the value in MDSTEPOP_EL1 is ignored.

R_{KPFLX} When executing from MDSTEPOP_EL1 is enabled, the instruction to be stepped is specified by the value of MDSTEPOP_EL1. That is, the PE executes an instruction from MDSTEPOP_EL1 instead of executing an instruction from memory.

R_{XTKVL} When the PE executes an instruction from MDSTEPOP_EL1, all of the following apply:

- The instruction address in the PC is checked by the PE as if the instruction is fetched from memory.
  For example, the instruction might generate any of the following exceptions based on the current value of PC:
  - PC alignment fault exception.
  - Instruction abort exception.
  - Breakpoint exception.
- A read of PC by the instruction returns the current value of PC.
- A write to PC updates the PC as normal.

I_{RJMRP} In R_{XTKVL}, reads of the PC includes indirect reads in the event of an exception or debug event being taken, as follows:

- If the instruction execution causes a synchronous exception, or is preempted by an asynchronous exception, then the preferred return address for the exception is based on the current PC value.
- If the instruction execution causes a synchronous entry to Debug state, or is preempted by an asynchronous entry to Debug state, then the preferred restart address for the debug event is based on the current PC value.

I_{VXWNT} When the PE executes an instruction from MDSTEPOP_EL1, it is CONSTRAINED UNPREDICTABLE whether the PE fetches an instruction from the memory location addressed by the current PC. This means that, in the case where the instruction fetch would generate a synchronous External abort, it is CONSTRAINED UNPREDICTABLE whether this exception will be generated. In the case where the instruction fetch would generate a synchronous External abort on a translation table fetch or translation table update, then the exception is generated because R_{XTKVL} requires that the translation table is checked.

If the PE does fetch an instruction from the memory location addressed by the current PC, then that instruction is ignored.

I_{LYLNF} Instruction execution properties that are derived from the current PC value use the same method whether the PE executes an instruction from MDSTEPOP_EL1 or from memory. For example, instruction execution properties that are derived from the PC being in a guarded page.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

Execution from MDSTEPOP_EL1 is not considered concurrent modification and execution of instructions. Tracing properties and performance monitoring of instruction execution from MDSTEPOP_EL1 are unchanged.

R_{DQFDD} The `MOVPRFX` instruction execution from MDSTEPOP_EL1 does not pair with another instruction.

I_{RDLQR} If a `BRK` instruction that is prefixed by a `MOVPRFX` instruction generates a Breakpoint Instruction exception then the ELR_ELx points to the PC of `BRK` instruction and the `MOVPRFX` instruction is required to have updated the architectural state. The debugger can use MDSTEPOP_EL1 to execute the original instruction that was replaced by the `BRK` instruction.

I_{XLQPG} Executing an instruction from MDSTEPOP_EL1 is an indirect read of MDSTEPOP_EL1.

D2.11.5.4 Summary of behavior in the active-not-pending state

Table D2-22 summarizes behavior in the active-not-pending state.

Table D2-22 Summary of behavior in the active-not-pending state

Event	Value written to PSTATE.SS	Target Exception level is using:	Details[a]	Value written to SPSR_ELx.SS	Next state
No exception	0	n/a	Disables Software step	n/a	Inactive
			Otherwise	n/a	Active-pending
Exception	0	AArch64	Supervisor Call (`SVC`) Hypervisor Call (`HVC`) Secure Monitor Call (`SMC`)	0	Active-pending or inactive[b]
			Other	1	
		AArch32	All	0	Active-pending

a. For the *No exception* rows, this column shows the effect of the event. For the *Exception* rows, this column shows the exception taken.

b. Which state software step enters depends on whether debug exceptions are enabled or disabled from the target Exception level. See Figure D2-3.

D2.11.6 Entering the active-pending state

Software step enters the active-pending state after any of the following operations, provided that both:

- MDSCR_EL1.SS is 1.
- Debug exceptions are enabled from the Exception level and Security state that execution is in after the operation.

The operations are:

While software step is in the active-not-pending state

The PE either:

- Executing the instruction to be stepped without taking any exceptions.
- Taking an exception.

While software step is in the active-pending state

The PE takes an asynchronous exception.

While software step is in the inactive state

The PE executes either:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- An Exception return instruction when SPSR_ELx.SS is 0.
- An instruction that enables debug by setting PSTATE.D to 0.

Note

If entry to the active-pending state is because of the PE taking an exception, it means that the exception is one that is taken to EL1 when MDCR_EL2.TDE is 1 and EL2 is implemented and enabled in the current Security state. Otherwise, debug exceptions are masked by PSTATE.D, therefore they would be disabled from the target Exception level of the exception.

In addition, software step might enter the active-pending state either:

- After a direct write to a System register, for example a write to MDSCR_EL1.KDE or MDSCR_EL1.SS. These writes require explicit synchronization to guarantee their effect. See Synchronization and the software step state machine.
- On exiting Debug state when DSPSR_EL0.SS or DSPSR.SS is 0. See Exiting Debug state.

D2.11.7 Behavior in the active-pending state

When the PE is in the active-pending state, a Software Step exception is taken before the PE executes an instruction.

The Software Step exception has higher priority than all other types of synchronous exception. However, the prioritization of this exception with respect to any unmasked pending asynchronous exception is not defined by the architecture.

For more information, see the following:

- Prioritization of Synchronous exceptions taken to AArch64 state.
- Prioritization of asynchronous exceptions.
- Architectural requirements for taking asynchronous exceptions.

D2.11.8 Stepping T32 IT instructions

The A-profile architecture permits a combination of an `IT` instruction and another 16-bit T32 instruction to comprise one 32-bit instruction.

For the purpose of stepping an item, it is IMPLEMENTATION DEFINED whether:

- The PE considers this combination to be one instruction.
- The PE considers this combination to be two instructions.

In an implementation that supports the ITD control, which can disable some uses of the `IT` instruction, it is then IMPLEMENTATION DEFINED whether this behavior depends on the value of the applicable ITD field. For example:

- The PE might consider this combination to be one instruction, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be two instructions, regardless of the state of the applicable ITD field.
- The PE might consider this combination to be one instruction when the applicable ITD field is 1, and two instructions when it is 0.

The applicable ITD field is one of:

- SCTLR_EL1.ITD if execution is at EL0 using AArch32 when EL1 is using AArch64.
- SCTLR.ITD if execution is at EL0 or EL1 when EL1 is using AArch32.
- HSCTLR.ITD if execution is at Non-secure EL2 using AArch32.

D2.11.9 Exception syndrome information and preferred return address

See the following:

- Exception syndrome information.
- Preferred return address.

D2.11.9.1 Exception syndrome information

On taking a Software Step exception, the PE optionally records information about the exception in the Exception Syndrome Register (ESR_ELx) at the Exception level the exception is taken to. See ISS encoding for an exception from a Software Step exception for more information.

If no syndrome is recorded, then ESR_ELx.{ISV, EX} are set to {0,0}.

If no instruction was stepped because software step entered the active-pending state from the inactive state without passing through the active-not-pending state, then no syndrome can be recorded.

When a syndrome is recorded:

- ESR_ELx.ISV is set to 1, to indicate that ESR_ELx.EX is valid.
- If the instruction stepped was a Load-Exclusive instruction, then ESR_ELx.EX is set to 1. Otherwise ESR_ELx.EX is set to 0.

Note

A Load-Exclusive instruction is any one of the following:

- In the A64 instruction set, any instruction that has a mnemonic starting with either `LDX` or `LDAX`.
- In the T32 and A32 instruction sets, any instruction that has a mnemonic starting with either `LDREX` or `LDAEX`.

Arm deprecates software use of ESR_ELx.{ISV, EX}. Table D2-23 summarizes the possible values that the PE can record in ESR_ELx.{ISV, EX}.

Table D2-23 Values that the PE can record in ESR_ELx.{ISV, EX}

Description	ESR_ELx.ISV	ESR_ELx.EX
Syndrome data is not available.	0	0
Syndrome data is available. The instruction stepped was an instruction other than a Load-Exclusive instruction.	1	0
Syndrome data is available. The instruction stepped was a Load-Exclusive instruction.	1	1

D2.11.9.2 Preferred return address

The preferred return of a Software Step exception is the address of the instruction that was not executed because the PE took the Software Step exception instead.

D2.11.10 Additional considerations

This section contains the following:

- Behavior when an Exception return instruction is an illegal exception return.
- Behavior when the instruction stepped writes a misaligned PC value.
- Stepping code that uses Exclusives monitors.
- Synchronization and the software step state machine.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D2.11.10.1 Behavior when an Exception return instruction is an illegal exception return

If the conditions for entering the active-not-pending state in Entering the active-not-pending state are met, but the PE executes an Exception return instruction that is an illegal exception return, the exception return must be taken to the same Exception level that it was taken from. In this scenario, even though the Exception level remains the same before and after the Exception return instruction, software step can advance from the inactive state to one of the active states. Consider the following case:

1. MDSCR_EL1.SS is 1 and software step is inactive. The current Exception level is EL1 using AArch64, the OS Lock and OS Double Lock are unlocked, and MDCR_EL2.TDE is 0, MDSCR_EL1.KDE is 1, and PSTATE.D is 1.
   PSTATE.D == 1 is the reason why software step is inactive, because PSTATE.D == 1 means that debug exceptions are disabled from the current Exception level.
2. The PE executes an Exception return instruction.
3. The intended target of the Exception return instruction is EL2. This means that the Exception return instruction is an illegal exception return because the intended target is higher than the Exception level the Exception return instruction it is executed at. In this case, the Exception return instruction must target EL1 instead of EL2.
   If SPSR_EL1.D is 0, then on the Exception return instruction PSTATE.D becomes 0 and debug exceptions become enabled from the current Exception level. Software step therefore advances from the inactive state to one of the active states.

Which active state software step advances to depends on whether SPSR_ELx.SS is 1 or 0:

- If SPSR_ELx.SS is 1, software step advances to the active-not-pending state.
  In this case, an Illegal Execution state exception is pending on the instruction to be stepped, and the PE takes the Illegal Execution state exception instead of executing the instruction to be stepped.
- If SPSR_ELx.SS is 0, software step advances to the active-pending state.
  In this case, a Software Step exception and an Illegal Execution state exception are both pending. The Software Step exception has higher priority. On taking the Software Step exception, the PE sets SPSR_ELx.IL to 1.

Note

Prioritization of Synchronous exceptions taken to AArch64 state shows the relative priorities of synchronous exceptions.

D2.11.10.2 Behavior when the instruction stepped writes a misaligned PC value

An indirect branch that writes a misaligned PC value might generate a PC alignment fault exception at the target of the branch. However, if the indirect branch is stepped using software step, the PE takes a Software Step exception instead, because the Software Step exception has higher priority. Behavior on returning from the Software Step exception depends on which Execution state the Exception level being returned to is using:

AArch64 A PC alignment fault exception is generated.

AArch32 The return from the Software Step exception forces the PC to the correct alignment, and no PC alignment fault exception is generated.

Debugger software must therefore take care when using software step to single-step an indirect branch instruction executed in AArch32 state, that it does not hide a PC alignment fault exception.

D2.11.10.3 Stepping code that uses Exclusives monitors

The A-profile architecture provides no mechanism for preserving the state of the Exclusives monitors when a Load-Exclusive or a Store-Exclusive instruction is stepped.

However, for certain progressions through the software step state machine, on taking a Software Step exception, the PE provides an indication of whether the instruction stepped was a Load-Exclusive instruction.

Debugger software can use this to detect the state of the Exclusives monitors. For example, if the PE reports that the instruction stepped was a Load-Exclusive instruction, the debugger is aware that the next Store-Exclusive operation will fail, because all Exclusives monitors are cleared on returning from the Software Step exception. The debugger must then take action to ensure that the code being stepped makes forwards progress.

For more information on how the PE reports whether the instruction stepped was a Load-Exclusive instruction, see Exception syndrome information and preferred return address.

D2.11.10.4 Synchronization and the software step state machine

Any of the following can cause transitions between software step states:

- A direct write to a System register.
- A direct write to a Special-purpose register.
- A write to an external debug register.

The software step state machine indirectly reads some of these registers and so is not guaranteed to observe any new values until after a Context Synchronization event has occurred.

Between a write to the register and the next Context Synchronization event, it is CONSTRAINED UNPREDICTABLE whether software step uses the state of the PE before the write, or the state of the PE after the write.

After a Context Synchronization event, the state machine must use the state of the PE after the write.

Example D2-11 Example of synchronization and software step state machine changing states

1. Software changes MDSCR_EL1.SS from 0 to 1 when debug exceptions are enabled.
2. The PE executes some instructions.
3. A Context Synchronization event occurs.

During step 2, it is CONSTRAINED UNPREDICTABLE whether software step remains in the inactive state, as if MDSCR_EL1.SS is 0, or enters the active-pending state because MDSCR_EL1.SS is 1. If it is in the:

- Inactive state, then after the Context Synchronization event, it must enter the active-pending state.
- Active-pending state, the PE might take a Software Step exception before the Context Synchronization event.

Note

A direct write to a Special-purpose register does not require explicit synchronization.

D2.11.11 Pseudocode description of Software Step exceptions

`SSAdvance()` advances software step from the active-not-pending state to the active-pending state, by setting PSTATE.SS to 0. It is called on completing execution of each instruction.

`CheckSoftwareStep()` checks whether software step is in the active-pending state, and if it is, generates a Software Step exception. It is called before each instruction executed, regardless of Execution state, before checking for any other synchronous exceptions.

`DebugExceptionReturnSS()` returns the value to write to PSTATE.SS on an exception return or an exit from Debug state. See Entering the active-not-pending state.

These functions are defined in A-profile Architecture Pseudocode.

Non-Confidential

D2.12 Synchronization and debug exceptions

The behavior of debug depends on all of the following:

- The state of the external debug authentication interface.
- Indirect reads of:
  - External debug registers.
  - System registers, including system debug registers.
  - Special-purpose registers.

If a change is made to any of these, the effect of that change on debug exception generation cannot be relied on until after a Context Synchronization event has occurred. Similarly, the effect of the change on the software step state machine cannot be relied on until after a Context Synchronization event has occurred.

For any instructions executed between the time when the change is made and the time when the next Context Synchronization event occurs, it is CONSTRAINED UNPREDICTABLE whether debug uses the state of the PE before the change, or the state of the PE after the change.

Example D2-12 Example of synchronization and Breakpoint exception generation

1. Software changes MDSCR_EL1.MDE from 0 to 1.
2. An instruction is executed, that would cause a Breakpoint exception if self-hosted debug uses the state of the PE after the change.
3. A Context Synchronization event occurs.

In this case, it is CONSTRAINED UNPREDICTABLE whether the instruction generates a Breakpoint exception.

Example D2-13 Example of synchronization and debug exceptions generation

1. Software unlocks the OS Lock.
2. The PE executes some instructions.
3. A Context Synchronization event occurs.

During the time when the PE is executing some instructions, step 2, it is CONSTRAINED UNPREDICTABLE whether debug exceptions other than Breakpoint Instruction exceptions can be generated.

Note

For more information, see:

- Accessing PSTATE fields.
- Synchronization requirements for AArch64 System registers.
- Synchronization of changes to the external debug registers.

Chapter D3
AArch64 Self-hosted Trace

This chapter describes the AArch64 self-hosted trace:

- About self-hosted trace
- Prohibited regions in self-hosted trace
- Self-hosted trace timestamps
- Synchronization in self-hosted trace

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D3.1 About self-hosted trace

A trace unit generates trace data to describe the program flow of the PE.

The trace unit can be an implementation of any of the following:

- In Armv8, a standard Arm Embedded Trace Macrocell (ETM). See *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4*.
- In Armv9, the Embedded Trace Extension (ETE). See The Embedded Trace Extension.
- An IMPLEMENTATION DEFINED trace function.

Self-hosted trace happens when the agent controlling the trace collection is part of the same software stack as the software being traced. The agent controls prohibited regions. The information collected by the agent is sent to a trace sink.

The trace unit and the PE must have the same view of the debug authentication interface. If FEAT_TRF is implemented, `ExternalNoninvasiveDebugEnabled()` is always TRUE.

D3.1.1 Trace sinks

The trace unit sends the trace data to a trace sink. A system might include multiple trace sinks, and allow software to configure which trace sink or sinks are used.

An example of an internal trace sink is an Embedded Trace Router (ETR), which allows software to define a buffer in memory. Trace data is written to this buffer.

If FEAT_TRBE is implemented, the PE includes a Trace Buffer Unit. Trace data is written directly to memory by the Trace Buffer Unit. See The Trace Buffer Extension.

In Armv8, Arm recommends that a system that includes FEAT_TRF incorporates an ETR, and follows the system architecture described by the *CoreSight Base System Architecture (CS-BSA)*.

D3.1.2 Register controls to enable self-hosted trace

R_{FHVLM} If FEAT_TRF is implemented, self-hosted trace is enabled if any of the following are true, and disabled otherwise:

- EDSCR.TFO == 0.
- EDSCR.TFO == 1, EL3 is implemented, MDCR_EL3.STE == 1, and `ExternalSecureNoninvasiveDebugEnabled()` == FALSE.
- EDSCR.TFO ==1, EL3 is not implemented, the PE executes in Secure state, and `ExternalSecureNoninvasiveDebugEnabled()` == FALSE.
- EDSCR.TFO ==1, FEAT_RME is implemented, MDCR_EL3.RLTE == 1, and `ExternalRealmNoninvasiveDebugEnabled()` == FALSE.

The pseudocode function `SelfHostedTraceEnabled()` shows these rules.

I_{ZSZXF} If FEAT_TRF is not implemented, self-hosted trace is disabled.

I_{RCXSF} While self-hosted trace is disabled, `ExternalNoninvasiveDebugAllowed()` controls whether tracing is prohibited or allowed in each Security state.

I_{KHRZF} The self-hosted trace extensions do not provide any mechanism to control software access to the trace unit external debug interface.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D3.2 Prohibited regions in self-hosted trace

Trace is not generated in prohibited regions. The pseudocode function `TraceAllowed()` indicates whether tracing is allowed in the current Security state and Exception level.

The IMPLEMENTATION DEFINED debug authentication interface can allow an external agent to disable the self-hosted trace extension.

If self-hosted trace is enabled and EL3 is implemented, tracing is prohibited in Secure state when MDCR_EL3.STE == 0.

If self-hosted trace is enabled, tracing is prohibited in Realm state when MDCR_EL3.RLTE == 0.

If self-hosted trace is enabled, tracing is prohibited in Root state.

D3.2.1 Controls to prohibit trace at Exception levels

If self-hosted trace is enabled, TRFCR_EL1 and TRFCR_EL2 control whether trace is prohibited at an Exception level. While self-hosted trace is disabled, the registers TRFCR_EL1 and TRFCR_EL2 are ignored.

If self-hosted trace is enabled, tracing is prohibited at EL0 if one of the following is true:

- The Effective value of HCR_EL2.TGE == 0 and TRFCR_EL1.E0TRE == 0.
- The Effective value of HCR_EL2.TGE == 1 and TRFCR_EL2.E0HTRE == 0.

If self-hosted trace is enabled, tracing is prohibited at EL1 if TRFCR_EL1.E1TRE == 0.

If self-hosted trace is enabled, tracing is prohibited at EL2 if TRFCR_EL2.E2TRE == 0.

If self-hosted trace is enabled, tracing is prohibited at EL3 if one of the following is true:

- EL3 is using AArch64 state.
- EL3 is using AArch32 state and TRFCR.E1TRE == 0.

The pseudocode `TraceAllowed()` shows the above rules.

If FEAT_ETE is not implemented, when self-hosted trace is enabled, no events are exported to the trace unit when tracing is prohibited.

If FEAT_ETE is not implemented, when self-hosted trace is disabled, no events are exported to the trace unit when the PE is in Secure state and counting in Secure state is prohibited.

If FEAT_ETE is implemented, see External inputs for the rules governing export of events to the trace unit.

If FEAT_ETE is not implemented, when PMCR_EL0.X==0 or PMCR.X==0, no PMU events are exported to the trace unit.

Otherwise, PMU events are exported to the trace unit.

If self-hosted trace is enabled, Table D3-1 shows the prohibited regions by Exception level and state.

In the table:

RLTE Means the Effective value of MDCR_EL3.RLTE.

STE Means the Effective value of MDCR_EL3.STE or SDCR.STE, as applicable.

EEL2 Means the Effective value of SCR_EL3.EEL2.

TGE Means the Effective value of HCR_EL2.TGE.

P Means prohibited.

E2TRE Means prohibited if TRFCR_EL2.E2TRE == 0.

E1TRE Means prohibited if TRFCR_EL1.E1TRE == 0.

E0HTRE Means prohibited if TRFCR_EL2.E0HTRE == 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E0TRE Means prohibited if TRFCR_EL1.E0TRE == 0.

n/a Not applicable.

If FEAT_TRBE is not implemented, trace is allowed unless otherwise prohibited in Table D3-1.

If FEAT_TRBE is implemented, the requirements in this section are extended. See The owning translation regime.

Table D3-1 Prohibited regions

Controls						Tracing prohibited at			
State	**RLTE**	**STE**	**EL3 using**	**EEL2**	**TGE**	**EL3**	**EL2**	**EL1**	**EL0**
Non-secure	x	x	x	x	0	n/a	E2TRE	E1TRE	E0TRE

					1	n/a	E2TRE	n/a	E0HTRE
Root	x	x	x	x	x	P	n/a	n/a	n/a

D3.2.2 Self-hosted trace and visibility of virtual data

A hypervisor can use TRFCR_EL2.CX to control visibility of CONTEXTIDR_EL2 and VTTBR_EL2.VMID.

If self-hosted trace is enabled and TRFCR_EL2.CX == 0, or if EL2 is not implemented:

- The values of CONTEXTIDR_EL2 and VTTBR_EL2.VMID are not traced.
- Comparisons between CONTEXTIDR_EL2 and VTTBR_EL2.VMID do not match and results of comparison are not exposed through the comparators.

The trace unit can either prohibit trace for these values, or can record a CONTEXTIDR_EL2 or VTTBR_EL2.VMID value of zero in the trace.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D3.3 Self-hosted trace timestamps

The trace timestamp is a value that represents the passage of time in real-time. It is calculated from a counter which increments all the time, when the PE is generating trace and when the PE is in a prohibited region.

While self-hosted trace is disabled, the external trace provides the trace timestamp. If the external trace is a standard CoreSight system, the relationship between CoreSight time and the Generic Timer counter is IMPLEMENTATION DEFINED.

When self-hosted trace is enabled, the trace timestamp is one of the following:

- Physical time, which is defined by the physical count value returned by `PhysicalCountInt()`.
- If FEAT_ECV is implemented, offset physical time, which is defined as the value of `PhysicalCountInt()` minus a physical offset.
  If any of the following are true, the value of physical offset is zero:
  — EL3 is using AArch32.
  — EL2 is not implemented.
  — FEAT_ECV_POFF is not implemented.
  — The Effective value of SCR_EL3.{NSE, NS, RW} is {0, 1, 0}.
  — CNTHCTL_EL2.ECV is 0.
  — EL3 is implemented and using AArch64, and SCR_EL3.ECVEn is 0.
  Otherwise the value of physical offset is the value of CNTPOFF_EL2.
- Virtual time, which is defined as the value of `PhysicalCountInt()` minus a virtual offset.
  If any of the following are true, the virtual offset is zero:
  — EL2 is not implemented.
  Otherwise, the virtual offset is always CNTVOFF_EL2, including when a read of CNTVCT_EL0 at the current Exception level would treat the virtual offset as zero.

The following fields control which counter is used for self-hosted trace:

- TRFCR_EL2.TS.
- TRFCR_EL1.TS.
- HTRFCR.TS.
- TRFCR.TS.

The timestamp used for trace is shown in Table D3-2.

Table D3-2 Timestamp used for trace.

`SelfHostedTraceEnabled()`	TRFCR_EL2.TS	TRFCR_EL1.TS	Timestamp traced
FALSE	xx	xx	CoreSight time
TRUE	`0b00`	`0b01`	`PhysicalCountInt()` - virtual offset
	`0b00`	`0b10`	`PhysicalCountInt()` - physical offset
	`0b00`	`0b11`	`PhysicalCountInt()`
	`0b01`	xx	`PhysicalCountInt()` - virtual offset
	`0b10`	xx	`PhysicalCountInt()` - physical offset
	`0b11`	xx	`PhysicalCountInt()`

Note

The counter value used for the trace timestamp is not affected by the Effective value of HCR_EL2.E2H, or whether EL2 is enabled or disabled in the current Security state.

D3.4 Synchronization in self-hosted trace

The trace unit is an indirect observer of the System registers.

If FEAT_TRBE is implemented, the requirements in this section are extended. See Synchronization and the Trace Buffer Unit.

While self-hosted trace is enabled, indirect reads of the trace filter control fields, TRFCR_EL1.{E1TRE, E0TRE} and TRFCR_EL2.{E2TRE, E0HTRE} are treated as indirect reads made by the instruction being traced. For these register fields, in addition to the standard requirements for synchronization of System register accesses, when a trace filter control value is changed and synchronization is not explicitly specified, one of the following occurs:

- The behavior of the PE must be consistent with the control value having the old value.
- The behavior of the PE must change the control value at a point in the simple sequential execution of the program, so that before that point, the behavior of the PE is consistent with the control value having the old value, and after that point the behavior of the PE is consistent with the control value having the new value.

If there are multiple direct writes to the register without explicit synchronization, the behavior is consistent with the writes occurring in program order.

The `TSB CSYNC` operation is used to ensure that a trace operation, due to a trace unit generating trace for an instruction has completed. The `TSB CSYNC` operation can be reordered with respect to other instructions, so must be combined with at least one Context synchronization event to ensure the operations are executed in the required order. This means that a direct write to TRFCR_EL1 or TRFCR_EL2 is guaranteed to be observed by the trace unit only after a subsequent Context synchronization event. For more information, see Trace Synchronization Barrier.

While self-hosted trace is disabled, the trace unit might impose stronger synchronization requirements.

Chapter D4
The Embedded Trace Extension

This chapter describes the *Embedded Trace Extension* (ETE). It contains the following sections:

- About the Embedded Trace Extension
- Programmers' model
- Trace elements
- Instruction and exception classification
- About the ETE trace unit
- Resource operation

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.1 About the Embedded Trace Extension

IJTPNL FEAT_ETE describes the operation of a trace unit. The trace unit provides details about software control flow running on a PE which can be used to aid debugging or optimization. The trace unit provides filtering functionality to allow the targeting of the information to specific code regions or periods of operation.

ILVKQS FEAT_ETE overlaps with the ETMv4 architecture, while also providing support for new architecture features. For more information on the ETMv4 architecture, see the *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4 (ARM IHI 0064)*. FEAT_ETE does not support all the features of ETMv4. For more information on the differences between FEAT_ETE and the ETMv4 architecture, see Differences between ETM and ETE.

D4.1.1 Attributes of tracing

IRGLSR The attributes of PE tracing are:

Trace is generated in real time.
Trace provides a means of observing the PE operation while the PE is running. For diagnostic purposes, this is useful as some types of erroneous behavior are only solvable by observing the system during runtime. In addition, because the PE trace can include cycle counts, trace can be used for PE profiling purposes.

Trace has a minimal effect on functional performance of the PE.
Usually, trace has no effect on the functional performance of the PE. This attribute does depend on the market use of the PE being debugged, however, and on the trace requirements for the PE and the trace solution that is adopted to meet those requirements. For some markets, some impact on PE performance is acceptable but for others, most notably in real-time systems, an impact on PE performance might be unacceptable.

Trace is available for self-hosted analysis.
The trace from a PE or process is available for analysis by software running on the target. See Self-hosted Trace.

Trace is deeply embedded in an SoC.
Trace provides a method of debugging software executing on PEs that are deeply embedded within an SoC.

Trace is available for external analysis.
The trace from a PE or process can be exported off chip for analysis by external tools.

D4.1.2 Self-hosted Trace

IFNMRL Self-hosted trace is used for various purposes, including:

Non-invasive single stepping:
The trace provides a history of execution similar to that obtained by single-stepping through code.

Failure logging:
This is similar to a stack trace dump when a failure occurs.

Performance analysis:
The trace might be used with other trace sources or performance analysis units to analyze program performance.

IVVSCJ Capturing the trace on-chip involves one of the following:

Use of system memory:
The trace output from the trace unit is directed to a buffer in main system memory through the Trace Buffer Unit defined by FEAT_TRBE.

Use of existing shared system memory, where some main system memory is reserved for trace capture:
The trace output from the trace unit is directed to the reserved memory over the main system bus, typically using CoreSight technology such as a CoreSight ETR.

Use of a dedicated on-chip buffer:
The trace output from the trace unit is directed to the dedicated memory, typically using CoreSight technology such as a CoreSight ETB. A dedicated bus such as AMBA ATB is also usually implemented between the trace unit and the dedicated memory. Use of dedicated memory means that PE tracing can be performed with zero or minimal effect on system behavior.
AMBA ATB is defined by the *AMBA® ATB Protocol Specification (ARM IHI 0032)*.

Non-Confidential

D4.1.3 External debug

I_{TQGBH} External debug is commonly used in trace applications that require long-term logging of behavior. In addition, external debug is more likely to be used when the impact of PE tracing on system performance must be minimized.

For example, external debug might be used:

- For debugging real-time systems.
- When analyzing programs that do not frequently vary their behavior.
- For debugging software, where a history of execution is required up to the point of failure.

Exporting the trace off-chip usually involves one of the following methodologies:

D4.1.3.1 Real-time continuous export

I_{VJBMM} This can be done using either:

- A dedicated trace port capable of sustaining the bandwidth of the trace.
- An existing interface on the SoC, such as a USB or other high-speed port.

Use of a dedicated trace port means that the trace can be exported off-chip with zero or minimum effect on system behavior. An existing interface is usually used when system constraints, such as cost or package size, mean that a dedicated trace port is not possible. However, use of an existing interface might affect system behavior, because both trace and normal interface traffic use the same port.

D4.1.3.2 Short-term on-chip capture with subsequent low speed export

I_{PXSSB} This option is used when a low-cost method of exporting the trace is required, or when system constraints prevent real-time continuous export. The trace output from the trace unit is stored temporarily on-chip, and then exported using either:

- An existing debug port on the SoC, such as a JTAG-DP or SW-DP.
- Another existing interface on the SoC, such as USB.

Typically, the temporary storage is a circular buffer. If the buffer is full, newer trace overwrites older trace, which means that the buffer always contains the most recent trace. In SoCs that employ Arm CoreSight technology, a dedicated Embedded Trace Buffer (ETB) is provided for the on-chip capture of trace.

D4.1.4 Trace output

R_{SVDBD} The trace unit outputs the trace byte stream to one or more of the following:

- The TRBE.
- One or more IMPLEMENTATION DEFINED interfaces. An AMBA ATB interface to a CoreSight subsystem is an example of such an IMPLEMENTATION DEFINED interface.

R_{LGVCX} If the Trace Buffer Unit is enabled, the trace byte stream is output solely to the Trace Buffer Unit.

R_{FJFNS} If the Trace Buffer Unit is disabled, the trace byte stream is output to one or more of the other interfaces.

R_{HBBDV} The ETE Trace Output Enable is always implemented when FEAT_ETEv1p3 is implemented and an IMPLEMENTATION DEFINED trace output interface is present.

R_{RPHPJ} The ETE Trace Output Enable is optional when FEAT_ETE is implemented and an IMPLEMENTATION DEFINED trace output interface is present.

R_{FTSZG} When the ETE Trace Output Enable is not implemented and the Trace Buffer Unit is disabled, trace is output to an IMPLEMENTATION DEFINED trace output interface unless such output is disabled by an IMPLEMENTATION DEFINED mechanism.

R_{PJYKY} When the ETE Trace Output Enable is implemented and TRCEVENTCTL1R.OE is 0 or the Trace Buffer Unit is enabled, trace is never output to any IMPLEMENTATION DEFINED trace output interface.

R_{MMCKW} When the ETE Trace Output Enable is implemented and TRCEVENTCTL1R.OE is 1 and the Trace Buffer Unit is disabled, trace is output to an IMPLEMENTATION DEFINED trace output interface.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The addition of TRCEVENTCTL1R.OE is not backward compatible, and requires a trace analyzer to explicitly enable trace output to any IMPLEMENTATION DEFINED trace output interface.

I_{TVDMT} If the trace output is captured by a single capture point dedicated to a PE, and does not mix with any other trace streams, then the value programmed into TRCTRACEIDR.TRACEID does not need to be unique among all values programmed into all trace units in the system. For example, the value `0x01` could be programmed into all trace units that have their own dedicated trace capture point.

- One example of a dedicated trace capture point is the Trace Buffer Extension. When FEAT_TRBE is implemented and enabled, the value of TRCTRACEIDR.TRACEID can be the same for all PEs that are using the Trace Buffer Extension. For more information, see The Trace Buffer Extension.
- Another example of a dedicated trace capture point is a CoreSight ETR connected through an AMBA ATB interface and dedicated to a PE. If the AMBA ATB interface connects to the ETR without mixing with any other trace streams, TRCTRACEIDR.TRACEID does not need to be unique when using the ETR, and when ensuring the trace does not go to any other trace capture points.

R_{RWPFG} If an AMBA ATB interface is implemented, the trace unit must support all of the following:

- ATB triggers, indicated by TRCIDR5.ATBTRIG.
- A 7-bit trace ID, indicated by TRCIDR5.TRACEIDSIZE.

I_{QJKVW} Arm recommends that if the trace unit implements either an AMBA ATB interface, or an IMPLEMENTATION DEFINED interface for trace output, then the path from the interface is not affected by a Warm reset of the PE. This ensures tracing is possible through a Warm reset of the PE, which is useful for low level debugging scenarios.

R_{NLSSL} While all trace outputs are disabled, the trace unit considers any generated trace data as having been output.

D4.1.5 Trace sessions

R_{GLTKQ} At any one time, the trace unit is either enabled or disabled. For more information on the possible states of the trace unit, see Trace unit programming states.

R_{XBPSQ} A *trace session* is the period between the trace unit becoming enabled, and when the trace unit next becomes disabled.

R_{MTLFH} While the trace unit is enabled, the ViewInst() function is either *active* or *inactive*. While ViewInst() is *active*, the trace unit generates trace for instructions that are executed, unless trace generation is *inoperative*.

R_{MFNWB} Whether ViewInst() is *active* or *inactive* is independent of whether trace generation is *operative* or *inoperative*.

R_{ZVNKV} Trace generation is *operative* while neither of the following are true:

- The trace unit is disabled.
- The trace unit is recovering from a trace unit buffer overflow.

R_{RDPSW} Trace generation *becomes operative* when trace generation transitions from being *inoperative* to *operative*, and occurs when any of the following occur:

- When the trace unit transitions from being disabled to being enabled.
- When the trace unit recovers from a trace unit buffer overflow.

R_{BDRKW} Trace generation *becomes inoperative* when trace generation transitions from being *operative* to *inoperative*, and occurs either:

- When the trace unit transitions from being enabled to being disabled.
- When the trace unit encounters a trace unit buffer overflow.

R_{LDDLP} When the trace unit is unable to generate at least one trace packet which is required by the architecture, a *trace unit buffer overflow* occurs.

I_{HDJWW} A trace unit buffer overflow is typically caused when any buffering in the trace unit is unable to receive more trace packets. Inability to receive trace packets is often caused by being unable to sustain output of trace packets to any trace capture infrastructure.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

A trace unit buffer overflow is independent of the Trace Buffer Unit filling or wrapping a trace buffer in memory. However a trace unit buffer overflow might be caused by the Trace Buffer Unit rejecting trace data due to insufficient capacity, and the limit of any trace unit internal buffers is subsequently reached.

D4.1.6 Trace unit programming states

R_{WMGGP} The trace unit is always in one of the states shown in Figure D4-1 and Table D4-1.

Figure D4-1 Trace unit programming states

Table D4-1 Trace unit programming states

State	TRCSTATR.IDLE	TRCSTATR.PMSTABLE	Trace unit enabled
Idle	`0b1`	`0b1`	No
Enabling	`0b1`	UNKNOWN	Yes
Running	`0b0`	UNKNOWN	Yes
Unstable	`0b0`	`0b0`	No
Stable	`0b0`	`0b1`	No

R_{DXFFN} When the trace unit becomes enabled, the trace unit transitions from the Idle state to the Enabling state.

R_{ZFPHC} The trace unit transitions from the Enabling state to the Running state in a finite amount of time.

R_{TZSRP} When the trace unit becomes disabled, the trace unit transitions from the Running state to the Unstable state.

R_{CZHWF} The trace unit transitions from the Unstable state to the Stable state in a finite amount of time.

R_{BPTKT} While the trace unit is in the Stable and Idle states, the states of the following fields do not change other than by direct writes or external writes:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- TRCVICTLR.SSSTATUS.
- TRCSEQSTR.STATE.
- TRCCNTVR<n>.VALUE.
- TRCSSCSR<n>.STATUS.
- TRCRSR.EVENT.
- TRCRSR.EXTIN.
- TRCRSR.TA.

I_{TDLZL} The trace unit programmers' model state can be safely read when in any of the Stable or Idle states.

R_{TRZCP} When the trace unit becomes fully idle and both of the following are true, the trace unit transitions from the Stable state to the Idle state:

- The trace unit is drained of any trace.
- With the exception of the programming interfaces, all external interfaces on the trace unit are quiescent.

R_{RWYQD} While the trace unit is not in the Idle state, direct writes and external writes to the trace unit registers are CONSTRAINED UNPREDICTABLE, except for the following registers:

- TRCPRGCTLR.
- TRCCLAIMSET.
- TRCCLAIMCLR.

This CONSTRAINED UNPREDICTABLE behavior is one of the following:

- The write is ignored.
- The register takes an UNKNOWN value.

The trace byte stream might also be corrupted and analysis of the byte stream might be impossible.

R_{MDZDN} While the trace unit is not in the Idle or Running states, changing the value of TRCPRGCTLR.EN is CONSTRAINED UNPREDICTABLE.

This CONSTRAINED UNPREDICTABLE behavior is one of the following:

- The write is ignored.
- The register takes an UNKNOWN value.

I_{PRQRD} For more information, see:

- Behavior on enabling.
- Behavior on disabling.
- Access permissions on the corresponding register page.

D4.2 Programmers' model

D4.2.1 Accessing ETE registers

IVYNRB The ETE architecture provides registers for programming the ETE trace unit and reading back the programmed settings. These registers can be accessed by using one or more of the following access mechanisms:

- An external debug interface, for use by an external debugger.
- System instructions, for use by self-hosted software running on the PE being traced.

RNBPML When register accesses occur simultaneously from multiple access mechanisms, the trace unit behaves as if all accesses occur atomically in any order.

D4.2.1.1 External debug interface

IKPYGY The external debug interface defines an address-mapped peripheral that occupies 4KB of address space.

Note

The PE does not have to be in Debug state to program the ETE registers.

ITBMWG Unless otherwise stated in this section, information for supported access sizes for external debug interface is covered in Supported access sizes and Endianness.

RVQWLY The trace unit supports the following access sizes:

- Word-aligned 32-bit accesses to access 32-bit registers or either half of a 64-bit register mapped to a doubleword-aligned pair of adjacent 32-bit locations.
- Doubleword-aligned 64-bit accesses to access 64-bit registers mapped to a doubleword-aligned pair of adjacent 32-bit locations. The order in which the two halves are accessed is not specified.

Note

This means that a system implementing the Debug registers using a 32-bit bus, such as AMBA APB in CoreSight systems, with a wider system interconnect must implement a bridge between the system and the debug bus that can split 64-bit accesses.

RVNNPF All registers are only single-copy atomic at word granularity.

RKYDTQ The trace unit does not support the following accesses:

- Byte.
- Halfword.
- Unaligned word. These accesses are not single-copy atomic at word granularity.
- Unaligned doubleword. These accesses are not single-copy atomic at doubleword granularity.
- Doubleword accesses to a pair of 32-bit locations that are not a doubleword-aligned pair forming a 64-bit register.
- Quadword or higher.
- Exclusives.

RCFRFW For accesses from the external debug interface, the size of an access is determined by the interface. In an Arm Debug Interface compliant Memory Access Port, MEM-AP, this is specified by the MEM-AP CSW register. The CoreSight APB-AP supports only word accesses.

RYFRMG The behavior of the accesses that are unsupported by the trace unit is CONSTRAINED UNPREDICTABLE and is one of the following:

- Accesses generate an External abort, and writes set the accessed register or registers to an UNKNOWN value or values.
- Reads return UNKNOWN data and writes are ignored.
- Reads return UNKNOWN data and writes set the accessed register or registers to an UNKNOWN value. This is the Arm preferred behavior.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{YSHRS} For accesses from the external debug interface which return an error response when `AllowExternalTraceAccess()` returns FALSE, EDPRSR.STAD is only set to 1 when this is the highest priority cause of the error. The following causes are higher priority than `AllowExternalTraceAccess()`:

- The trace unit Core power domain is powered down.
- The OS Lock is locked and the register is defined to return an error response due to the OS Lock being locked.

R_{KQMKX} Accesses from the external debug interface to unimplemented or Reserved trace unit registers behave as follows:

- When the trace unit core power domain is off, the access returns an error.
- Otherwise:
  - For accesses in the range of offsets `0xF00` to `0xFFC`, the access behaves as RES0H.
  - For accesses in the range of offsets `0x000` to `0xEFC`:
    - When the OS Lock is locked, the response is a CONSTRAINED UNPREDICTABLE choice of an error response or behaving as RES0H.
    - When the OS Lock is unlocked and AllowExternalTraceAccess() returns FALSE, the response is a CONSTRAINED UNPREDICTABLE choice of an error response or behaving as RES0H.
    - Otherwise, the access behaves as RES0H.

R_{WXKDP} Reads of write-only registers are Reserved.

R_{SVSNR} Writes to read-only registers are Reserved.

I_{WTJFD} For accesses that return an error, see Behavior of a not permitted memory-mapped access for more details on how this error is handled.

D4.2.1.2 System instructions

R_{VGVTS} Instructions with `CRn >= 0b1000` are not allocated for accessing trace unit registers.

R_{SGPQB} While the PE is in EL0, all accesses are UNDEFINED.

I_{WCXDT} For consistency with the Arm architecture, System instruction accesses to registers which are not implemented generate an Undefined Instruction exception. These accesses include:

- Writes to read-only registers.
- Reads from write-only registers.
- Accesses to registers which are not present due to the configuration of the trace unit.

D4.2.2 Synchronization of register updates

D4.2.2.1 System registers

I_{KWCGH} As defined in Synchronization requirements for AArch64 System registers, direct writes to trace unit registers are only guaranteed to be visible to execution after a subsequent Context synchronization event, which consists of one of the following:

- Taking an exception.
- Returning from an exception.
- Performing an Instruction Synchronization Barrier operation.
- Exit from Debug state.
- Executing a `DCPS` instruction in Debug state.
- Executing a `DRPS` instruction in Debug state.

I_{PNZZH} Direct reads of trace unit registers while the trace unit is not in the Stable or Idle states are not guaranteed to contain the results of the trace operation of execution previous to the direct read operation.

I_{QPVJQ} As defined in Synchronization requirements for AArch64 System registers, a direct write to a register using the same register number that was used by a previous System instruction to write it, the final result is the value of the second write, without requiring any context synchronization between the two write instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{WLGQK} As defined in Synchronization requirements for AArch64 System registers, a direct read of a register using the same register number that was used by an earlier direct write is guaranteed to observe the value that was written, without requiring any context synchronization between the write and read instructions.

S_{HSXGZ} Context synchronization events are important when changing the value of TRCPRGCTLR.EN or when changing the OS Lock. After writing to TRCPRGCTLR to change the value of TRCPRGCTLR.EN, one read of TRCSTATR is required before programming any other registers. A Context synchronization event is required between writing to TRCPRGCTLR and reading TRCSTATR. If multiple reads of TRCSTATR are required, a Context synchronization event is required between each read of TRCSTATR to ensure any change to the trace unit state is observed.

R_{WPWWS} When indirect writes or external writes to the registers in Table D4-2 occur, both of the following can observe the writes:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

Table D4-2 Registers with a guarantee of observability

Register	Notes
TRCCLAIMSET	Claim Tag Set Register
TRCCLAIMCLR	Claim Tag Clear Register
TRCCNTVR<n>	Counter Value Register <n>
TRCSEQSTR	Sequencer State Register
TRCSSCSR<n>	Single-shot Comparator Control Status Register

R_{JQTMC} When the trace unit becomes enabled or disabled as a result of a direct write, for any instruction in program order before the direct write, the new state of the trace unit does not affect trace operations.

R_{KNQWS} When the trace unit becomes enabled or disabled as a result of a direct write, for any instruction after a Context synchronization event in program order after the direct write, the new state of the trace unit takes effect for any trace operations.

Note

The registers which control whether the trace unit is enabled or disabled are:

- TRCPRGCTLR.
- OSLAR_EL1.

S_{YKGMP} Arm recommends that a Context synchronization event is executed after programming the Trace Unit registers, to ensure that all updates are synchronized to the trace unit before normal code execution resumes.

R_{WZQWC} When a Context synchronization event occurs while the trace unit is in the Idle or Stable states, and at no other time, indirect writes to the trace unit registers are guaranteed to be visible to direct reads.

R_{GQKGX} When either of the following events occurs, and at no other time, indirect writes to the trace unit registers are guaranteed to be visible to indirect reads or external reads:

- The trace unit transitions into the Stable state.
- The trace unit transitions into the Idle state.

R_{XLXQL} The trace unit functions perform indirect writes to the registers and indirect reads from the registers in architectural order.

I_{RCKQJ} See Trace unit programming states for more details on programming the trace unit.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.2.2.2 External debugger registers

I_{KNWDX} As defined in the Synchronization of changes to the external debug registers, this section refers to accesses from the external debug interface as *external reads* and *external writes*.

I_{HMNWB} As defined in Synchronization of changes to the external debug registers, explicit synchronization is not required for an external read or an external write by an external agent to be observable to a following external read or external write by that agent to the same register using the same address, so explicit synchronization is never required for registers that are accessible only in the external debug interface.

I_{YXWFD} As defined in Synchronization of changes to the external debug registers, when an external write to a register using the same register number that was used by a previous external write is performed, the final result is the value of the second write, without requiring any context synchronization between the two write accesses.

R_{PGTLX} The trace unit does not require explicit synchronization for an external write to be visible to indirect reads.

R_{DYRZC} The trace unit does not require explicit synchronization for an external write to be visible to subsequent external reads.

I_{RDFSX} As defined in Synchronization of changes to the external debug registers, explicit synchronization is required for an external write to be visible to direct reads.

R_{MMYRJ} While the trace unit is in the Stable or Idle states, the trace unit does not require explicit synchronization for indirect writes to be visible to external reads.

D4.2.2.3 Synchronization and the authentication interface

R_{WYWMJ} Changes to the authentication interface are indirect writes to TRCAUTHSTATUS by the controller of the authentication interface. It is IMPLEMENTATION DEFINED whether a change on the authentication interface is guaranteed to be observable to an external read of the register only after a Context synchronization event or in finite time.

I_{XVVKN} For more information, see Synchronization and the authentication interface.

D4.3 Trace elements

IFNFWZ Trace elements form an AST which is used to describe the control flow of program execution. Different sequences of the trace elements can be used to imply the same operation. In this way FEAT_ETE can be used by different micro-architectures. This is similar to the approach used in previous trace protocols. For more information, see the *Arm® Embedded Trace Macrocell Architecture Specification, ETMv4 (ARM IHI 0064)*.

IXXBMZ A trace unit compresses the information on the execution of the PE and outputs a trace byte stream that comprises of multiple packets of encoded data. The compression techniques that are used include:

Not having a trace element for every executed instruction in the instruction trace element stream

Instead, the trace unit generates *P0 elements* in the trace element stream when certain types of instruction are executed. These certain types of instructions are known as *P0 instructions*. A *P0 element* acts as a signpost in the program flow, indicating that execution is proceeding along a given path.

Consequently, the stream of *P0 elements* implies the execution of a greater number of instructions, and a trace analyzer can reconstruct the stream of instructions that are executed between *P0 elements* by using the P0 element stream and the program image.

Multiple trace elements in single packets

Common sequences of trace elements are encoded into single packets.

Removal of program addresses from the trace element stream

The trace analyzer can infer the addresses from the program image and previous history. This includes the targets of direct branch instructions, where the target address is encoded in the instruction itself.

Removal of predictable trace elements

Some trace elements can be removed from the AST representation if the contents of the trace element can be predicted by previous control flow choices in the software flow. For example the *Target Address element* for returning from a subroutine might not be required if the branch to the subroutine has been traced.

D4.3.1 Layer model

IXMFJT FEAT_ETE is based on a layer model. Each layer deals with a unique aspect of tracing the PE.

Figure D4-4 Layer model for compression and decompression

IGLPQZ Transport Layer

The transport layer either provides either:

- A path off chip.
- A path to a memory buffer for trace to be stored.

Layer 1

Layer 1 provides compression by:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Grouping trace elements together to form packets.
- Removing trace elements that can be implied.
- Compression against previous values.
- Leading zero compression.
- Reordering of trace elements.

Layer 2

Layer 2 provides:

- Speculation resolution.

Layer 3

At layer 3:

- PE behavior is converted into trace elements.
- Compression is achieved by removing the trace elements which can be predicted using the program image:
  - Direct branch target addresses.
  - Return stack optimization.
- Knowledge of the application is required in order to decompress. Processes that modify the instruction opcodes require additional information to allow debugging.

D4.3.2 Trace protocol synchronization

I_{CLTCM} The trace byte stream of a trace unit is typically stored in a circular buffer where, if the buffer is full, newer trace overwrites older trace. To ensure that a trace stream can be analyzed when the trace has been stored in a circular buffer, a trace unit must periodically generate trace protocol synchronization points in the trace byte stream.

I_{BPNSY} The following trace elements or packets are used to provide synchronization information in the different layers.

Table D4-3 Control of each layer

Layer	Control
Layer 3	*Context element* and *Target Address element*
Layer 2	*Trace Info element*
Layer 1	Trace Info packet
Transport Layer	Alignment Synchronization packet

I_{SFXXD} Whenever a trace analyzer receives a Trace Info packet, the trace analyzer receives information about the current state of the trace. However, the trace analyzer cannot begin analysis of program execution until it knows the context in which instructions are being executed and it has an instruction address to start analysis from.

R_{PGHPW} When a *Trace Info element* is generated, the trace unit generates a *Context element* and a *Target Address element* soon after the *Trace Info element*.

Note

There are common use cases where the ratio between the number of bytes associated with trace protocol synchronization and other trace bytes increases significantly, resulting in a degradation of the usability of the trace. Therefore Arm recommends that trace protocol synchronization only occurs when required.

D4.3.2.1 Non-periodic trace protocol synchronization

R_{QZRMQ} When the trace unit becomes operative, non-periodic trace protocol synchronization occurs.

R_{TTLJC} When non-periodic trace protocol synchronization occurs, the trace unit generates an Alignment Synchronization packet in the trace byte stream before any other trace packets are generated.

R_{HMDGL} When non-periodic trace protocol synchronization occurs, the trace unit generates a *Trace Info element* in the trace element stream before any other trace elements are generated, except *Event elements* and *Instrumentation elements*.

I_{MQNBT} Arm recommends that if a trace protocol synchronization request occurs while ViewInst() is *inactive*, the Alignment Synchronization packet is not output in the trace byte stream until just before any of the following:

- ViewInst() becomes active.
- An Event packet is output.
- An Instrumentation packet is output.

I_{MHGVF} The generation of Instrumentation packets is independent of the ViewInst() function. Instrumentation packets can therefore be generated when ViewInst() indicates instruction tracing is inactive.

D4.3.2.2 Periodic trace protocol synchronization

I_{YPRYM} The trace unit can be programmed to generate trace protocol synchronization requests on a periodic basis, so that the trace element streams and the trace byte streams can be analyzed when stored in a circular trace buffer. TRCSYNCPR.PERIOD controls periodic trace protocol synchronization requests.

I_{NTFYC} Periodic trace protocol synchronization can also be requested by the trace capture infrastructure, for example if a trace protocol synchronization request is received on an Arm AMBA ATB interface. For more information on the Arm AMBA ATB interface, see the *AMBA® ATB Protocol Specification (ARM IHI 0032)*.

R_{QHHSY} When periodic trace protocol synchronization is requested, either by TRCSYNCPR.PERIOD or by other sources, the trace unit performs periodic trace protocol synchronization.

R_{VMPYW} When periodic trace protocol synchronization occurs, the trace unit generates an Alignment Synchronization packet. The trace unit then generates a *Trace Info element* to indicate a point where program execution trace analysis can start. A *Trace Info element* is not required if only *Event elements* and *Instrumentation elements* are output.

I_{QYQRY} Arm recommends that an Alignment Synchronization packet is only output in the trace byte stream if other trace packets have been output since the previous Alignment Synchronization packet. This reduces the risk of a circular buffer filling and overwriting trace.

I_{NQYXW} If two or more periodic trace protocol synchronization requests occur, and no trace is generated between these two requests, then Arm recommends that a non-periodic trace protocol synchronization occurs before any further trace is generated. This ensures that when tracing has been inactive for a long period of time, the trace stream is fully synchronized when tracing is re-activated.

D4.3.2.3 Synchronization of instruction trace

R_{KKQGK} When non-periodic trace protocol synchronization occurs, the trace unit generates a *Context element* and a *Target Address element* before any *P0 elements* are generated, to provide the trace analyzer with *Context information* and *Address information*.

R_{SVGNN} When periodic trace protocol synchronization occurs, and ViewInst() is active when the corresponding *Trace Info element* is generated, the trace unit generates a *Context element* and a *Target Address element* which provide the *Context information* and *Address information* for the target of the most recent non-canceled *P0 elements*.

Note

If the trace unit generates the *Context element* and *Target Address element* immediately after the *Trace Info element*, then the most recent non-canceled *P0 elements* might have occurred before the *Trace Info element*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure D4-5 Example of Target Address element after Trace Info element.

R_{DLPYX} When periodic trace protocol synchronization occurs, and ViewInst() is inactive when the corresponding *Trace Info element* is generated, when ViewInst() becomes active and a *Trace On element* is generated, the trace unit generates a *Context element* and a *Target Address element* before any *Atom elements*, *Q elements*, or *Exception elements* are generated. This provides the trace analyzer with *Context information* and *Address information*.

Figure D4-6 Example of Target Address element after Trace Info element in a filtered region.

I_{YZPCB} If a *Cancel element* cancels any *P0 elements* before a *Trace Info element*, then the trace analyzer discards all of the following:

- The canceled *P0 elements*.
- The *Trace Info element*.
- All elements after the *Trace Info element*, up to and including the *Cancel element*. This includes any *Context elements* or *Target Address elements*.

Note

In this scenario, information from the canceled *Trace Info element* can still be used.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure D4-7 Example of Target Address element after Trace Info element in a mispredicted region.

R_{KGPTB} When a *Cancel element* is generated which cancels any *P0 elements* before a *Trace Info element*, the trace unit generates a new *Context element* and a new *Target Address element*, which indicate the target of the most recent *P0 element* that has not been canceled.

I_{CHTFM} The *Target Address element* and *Context element* might indicate the target of a *P0 element* from before the *Trace Info element*, or might be delayed until after the next *P0 element*, and therefore indicate the target of that *P0 element*.

Note

If the trace unit generates the new *Context element* and *Target Address element* prior to the next new *P0 element*, then this might prevent the indication of execution of some instructions before the *Trace Info element*.

I_{NSWTK} If the *Cancel element* cancels all *P0 elements* after a *Trace Info element*, but no *P0 elements* prior to the *Trace Info element*, then it might be necessary for the trace unit to immediately generate a *Context element* and *Target Address element*. This is because a *Context element* and *Target Address element* might have been present in the trace element stream after the *Trace Info element*, and those *Context element* and *Target Address element* are now discarded.

D4.3.3 Speculation in the trace element stream

I_{NVBWS} FEAT_ETE supports the correction of trace. This might be because of the tracing of speculative execution of instructions by a PE.

I_{RTJNK} A FEAT_ETE trace unit traces speculatively-executed instructions in the same way as all other instructions, so that both speculatively-executed instructions and architecturally-executed instructions appear in the instruction trace element stream. This means that some of the program execution information that is shown in the trace element stream might be incorrect, because some of the speculatively executed instructions might be mis-speculated.

Note

The level of speculation that is revealed in the trace is IMPLEMENTATION SPECIFIC.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{XLLKT} The trace unit resolves this speculation by generating trace elements to confirm the status of each instruction in the instruction trace element stream. That is, the trace unit generates trace elements to show whether each instruction has been committed for execution, or canceled because of mis-speculation. This means that a trace analyzer does not know the status of a traced instruction until the trace analyzer receives a trace element that indicates whether the instruction has been committed for execution, or canceled because the instruction was mis-speculated.

R_{ZJJKY} When speculatively-executed instructions are traced, the trace unit subsequently generates trace elements that indicate whether the instructions have been committed for execution, or have been canceled.

I_{KYXKZ} A trace analyzer takes the appropriate action, which might involve canceling some trace elements, to determine the actual program execution.

I_{GGFML} Trace elements that resolve the status of a traced instruction are called *speculation resolution elements*. For more information on speculation elements, see Speculation Resolution Elements.

R_{KYGRF} When trace is generated for speculative execution, for mis-speculated execution, the trace unit does not trace any information that cannot be accessed by software executing at the same or at a lower level of privilege than the mis-speculated execution.

R_{QHQLY} When a Context synchronization event is speculated as being taken or executed, the trace unit does not generate trace for any speculative execution after the Context synchronization event until the Context synchronization event is resolved.

R_{LWJCQ} When a speculated Context synchronization event is resolved as being not taken or not executed, the trace unit does not generate trace for mis-speculated execution that occurred after the Context synchronization event.

R_{YGSGJ} When an exit from a Trace Prohibited region is speculated as being taken, the trace unit does not generate trace for any speculative execution after the exit from the Trace Prohibited region, until the exit from the Trace Prohibited region is resolved.

R_{SRLCG} When a speculated exit from a Trace Prohibited region is resolved as being not taken, the trace unit does not generate trace for mis-speculated execution that occurred after the exit from a Trace Prohibited region.

D4.3.4 Trace element stream

I_{LTBWR} A *Trace element stream* is a sequence of elements which describe:

- The software control path of PE execution traced by the trace unit.
- Event-based trace.
- Temporal information.

I_{LBSZF} A Trace Info element provides a point in the trace element stream where analysis of the trace element stream can begin. Trace Info elements include setup information about:

- The static trace programming that does not change during a trace session, including whether cycle counting is enabled, and if enabled, the cycle count threshold.
- Dynamic information that might change during a trace session, such as the speculation depth, which indicates how many unresolved P0 elements were traced before the Trace Info element.

D4.3.5 P0 element

I_{LLDBJ} P0 elements imply the execution of instructions.

I_{XPZXL} P0 elements are generated speculatively and must be either committed or canceled. For more information on speculation elements, see Speculation Resolution Elements.

R_{XVHWG} P0 elements must be generated in sequential execution order.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.3.5.1 Atom element

IXPFJG An *Atom element* implies that one or more instructions have been executed, up to and including the next *P0 instruction*. Only certain instructions generate an *Atom element*. See Instruction and exception classification for more information on these instructions.

RPRNZH The *Atom element* is one of the following types:

- E Atom.
- N Atom.

ICYMYM The meaning of the type of an *Atom element* depends on the instruction it is encoding. For example, branch instructions are represented as an E *Atom element* if the branch was taken and an N *Atom element* if not taken.

D4.3.5.2 Exception element

IYVMSC An *Exception element* indicates a change in program flow which cannot be calculated by the analysis of the program image, or which is caused by an instruction which is not a *P0 instruction*. Such a change in program flow is described as an Exceptional occurrence.

RMKPFJ An Exceptional occurrence consists of the following:

- PE Architectural exceptions.
- ETE defined exceptions.
- IMPLEMENTATION DEFINED exceptions.

IJLZPY An *Exception element* indicates:

- That an Exceptional occurrence has occurred.
- The type of Exceptional occurrence.
- The virtual address where the Exceptional occurrence was taken from, also known as the preferred exception return address.

RDXJBQ The instruction set for the preferred exception return address for an *Exception element* is one of the following:

- AArch64 A64.
- AArch32 A32.
- AArch32 T32.

RYPPRH An *Exception element* is a *P0 element*.

D4.3.5.2.1 PE Architectural exceptions

RPZRFL The following exception types are used to indicate PE Architectural exceptions:

- IRQ.
- FIQ.
- Trap.
- Call.
- Inst fault.
- Data fault.
- Inst debug.
- Data debug.
- Alignment.
- System Error.
- Debug halt.

See Instruction and exception classification for information on the mapping between the PE Architectural exceptions and these exception types.

RSFYMW Table D4-4 defines the preferred exception return address for each exception type for PE Architectural exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D4-4 Preferred exception return address for PE Architectural exceptions

Exception type	Preferred exception return address
IRQ	Instruction after the last executed instruction
FIQ	Instruction after the last executed instruction
Trap	For a trapped instruction or UNDEFINED instruction, the preferred exception return address is the address of the instruction. For a trapped exception, the preferred exception return address is the address of the instruction that caused the exception.
Call	Instruction after the call instruction
Inst fault	Instruction that caused the exception
Data fault	Instruction that caused the exception
Inst debug	Instruction that caused the exception
Data debug	Instruction that caused the exception
Alignment	Instruction that caused the alignment exception
System Error	Instruction after the last executed instruction
Debug halt	The instruction after the last executed instruction, that is, the value loaded into the DLR register.

I_{GZKGC} The nature of System Error means that execution might not complete up to the preferred exception return address, or it might perform some operations after the preferred exception return address. This behavior is IMPLEMENTATION DEFINED and might vary depending on the cause of the exception.

R_{GFJZF} When an imprecise System Error exception occurs, the preferred exception return address is the address stored in the relevant ELR when the exception is taken.

S_{GKMTH} When a System Error exception occurs, the trace analyzer must be aware that the preferred exception return address might not indicate the exact point at which program execution was interrupted. The trace analyzer should not rely on the preferred exception return address for inferring exactly which instructions were executed. This behavior only occurs for imprecise System Error exceptions.

R_{LBLWT} When an imprecise Debug halt exception occurs, the preferred exception return address is the address stored in DLR or DLR_EL0 when the exception is taken.

S_{RDJXM} When an imprecise Debug halt exception occurs, the trace analyzer must be aware that the preferred exception return address might not indicate the exact point at which program execution was interrupted. The trace analyzer should not rely on the preferred exception return address for inferring exactly which instructions were executed. An imprecise Debug halt exception can only occur under direct control of a debugger, usually by controlling EDRCR.CBRRQ.

D4.3.5.2.2 ETE defined exceptions

R_{MZJTJ} In addition to the Arm Architectural exceptions, the ETE specifies the following Exceptional occurrences that are traced using *Exception elements*:

- PE Reset, which indicates that a PE Warm reset has occurred.

R_{NRJGC} Table D4-5 defines the preferred exception return address for each exception type for ETE defined exceptions.

Table D4-5 Preferred exception return address for ETE defined exceptions

Exception type	Preferred exception return address
PE Reset	UNKNOWN

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{JRNYF} When a PE Reset occurs, the preferred exception return address and context are UNKNOWN. Therefore for an *Exception element* indicating a PE Reset the preferred exception return address and context are UNKNOWN. No instruction execution is indicated between the previous *P0 element* and the *Exception element*.

I_{QJYYZ} When an *Exception element* indicating a PE Reset occurs:

- The target address and target context of the previous *P0 element* might be UNKNOWN.
- If there are no *P0 elements* between a *Trace On element* and the *Exception element*, then the initial address and context after the previous *Trace On element* might be UNKNOWN.

D4.3.5.2.3 IMPLEMENTATION DEFINED exceptions

R_{ZVYQW} ETE defines some exception types which are IMPLEMENTATION DEFINED, including but not limited to:

- ECC error correction.
- Generic replay of program execution.

I_{XHFLL} The use of the IMPLEMENTATION DEFINED exceptions is optional and IMPLEMENTATION DEFINED. IMPLEMENTATION DEFINED exceptions are not required to be traced but are intended to be used to simplify tracing of certain micro-architectural situations.

I_{DFLDJ} In general, the preferred exception return address is the address of the instruction after the last executed instruction, before the exception occurs.

D4.3.5.3 Source Address element

I_{DJTGL} The *Source Address element* indicates execution up to and including a provided *P0 instruction* address, and indicates the *P0 instruction* is taken. All *P0 instructions* except the final *P0 instruction* are not taken, which means that explicit N *Atom elements* are not required to be traced for those *P0 instructions*. A *Source Address element* indicates both of the following for the final *P0 instruction*:

- The instruction set.
- The virtual address of the instruction.

R_{HVVRK} The instruction set for a *Source Address element* is one of the following:

- AArch64 A64.
- AArch32 A32.
- AArch32 T32.

R_{WTRBB} A *Source Address element* is a *P0 element*.

D4.3.5.4 Q element

R_{JRFYT} A *Q element* belongs to the *P0 element* group in the instruction trace element stream, and must be explicitly resolved or canceled.

I_{XPNWS} A *Q element* can optionally include a number, M. The number is a count of the instructions that are executed since the most recent *P0 element*, which might be a *Q element*. If it does not include a count of instructions, then the number of instructions that are executed since the most recent *P0 element* is UNKNOWN.

R_{XWBMW} The trace unit generates *Q elements* in the program order in which they occur, and the trace protocol encode and decode process maintains this order.

R_{JBYXC} A *Q element* does not imply Exceptional occurrences.

R_{KPNGG} When a *Q element* implies an Exception return instruction which is taken, that instruction is the last instruction that is implied by the *Q element*.

R_{YRLJR} When a *Q element* implies an executed `ISB` instruction, this is the last instruction implied by the *Q element* if execution continues from a new context after the `ISB`.

R_{LZLDH} When execution continues from a new context after a *Q element* is generated, the trace unit generates a *Context element* after the *Q element*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{BTNZC} The *Context element* might be generated before or after the *Target Address element* that is also required after the *Q element*.

If a context change occurs at a point that is not a Context synchronization event, then the last instruction that is implied by a *Q element* must be the last instruction that is executed with the old context. The trace unit can then generate a *Context element* after the *Q element* to indicate the new context.

D4.3.6 Virtual Address Space Element

D4.3.6.1 Trace On element

R_{NHDCF} A *Trace On element* indicates a discontinuity in the trace element stream. The trace unit inserts a *Trace On element* after a gap in the generation of the trace element stream:

- When the trace generation becomes operative and before any *P0 elements*.
- If some instructions are filtered out of the trace.
- The first traced instructions after:
  - A Trace Prohibited region.
  - The PE leaves Debug state.
- When instruction trace is lost because a trace unit buffer overflow occurs.

R_{KMFKP} When a *Trace On element* is generated, the trace unit generates a *Target Address element* before the next *P0 element*.

R_{TJLYH} When a *Trace On element* is generated, the trace unit generates a *Context element* before the next *Atom element*, *Exception element* or *Q element*, to indicate where tracing starts, unless the context has not changed since the previous *Context element* was output.

R_{JKFBS} When the first *Trace On element* is generated, the trace unit outputs the corresponding *Context element* before the first *P0 element*.

D4.3.6.2 Target Address element

R_{QWBLT} A *Target Address element* indicates both of the following for the next instruction to be executed:

- The instruction set.
- The virtual address of the instruction.

R_{JYKHH} The instruction set for a *Target Address element* is one of the following:

- AArch64 A64.
- AArch32 A32.
- AArch32 T32.

R_{HMWHY} The trace unit generates *Target Address elements* in program order relative to other *P0 elements*.

I_{XCKNM} *Target Address element* values can be corrected by another *Target Address element* if both *Target Address elements* are generated before the next *P0 element* or *Trace On element*.

D4.3.6.3 Context element

I_{KQKFF} The *Context element* indicates the execution context for the next instruction to be executed.

R_{VHQYV} The *Context element* provides the following *Context information*:

- The Security state.
- The Exception level.
- The Execution state of the PE.

R_{WSVRL} The *Context element* can optionally provide the following *Context information*:

- The Context identifier.
- The Virtual context identifier.

R_{WJDWF} The trace unit generates *Context elements* in program order relative to *P0 elements*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.3.7 Temporal elements

I_{HHXND} Temporal elements provide information about the passage of time within the trace element stream. The following temporal elements are supported by ETE:

The Cycle Count element
Indicates the passage of PE clock cycles within the trace element stream.

The Timestamp element
Indicates the passage of time within the trace element stream.

The Timestamp Marker element
Indicates that the most recent *P0 element*, *Event element*, *Instrumentation element* has been timestamped and that a subsequent *Timestamp element* contains the timestamp value.

D4.3.7.1 Cycle Count element

I_{NVGJP} Each *Cycle Count element* is associated with a *Commit element*, and when a *Commit element* is generated, a *Cycle Count element* might also be generated.

R_{BZQWX} Each *Cycle Count element* is associated with the most recent *Commit element*.

R_{VZXNN} A *Cycle Count element* indicates the number of PE clock cycles between the two most recent *Commit elements* that both have an associated *Cycle Count element*.

I_{FHGKM} Not every *Commit element* is required to have an associated *Cycle Count element*.

R_{VNYMN} *Cycle Count elements* are generated in order relative to *Commit elements*.

D4.3.7.2 Timestamp element

I_{LKDJM} The *Timestamp element* inserts a global timestamp value into the trace element stream.

I_{BLBJX} The source for timestamp reported in the timestamp element is controlled by:

- TRFCR_EL1.TS.
- TRFCR_EL2.TS.

R_{BRJJF} A timestamp value of zero indicates that the timestamp value is UNKNOWN.

I_{VTLTF} An UNKNOWN timestamp value might occur if the system does not support timestamping or if the timestamp is temporarily unavailable.

I_{YQJDR} The source for the payload of *Timestamp elements* is controlled by the TRFCR registers and the virtual timers. It is expected that these registers will be changed by context switch software. As a result it is possible that payloads of *Timestamp elements* might appear to have discontinuities, and even go backwards, if the source of the timestamp changes, or any context switching changes the System registers which control the timestamp value.

R_{MCSGX} If FEAT_ETEv1p1 is implemented, then when there has been a *Timestamp Marker element* before the *Timestamp element*, the *Timestamp element* contains the timestamp value of the most recent of the following before the *Timestamp Marker element*:

- P0 element.
- Event element.
- Instrumentation element.

R_{DGTJZ} If FEAT_ETEv1p1 is not implemented or if there has not been a *Timestamp Marker element* before the *Timestamp element*, the *Timestamp element* contains the timestamp value of the most recent of the following before the *Timestamp element*:

- P0 element.
- Event element.
- Instrumentation element.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{PXZVX} If TRCIDR0.TSMARK is 1 and there is no previous *Timestamp Marker element*, the *Timestamp element* is for a *P0 element*, *Event element*, or *Instrumentation element* which is before the start of the trace. This scenario might occur when trace analysis starts at a *Trace Info element* which is not the first *Trace Info element*, and the *Timestamp Marker element* was generated before the *Trace Info element*.

I_{CSZYW} The requirement for a *Timestamp Marker element* for every *Timestamp element* is to avoid needing to indicate if there has been a *Timestamp Marker element* at a Trace Info point. This allows a trace analyzer to assume there is a *Timestamp Marker element* (or not) before the Trace Info, based on a static piece of information.

D4.3.7.3 Timestamp Marker element

R_{RFYPT} The *Timestamp Marker element* indicates the most recent *P0 element*, *Event element*, or *Instrumentation element* has been timestamped, and that a *Timestamp element* will follow containing the timestamp value.

R_{SZRHP} *Timestamp Marker element*s are generated in order with respect to *P0 element*s, *Event element*s, and *Instrumentation element*.

R_{DCRVK} *Timestamp Marker element*s are not canceled by *Cancel elements*.

I_{DLCLX} A *Cancel element* might cause a *P0 element* to be canceled and if there is a *Timestamp Marker element* that is associated with that *P0 element* then the *Timestamp Marker element* is not associated with any *P0 element*. The *Timestamp element* which is associated with the *Timestamp Marker element* is unaffected, and is still usable for timestamping the approximate position in the trace stream.

R_{VWJVC} If 2 *Timestamp Marker element*s occur without a *Timestamp element* between them, the oldest *Timestamp Marker element* is ignored.

R_{JNWJY} If an *Overflow element* or *Discard element* occurs after a *Timestamp Marker element* and before a *Timestamp element*, the *Timestamp Marker element* is ignored.

R_{LWZXK} If *Timestamp Marker element*s are generated by the trace unit, every *Timestamp element* must have a corresponding *Timestamp Marker element* generated before the *Timestamp element*.

I_{JGKZJ} The generation of *Timestamp Marker element*s is indicated in TRCIDR0.TSMARK.

D4.3.8 Speculation Resolution Elements

I_{YYMXT} The ETE architecture allows trace to be generated speculatively and then later committed or removed by the decompression process. Each *P0 element* is traced and is considered speculative until either committed by a *Commit element* or canceled by a *Cancel element*. This method of generating speculative trace allows for the tracing of speculative execution.

I_{SRRZZ} Speculation resolution elements provide a trace analyzer with information about which trace elements were correctly or incorrectly generated, and ensure the trace analyzer can reconstruct the program execution. The following speculation resolution elements are supported by ETE:

The Mispredict element
Corrects the most recent *Atom element*.

The Cancel element
Indicates that one or more *P0 elements* are canceled.

The Commit element
Indicates that one or more *P0 elements* are resolved for execution.

The Discard element
Removes all speculative *P0 elements*.

I_{XLHWT} TRCIDR8.MAXSPEC specifies the maximum number of uncommitted *P0 elements* which can be discarded at a later stage using *Cancel elements*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.3.8.1 Commit element

I_{KQQML} A *Commit element* indicates that a number of unresolved *P0 elements* have been resolved for execution. The resolved *P0 elements* are the oldest *P0 elements*.

R_{PNBGQ} The *Commit element* resolves all types of *P0 element*.

I_{KHYLN} *Commit elements* might be merged if the total number of *P0 elements* resolved is less than TRCIDR8.MAXSPEC. *Commit elements* are merged by adding their respective commit count values together.

Figure D4-8 shows an example operation for a *Commit element*:

Figure D4-8 Commit Operation Example

D4.3.8.2 Cancel element

I_{MRGLC} The *Cancel element* indicates the number of youngest unresolved and uncanceled *P0 elements* that are canceled from execution. A trace unit might cancel elements because of many reasons, including but not limited to:

- A *P0 instruction* is mis-speculated.
- An exception occurs.

R_{WLTNX} The *Cancel element* cancels all types of *P0 element*.

I_{NDQKN} *Cancel elements* might be merged if no *P0 elements* have been generated in between. *Cancel elements* are merged by adding their respective cancel numbers together.

Figure D4-9 shows an example operation for a *Cancel element*:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure D4-9 Cancel Operation Example

D4.3.8.3 Discard element

I_{TCWCN} A *Discard element* is generated if uncommitted *P0 elements* remain when trace generation becomes inoperative or if the resolution of uncommitted *P0 elements* cannot be output by the trace unit.

I_{STXQZ} If trace generation remains inoperative, the outcomes of instructions that are traced by *P0 elements*, such as conditional *P0 instructions*, cannot be resolved, and therefore a *Discard element* indicates that all uncommitted *P0 elements* must be discarded.

D4.3.8.4 Mispredict element

I_{GBKKQ} The *Mispredict element* indicates that the most recent non-canceled *Atom element* has the incorrect E or N status.

I_{RGVGL} For example, if a branch instruction is predicted as taken, it is traced with an E *Atom element*. If the prediction becomes incorrect, then a *Mispredict element* is traced to indicate to a trace analyzer that the E *Atom element* changes to an N *Atom element*.

D4.3.9 Instrumentation element

I_{ZLFFN} The *Instrumentation element* indicates execution of a `TRCIT` instruction.

R_{BXTXK} If Instrumentation tracing is prohibited, then no trace is generated by the `TRCIT` instruction, and `TRCIT` behaves as a `NOP`.

R_{JJZXW} If tracing is prohibited, then no ETE trace is generated by the `TRCIT` instruction, and `TRCIT` behaves as a `NOP`. `TraceAllowed()` defines when tracing is prohibited.

R_{BWHCS} If Instrumentation tracing is not prohibited and tracing is enabled and not prohibited, then execution of the `TRCIT` instruction requests an Instrumentation element to be generated in the ETE trace stream. `TraceInstrumentationAllowed()` defines when Instrumentation tracing is not prohibited.

R_{NHJLQ} When an Instrumentation element is requested, the Instrumentation element is generated if and only if the `TRCIT` instruction is architecturally executed.

R_{VPFGH} If the Instrumentation element cannot be generated when required, then a trace unit buffer overflow occurs.

R_{CJRNL} Instrumentation elements are not discarded by Cancel elements.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.3.10 Other elements

D4.3.10.1 Event element

I_{RBKYZ} The *Event element* indicates when a programmed *ETEEvent* occurs and its payload contains a number to identify the *ETEEvent* number. See TRCEVENTCTL0R, and TRCEVENTCTL1R, for information about the programming of arbitrary *ETEEvents*.

R_{SMLVB} *Event elements* maintain order relative to other *Event elements*.

D4.3.10.2 Overflow element

I_{RFQKZ} The *Overflow element* indicates that the trace unit buffer has overflowed, and at least one trace element might have been lost.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.4 Instruction and exception classification

INMJBZ This section defines all of the *P0 instructions*.

RPBVZM *P0 instructions* comprise all of the following:

- All direct *P0 instructions*.
- All indirect *P0 instructions*.

RGFNRJ Direct *P0 instructions* comprise all of the following:

- All direct branch instructions.
- `ISB` instructions.
- `TSTART` instructions.
- `WFE`, `WFET`, `WFI`, and `WFIT` instructions, when indicated by TRCIDR2.WFXMODE.

RDJMQM Indirect *P0 instructions* comprise all of the following:

- All indirect branch instructions.

RKJTCL All uses of `ISB` in this section apply to all variants of the `ISB` instruction, including the `CP15ISB` instruction.

D4.4.1 AArch64 instructions

D4.4.1.1 Direct P0 instructions

RTWTMK The following table describes the A64 direct *P0 instructions*.

Table D4-6 A64 direct P0 instructions

Instruction	Description
B	Unconditional Branch
B.cond	Conditional Branch
BC.cond	Branch Consistent conditionally
BL	Branch with link
CB<cc> (immediate)	Compare register with immediate and branch
CB<cc> (register)	Compare registers and branch
CBB<cc>	Compare bytes and branch
CBH<cc>	Compare halfwords and branch
CBZ or CBNZ	Compare with zero and branch
ISB	Instruction Synchronization Barrier
TBZ or TBNZ	Test and branch
WFE, WFET	Wait For Event
WFI, WFIT	Wait For Interrupt

D4.4.1.2 Indirect P0 instructions

RLTZGC The following table describes the A64 indirect *P0 instructions*.

D4.5 About the ETE trace unit

I_{GBYNF} Figure D4-10 shows the stages of trace generation:

Figure D4-10 Stages of trace generation

D4.5.1 Resetting the trace unit

R_{PCXJC} A trace unit includes a trace unit reset, which resets all of the:

- Trace unit trace registers.
- Trace unit management registers.

R_{PTZDH} When the trace unit Core power domain is powered up, a trace unit reset is applied.

I_{ZXRHG} It is IMPLEMENTATION DEFINED whether the system has a mechanism to initiate a trace unit reset on demand.

S_{WVMHS} In a PE with FEAT_TRF, a PE Cold reset causes EDSCR.TFO to be reset to 0 which means that tracing is prohibited after the Cold reset until explicitly permitted by software. If tracing from a Cold reset is required, the debugger needs to ensure any relevant controls, including EDSCR.TFO, are programmed to permit tracing. Programming such registers might involve causing the PE to enter Debug state to ensure the registers can be programmed before the PE starts executing instructions.

R_{WKLGX} When a trace unit reset is applied, the trace unit resets the values of all trace unit registers to the values described in the individual register descriptions.

I_{CQWFH} Some other Arm trace architectures support multiple types of reset for the trace unit.

D4.5.2 System behaviors

R_{GFMRH} The trace unit outputs all of the trace byte stream, without external stimulus, within finite time.

D4.5.2.1 Behavior on enabling

R_{VBMLV} While both of the following are true, the trace unit is enabled:

- TRCPRGCTLR.EN is set to 1.
- The OS Lock is unlocked.

I_{LFBBP} Some Arm trace architectures have a dedicated trace unit OS Lock, whereas ETE depends on the PE OS Lock.

R_{KBFFQ} While the trace unit is enabled, the trace unit can trace all PE execution, except when any of the following are true:

- A trace unit buffer overflow occurs.
- The authentication interface prohibits the tracing of certain pieces of code.
- FEAT_TRF or FEAT_TRBE prohibit the tracing of certain pieces of code.

I_{KCDMH} No sequences of code or PE operations are exempt from this requirement. However, while the trace unit is transitioning from an enabled to a disabled state, or from a disabled to an enabled state, some loss of trace is permitted.

I_{GDNWY} While the trace unit is enabled, writes to most trace unit trace registers might be ignored. It is UNKNOWN whether writes to these registers succeed. When the writes are successful, the behavior of the trace unit is UNPREDICTABLE.

S_{BXQJH} Trace analyzers must not write to most trace unit trace registers while the trace unit is enabled, or if TRCSTATR.IDLE indicates that the trace unit is not idle.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{TPTRW} While the trace unit is enabled or idle, all resources that are visible in the programmers' model might have unstable values. Therefore, a trace analysis tool must be aware that the following values might be dynamically changing as they are being read:

- The Counter values, indicated by the TRCCNTVR<n>.
- The Sequencer state, indicated by TRCSEQSTR.
- The ViewInst start/stop function, indicated by TRCVICTLR.
- The Single-shot Comparator Control status, indicated by the TRCSSCSR<n>.

R_{VNGFG} When the trace unit becomes enabled, the trace unit does not reset the state of any of the resources in the trace unit, including the Counters, the Sequencer, and the ViewInst start/stop function.

S_{LMPNV} While the trace unit is disabled, and before it is enabled, a trace analyzer ensures the trace unit resources are programmed with a valid initial state.

D4.5.2.2 Behavior on disabling

I_{GZPBM} While the trace unit is disabled:

- The trace unit cannot generate trace.
- The trace unit resources are disabled.

For more information, see Behavior of the resources while in the Pausing state.

R_{TMLTF} While either of the following is true, the trace unit is disabled:

- TRCPRGCTLR.EN is set to 0.
- The OS Lock is locked.

I_{WSFFP} Some Arm trace architectures have a dedicated trace unit OS Lock. ETE depends on the PE OS Lock.

R_{ZDTLK} When the trace unit becomes disabled, the trace unit stops generating trace and empties the trace buffers by outputting any data in them.

R_{TNYDD} When the trace buffers are empty, after the trace unit has become idle after becoming disabled, TRCSTATR.IDLE indicates that the trace unit is idle.

R_{TMVLW} When the trace unit becomes disabled, all resources that are visible in the programmers' model retain their values and become stable at those values.

R_{QVYMJ} When the trace unit becomes disabled, when the resources are stable, TRCSTATR.PMSTABLE indicates that the programmers' model is stable.

R_{GLBHL} When the trace unit becomes disabled after the trace unit has generated Event elements, the trace unit outputs the Event elements before TRCSTATR.IDLE indicates that the trace unit is idle.

R_{YFLJT} While the trace unit is disabled, the following are true:

- No trace is generated.
- All trace unit resources and *ETEEvents* are disabled.

D4.5.2.3 Behavior on flushing

I_{XRMWS} The trace unit is allowed to buffer the trace byte stream to make efficient use of system infrastructure.

I_{WHZBD} As the trace unit is allowed to delay the output of the trace byte stream to the system infrastructure, there are system events that require all of the trace byte stream to be observable to other observers in the system.

I_{CXLCR} Making the trace byte stream visible to other observers is known as a trace unit flush.

R_{JLRQH} When any of the following occur, a trace unit flush is requested:

- The trace unit transitions from an enabled to a disabled state.
- The trace capture infrastructure requests a trace unit flush.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A `TSB CSYNC` instruction is executed in a Trace Prohibited region while the Trace Buffer Extension is implemented and enabled.

I_{KGJRL} A trace unit flush might be requested for IMPLEMENTATION DEFINED reasons. For example:

- Before the trace unit enters either:
  - The low-power state.
  - A powerdown state.
- The PE enters Debug state.

I_{ZWHKM} An example of a trace unit flush is one requested on an Arm AMBA ATB interface. For more information on the Arm AMBA ATB interface, see the *AMBA® ATB Protocol Specification (ARM IHI 0032)*.

R_{HGYLG} When a trace unit flush is requested, the trace unit performs the following tasks before responding to the flush request:

1. Encode any remaining elements into trace packets.
2. Complete any packets that are in the process of being generated.
3. Output all trace packets for all PE execution that occurred before the flush request was received.

I_{LMVMT} An example of when the trace unit might need to encode remaining elements into trace packets before a trace unit flush is when there are *Commit elements* that are not yet encoded.

R_{TWBVY} When a trace unit flush occurs while the trace unit is recovering from a trace unit buffer overflow, the trace unit outputs the corresponding *Overflow element* before responding to the flush request.

I_{GHKFH} When a trace unit flush occurs, the trace unit either continues to generate trace or stops generating trace, depending on what condition caused the trace flush. For example, if a flush occurs because the trace unit is entering a disabled state, then tracing becomes inactive after the trace flush.

R_{TTDBB} When a condition causes both a trace unit flush and the trace unit to stop generating trace, the trace unit stops generating trace before responding to the flush request, and before indicating that the trace unit is idle.

I_{NHBMZ} On entry to Debug state, Arm recommends that the *Exception element* indicating entry to Debug state is included in the flushed trace data if tracing is active.

R_{PFHWW} When a trace unit flush is requested, the trace unit outputs the data within a finite period.

R_{DKFRL} When a trace unit flush is requested and the cause of the flush request requires an acknowledgment, the trace unit generates the acknowledgment within a finite period.

I_{SCBMG} The flush request mechanism on AMBA ATB is an example of a cause of a flush request that also requires an acknowledgment.

D4.5.2.4 Low-power state

I_{GHHNW} The low-power state in the trace unit is a mechanism to improve energy efficiency during periods where trace generation is limited.

Scenarios where the trace unit might be in the low-power state are any of the following:

- The PE is in a low-power state.
- The PE is in Debug state.

R_{LHDSS} The trace unit is only permitted to be in the low-power state when any of the following are true:

- The PE is in a low-power state due to the Wait for Event mechanism.
- The PE is in a low-power state due to the Wait for Interrupt mechanism.
- The PE is in Debug state.
- The trace unit is Disabled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.2.5 Trace unit behavior when the PE is in a low-power state

I_{MSTWP} The PE that is being traced might support a low-power state where no execution occurs. This low-power state might be invoked, for example, when the PE executes a `WFI`, `WFIT`, `WFE`, or `WFET` instruction.

I_{DPFXN} When the PE is in a low-power state, it might be advantageous if the trace unit also enters a low-power state.

R_{FBMYZ} It is IMPLEMENTATION DEFINED whether a trace unit supports the low-power state.

R_{WMPTL} While the trace unit is in the disabled state, the trace unit does not stop the PE from entering a low-power state.

R_{YLDDV} While the trace unit is in Low-power Override Mode, the trace unit does not affect the operation of the PE.

D4.5.2.6 Trace unit behavior in the low-power state

R_{FMXFM} While the trace unit is enabled, when the trace unit enters the low-power state, the trace unit continues to appear enabled throughout the time it is in the low-power state.

R_{KQVNN} When the trace unit enters or leaves the low-power state, the trace unit does not lose resource events that are in transition through the trace unit, except those permitted when moving through the Pausing state of the resources. For more information on the resource events that are permitted to be lost when in the Pausing state, see Behavior of the resources while in the Pausing state.

I_{RVKHK} Observation of resource events that are in transition through the trace unit when it enters the low-power state might not occur until after the trace unit leaves the low-power state.

R_{RGFJY} While the trace unit is not in the low-power state, and before it enters the low-power state, the resources enter the Paused state. For more information on the pausing of resources, see Behavior of the resources while in the Paused state.

I_{MXHHN} If `WFI` and `WFE` instructions are classified as P0 instructions, see TRCIDR2.WFXMODE, and the trace unit enters the low-power state as a result of a `WFI` or `WFE` instruction, Arm strongly recommends that the following elements are generated before the trace unit enters the low-power state:

- The *Atom element* that represents a `WFI`, `WFIT`, `WFE`, or `WFET` instruction.
- Any pending *Commit elements*.

R_{LBDSM} While the trace unit is in the low-power state, the trace unit does not generate trace, including *ETEEvent* trace.

R_{MFBDT} While the trace unit is in the low-power state, the resources remain in the state that they were in before the trace unit entered the low-power state.

I_{QXBYK} The resources are:

- The Counters.
- The Sequencer.
- The ViewInst start/stop function.
- The Single-shot Comparator Controls.

R_{FHYHC} While the trace unit is in the low-power state, the trace unit drives all External Outputs low.

R_{DNKDV} While the trace-unit is in the low-power state, the PE and external debuggers ability to access the trace unit trace registers and trace unit management registers is unaffected.

R_{XTBQX} While the trace unit is in the low-power state, when a trace protocol synchronization request occurs, the trace unit handles the trace protocol synchronization request correctly. For more information on how the trace unit handles trace protocol synchronization requests, see Trace protocol synchronization.

R_{TWQJT} While the trace unit is in a retention state, external debugger accesses to the trace unit behave as if there is no power to the trace unit Core power domain.

I_{RCXZX} While the trace unit is in the low-power state, the trace unit might not recognize external events, such as the assertion of any External Inputs.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{BPQTL} While the trace unit is in the low-power state, it is IMPLEMENTATION DEFINED whether the cycle counter continues to count or not.

I_{VTRBC} While the trace unit is in the low-power state, timestamp requests might be ignored.

I_{ZTDMB} It is possible that the trace unit might intermittently leave and reenter the low-power state while the PE is in a low-power state. If this happens, the trace unit resources might become intermittently active during this time. In addition, trace generation might also become intermittently active, and this means that the trace unit might output some packets. This behavior is IMPLEMENTATION DEFINED.

I_{ZVDSF} There is no additional requirement for the trace unit to generate a *Trace Info element* or *Trace On element* when leaving the low-power state. However, if the trace unit entered the low-power state because the PE was in Debug state, the normal requirements for restarting trace after leaving Debug state apply, including generation of a Trace On element. For more information on the PE Debug state, see Trace unit behavior while the PE is in Debug state.

I_{LQFRD} The trace unit can be programmed so that it does not enter the low-power state, by enabling Low-power Override Mode. Low-power Override Mode is selected using TRCEVENTCTL1R.LPOVERRIDE.

R_{VHSFL} When Low-power Override Mode is enabled, the resources continue operating and the trace unit can generate trace.

I_{FRMMP} Low-power Override Mode does not affect the operation of the PE, however it is not required to prevent the PE from entering a low-power state. This means that even though the trace unit can generate trace, it might only generate Event elements.

D4.5.3 Trace unit behavior while the PE is in Debug state

R_{XJXQS} While ViewInst is active, when the PE enters Debug state, the trace unit generates an Exception element which indicates that the PE has entered Debug state.

R_{YMJFJ} When the PE enters Debug state, ViewInst becomes inactive, and remains inactive throughout the time the PE is in Debug state.

R_{DPKSC} While the PE is in Debug state, the trace unit does not trace:

- Instructions that are executed.
- The effects of instructions that are executed.
- Exceptional occurrences.

R_{HBNFJ} When the PE exits Debug state and ViewInst becomes active, the trace unit generates a Trace On element.

R_{TGFHM} While the PE is in Debug state, the ViewInst start/stop function maintains its state.

I_{WFYLQ} If an Exceptional occurrence occurs between the PE exiting Debug state and the PE executing the first instruction, the value of TRCRSR.TA is used to determine if the Exceptional occurrence is traced. In general, if the entry to Debug state was traced then TRCRSR.TA will be set to 1, and therefore this Exceptional occurrence on exit from Debug state is traced.

I_{NPQLT} If a PE Reset occurs when the PE is in Debug state this is treated as leaving Debug state. This means that a Trace On element and an Exception element indicating a PE Reset are traced if tracing is not prohibited and either of the following are true:

- TRCRSR.TA is 1.
- Forced tracing of PE Resets is active.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.4 Trace unit behavior on a trace unit buffer overflow

R_{PQGXB} When a trace unit buffer overflow occurs, trace generation becomes inoperative until the trace unit can recover from the overflow.

R_{RQHFH} When a trace unit buffer overflow occurs, the trace unit does not output a partial trace packet, that is, the trace unit can only output complete packets.

I_{TDCNT} The *Overflow element* indicates to a trace analyzer that a trace unit buffer overflow has occurred. For more details on the generation of an *Overflow element*, see Overflow element.

R_{DQBDH} When the trace unit recovers from a trace unit buffer overflow, the following occur:

- Trace protocol synchronization is requested.
- Trace protocol synchronization occurs before the trace unit outputs any packets.

I_{VQYYH} When an Overflow packet is generated, the trace unit might output any of the following packets before it outputs an Alignment Synchronization packet:

- Event packet.
- Overflow packet.
- Discard packet.
- Ignore packet.

I_{YYNRQ} Arm recommends that the Alignment Synchronization packet is the first packet output after the Overflow packet.

D4.5.5 Instrumentation extension

I_{TLZTW} FEAT_ITE provides a mechanism to allow software to inject instrumentation information into the ETE trace stream, allowing the ETE trace to be augmented with software-defined information that can aid with debugging and interpretation of the ETE trace.

Examples of instrumentation information include the following:

- Context information about the program being executed.
- Parameters to functions.
- Data addresses and values of variables and other data structures.

I_{GRJLV} All of the following registers control the behavior of FEAT_ITE:

- TRCITECR_EL1, providing EL1 with controls over FEAT_ITE.
- TRCITECR_EL2, providing EL2 with controls over FEAT_ITE.
- TRCITEEDCR, TRCCONFIGR and EDSCR.TFO, providing an external debugger with controls over FEAT_ITE.
- MDCR_EL3.EnITE, providing an EL3 trap control over access to TRCITECR_EL1 and TRCITECR_EL2.
- HDFGRTR2_EL2.nTRCITECR_EL1 and HDFGWTR2_EL2.nTRCITECR_EL1, providing EL2 trap controls over access to TRCITECR_EL1.

I_{CMDFW} The controls provided in TRCITECR_EL1 and TRCITECR_EL2 are similar in function to TRFCR_ELx provided for FEAT_TRF.

R_{FLGVJ} If self-hosted trace is enabled, then the controls in TRCITECR_EL1 and TRCITECR_EL2 control when Instrumentation trace is prohibited.

See `TraceInstrumentationAllowed()`.

R_{RTKDL} If self-hosted trace is disabled and TRCCONFIGR.ITO is 1, then the fields in TRCITEEDCR control when Instrumentation trace is prohibited.

See `TraceInstrumentationAllowed()`.

R_{DKCFL} If self-hosted trace is disabled and TRCCONFIGR.ITO is 0, then the fields in TRCITEEDCR, TRCITECR_EL1, and TRCITECR_EL2 control when Instrumentation trace is prohibited.

See `TraceInstrumentationAllowed()`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{SRTGR} TRCCONFIGR.ITO and TRCITEEDCR allow an external debugger to one of the following:

- Completely control when Instrumentation trace is allowed and prohibited.
- Share control of when Instrumentation trace is allowed with software running on the PE.

D4.5.6 Trace unit power states

I_{GNFXM} The Arm architecture defines the following power states:

Normal
The trace unit Core power domain is fully powered up and the trace unit registers are accessible.

Standby
The trace unit Core power domain is on, but there are measures to reduce energy consumption. Standby is transparent, meaning that to software and to an external debugger it is indistinguishable from normal operation.

Retention
The OS takes some measures, including IMPLEMENTATION DEFINED code sequences and registers, to reduce energy consumption. Trace unit registers cannot be accessed. A trace unit reset does not occur on leaving retention.

Powerdown
The OS takes some measures to reduce energy consumption by turning the trace unit Core power domain off. Trace registers cannot be accessed. A trace unit reset occurs on leaving powerdown.

I_{MNDVQ} A trace unit might support a low-power state, which is equivalent to the standby state.

I_{BMSVN} A trace unit might support a retention state or a powerdown state, and both of these states are considered to be a state where the trace unit Core power domain is powered down.

I_{ZVBZF} If the trace unit is implemented in a power domain which is separate from the PE power domain, all of the following are true:

- The trace unit Core power domain might be able to be powered down without powering down the PE power domain.
- The trace unit Core power domain is always powered down when the PE power domain is powered down.

I_{CNZJH} A read of TRCPDSR returns information about the current state of the trace unit.
Table D4-21 describes the meanings of the returned value.

Table D4-21 Meaning of TRCPDSR values

STICKYPD	POWER	Meaning
`0b0`	`0b1`	The trace unit Core power domain is powered and the trace unit registers are accessible.
`0b1`	`0b1`	The trace unit Core power domain is powered and the trace unit registers are accessible. A trace unit reset or power interruption has occurred so the trace unit register state might not be valid.

R_{CMKXK} When the trace unit Core power domain transitions from powered down to powered up, if the trace unit register state has been preserved over the powerdown, then TRCPDSR.STICKYPD is restored to the value before powerdown.

R_{FQMXQ} When the trace unit Core power domain transitions from powered down to powered up, if the trace unit register state has not been preserved over the power down then TRCPDSR.STICKYPD is set to `0b1`.

Note

ETE only supports a single power domain and therefore TRCPDSR.POWER is always `0b1`.

I_{FRMBB} A system might support a Debug power domain that contains the interface between the trace unit and the external debugger. The Debug power domain usually needs to be powered up when the external debugger needs to connect to the system. Such a Debug power domain is described in Resets and power domains.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{GYLKD} If the trace unit Core power domain can be powered down independently of the Debug power domain, Arm recommends that the system implements an external debug component with a powerup request mechanism which can request the trace unit Core power domain to be powered up.

R_{ZNSNS} Arm strongly recommends the powerup request mechanism is a CoreSight Class `0x9` ROM Table containing a parent entry for the trace unit. A parent entry of a component is one of:

- An entry in the ROM table that locates the component.
- An entry in a first ROM table that locates a second ROM table that includes a parent entry for the component.

The second ROM table is a descendant of the first ROM table.

I_{TLYXG} This definition of a parent entry is recursive, and therefore the powerup request mechanism might be high up in a hierarchy of ROM tables. The ROM table and any descendants might describe other debug components, including debug components for other PEs. The ROM table might have parent entries in other ROM tables, and those parent entries might also have a powerup request mechanism in those ROM tables.

R_{ZPCZC} If the powerup request mechanism is implemented, in the Class `0x9` ROM Table containing the powerup request mechanism for the trace unit:

- The POWERIDVALID bit in the parent entry must be `0b1`.
- The POWERID field in the parent entry has an IMPLEMENTATION DEFINED value.

I_{DXHPS} It is IMPLEMENTATION DEFINED whether the trace unit Core power domain is the PE Core power domain or some other power domain. For more information on the CoreSight Class `0x9` ROM Table, see the Arm® CoreSight™ Architecture Specification (ARM IHI 0029).

D4.5.7 Visibility of the PE operation

I_{BMPFH} This section describes the ability of the trace unit to trace the execution of the operation of the PE.

R_{QCFMC} When the trace unit performs indirect reads of PE System registers, the trace unit complies with the rules associated with Context synchronization events.

R_{QHTYC} When the trace unit performs indirect reads of PE System registers, the trace unit complies with the rules associated with the `TSB CSYNC` instruction as defined in The Trace Buffer Extension.

R_{QCFSS} When instructions are executed outside of any Trace Prohibited region, the trace unit observes the execution.

R_{CDNKX} When observable instructions are executed, the trace unit observes all execution before a PE Context synchronization event occurs, as defined in The Trace Buffer Extension.

R_{QMBKJ} When an Exceptional occurrence occurs outside of any Trace Prohibited region, the trace unit observes the *Exceptional occurrence*.

I_{XBJFP} Executing a `TSB CSYNC` instruction generates a Trace synchronization event as defined in The Trace Buffer Extension.

R_{FCBLJ} When a `TSB CSYNC` instruction is executed in a Trace Prohibited region, the `TSB CSYNC` instruction does not become microarchitecturally-finished until the resources are in the Paused state or the trace unit is in the Idle or Stable state.

I_{JYJDZ} After a `TSB CSYNC` instruction executed inside a Trace Prohibited region generates a Trace synchronization event, the Trace synchronization event is microarchitecturally-finished when the *trace operation* has microarchitecturally-finished for every instruction before the Context synchronization event before the `TSB CSYNC` instruction that generated the Trace synchronization event.

For more details on the `TSB CSYNC` instruction, see R_{MRVPT}.

R_{XLVQM} When a `TSB CSYNC` instruction executed in a Trace Prohibited region becomes microarchitecturally-finished, the trace unit generates no more trace until the PE leaves the Trace Prohibited region.

I_{CZLXW} When a `TSB CSYNC` is executed in a Trace Prohibited region, the rules around generation of a trace flush and requiring no more trace to be generated in the Trace Prohibited region mean that only whole trace packets are output, and the last byte output is the end of a packet.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{GSXJJ} These rules ensure that no new trace is generated and allows various System registers to be changed, such as those controlling the Trace Buffer Extension, without the risk of any trace being generated while those registers are being changed.

R_{XRWPV} When the trace unit becomes enabled in a Trace Prohibited region, the trace unit generates no trace until the PE leaves the Trace Prohibited region.

Note

This ensures that no trace is generated until the PE leaves the Trace Prohibited region, and therefore allows various System registers to be changed, such as those controlling the Trace Buffer Extension, without the risk of any trace being generated while those registers are being changed.

I_{KXDDS} The trace operation as defined in The Trace Buffer Extension can be split into operations that are performed by one of the following:

- The PE.
- The ETE trace unit.
- The trace buffer.

The operation of the trace unit is defined by the *ETE trace operation*.

R_{RFJQN} If the Trace Buffer Unit is implemented and enabled, when a Trace synchronization event occurs, and after all of the trace byte stream generated by the trace unit is flushed to the trace buffer, the Trace synchronization event completes.

I_{CNJYL} Table D4-22 describes the labels used in the ordering diagrams present in this Chapter.

Table D4-22 Labels for ordering diagrams

Notation	Name	Description
po	program-order	*head* is in program order after *tail*.
rf	Reads-from	*tail* Reads-from *head*.
co	Coherence-after	*head* is Coherence-after *tail*.
fr	from-read	As *co*, except that the operation at *head* is a read.
ob	Observed-by	*tail* is Observed-by *head*. Only applies for different Observers.
tb	traced-by	*head* is the *trace operation* for the instruction at *tail*.
gb	generated by	*head* is an operation generated by the instruction at *tail*.
seo	speculative execution-order	The PE speculated that the instruction at *head* was executed after *tail*, but the instruction was later Canceled. An *seo* arrow might be paired with a *can* arrow that shows this.
can	canceled	The instruction at *tail* was Canceled when the instruction at *head* was resolved.

D4.5.7.1 ETE trace operation

R_{YCJXC} Each instruction has all of the following state information:

- PC.
- PSTATE.T.
- PSTATE.EL.
- The Security state.
- CONTEXTIDR_EL1.PROCID.
- CONTEXTIDR_EL2.PROCID.
- TRFCR_EL1.
- TRFCR_EL2.
- MDCR_EL3.STE.
- TxNestingLevel.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{GCLMS} The trace information generated contains *Address information* in *Target Address elements*, *Source Address elements*, *Exception elements*, and *Q elements*. The *Address information* contains:

- The virtual address of an instruction.
- The instruction set, known as the sub_isa.

I_{JTLPL} The trace information generated contains *Context information* in *Context elements*. The *Context information* contains:

- The current Security state.
- The current Exception level.
- The current Execution state.
- The current Context identifier, as stored in CONTEXTIDR_EL1.PROCID.
- The current Virtual context identifier, as stored in CONTEXTIDR_EL2.PROCID.

R_{WBCRN} When an instruction is executed and all the trace elements for the instruction have been generated, the trace operation for the instruction is complete.

I_{WXNXB} Trace elements generated for an instruction might include:

- Global timestamp elements.
- Cycle count elements.
- Speculation resolution elements.

I_{FKTKY} For example, the tracing of PE execution is where:

- Resolved instruction A is executed in program order before a Resolved instruction B.
- t_A is all the trace elements that are generated due to the tracing of instruction A.
- t_B is all the trace elements that are generated due to the tracing of instruction B.
- The trace elements for t_A must be observed before t_B.

This is shown in Figure D4-11.

Figure D4-11 Trace operation

D4.5.7.2 Impact on PE behavior

I_{LLKFT} The ETE architecture places no requirements on the impact that trace generation has on the functional performance of a PE. Arm expects that trace unit implementations are designed according to the market requirements of the PEs being traced, and according to the trace requirements for those PEs. For some markets and trace requirements, the trace solution might always have some performance impact on the PE and the ETE architecture does not prohibit this.

D4.5.7.3 Behavior on a PE Warm reset

R_{YYHBF} A PE Warm reset does not cause a Trace unit reset.

Note

This ensures that tracing is possible through a PE Warm reset.

I_{QBSCX} A PE Warm reset might occur at the same time as a Trace unit reset, however, these are asynchronous and unrelated events.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.7.4 Instruction block

I_{TYXHR} How instructions are executed can vary significantly between PE designs. To allow for these variations the ETE architecture allows some flexibility within the filtering model. Rather than applying the filtering model to individual instructions it is applied to blocks of instructions.

R_{BQTBL} An instruction block contains one or more instructions.

R_{GDZBX} An instruction block can contain zero or one *P0 instruction*.

R_{CVJQH} When an instruction block is generated which contains a *P0 instruction*, the instruction block has the *P0 instruction* as the last instruction in the block.

R_{HPJTP} *Exceptional occurrences* do not occur between instructions in an instruction block.

R_{LDJXZ} The addresses of the instructions within an instruction block are sequential.

I_{JCQHC} The number of instructions in a block can vary from block to block and can vary each time the same sequence of instructions are executed.

I_{HRBJG} For example, the tracing of an instruction block is where:

- Resolved instruction A is executed in program order before a Resolved instruction B.
- t_A is all the trace elements that are generated due to the tracing of instruction A.
- t_A is all the trace elements that are generated due to the tracing of instruction B.

This is shown in Figure D4-12.

Figure D4-12 Instruction block trace operation

D4.5.7.5 Exposing speculation

I_{DCDNQ} For some PE microarchitectures, the tracing of execution-order only might not be achievable. The ETE architecture provides the ability to trace speculatively executed instructions.

R_{TRVLX} When speculative instructions are observed, the trace unit indicates whether each instruction is resolved or canceled with a resolve operation or a cancel operation.

R_{PPJSK} A resolve operation indicates that one or more instructions have, or will be, architecturally executed.

R_{WZBLY} A cancel operation indicates that one or more instructions, although observed by the trace unit, did not architecturally execute.

I_{KQYZB} There is no requirement to expose any speculation to the trace unit.

I_{DKDHD} For example, the tracing of speculation execution is where:

- S is executed in speculative execution-order after a Resolved instruction A.
- A is executed in program order before a Resolved instruction B.
- S is not in speculative execution-order after B.
- Q is executed in speculative execution-order after a Resolved instruction B.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This is shown in Figure D4-13.

Figure D4-13 Observation of Speculative Trace operation

D4.5.7.6 Trace Prohibited Regions

I_{THCBC} Trace Prohibited regions are instruction address regions or periods of execution by the PE that are not to be traced. Instructions and Exceptional occurrences which are not prohibited are not necessarily traced because the trace unit has a number of trace filtering functions to limit the amount of trace generated to the sections or periods of interest.

I_{RJYNL} An executable program might contain regions of code that are prohibited to trace. These regions might be associated with another Security state, or with the PE entering a privileged mode so that it can execute the instructions that are contained within them.

Tracing might be prohibited while the PE is operating in certain states or modes. For example:

- Non-invasive debug might be prohibited while the PE is in Secure, Realm, or Root state.
- FEAT_TRF might prohibit tracing.
- FEAT_TRBE might prohibit tracing.

Trace might also become prohibited if, while tracing program execution, an authentication interface changes the currently permitted level of non-invasive debug. For example, if trace is permitted and active while the PE is operating in Secure state, and then the permitted level of non-invasive debug changes from being permitted for Secure state, to not permitted, then trace becomes prohibited.

I_{ZPXRJ} The Trace Buffer Extension describes when FEAT_TRBE prohibits tracing.

R_{HYZLQ} If an optional authentication interface is implemented, while non-invasive debug is disabled in a Security state other than Non-secure state according to that optional authentication interface and while self-hosted trace is disabled, then for execution in that Security state, the PE executes in a Trace Prohibited region.

I_{NVSDD} An example of an optional authentication interface is the CoreSight Authentication interface. For more information, see the Arm® CoreSight™ Architecture Specification (ARM IHI 0029).

R_{FFVYM} While the PE is executing code from a Trace Prohibited region, the trace unit does not trace instructions or Exceptional occurrences, including PE Resets.

R_{KTMLZ} While the PE is executing code from a Trace Prohibited region, instruction Address Comparators do not match on any instructions in the Trace Prohibited region.

R_{SZRZR} While cycle counting is enabled and the PE is executing code from a Trace Prohibited region, the cycle counter continues to count.

I_{MCCBH} When the PE leaves a Trace Prohibited region and tracing restarts, the cycle counter includes cycles spent in the Trace Prohibited region in the cycle count.

I_{SDSGK} The behavior of the resources when entering a Trace Prohibited region is defined in Behavior of the resources while in the Paused state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{VHRGM} While the PE is executing code from a Trace Prohibited region, the trace unit does not output any trace that might provide information about the execution in the Trace Prohibited region.

I_{JSKLD} Examples of information about execution in a Trace Prohibited region that trace might provide are the context of execution, instruction addresses, and the address of the first instruction in the Trace Prohibited region.

I_{MKQWS} The most common cause of an entry into a Trace Prohibited region is an *Exceptional occurrence* or Context synchronization event.

R_{THBVD} When an *Exceptional occurrence* that must be traced causes the PE to enter a Trace Prohibited region, the trace unit generates an *Exception element* that indicates the exception type.

R_{CKZMR} When the PE enters a Trace Prohibited region and there are unresolved speculative *P0 elements* remaining in the trace byte stream, when the resolution of the speculative elements is known the trace unit generates the appropriate *Commit elements* or *Cancel elements*.

R_{RXMJF} When the PE leaves a Trace Prohibited region and ViewInst is active, that is, any filtering applied dictates that ViewInst is active, the trace unit generates a *Trace On element*.

I_{QGFJF} The purpose of the trace unit generating a *Trace On element* when the PE exits a Trace Prohibited region and ViewInst is active is to indicate to the trace analyzer that there has been a discontinuity in the trace element stream.

I_{JBFTB} If the PE leaves a Trace Prohibited region other than when a Context synchronization event occurs, the Trace Prohibited region is permitted to extend up to the next Context synchronization event. Typically, a PE leaves a Trace Prohibited region through a Context synchronization event, but a PE might leave a Trace Prohibited region when the authentication interface changes, or when moving from a higher Security state to a lower Security state without an exception return.

I_{DMXPF} If an *Exceptional occurrence* occurs between the PE exiting a Trace Prohibited region and the PE executing the first instruction, the value of TRCRSR.TA is used to determine if the *Exceptional occurrence* is traced.

D4.5.7.7 Multi-threaded processor

R_{KBZTZ} Processors with multiple threads or PEs have a trace unit for each thread or PE.

I_{KHSWQ} The processor might support enabling and disabling of threads, either at PE Reset time or dynamically. The trace units for the threads that are disabled might behave in one of the following ways:

- The trace unit Core power domain is powered down.
- The trace unit Core power domain is held in the trace unit reset state.

I_{RFSNL} Arm recommends that the trace units for threads that are permanently disabled are not visible: either they are not included, or they are marked as not present in any ROM tables that describe the system.

D4.5.7.8 Sharing between multiple PEs

I_{TSWXS} Previous Trace architectures have allowed the trace unit to be shared between multiple PEs.

R_{TLJSQ} A trace unit only traces a single PE, that is, it cannot be shared between multiple PEs.

D4.5.8 Speculation resolution

I_{RKYCD} The trace unit implements a maximum speculation depth, that is, the maximum permitted number of *P0 elements* that can be speculative at any instance. TRCIDR8.MAXSPEC indicates the IMPLEMENTATION DEFINED maximum speculation depth.

R_{GLQPL} The trace unit never outputs more speculative *P0 elements* than the maximum speculation depth.

I_{KCFGW} If a trace unit is not exposed to any speculative execution, then Arm recommends that the trace unit implements a maximum speculation depth of zero, and in this case:

- *Cancel elements* are not generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- *Commit elements* are generated after each *P0 element*, causing each *P0 element* to be immediately resolved when it is generated. The instruction trace protocol implicitly generates these *Commit elements* for each *P0 element*, meaning that explicit Commit packets are not required.
- *Mispredict elements* are not generated.

IQLKDL The ETE architecture defines *Commit element* and *Cancel elements* to allow the speculation of the *P0 elements* to be resolved by the trace analyzer. The trace unit is required to calculate the number of *P0 elements* which are committed or canceled. There are many methods by which these numbers can be calculated, but in the generic case the trace unit can use the following mathematical procedure.

The PE can speculatively indicate blocks of instructions to the trace unit. Each block of instructions is given a tag where *tag* belongs to 0. . .*m* and *m* is the number of rewind points supported by the PE.

The number of instructions per block can be random from the set *N* and there is a maximum of one *P0 instruction* per block. The order in which the tags are used can be random, but a tag cannot be reused until the previous block with that tag has been resolved, canceled or merged.

This procedure generates a transform from the potentially random sequence of core tags to a more usable space. The transform T evolves over time as the tags are reused and provides the mapping onto the new space,

$$T_t = [c_0, \ldots, c_m]$$

c_i is the mapping for core tag *i*.

c_i belongs to 0. . .*q*, where *q* is greater than *m*.

D4.5.8.1 Initialization

IHRDQL To perform the necessary calculations, the trace unit tracks the transform of the last resolved block. γ_t is the last committed indicator. The algorithm is initialized at *t=0* to

$$\forall i \in 0, \ldots, m : T_0[i] = \gamma_0$$
$$x_0 = \gamma_0$$

D4.5.8.2 New block operation

ISMGSG The sequence of the numbers in the transformed space, x_t, is defined by the following equation:

$$x_{t+1} = \begin{cases} |(x_t + 1) \bmod q| & \text{If a traced P0 instruction} \\ x_t & \text{Otherwise} \end{cases}$$

$$T_{t+1}[tag_t] = \begin{cases} |(x_t + 1) \bmod q| & \text{If a traced P0 instruction} \\ T_t[tag_t] & \text{Otherwise} \end{cases}$$

D4.5.8.3 Resolved operation

IBJFLR The PE can resolve one or more blocks in an atomic operation. This is performed by indicating the youngest block's tag to be resolved, and by inference all older blocks.

The number required by the *Commit element* is calculated by

$$n_+ = |(T_t[l] - \gamma_t) \bmod q|$$

The state of the transform is updated by

$$\gamma_{t+1} = T_t[l]$$

where *l* is the *youngest block's tag*.

D4.5.8.4 Cancel operation

IHJYQH The PE can cancel one or more blocks in an atomic operation. This is performed by indicating the oldest block to be canceled.

The number required by the *Cancel element* is calculated by

$$n_- = |(x_t - T_t[r]) \bmod q|$$

The state of the transform is updated by

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

$$x_{t+1} = T_t[r]$$

where *r* is the *oldest block's tag*.

D4.5.9 Filtering trace generation

I_{CCWZG} The amount of trace that can be generated by the trace unit can be significant. Not all the operations of the PE are always relevant. The amount of trace generated can be reduced by the use of the trace unit filter functions.

D4.5.9.1 ViewInst function

R_{GQFSB} The filtering function of the instruction trace is expressed as a calculation evaluated for each instruction.

$$\text{ViewInst}_i = \begin{cases} 0 & \text{When Prohibited} \\ 0 & \text{When in Debug state} \\ S_i \wedge I_i \wedge E_i \wedge N_i & \text{Otherwise} \end{cases}$$

$$\begin{aligned} S_i &= \text{ViewInst start/stop function} \\ I_i &= \text{ViewInst include/exclude function} \\ E_i &= \text{Exception level filtering} \\ N_i &= \text{Resource event based filtering} \end{aligned}$$

R_{BZXFH} While ViewInst is high, the trace unit traces all instructions.

I_{MJMCV} Instructions for which ViewInst is low might be traced. This might be as a result of tracing the next *P0 element* or optimizations in the trace unit.

R_{XPNZL} When ViewInst is high for an instruction in an instruction block, the trace unit traces the entire instruction block.

R_{KHDNX} When ViewInst becomes high, the trace unit traces the next *P0 instruction* or Exceptional occurrence.

I_{NSMSV} Some instruction types cause the trace unit to generate *P0 elements*, so that they are explicitly traced. Other instruction types however are not explicitly traced. The execution of these other instruction types can be inferred from the *P0 elements*. This means that the following scenario is possible:

- While ViewInst is high, some instructions are executed. This means that ViewInst is indicating that those instructions must be traced. However, none of the executed instructions cause the trace unit to generate a *P0 element*, therefore none of the instructions are traced.
- ViewInst then goes low.
- The PE then executes an instruction that, whenever ViewInst is high, causes the trace unit to generate a *P0 element*.

In this scenario, although ViewInst is low when the instruction in step 3 is executed, indicating that the instruction is not traced, tracing of the instruction is permitted because this is the only way that the preceding instructions can be traced.

I_{FGSBW} There is no requirement for the target address of a *P0 instruction* or Exceptional occurrence to be traced if ViewInst has transitioned to a low state by the time program execution has moved to the target.

I_{LCXHX} Unless the target instruction block is traced, any *Target Address elements* indicating the target address of a *P0 instruction* or Exceptional occurrence cannot be relied on.

D4.5.9.1.1 Resource event based filtering

R_{BQNWP} The resource event based filtering part of the ViewInst function is expressed as the following equation:

$$N_i = \text{Fn}(\text{TRCVICTLR.EVENT.SEL}, \text{TRCVICTLR.EVENT.TYPE})$$

Where Fn(TRCVICTLR.EVENT.SEL, TRCVICTLR.EVENT.TYPE) selects the combination of Resource Selectors used for resource event based filtering.

I_{KMXNS} The timing of the resource event based filtering is IMPLEMENTATION SPECIFIC.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{DWWVR} Resource event based filtering can be used to make ViewInst active based on system conditions or on trace unit resources. For example:

- Sampling based on cycle counts.
- Activating tracing on the nth function call.
- Performance Monitoring Unit events.

R_{NBYKR} When an instruction block is processed by the trace unit during a cycle, the trace unit samples the ViewInst function resource event input during that cycle.

R_{SRMMD} When no instruction blocks are processed by the trace unit during a cycle, the trace unit does not sample the ViewInst function resource event input during that cycle.

D4.5.9.1.2 Exception level filtering

I_{HNPYV} This function provides a simple method of filtering out information about different Exception levels without the need to use of additional resources.

R_{LWYJR} The Exception level based filtering part of the ViewInst function is expressed as the following equation:

$$E_i = \begin{cases} \neg\text{TRCVICTLR.EXLEVEL_S_EL0} & \text{Secure EL0} \\ \neg\text{TRCVICTLR.EXLEVEL_S_EL1} & \text{Secure EL1} \\ \neg\text{TRCVICTLR.EXLEVEL_S_EL2} & \text{Secure EL2} \\ \neg\text{TRCVICTLR.EXLEVEL_S_EL3} & \text{EL3} \\ \neg\text{TRCVICTLR.EXLEVEL_NS_EL0} & \text{Non-secure EL0} \\ \neg\text{TRCVICTLR.EXLEVEL_NS_EL1} & \text{Non-secure EL1} \\ \neg\text{TRCVICTLR.EXLEVEL_NS_EL2} & \text{Non-secure EL2} \\ \neg(\text{TRCVICTLR.EXLEVEL_RL_EL0} \oplus \text{TRCVICTLR.EXLEVEL_NS_EL0}) & \text{Realm EL0} \\ \neg(\text{TRCVICTLR.EXLEVEL_RL_EL1} \oplus \text{TRCVICTLR.EXLEVEL_NS_EL1}) & \text{Realm EL1} \\ \neg(\text{TRCVICTLR.EXLEVEL_RL_EL2} \oplus \text{TRCVICTLR.EXLEVEL_NS_EL2}) & \text{Realm EL2} \end{cases}$$

D4.5.9.2 ViewInst start/stop function filtering

I_{PJQSC} The ViewInst start/stop function is useful when the requirement is to trace a particular piece of code with all the functions that the piece of code calls.

The ViewInst start/stop function uses the Single Address Comparators and the PE Comparator Inputs to define start points and stop points.

A start point is any of the following:

- The instruction address which matches a Single Address Comparator selected for the ViewInst start/stop function using TRCVISSCTLR.START.
- The instruction address which matches a PE Comparator selected for the ViewInst start/stop function using TRCVIPCSSCTLR.START.

A stop point is any of the following:

- The instruction address which matches a Single Address Comparator selected for the ViewInst start/stop function using TRCVISSCTLR.STOP.
- The instruction address which matches a PE Comparator selected for the ViewInst start/stop function using TRCVIPCSSCTLR.STOP.

Multiple start points can be selected. Multiple stop points can be selected.

R_{MVDJT} When a start point is encountered, the ViewInst start/stop function becomes active for the instruction at the start point.

R_{CDFBP} When a stop point is encountered, the ViewInst start/stop function becomes inactive immediately after the instruction at the stop point.

R_{LMQPR} When the ViewInst start/stop function causes ViewInst to become active, the trace unit traces the instruction at the start address.

R_{BWXLS} When the ViewInst start/stop function causes ViewInst to become inactive, the trace unit traces up to and including the instruction at the stop address.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{XHFYQ} While a ViewInst start/stop function start address is the same as a stop address, the behavior of the ViewInst start/stop function is UNPREDICTABLE.

R_{KCYTR} The ViewInst start/stop function part of the ViewInst function is expressed as the following equations:

$$\text{TRCVICTLR.SSSTATUS}_{i+1} = S_i \wedge \neg\text{Stop}_i$$
$$S_i = \text{TRCVICTLR.SSSTATUS}_i \vee \text{Start}_i$$

If TRCIDR4.NUMPC == `0b0000`, then:

$$\text{Start}_i = \sum_n (\text{SAC}[n] \wedge \text{TRCVISSCTLR.START}[n])$$
$$\text{Stop}_i = \sum_n (\text{SAC}[n] \wedge \text{TRCVISSCTLR.STOP}[n])$$

If TRCIDR4.NUMPC != `0b0000`, then:

$$\text{Start}_i = \sum_n (\text{SAC}[n] \wedge \text{TRCVISSCTLR.START}[n]) \vee \sum_m (\text{PECMP}[m] \wedge \text{TRCVIPCSSCTLR.START}[m])$$
$$\text{Stop}_i = \sum_n (\text{SAC}[n] \wedge \text{TRCVISSCTLR.STOP}[n]) \vee \sum_m (\text{PECMP}[m] \wedge \text{TRCVIPCSSCTLR.STOP}[m])$$

R_{MVFYN} The following have no effect on the ViewInst start/stop function:

- Exceptional occurrences.
- Execution in Debug state.
- Execution in a Trace Prohibited region.
- A trace unit buffer overflow.

R_{GRSVY} When disabling the trace unit, the ViewInst start/stop function becomes static and retains its state until the trace unit is enabled again.

S_{XMMLP} For each of TRCVICTLR.SSSTATUS, TRCVISSCTLR, and TRCVIPCSSCTLR, if the register is implemented, it must be programmed with an initial state when the trace unit is programmed before a trace session.

R_{HYLDM} If an implementation makes speculation visible to the trace unit, the ViewInst start/stop function behaves as if no speculation has occurred. That is, when the instruction at a start or stop point is executed speculatively and is later canceled, the ViewInst start/stop function behaves as if the instruction at the start or stop point was not executed.

R_{BZSXR} When the trace unit becomes disabled and there are instructions at start points or stop points which are still speculative, the behavior of the ViewInst start/stop function is IMPLEMENTATION DEFINED and one of the following:

- The ViewInst start/stop function behaves as if the instructions at the start points or stop points were incorrectly speculated. That is, the trace unit behaves as if those start points and stop points did not occur.
- The ViewInst start/stop function behaves as if the instructions at the start points or stop points were correctly speculated. That is, the trace unit updates the state of the ViewInst start/stop function as if those start points and stop points occurred.

R_{HMKSZ} When mis-speculation occurs and the PE returns to a point in execution before the trace unit was enabled, the ViewInst start/stop function reverts to the state it was in when the trace unit became enabled.

R_{PBFMY} When the state of the ViewInst start/stop function is changed by anything other than a direct write to TRCVICTLR, the PE considers the write to be an indirect write to TRCVICTLR.SSSTATUS.

D4.5.9.2.1 Instruction blocks

R_{PTTKL} When an instruction block that contains instructions at ViewInst start points and no instructions at ViewInst stop points is executed, the ViewInst start/stop function remains active for the entire instruction block.

R_{WJLMR} While the ViewInst start/stop function is active, when an instruction block is executed that contains at least one ViewInst stop address and no ViewInst start addresses, the ViewInst start/stop function remains active for the whole instruction block and becomes inactive for the next instruction block, unless the next instruction block contains a ViewInst start address.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{SMGJZ} When an instruction block that contains at least one instruction at a ViewInst start point and at least one instruction at a ViewInst stop point is executed, the ViewInst start/stop function obeys the order of the start and stop points in the block, with the following consequences:

- The ViewInst start/stop function is active for the whole of the instruction block.
- When the final instruction in the block at a ViewInst start or stop point is at a ViewInst start point, the ViewInst start/stop function is active for the next instruction block.
- When the final instruction in the block at a ViewInst start or stop point is at a ViewInst stop point, the ViewInst start/stop function is inactive for the next instruction block, unless the next block contains an instruction at a new ViewInst start point.

R_{SFXZB} The trace analyzer ensures that for all of the SACs selected for ViewInst start points or stop points, any SAC programmed with a lower address than another SAC is a lower-numbered SAC than the other SAC. That is, the SACs contain addresses in address order.

I_{RYPMM} While the SACs selected for ViewInst do not contain addresses in address order, the behavior of the ViewInst start/stop function is UNPREDICTABLE.

R_{ZLDKC} The trace analyzer ensures that for all of the PE Comparator Inputs selected for ViewInst start points or stop points, any PE comparator programmed with a lower address than another PE comparator is a lower-numbered PE comparator than the other PE comparator. That is, the PE comparators contain addresses in address order.

I_{CKTWT} While the PE Comparator Inputs selected for ViewInst do not contain addresses in address order, the behavior of the ViewInst start/stop function is UNPREDICTABLE.

R_{VFFWS} If more than one instruction Address Comparator is programmed with the same instruction address, then programming one or more of those comparators as start comparators, and one or more as stop comparators, results in the following CONSTRAINED UNPREDICTABLE behavior of the ViewInst start/stop function:

- The ViewInst start/stop function is either active or inactive for the instruction at that address.
- The ViewInst start/stop function is either active or inactive after that instruction.

D4.5.9.3 ViewInst include/exclude function filtering

I_{NDYFG} The ViewInst include/exclude function is useful if:

- Specific ranges of instructions are required to be included in the trace.
- Specific ranges of instructions are required to be excluded from the trace.
- A combination of including and excluding instruction ranges is required.

I_{LDDGL} The ViewInst include/exclude function is comprised of two functions:

Function	Meaning
ViewInst include function	Includes one or more instruction address ranges
ViewInst exclude function	Excludes one or more instruction address ranges

There are between zero and eight instruction Address Range Comparators available for the ViewInst include/exclude function. Some of these comparators can be selected for the ViewInst include function, and some for the ViewInst exclude function.

S_{VNWYT} For example, if all instructions in the address range from `0x00` to `0x2C` are required, but no other instructions are required, an Address Range Comparator can be selected for the ViewInst include function and be programmed with these two addresses. All instructions that are in this address range, including those at the start and end addresses, are traced.

I_{NKLJR} The ViewInst include/exclude function differs from the ViewInst start/stop function in the following ways:

- When the ViewInst start/stop function is used, the trace unit starts tracing on a specified start instruction address and stops tracing on a specified stop instruction address. However, if execution branches or jumps to an address between the start and stop points, without first accessing the instruction at the start address, then the instruction that it has branched or jumped to is not traced. Instructions in the start/stop range are only traced if the instruction at the start address is accessed, so that the trace unit is triggered to start tracing. When triggered, and as execution continues sequentially towards the stop address, all functions that the piece of code calls are traced.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the ViewInst include/exclude function is used, for example by programming an Address Range Comparator with an include address range, then if execution branches or jumps to any instruction address anywhere in that range, that instruction is always traced. This is true regardless of whether the instruction at the start address has been accessed or not.

In addition, unlike the ViewInst start/stop function, as program execution continues through the address range towards the end address, no functions that the piece of code calls are traced.

R_{SKZHH} The ViewInst include/exclude function part of the ViewInst function is expressed as the following equations:

$$I_i = \text{Include}_i \wedge \neg\text{Exclude}_i$$
$$\text{Include}_i = \sum_n (\text{ARC}[n] \wedge \text{TRCVIIECTLR.INCLUDE}[n]) \vee \prod_n \neg\text{TRCVIIECTLR.INCLUDE}[n]$$
$$\text{Exclude}_i = \sum_n (\text{ARC}[n] \wedge \text{TRCVIIECTLR.EXCLUDE}[n])$$

D4.5.9.3.1 Instruction blocks

R_{RNPWD} When an instruction in an instruction block is included to be traced by the ViewInst include/exclude function, the ViewInst include/exclude function includes all of the instruction block.

R_{PLCQJ} When an instruction block contains at least one instruction excluded by the ViewInst include/exclude function, and only when all the instructions in the instruction block are excluded, the ViewInst include/exclude function excludes the instruction block.

I_{LBNVM} If a block of instructions is not entirely covered by at least one individual ARC selected by TRCVIIECTLR.EXCLUDE, it is CONSTRAINED UNPREDICTABLE whether the block is excluded or not. This applies even if other ARCs selected by TRCVIIECTLR.EXCLUDE cover the rest of the block.

D4.5.9.4 Guidelines for interpreting the ViewInst function result

I_{TCGMV} The result of the ViewInst function is either:

Result	Meaning
High	Indicates that instructions being executed must be traced
Low	It is expected that instructions being executed are not traced

If it is expected that instructions being executed are not traced, then there are occasions when it is permitted to trace some of those instructions. This section provides guidelines for when it is permitted to trace instructions that ViewInst indicates are not traced.

D4.5.9.4.1 When ViewInst transitions from low to high

I_{GMYYC} If execution occurs while ViewInst is low, it is permitted for a trace unit to trace instructions in certain circumstances. For more information on ViewInst low, see Occasions when tracing instructions when ViewInst is low is permitted.

I_{RVCQT} Tracing of instructions is permitted while ViewInst is low, but if no instructions or Exceptional occurrences that occur are traced, then there is a discontinuity in the trace. When a discontinuity in the trace occurs, when ViewInst becomes high, a *Trace On element* must be generated.

I_{YXGLK} Any instructions that are executed while ViewInst is high must be traced.

D4.5.9.4.2 Occasions when tracing instructions when ViewInst is low is permitted

I_{VFYXG} ETE permits tracing of instructions when ViewInst is low, in the following scenarios:

- When the instruction that ViewInst indicates is not to be traced is in the same instruction block as an instruction that ViewInst indicates must be traced. This is because the only way to trace the instruction that must be traced is to trace the whole instruction block.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the instruction that ViewInst indicates is not to be traced is in an instruction block that precedes or follows an instruction block containing an instruction that ViewInst indicates must be traced.

An implementation always traces the instruction block that contains an instruction that must be traced. However, additional blocks of instructions might also be traced. This is more likely to occur when many instructions are executed in close proximity.

I_{CDLHB} Except for the scenarios that are mentioned, if the ViewInst function indicates that an instruction is not to be traced, then in general it is expected that it is not traced.

I_{FJMHL} In Figure D4-14, the instruction block 1 is in execution order before instruction block 2. The ViewInst calculation for the second block returns true, as indicated by the transition labeled (a). As ViewInst is true for this instruction block then all the instructions in this block must be traced, as indicated by the transition labeled (b). Instruction block 1 might be traced as it is in the same PE cycle as block 2, as indicated by the transition labeled (c).

Figure D4-14 Example of close proximity

D4.5.9.5 Rules for tracing Exceptional occurrences

R_{CGVJD} When an Exceptional occurrence occurs, the Exceptional occurrence does not affect the comparators used by the ViewInst function, and none of the comparators used by the ViewInst function match.

I_{VFDMQ} The comparators used by the ViewInst function include the following:

- Single Address Comparators.
- Address Range Comparators.
- Context Identifier Comparators.
- Virtual Context Identifier Comparators.

I_{VFNZR} When an *Exception element* is traced, it might indicate execution of instructions up to a specified address. These instructions might have an impact on the comparators, but the Exceptional occurrence itself does not.

This means that when an Exceptional occurrence occurs, the ViewInst function does not indicate whether the Exceptional occurrence must be traced. However, it is useful to trace Exceptional occurrences, to determine why execution has departed from the normal program flow.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{BVGXZ} When an instruction executes or Exceptional occurrence occurs outside a Trace Prohibited region, the trace unit remembers whether the instruction or Exceptional occurrence was traced. The trace unit performs indirect writes to TRCRSR.TA to store this state. When an Exceptional occurrence occurs, the trace unit uses TRCRSR.TA to determine whether to trace the Exceptional occurrence.

R_{BFSWZ} When an instruction executes or Exceptional occurrence occurs outside a Trace Prohibited region and the instruction or Exceptional occurrence is traced, TRCRSR.TA is set to 1.

R_{MLTTK} When an instruction executes or Exceptional occurrence occurs outside a Trace Prohibited region and the instruction or Exceptional occurrence is not traced, TRCRSR.TA is set to 0.

R_{CJTJM} When an instruction or Exceptional occurrence is canceled, TRCRSR.TA is set to the value of TRCRSR.TA immediately before the canceled instruction or Exceptional occurrence.

R_{DPMBQ} When an Exceptional occurrence occurs, it is traced if all of the following are true:

- The PE is not in Debug state.
- TRCRSR.TA is 1.

R_{BJQDP} While any of the following are true, TRCRSR.TA is unchanged by any execution:

- The PE is in Debug state.
- The PE is in a Trace Prohibited region.

R_{QZPJD} When a trace unit buffer overflow occurs, the behavior of TRCRSR.TA is IMPLEMENTATION DEFINED and is one of the following:

- TRCRSR.TA is set to 0.
- TRCRSR.TA is set to the value of TRCRSR.TA for the most recent instruction or Exceptional occurrence before the trace unit buffer overflow occurred.

D4.5.9.6 Forced tracing of Exceptional occurrences

I_{MFQND} The trace unit can be programmed so that it always traces certain Exceptional occurrences, regardless of whether the instruction or Exceptional occurrence immediately before the Exceptional occurrence must be traced. This option is enabled by setting either or both:

- TRCVICTLR.TRCERR to 1. This forces the trace unit to trace System Error exceptions regardless of the value of ViewInst.
- TRCVICTLR.TRCRESET to 1. This forces the trace unit to trace PE Resets regardless of the value of ViewInst.

R_{SJXYS} While the PE is executing in a Trace Prohibited region, forced tracing of System Error exceptions is inactive.

R_{VLNMN} While the PE is not executing a Trace Prohibited region and forced tracing of System Error exceptions is enabled, forced tracing of System Error exceptions is active.

R_{LTLBB} While forced tracing of System Error exceptions is active, when a System Error exception occurs, the trace unit generates an *Exception element* indicating a System Error exception, regardless of the value of ViewInst.

R_{NCXJN} While the PE is executing in a Trace Prohibited region, forced tracing of PE Resets is inactive, regardless of whether the PE Reset causes the PE to leave a Trace Prohibited region or not.

R_{NQJNL} While the PE is not executing in a Trace Prohibited region, while forced tracing of PE Resets is enabled, forced tracing of PE Resets is active.

R_{GPKSH} While forced tracing of PE Resets is active, when a PE Reset occurs, the trace unit generates an *Exception element* indicating a PE Reset, regardless of the value of ViewInst.

R_{BBBBT} While tracing is inactive, before an *Exception element* is generated due to forced tracing of either a PE Reset of a System Error exception, the trace unit generates a *Trace On element* and then a *Target Address element*.

I_{LXLKS} When an *Exception element* is generated as a result of forced tracing, the *Trace On element* generated before the *Exception element* indicates that tracing becomes active, and the *Target Address element* indicates where tracing becomes active.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{NZNDM} When a System Error exception occurs and TRCRSR.TA is 0 and the exception is traced because forced tracing of System Error exceptions is enabled, then it is IMPLEMENTATION DEFINED whether TRCRSR.TA is set to 1 or remains at 0.

R_{YFKGM} When a PE Reset occurs and TRCRSR.TA is 0 and the PE Reset is traced because forced tracing of PE Resets is enabled, then it is IMPLEMENTATION DEFINED whether TRCRSR.TA is set to 1 or remains at 0.

I_{GWHRM} In scenarios where a System Error exception occurs at approximately the same time as an exit from a Trace Prohibited region, after all execution inside the Trace Prohibited region and before any instruction execution outside the Trace Prohibited region, it is UNPREDICTABLE whether the System Error exception is considered to have occurred inside or outside the Trace Prohibited region. It is also UNPREDICTABLE whether the forced tracing of System Error exceptions is active for this exception.

These scenarios do not include scenarios where the System Error exception caused the exit from a Trace Prohibited region, because the System Error exception occurred inside the Trace Prohibited region.

I_{JGVSY} In scenarios where a System Error exception occurs at approximately the same time as an entry to a Trace Prohibited region, after all execution before the Trace Prohibited region and before any instruction execution inside the Trace Prohibited region, it is UNPREDICTABLE whether the System Error exception is considered to have occurred inside or outside the Trace Prohibited region. It is also UNPREDICTABLE whether the forced tracing of System Error exceptions is active for this exception.

These scenarios do not include scenarios where the System Error exception caused the entry to a Trace Prohibited region, because the System Error exception occurred outside the Trace Prohibited region.

R_{TSVKN} When a System Error exception occurs immediately after the PE exits a Trace Prohibited region and the System Error exception is traced, the preferred exception return address in the *Exception element* indicating the System Error exception does not include information about the Trace Prohibited region.

I_{PXJWM} In scenarios where a PE Reset occurs at approximately the same time as an exit from a Trace Prohibited region, after all execution inside the Trace Prohibited region and before any instruction execution outside the Trace Prohibited region, it is UNPREDICTABLE whether the PE Reset is considered to have occurred inside or outside the Trace Prohibited region. It is UNPREDICTABLE whether the forced tracing of PE Resets is active for this PE Reset.

These scenarios do not include scenarios where the PE Reset caused the exit from a Trace Prohibited region, because the PE Reset occurred inside the Trace Prohibited region.

I_{JKQHF} In scenarios where a PE Reset occurs at approximately the same time as an entry to a Trace Prohibited region, after all execution before the Trace Prohibited region and before any instruction execution inside the Trace Prohibited region, it is UNPREDICTABLE whether the PE Reset is considered to have occurred inside or outside the Trace Prohibited region. It is UNPREDICTABLE whether the forced tracing of PE Resets is active for this PE Reset.

These scenarios do not include scenarios where the PE Reset caused the entry to a Trace Prohibited region, because the PE Reset occurred outside the Trace Prohibited region.

R_{NRNFS} When a PE Reset occurs immediately after the PE exits a Trace Prohibited region and the PE Reset is traced, the preferred exception return address in the *Exception element* indicating the PE Reset does not include information about the Trace Prohibited region.

D4.5.10 Element Generation

D4.5.10.1 Trace Info element generation

R_{TFQRM} When a trace protocol synchronization request is serviced, the trace unit generates a *Trace Info element* to indicate where program execution trace analysis can start. A *Trace Info element* is not required to indicate where *Event element* and *Instrumentation element* analysis can start.

Note

There is no requirement to generate a new *Trace Info element* every time that ViewInst becomes active. This is because, despite the discontinuity in the trace that is caused by the filtering, the programming of the trace remains the same.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.10.2 Atom element

R_{XCJGD} When a *P0 instruction* is taken, the trace unit generates one of the following:

- An E *Atom element*.
- A *Source Address element*.

R_{SRYKV} When a *P0 instruction* is not taken, the trace unit generates one of the following:

- An N *Atom element*.
- Nothing.

R_{TZZRH} When a *P0 instruction* is not taken and the trace unit does not generate an N *Atom element*, for all future not taken *P0 instructions* until the next taken *P0 instruction* or Exceptional occurrence, the trace unit does not generate an N *Atom element*.

R_{NZTGQ} When a *P0 instruction* is not taken and the trace unit does not generate an N *Atom element*, when an Exceptional occurrence occurs before the next taken *P0 instruction*, the trace unit generates an *Exception element*.

R_{FWCQR} When a *P0 instruction* is not taken and the trace unit does not generate an N *Atom element*, when no Exceptional occurrence occurs before the next taken *P0 instruction*, the trace unit generates a *Source Address element* for the next taken *P0 instruction*.

R_{NTMMM} When a *P0 instruction* is not taken and the trace unit does not generate an N *Atom element*, and the *P0 instruction* is subsequently mispredicted, the trace unit generates a *Source Address element* and does not generate a *Mispredict element*.

R_{ZRYPK} The trace unit generates *Atom elements* in the program order in which they occur, and the trace protocol encode and decode process maintains this order.

I_{TGQNB} For conditional branch instructions, an E *Atom element* indicates that the instruction passed its condition code check, and an N *Atom element* indicates that the instruction failed its condition code check, although a trace unit might use a *Mispredict element* to modify the *Atom element*.

I_{BXBNQ} The trace unit might trace unconditional *P0 instructions* using an E *Atom element* or an N *Atom element*.

R_{RNYNV} When an unconditional *P0 instruction* is traced using an N *Atom element*, the trace unit generates either a *Mispredict element* or a *Cancel element* to correct the N *Atom element*.

R_{LMDZV} When an `ISB` instruction does not pass the condition code check, and the `ISB` instruction does not perform a Context synchronization event, the trace unit treats the `ISB` instruction as a not taken instruction.

R_{NZPLB} When an `ISB` instruction does not pass the condition code check, and the `ISB` instruction performs a Context synchronization event, the trace unit treats the `ISB` instruction as a taken instruction.

R_{CPFBS} When an `ISB` instruction passes the condition code check, the trace unit treats the `ISB` instruction as a taken instruction.

Note

For an `ISB` instruction, a trace analyzer must not infer the value of the PSTATE condition flags from an *Atom element*.

R_{QBGXJ} It is IMPLEMENTATION DEFINED whether the trace unit classifies `WFI`, `WFIT`, `WFE`, and `WFET` instructions as *P0 instructions*. When `WFI`, `WFIT`, `WFE`, and `WFET` are classified as *P0 instructions*, execution of these instructions generates an *Atom element*. See Low-power state and TRCIDR2.WFXMODE.

R_{HJHHV} When `WFI`, `WFIT`, `WFE`, and `WFET` instructions are classified as *P0 instructions* and a conditional `WFE` or `WFI` instruction is executed, if the instruction passes its condition code check then an E *Atom element* is generated.

R_{BMXDT} When `WFI`, `WFIT`, `WFE`, and `WFET` instructions are classified as *P0 instructions* and a conditional `WFE` or `WFI` instruction is executed, if the instruction fails its condition code check then either an E *Atom element* or an N *Atom element* is generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

For a `WFI`, `WFIT`, `WFE`, or `WFET` instruction which is classified as a *P0 instruction*, a trace analyzer must not infer the value of the PSTATE condition flags from an E *Atom element*.

I_{PZRCT} *P0 instructions* that fail or are predicted to fail their condition code check either generate an Undefined Instruction exception or are executed as a NOP, if the instruction is also UNDEFINED.

R_{YCRVD} When a *P0 instruction* fails or is predicted to fail its condition code check, and the *P0 instruction* is executed as a NOP, the trace unit generates an N *Atom element* for the *P0 instruction*.

R_{TSQGH} When a *P0 instruction* fails or is predicted to fail its condition code check, and the *P0 instruction* generates an Undefined Instruction exception, the trace unit does not generate an *Atom element* for the instruction and generates an *Exception element* instead. The preferred exception return address for the generated *Exception element* is the UNDEFINED instruction, which indicates that the instruction did not execute.

R_{NQPPX} The trace unit generates all *Atom elements* speculatively, and explicitly resolves or cancels each *Atom element* by generating *Commit elements* or *Cancel elements*.

I_{NGJYB} A trace analyzer can infer execution from an *Atom element*, but only after the *Atom element* has been resolved by a *Commit element*.

S_{MFDNZ} For taken direct *P0 instructions*, a trace analyzer must infer the target address and instruction set of the instruction from the opcode in the program image.

S_{TJSRY} If a taken direct *P0 instruction* is from a branch broadcasting region, the trace analyzer does not need to infer the target address and instruction set because this is explicitly traced using a *Target Address element*.

D4.5.10.3 Exception element

R_{QHRVX} When an Exceptional occurrence occurs, if the Exceptional occurrence is required to be traced, the trace unit generates an *Exception element*.

R_{LYYMG} The trace unit generates *Exception elements* in program order relative to other *P0 elements*.

I_{PCMYT} To be consistent with the rules for generating *Target Address elements*, under the following scenarios the trace unit must generate a *Target Address element* before an *Exception element*, unless the *Target Address element* would be removed due to a return stack match:

- The Exceptional occurrence is taken from the target of a taken indirect *P0 instruction*.
- The Exceptional occurrence is taken from the target of a taken direct *P0 instruction* in a branch broadcasting region.
- The Exceptional occurrence is taken from the target of another *Exception element*.

R_{XGXKK} When an Exceptional occurrence occurs, if the *Context information* changes at the target of the *P0 element* preceding the Exceptional occurrence, then the trace unit generates a *Context element* before the *Exception element*. The *Context element* provides *Context information* about the address and context where the Exceptional occurrence was taken from.

I_{CMRCN} An invalid address is one where bits [63:P] are not all zeros or all ones, where P is defined as one of the following:

- When FEAT_LVA3 is implemented, 56.
- When FEAT_LVA is implemented, 52.
- Otherwise, 48.

R_{RJCBT} When the PE attempts to execute an instruction at an invalid address and the trace unit generates an *Exception element*, the preferred exception return address in the *Exception element* indicates one of the following:

- The full 64-bit invalid address.
- Any other invalid address, with address bits [P-1:0] the same as the full invalid address.

I_{GYJKB} When a branch to an invalid address occurs and an *Exception element* is generated for an exception taken from that invalid address, Arm recommends that the preferred exception return address in the *Exception element* is the same as the invalid address indicated by the *Target Address* element for the branch.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.10.4 Source address element

R_{DCHPQ} When a *P0 instruction* which must be traced is not taken and the trace unit does not generate an N *Atom element*, then when a subsequent *P0 instruction* is taken, the trace unit generates a *Source Address element*.

I_{KDTRV} A trace unit can generate a *Source Address element* to imply that at least one instruction has been executed, including a taken *P0 instruction*.

R_{WVBQW} When the trace unit generates a *Source Address element* to imply that a taken *P0 instruction* has been executed, the address associated with the *Source Address element* is the virtual address of the taken *P0 instruction*.

D4.5.10.5 Q element

R_{FZTZP} A trace unit can generate a *Q element* to imply that at least one instruction has been executed, possibly including *P0 instructions*.

R_{WHLPS} When a *Q element* is generated, the trace unit generates a *Target Address element* that indicates where execution is to continue after all the instructions that are implied by the *Q element* have been executed.

R_{MNWCK} When a *Q element* is generated and the last instruction implied by the *Q element* is a *P0 instruction*, the trace unit generates a *Target Address element* that indicates the target of the *P0 instruction*.

R_{BJLRS} When a *Q element* is generated and the last instruction implied by the *Q element* is not a *P0 instruction*, the trace unit generates a *Target Address element* that indicates the instruction address immediately following the last instruction that is implied by the *Q element*.

R_{FPHFM} When the PE leaves a region where *Q elements* are permitted, either by a *P0 instruction* or by sequential execution out of the region, and a *Q element* implies the execution of the last instruction in the region, the *Q element* does not imply any more instructions after the last instruction in the region.

R_{DTWYZ} When the PE enters a region where *Q elements* are permitted, either by a *P0 instruction* or by an Exceptional occurrence, the trace unit traces the *P0 instruction* or Exceptional occurrence using elements other than *Q elements*.

Note

Although the trace unit does not trace with *Q elements* a *P0 instruction* or Exceptional occurrence that causes the PE to enter a region where *Q elements* are permitted, any subsequent instructions in the region where *Q elements* are permitted might be traced using *Q elements*.

I_{YRZWY} When the PE enters by sequential execution a region where *Q elements* are permitted, any instructions that are executed since the last *P0 element* outside the permitted region might be traced using a *Q element*. These instructions can always be inferred unambiguously from the *Q element*.

R_{SJSGX} When the PE enters by sequential execution a region where *Q elements* are permitted, and *P0 instructions* executed since the last *P0 element* outside the permitted region are traced by a *Q element*, the *Q element* does not indicate execution of any *P0 instructions* outside the permitted region.

D4.5.10.6 Event element

R_{WJPTB} The trace unit generates *Event elements* independently of ViewInst.

R_{KKLYB} While TRCEVENTCTL1R.INSTEN<n> is 1 and the resource event selected by TRCEVENTCTL0R.EVENT<n> is active, while trace generation is operative, the trace unit generates an *Event element* <n> on each PE clock cycle.

R_{SPYTT} When an *Event element* is generated between two *P0 elements* or at the same time as a *P0 element* that follows another, the trace unit inserts the *Event element* after the first *P0 element* but before the *P0 element* that is an IMPLEMENTATION DEFINED number of *P0 elements* after the first *P0 element*.

I_{XLJKP} Arm recommends that the IMPLEMENTATION DEFINED number of *P0 elements* is less than or equal to the number of *P0 elements* the PE can process simultaneously.

R_{SHYMY} While trace generation is inoperative due to a trace unit buffer overflow, when a programmed *ETEEvent* <n> occurs, the trace unit generates at least one *Event element* <n> before it generates the *Overflow element* corresponding to the trace unit buffer overflow.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.10.7 Cancel element generation

R_{HYCXR} When one or more *P0 elements* are canceled, the trace unit generates a *Cancel element*.

R_{GKDYR} The trace unit generates *Cancel elements* in execution order relative to *P0 elements*.

R_{KDTVX} When a *Cancel element* causes execution to return to a point in the program flow that is not adjacent to a *P0 instruction*, the trace unit generates an *Exception element* that indicates which instructions were executed up to that point in the program flow before it generates any *P0 elements*.

D4.5.10.8 Commit element generation

R_{QNLYJ} When one or more traced *P0 elements* are resolved for execution, the trace unit generates a *Commit element*.

I_{MDSCN} An *Atom element* might be corrected using a *Mispredict element* after it has been resolved.

R_{MNXTW} The trace unit never generates more speculative *P0 elements* than the maximum speculation depth of the trace unit.

R_{XXFBC} When trace generation becomes inoperative due to the trace unit being disabled, the trace unit outputs any *Commit elements* which have not been output.

I_{BNLZT} If cycle counting is enabled some *Commit elements* have *Cycle Count elements* associated with them, that provide counts of processor clock cycles. The cycle count values given in *Cycle Count elements* can be used to obtain a cumulative count.

R_{ZHWDD} *Commit elements* with associated *Cycle Count elements* cannot be merged with later *Commit elements*.

I_{PSFTD} For more information, see Cycle Count element.

D4.5.10.9 Context element

R_{BDFDQ} The trace unit generates a *Context element* in the following situations:

- While tracing is active, when any of the *Context information* changes, before any *P0 element* which indicates execution from the new context.
- After a *Trace Info element* is generated due to a non-periodic trace protocol synchronization request, and before any *P0 element*.
- After a *Trace Info element* is generated due to a periodic trace protocol synchronization request.
- When mis-speculation results in an incorrect *Context element* being output, before any *P0 element* which indicates execution from the correct context.

R_{JNXJT} While Virtual context identifier tracing is enabled and TRFCR_EL2.CX disallows the tracing of the Virtual context identifier, when the trace unit generates a *Context element*, the Virtual context identifier in the *Context element* has the value `0x0`.

I_{TBJPL} A *Context element* might also be output at other points, which might include after all Context synchronization events, or at any other point at which the *Context information* changes.

R_{MKKZN} If the highest implemented Exception level is using AArch64, the Context identifier value is the value of CONTEXTIDR_EL1.

I_{WXVHT} Some of the *Context information* might change at points other than at Context synchronization events. These changes occur when system instructions are used to change a piece of *Context information*, including:

- Writes to the current CONTEXTIDR_EL1.
- Writes to the CONTEXTIDR_EL2.
- Changes from a higher Security state to a lower Security state without using an exception return.
- Changes in Exception level other than due to an exception or an exception return.

R_{HXNXF} When a System instruction writes to a System register and the *Context information* changes, the trace unit generates a *Context element* containing the new context value, after the *P0 element* prior to the System instruction but before the *P0 element* following a Context synchronization event after the System instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If the *Context element* is output before the first *P0 element* after the System instruction, this might imply that some instructions before the System instruction were executed with the new context. This is acceptable because the code which changes the context is usually executed in a state where it does not matter whether the old or new context values are used.

I_{WTSTB} If the PE takes an exception after performing a write to a System register that changes the context, but a *P0 element* has not been generated since the write, then a *Context element* indicating the new context is not required to be output before the *Exception element*. This is because no instructions or Exceptional occurrences are indicated to have been executed from the new context. A *Context element* indicating the new context must be generated after the *Exception element* if the Exceptional occurrence is a Context synchronization event. If the Exceptional occurrence changes the context, then the *Context element* must indicate the new context. This might happen if, for example, the Security state changes.

R_{HTYGF} When a PE reset occurs, until the relevant PE registers are updated, the trace unit traces the Context identifier and Virtual context identifier as zero.

I_{KTPVJ} A trace unit is not required to generate a *Context element* if tracing becomes inactive before any instructions are executed in the new context.

I_{QWSVJ} Additional *Context elements* might be output by a trace unit in some scenarios, but these must only be output where they do not affect the analysis of the trace element stream. Such a scenario might include when a change in the *Context information* is incorrectly speculated and a subsequent *Context element* corrects the value of a previous incorrect *Context element*. Arm recommends that the generation of additional unnecessary *Context elements* is minimized to ensure trace bandwidth is minimized.

D4.5.10.10 Target Address element

R_{HLRZJ} When the trace analyzer cannot infer the address or instruction set from the trace, the trace unit generates a *Target Address element*.

I_{FRTGM} Occasions when the trace analyzer might not be able to infer the address or instruction set from previous trace include:

- At the target of an indirect *P0 instruction* which is taken.
- At the target of a direct *P0 instruction* which is taken in a branch broadcasting region, see TRCBBCTLR for more information.
- At the target of an Exceptional occurrence.
- When mis-speculation occurs and the address cannot be inferred.
- After a *Q element* is generated.

R_{ZRYSN} When the trace analyzer cannot infer the address or instruction set from the trace, the trace unit generates the resulting *Target Address element* before the next *P0 element*, unless any of the following are true:

- The *Target Address element* can be omitted because of a return stack match.
- Tracing is inactive at the target of the *P0 instruction* or Exceptional occurrence.

R_{RGPTK} When non-periodic trace protocol synchronization occurs, the trace unit generates a *Target Address element* after the *Trace Info element* and *Trace On element* corresponding to the non-periodic trace protocol synchronization, and before the next *P0 element* is generated.

R_{MDTYL} When periodic trace protocol synchronization occurs, after the corresponding *Trace Info element* has been generated, the trace unit generates a *Target Address element* containing the address of the target of the most recent *P0 element* before the *Target Address element*.

I_{YMLXQ} When non-periodic trace protocol synchronization occurs, the *Target Address element* does not need to indicate the target of the most recent *P0 element*, since tracing might not become active at the target of a *P0 element*.

I_{GBMWG} When periodic trace protocol synchronization occurs, the *Target Address element* needs to indicate the target of the most recent *P0 element*, since tracing is continuing from that *P0 element*. Furthermore, the *Target Address element* might indicate the target of a *P0 element* from before the *Trace Info element*.

R_{QCSJJ} When a *Trace On element* is generated, the trace unit generates a *Target Address element* before the next *P0 element*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{DTQDH} Typically, a *Target Address element* is required after an *Exception element* to indicate the target of the Exceptional occurrence, since a trace analyzer is not usually able to infer the target of an Exceptional occurrence.

I_{YHQGL} In some scenarios, an *Exception element* might be generated in the trace where the Exceptional occurrence target address is the next sequential instruction from the last instruction before the Exceptional occurrence. This behavior depends on many factors and might only occur for IMPLEMENTATION DEFINED Exceptional occurrences. If an Exceptional occurrence is taken to the next sequential instruction, the trace unit is not required to output a *Target Address element* indicating the target address of the Exceptional occurrence because this can be inferred from the previous execution.

I_{GVZJZ} A trace analyzer needs both a *Target Address element* and a *Context element* before it can determine the instruction set in use, because the *Target Address element* provides the instruction set and the *Context element* provides information on which Execution state the PE is in.

R_{RHDMW} When a change of instruction set occurs that switches between AArch32 state and AArch64 state, the trace unit generates a *Context element* indicating the new state.

I_{KZXQW} An invalid address is one where bits [63:P] are not all zeros or all ones, where P is defined as one of the following:

- When FEAT_LVA3 is implemented, 56.
- When FEAT_LVA is implemented, 52.
- Otherwise, 48.

R_{VWVWR} When the PE attempts to execute an instruction at an invalid address and the trace unit generates a *Target Address element*, the *Target Address element* indicates one of the following:

- The full 64-bit invalid address.
- Any other invalid address, with address bits [P-1:0] the same as the full invalid address.

I_{YJYFM} When a branch to an invalid address occurs and an *Exception element* is generated for an exception taken from that invalid address, Arm recommends that the preferred exception return address in the *Exception element* is the same as the invalid address indicated by the *Target Address* element for the branch.

R_{SBCPK} While tagged addresses are in use, the virtual address in the trace element stream does not include the tag and is the PC value, that is, depending on the state of the PE at the address, bits[63:56] are one of the following:

- The sign-extension of bit[55].
- Zero.

I_{YGGGK} The Translation Control Registers, TCR_ELx, contain the TBI field for controlling whether to ignore the top byte of an address. If the current TBI field is changed from 0 to 1, and before the next Context synchronization event the PE takes an exception because of an invalid top address byte, the branch target address to the invalid address or the preferred exception return address of the *Exception element* might not contain the full invalid address and might contain the address with the top byte masked. Furthermore, the branch target address might be the invalid address and therefore might be different from the preferred exception return address. Trace analysis tools must be aware that if a branch target address is substantially different from a preferred exception return address which follows, then there might have been a change in the TBI field which caused this large change in address.

R_{HHKGB} When a pointer authentication check fails and an exception is taken from the resulting invalid address, the preferred exception return address is one of the following:

- The full 64-bit invalid address.
- Any other invalid address, with address bits [P-1:0] the same as the full invalid address.

I_{CRSTX} Arm recommends that when a pointer authentication check fails and an exception is taken from the resulting invalid address, the preferred exception return address is the full 64-bit invalid address.

R_{FSWRC} The bottom bits of an address are ignored, in the following way:

- Bits[1:0] of addresses that are used in A64 or A32 instructions are always traced as zero.
- Bit[0] of addresses that are used in T32 instructions is always traced as zero.

I_{MDZJL} Additional *Target Address elements* might be output by a trace unit in some scenarios, but these must only be output where they do not affect the analysis of the trace element stream. These scenarios include, but are not limited to:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When an instruction address is incorrectly speculated, and a subsequent *Target Address element* corrects the value of a previous incorrect *Target Address element*.
- When an instruction address can be inferred by the trace analyzer, for example for the target of a direct *P0 instruction*, but a *Target Address element* is output anyway with the same address.

Arm recommends that the generation of additional unnecessary *Target Address elements* is minimized to ensure trace bandwidth is minimized.

D4.5.10.11 Mispredict element

R_{YJCNT} When the status of the last non-canceled *Atom element* has been changed by the PE, the trace unit generates a *Mispredict element*.

R_{SCKBZ} The trace unit only generates a *Mispredict element* to change the status of an *Atom element*.

I_{XYDNP} A trace unit might generate multiple *Mispredict elements* for the same *Atom element*. A trace analyzer must use each *Mispredict element* to determine the final status of the *Atom element*. For example, if an E *Atom element* has two *Mispredict elements*, the first *Mispredict element* indicates the *Atom element* is an N *Atom element* and the second *Mispredict element* indicates it is an E *Atom element*.

I_{HVWCN} If a PE mispredicts only the target address of a *P0 element*, then it does not generate a *Mispredict element*.

The trace unit uses a *Target Address element* to correct the mispredicted target address. When analyzing a *Mispredict element*, any *Target Address elements* between the mispredicted *Atom element* and the *Mispredict element* must be discarded.

D4.5.10.12 Overflow element

R_{HRYKY} When a trace unit buffer overflow occurs, after all trace elements that were generated prior to the trace unit buffer overflow are output, the trace unit outputs an *Overflow element*.

R_{RPSPH} When a trace unit buffer overflow occurs, and the trace unit is disabled after recovering from the trace unit buffer overflow, the trace unit outputs the corresponding *Overflow element* before the trace unit becomes idle.

D4.5.10.13 Timestamp element

R_{YYWTR} While TRCCONFIGR.TS is 1 and any of the following occur, a timestamp request occurs:

- The timestamp resource event occurs, as controlled by TRCTSCTLR.
- The trace unit generates a *Trace Info element*.
- The trace unit recovers from a trace unit buffer overflow.
- When not in a Trace Prohibited region and a Context synchronization event is caused by any of the following:
  - The PE takes an exception.
  - The PE returns from an exception.
  - An `ISB` instruction is executed.
- A trace unit flush is requested.

R_{CKNFV} While TRCCONFIGR.TS is 1 and when not in a Trace Prohibited region, a timestamp request might occur when any of the following occur but do not cause a Context synchronization event:

- The PE takes an exception.
- The PE returns from an exception.
- An `ISB` instruction is executed.

R_{NGXNQ} The state of the ViewInst function does not affect whether a timestamp request occurs.

R_{HZSYP} When a timestamp request occurs and ViewInst is inactive, the timestamp request is permitted to be delayed until after the first of the following occurs:

- A *P0 element* is generated.
- An *Event element* is generated.
- An *Instrumentation element* is generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{WFXVV} There is no requirement for a *Timestamp element* to be generated in the trace element stream on each occasion that ViewInst becomes active.

R_{RMSVV} When a timestamp request occurs and is not ignored, the trace unit generates a *Timestamp element*.

R_{DWCYP} When a timestamp request occurs but the trace unit does not have the capacity to generate the *Timestamp element* immediately, then the generation of the *Timestamp element* is delayed until there is capacity.

I_{TQDHQ} A trace unit might not have the capacity to generate a *Timestamp element* for multiple reasons, including avoiding a trace unit buffer overflow. A delayed *Timestamp element* means that a timestamp value might not be the exact time of the incident that resulted in the timestamp request. A timestamp is only a time indicator inserted in the trace element stream somewhere near the time of the request.

R_{XMJGY} When a timestamp request occurs while in a Trace Prohibited region, then the generation of the *Timestamp element* is delayed until the PE leaves the Trace Prohibited region.

R_{CWHHW} When the first timestamp request occurs after trace generation becomes operative, the trace unit delays generation of the corresponding *Timestamp element* until after the trace unit has generated either a *P0 element*, an *Event element*, or an *Instrumentation element*.

I_{SDPZZ} This is so that the timestamp value can correspond to the most recent of these elements.

R_{SZNMB} A timestamp request is permitted to be ignored if a previous timestamp request has not yet generated a *Timestamp element*, due to a delay in the generation.

R_{DWFTT} A trace unit might ignore the second request of two successive timestamp requests if all of the following are true:

- The second request is not caused as a result of a trace protocol synchronization request.
- No *P0 elements*, *Event elements*, or *Instrumentation elements* have been generated between the two requests.
- The timestamp value would be the same in both *Timestamp elements*.

R_{ZMQLT} While TRCCONFIGR.CCI is 1, each *Timestamp element* contains a cycle count that indicates the number of cycles between the element with which the Timestamp is associated and the most recent *Cycle Count element* before that element.

R_{MWJHD} The cycle count associated with a *Timestamp element* is different from the *Cycle Count element* in the following ways:

- The cycle count does not affect the cumulative cycle count.
- The cycle count value can be zero.

I_{HTGCM} When the cycle count associated with a *Timestamp element* is zero, this indicates that no cycles passed between the previous *Cycle Count element* and the element with which the *Timestamp element* is associated.

I_{TYVDN} The cycle count associated with a *Timestamp element* is not a *Cycle Count element*, and therefore has no effect on the cycle counter.

R_{JNSWW} When the trace unit is first enabled, while cycle counting is enabled, when a *Timestamp element* is generated before any *Cycle Count elements*, the *Timestamp element* reports the cycle count as UNKNOWN.

R_{NPYKS} When a *Timestamp element* is generated and the cycle counter has exceeded the maximum supported value, the *Timestamp element* reports the cycle count as UNKNOWN.

D4.5.10.14 Trace On element

R_{LMLSN} When an instruction block is traced immediately after an instruction block was not traced or a trace unit buffer overflow occurred, the trace unit generates a Trace On element.

I_{GPQZW} When an *Exception element* indicating a PE reset is traced, the preferred exception return address is UNKNOWN. Any instructions since the most recent unresolved *P0 element* are not traced. If ViewInst was active for these instructions, this is not considered a gap in the trace element stream and a *Trace On element* is not required.

In some scenarios where mis-speculation occurs or instructions are canceled, after *Cancel elements* have been processed there might be *Trace On elements* in the trace element stream even though no trace discontinuity occurred in the architecturally-executed instruction trace. This typically only occurs when the trace is filtered using the ViewInst function, which causes the *Trace On element* to be inserted.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{MHFJB} Trace analyzers must be aware that these additional *Trace On elements* might be traced.

D4.5.10.15 Cycle Count element

R_{TYNZR} The cycle counter has an IMPLEMENTATION DEFINED size of between 12 and 20 bits, as indicated by TRCIDR2.CCSIZE. The cycle counter therefore supports values from 1 to 2^{20}-1.

R_{GWQGS} While TRCCONFIGR.CCI is 1 and the cycle count is equal to or greater than the value of TRCCCCTLR.THRESHOLD, when a Commit element is generated, a *Cycle Count element* request occurs.

R_{KJXDK} While TRCCCCTLR.THRESHOLD is programmed with a value less than TRCIDR3.CCITMIN, the generation of *Cycle Count elements* is CONSTRAINED UNPREDICTABLE.

R_{GDTBW} When a request for a *Cycle Count element* occurs, one of the following occurs:

- The trace unit generates a *Cycle Count element* immediately and before any future *Commit element*.
- The trace unit delays generation of the *Cycle Count element* until after one or more further *Commit elements* have been generated.

I_{TCFRL} Arm recommends that when a request for a Cycle Count element occurs, the *Cycle Count element* is generated immediately, and that *Cycle Count element* generation is only delayed in rare and non-repetitive circumstances.

R_{BMVKB} When a *Cycle Count element* is generated, the *Cycle Count element* contains the value of the cycle counter at the time the most recent *Commit element* was generated, and the cycle counter is reset to the number of cycles since the most recent *Commit element* was generated.

R_{PFZXK} A value of 0 indicates that the cycle count value is UNKNOWN.

R_{YVWJW} When the cycle counter exceeds the maximum supported value, the cycle count value is UNKNOWN.

R_{YFMWB} When the trace unit becomes enabled, an UNKNOWN cycle count value occurs for the first *Cycle Count element* generated.

R_{HQKWH} When a trace unit buffer overflow occurs, an UNKNOWN cycle count value occurs for the first *Cycle Count element* generated.

I_{PDBDY} The first *Cycle Count element* after the PE clock has been restarted should have an UNKNOWN cycle count.

D4.5.10.16 Discard element

R_{WDWGV} When trace generation becomes inoperative after *P0 elements* have been generated but the trace unit is unable to output the resolution of those *P0 elements*, the trace unit generates a *Discard element*.

R_{FHQDX} When trace generation becomes inoperative due to the trace unit becoming disabled, and a *Discard element* is generated, the trace unit outputs the *Discard element* after all other elements.

R_{NSMJF} When a PE reset occurs after *P0 elements* have been generated but the trace unit is unable to output the resolution of those *P0 elements*, the trace unit generates a *Discard element*.

I_{SKJSP} A trace unit might not generate a *Discard element* if no *P0 elements* are speculative.

I_{TGXKV} A trace unit might generate a *Discard element* even if no *P0 elements* are speculative.

R_{CTYFK} When a *Discard element* is generated, all uncommitted *P0 elements* are discarded, that is, the current speculation depth is set to zero.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.10.17 Instrumentation element

R_{STQSN} The Instrumentation element for a first `TRCIT` instruction is generated before the Instrumentation element for any `TRCIT` instruction in program order after that first `TRCIT` instruction.

R_{WYYPN} The Instrumentation element contains the following information:

- The doubleword contained in the `Xt` register parameter of the `TRCIT` instruction.
- The Exception level at which the `TRCIT` instruction was executed.

I_{XWZNW} If Instrumentation tracing is prohibited and tracing is not prohibited, then Arm recommends that the behavior of the `TRCIT` instruction is unaffected by the state of the trace unit.

I_{KGBZX} The `TRCIT` instruction is added to the list of instructions that support concurrent modification and execution, to allow live patching of the `TRCIT` instruction. A `TRCIT` instruction is only permitted to be modified to be a `NOP` instruction or another encoding of the `TRCIT` instruction. Only a `NOP` instruction or a `TRCIT` instruction is permitted to be modified to be a `TRCIT` instruction.

R_{SRSGF} The architecture guarantees that for `NOP` and `TRCIT` instructions, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

R_{LGWQF} Each Instrumentation element generates an Instrumentation packet.

I_{BXHZM} When non-periodic trace protocol synchronization occurs, the trace unit generates an Alignment Synchronization packet before any Instrumentation packet. See R_{TTLJC}.

I_{YWJZW} There are no requirements on the order between Instrumentation packets and other ETE packets, except for the requirements around an Alignment Synchronization packet and the requirements for ordering Timestamp packets and Timestamp Marker packets.

D4.5.11 Trace unit features

I_{BFHRC} The architecture defines a number of optional and mandatory features that are provided to modify the trace element stream to provide additional information to aid debugging. These features include the following:

- *Q element* regions.
- Branch broadcasting.
- Context identifier tracing.
- Cycle counting.
- Event trace.
- No overflow.
- PE Stalling and overflow avoidance.
- Timestamping.
- Virtual context identifier tracing.

For the optional features, the inclusion of these optional features is indicated in TRCIDR0-TRCIDR13.

D4.5.11.1 Q regions

I_{XFPKH} The support for *Q element* is OPTIONAL, as indicated by TRCIDR0.QSUPP.

I_{FSXRY} The use of *Q elements* must be explicitly enabled if the trace unit is to use them.

I_{CGQZJ} While *Q elements* are enabled, the trace element stream might not contain enough information to determine the complete program flow, because some changes in flow might not be explicitly indicated.

I_{QLVSG} Arm recommends that *Q elements* are only used in cases where generating the full ETE instruction trace element stream might cause the performance of the PE being traced to degrade significantly.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{TNPWC} The use of *Q elements* degrades the information that can be extracted from the trace element stream. Arm recommends that *Q element* filtering, as indicated by TRCIDR0.QFILT, is also implemented.

I_{CBKXZ} If TRCQCTLR is implemented, the trace unit supports the ability to control when *Q elements* are permitted in the trace element stream using ARCs. The *Q element* filtering operates in either Exclude mode, or Include mode, selected by TRCQCTLR.MODE.

R_{DSFJZ} If *Q elements* are enabled and *Q element* filtering is in Include mode, the ARCs selected by TRCQCTLR.RANGE define where *Q elements* are permitted.

R_{WXRDY} If *Q elements* are enabled and *Q element* filtering is in Exclude mode, the ARCs selected by TRCQCTLR.RANGE define where *Q elements* are not permitted.

R_{RBPJF} When an instruction block contains at least one instruction where *Q elements* are permitted, the entire instruction block is permitted to generate *Q elements*.

R_{NQSLS} The following equation is calculated for each instruction block and defines when *Q elements* are permitted.

$$\text{Q_PERMITTED}_i = \begin{cases} \sum_n \text{ARC}_i[n] \wedge \text{TRCQCTLR.RANGE}[n] & \text{Include mode} \\ \neg \sum_n \text{ARC}_i[n] \wedge \text{TRCQCTLR.RANGE}[n] & \text{Exclude mode} \end{cases}$$

R_{SGFHP} While TRCCONFIGR.QE indicates that *Q elements* are disabled, the trace unit does not generate any *Q elements*.

R_{CGHSK} While TRCCONFIGR.QE indicates that *Q elements* are disabled, the trace unit is able to generate all of the elements required to trace the instruction sequence.

D4.5.11.2 Branch broadcasting

I_{WLPLZ} The branch broadcasting feature forces the trace unit to explicitly trace the target addresses of taken direct *P0 instructions*.
The target addresses are traced using *Target Address elements* in the instruction trace stream.

I_{DCYQT} Branch broadcasting is enabled by performing both of the following actions:

- Setting TRCCONFIGR.BB to 1.
- Programming TRCBBCTLR to specify how branch broadcasting behaves. TRCBBCTLR selects Address Range Comparators to define when branch broadcasting is active, and selects the operating mode of branch broadcasting:
  - — Branch broadcasting is active for all instructions inside the selected ranges. This is known as Include mode.
  - — Branch broadcasting is active for all instructions outside the selected ranges. This is known as Exclude mode.

R_{MHYFV} When a direct *P0 instruction* for which branch broadcasting is active is taken, the trace unit generates a *Target Address element* to explicitly trace the target of the instruction, regardless of whether the *P0 instruction* is mispredicted.

R_{VQTVR} While branch broadcasting is enabled, while the return stack is enabled, the trace unit prioritizes branch broadcasting over the return stack, that is, the return stack does not match on the target of any instruction for which branch broadcasting is active.

R_{XSVSX} If TRCBBCTLR is not implemented, while branch broadcasting is enabled, branch broadcasting is active for all instructions.

D4.5.11.3 Context identifier tracing

I_{RJJZW} The trace unit can be programmed to include information about the current execution context of the program being executed on the PE, including:

- The current process identifier, stored in CONTEXTIDR_EL1. This is known as the *Context identifier*.
- The current VMID, stored in CONTEXTIDR_EL2. This is known as the *Virtual context identifier*.

R_{GVMFG} The trace unit supports tracing of the Context identifier, with TRCIDR2.CIDSIZE indicating a 32-bit Context identifier size.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.11.4 Cycle counting

I_{MKQVC} The use of the cycle counting feature introduces *Cycle Count elements* into the trace element stream to indicate the passage of PE clock cycles.

I_{BMCMB} Counting the number of clock cycles the PE uses to perform a certain function can be useful as a way of measuring program performance, or for profiling the PE.

R_{JMLLY} While cycle counting is enabled, the trace unit outputs Cycle Count packets that contain processor clock cycle count values.

I_{TVCCV} *Cycle Count elements* are associated with *Commit elements*, so that when a *Commit element* is generated, a *Cycle Count element* might also be generated. Whether a *Cycle Count element* is generated when a *Commit element* is generated depends on what cycle count threshold has been specified when programming TRCCCCTLR.THRESHOLD.

When a *Commit element* is generated and the cycle count value is equal to or more than the threshold value, then a *Cycle Count element* is generated and a Cycle Count packet is output. The cycle count value that is contained in that packet is associated with the *Commit element* that triggered it.

R_{BHYWB} While cycle counting is enabled, and when a *Commit element* is generated and the cycle count value is greater than or equal to the threshold value that is programmed in TRCCCCTLR.THRESHOLD, the trace unit generates a *Cycle Count element*.

I_{LFLCZ} Also, because cycle counting is associated with *Commit elements*, a Cycle Count packet might imply the generation of *Commit elements*, and so in addition to the cycle count value, some Cycle Count packets also contain a value for the number of *Commit elements* that the trace unit has generated.

I_{MWQNZ} The value of cycle count that is given in a new Cycle Count packet indicates the number of processor clock cycles between the new *Commit element* that the packet is associated with, and the most recent *Commit element* prior to the new *Commit element* that had a *Cycle Count element* associated with it.

This means that if there is a requirement for a cumulative cycle count total, the cycle count values from the successive Cycle Count packets can be added together to obtain this.

D4.5.11.5 Event trace

I_{GGMQT} The ETE architecture supports the tracing of additional information in the trace stream. These are known as *ETEEvents*, also known as Event trace. The trace unit supports up to 4 *ETEEvents*. The generation of *ETEEvents* is controlled by selecting resources selectors. The occurrence of *ETEEvents* can be communicated in the following ways:

- To the system by External Outputs.
- To the trace analyzer by Event Packet.

D4.5.11.6 No overflow

I_{DJCLX} A trace unit might include an optional feature to prevent overflows, which is indicated by TRCIDR3.NOOVERFLOW.

R_{YSPHL} TRCSTALLCTLR.NOOVERFLOW controls the no overflow feature.

S_{BSPDF} Enabling the no overflow feature might have a significant impact on PE performance.

R_{LCGZJ} While the no overflow feature is enabled, and while the number or frequency of *ETEEvents* is below an IMPLEMENTATION DEFINED threshold, the trace unit does not overflow.

R_{VHMZX} The threshold is greater than or equal to one of each numbered *ETEEvent*, for each trace session.

R_{MYMKW} When TRCIDR3.SYSSTALL is 0 the Effective value of TRCSTALLCTLR.NOOVERFLOW is 0 which means the no overflow feature is disabled.

R_{JYYLV} When TRCSTALLCTLR.ISTALL is 0 and TRCSTALLCTLR.NOOVERFLOW is 1, it is CONSTRAINED UNPREDICTABLE whether any stalling is disabled or whether the no overflow feature is enabled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.11.7 Stalling the execution of the PE

I_{MPBVQ} The trace unit can be programmed to reduce the likelihood of a trace unit buffer overflow. If the trace unit is configured to support PE stalling, TRCIDR3.STALLCTL indicates that PE stalling is implemented and TRCIDR3.SYSSTALL indicates that PE stalling is permitted, then the execution of the PE can be slowed.

I_{HPFQP} It is permissible that the operation of the PE can be affected by the programming of the trace unit. The amount of intrusion and when stalling occurs is IMPLEMENTATION DEFINED. Additional stalling of the PE execution can be achieved by enabling this feature.

I_{VZSVK} Trace unit stalling of the PE is independent of the operation of the PE.

R_{NVBGS} PE operations which explicitly interact with the trace unit complete independently of the programming of the ability of the trace unit to stall the PE.

R_{SCLVV} The trace unit does not stall the PE while any of the following are true:

- The trace unit is in the Disabled state.
- The PE is executing in a Trace Prohibited region (see Trace Prohibited Regions).
- The PE is in Debug State.
- The PE does not allow stalling, that is, TRCIDR3.SYSSTALL == `0b0`.
- Self-hosted trace is disabled and `ExternalInvasiveDebugEnabled()` == FALSE.
- When TRCSTALLCTLR.ISTALL == `0b0` and TRCSTALLCTLR.NOOVERFLOW == `0b0`.
- Trace output is disabled.

R_{RWTYJ} When all of the following are true, the trace unit is permitted to stall the PE:

- Stalling of the PE is not prohibited by R_{SCLVV}.
- TRCSTALLCTLR.ISTALL == `0b1`.
- Any of the following are true:
  - TRCSTALLCTLR.NOOVERFLOW == `0b1`.
  - The available space in the internal storage of the trace unit is below the level indicated in TRCSTALLCTLR.LEVEL.

Otherwise, the trace unit does not stall the PE due to the stalling feature or no overflow feature.

R_{NVKXX} The trace unit does not indefinitely stall the operation of the PE.

I_{XPRQJ} In a multi-threaded processor, if the trace unit stalls a PE, Arm recommends that stalling or disruption of the processing of other PEs is minimized. In particular, if tracing of one or more PEs in a multi-threaded processor is enabled but tracing of other PEs in the multi-threaded processor is disabled, Arm recommends that if the PEs being traced are stalled by their respective trace units then the stall has minimal effect on the PEs which are not being traced.

I_{KBXXH} The levels indicated in TRCSTALLCTLR.LEVEL are the levels of intrusion allowed.

I_{ZRQBK} A summary of the stalling and no overflow scenarios is shown in Table D4-25, when TRCIDR3.STALLCTL is 1 and TRCIDR3.SYSSTALL is 1.

Table D4-25 Summary of TRCSTALLCTLR stalling and no overflow features

ISTALL	NOOVERFLOW	LEVEL	Description
0	0	x	Stalling is disabled.
0	1	x	It is CONSTRAINED UNPREDICTABLE whether the no overflow feature is enabled or stalling is disabled.
1	0	Zero	Stalling is enabled at the minimum level.
1	0	Nonzero	Stalling is enabled and is based on the value in TRCSTALLCTLR.LEVEL.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISTALL	NOOVERFLOW	LEVEL	Description
1	1	Zero	The no overflow feature is enabled, preventing overflows.
1	1	Nonzero	The no overflow feature is enabled, preventing overflows, and TRCSTALLCTLR.LEVEL might cause stalling earlier than necessary to prevent overflows.

D4.5.11.8 Timestamping

I_{YVBBW} The trace unit supports timestamping, where a common global time value is inserted in to the trace stream. These timestamps may be used to correlate between multiple trace streams, including those from other PEs or other sources of trace. These timestamps may be used to determine the passage of time, for analyzing performance.

I_{VFWQS} When timestamping is enabled, the trace unit inserts *Timestamp elements* in to the trace stream. Each Timestamping element indicates the time that a recent *P0 element*, *Event element*, or *Instrumentation element* occurred, and can be used to accurately determine when that element occurred.

I_{YFPDZ} The time value included in *Timestamp elements* is selected by TRFCR_EL1 and TRFCR_EL2 and is one of:

- Physical time, as seen by the generic timers in the PE.
- Virtual time, as seen by the generic timers in the PE.
- An IMPLEMENTATION DEFINED time value, often supplied by a CoreSight system.

I_{CLZKR} The insertion of *Timestamp elements* is controlled by TRCCONFIGR.TS and TRCTSCTLR.

D4.5.11.9 Virtual context identifier tracing

I_{VMGBJ} Whether an implementation supports Virtual context identifier tracing is IMPLEMENTATION DEFINED. If it does, the trace unit can be programmed to output the identifier of a virtual machine that the PE is executing.

I_{FDDXM} This option is enabled by setting TRCCONFIGR.VMID to `0b1`.

R_{PTVYD} If the PE implements EL2, the trace unit supports a 32-bit Virtual context identifier, with TRCIDR2.VMIDSIZE indicating a 32-bit Virtual context identifier size. The source of the Virtual context identifier is CONTEXTIDR_EL2.PROCID.

R_{BRDYF} If the PE does not implement EL2, the trace unit does not support a Virtual context identifier, with TRCIDR2.VMIDSIZE indicating Virtual context identifier tracing is not supported.

Note

Previous trace architectures from Arm supported the ability to select the source of the Virtual context identifier. This specification does not support Virtual context identifier selection, and only permits CONTEXTIDR_EL2.PROCID as the source of the Virtual context identifier. See TRCIDR2.VMIDOPT for more details.

D4.5.12 Compression

I_{WVBMT} Additional compression of the trace byte stream is achieved by the following methods:

- Removing elements that can be implied by the trace analyzer:
  - Implying the existence of *Commit elements* based on the tracing of other elements.
  - Removing *Target Address elements* that can be calculated by the trace analyzer by analysis of previous traced PE execution.
- Combining multiple elements together into a single packet:
  - Combining *Atom elements* into a single packet.
  - Combining *Cancel elements* and *Mispredict elements* into a single packet.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.12.1 Implied commits

I_{BTGGX} The ETE trace protocol provides mechanisms to minimize the number of *Commit elements* which need to be explicitly output in the trace byte stream. When a *P0 element* is output in the trace byte stream, if the number of speculative *P0 elements* output exceeds TRCIDR8.MAXSPEC, then a *Commit element* is implied which resolves the oldest speculative *P0 element*.

R_{YKLRM} The trace unit does not generate commit packets for *Commit elements* that have been implied by the trace protocol.

D4.5.12.2 Atom packing

I_{QMVNP} The ETE trace protocol provides packets which allow groups of consecutive *Atom elements* to be packed into a single trace packet. Figure D4-15 shows the decision tree for generating the different formats of Atom packets.

Figure D4-15 Atom packing

I_{XXSGS} Cancel Packets can indicate a number of *Atom elements* and the *Cancel element*.

I_{KWWHP} The Mispredict Packets can indicate a number of *Atom elements* and the *Mispredict element*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.5.12.3 Address compression

I_{LFFCR} The trace unit can remove program addresses from the trace stream. The trace analyzer can infer the addresses from the program image and previous history.

This includes the targets of direct *P0 instructions*, where the target address is encoded in the instruction itself.

R_{SJPYH} The trace unit retains the *Address information* of up to the last three addresses that were explicitly output in the trace protocol, as contained in:

- Target Address packets.
- Source Address packets.
- Exception packets.
- PE Reset packets.
- Q packets.

I_{SXNYK} The explicitly output addresses that the trace unit retains are known as the address history buffer.

I_{LPYRK} For optimized trace protocol efficiency, Arm recommends that the address history buffer is three entries deep.

R_{LMHFW} When any of the following packets are generated, the trace unit pushes the address value and sub_isa to the address history buffer:

- Target Address packet.
- Source Address packet.
- Q packet that implies a *Target Address element*.

R_{CMCRT} When an Exception packet is generated, the trace unit pushes the preferred exception return address value and sub_isa to the address history buffer.

R_{FPDFJ} When a PE Reset packet is generated with an UNKNOWN address, the trace unit pushes an address value of `0x0` and sub_isa of IS0 to the address history buffer.

R_{BPRDC} When a Target Address packet is generated, the trace unit uses the address history buffer to identify when a Target Address Exact Match packet can be used. When a Target Address Exact Match packet cannot be used, the most recent entry in the address history buffer is used for the Target Address packet selection.

R_{GWKFD} When a Source Address packet is generated, the trace unit uses the address history buffer to identify when a Source Address Exact Match packet can be used. When a Source Address Exact Match packet cannot be used, the most recent entry in the address history buffer is used for the Source Address packet selection.

R_{YLXFK} When an Exception packet is generated, the trace unit uses the address history buffer to identify when an Exception Exact Match Address packet can be used. When an Exception Exact Match Address packet cannot be used, the most recent entry in the address history buffer is used for the Exception Address packet selection.

R_{YCMCG} When a Q packet is generated which implies a *Target Address element*, the trace unit uses the address history buffer to identify when a Q with Exact Match Address packet can be used. When a Q with Exact Match Address packet cannot be used, the most recent entry in the address history buffer is used for the Q Address packet selection.

R_{BTWGD} When a Trace Info packet is generated, the trace unit sets all entries of the address history buffer to have an address value of `0x0` and sub_isa of IS0.

D4.5.12.4 Return stack address matching

I_{NHWVZ} The trace unit might contain the optional return stack function. The return stack operates when Branch with Link instructions or indirect *P0 instructions* are taken, and provides a mechanism to allow the trace unit to remove certain *Target Address elements* from the trace element stream. The trace analyzer maintains an independent copy of the return stack which is used to determine when *Target Address elements* have been removed and then infer the target of indirect *P0 instructions*.

R_{HNDJJ} The depth of the return stack is IMPLEMENTATION DEFINED from 0 to 15 entries.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{BLYHW} For optimized trace protocol efficiency, Arm recommends the trace unit implements the return stack with at least 3 entries.

R_{HFCTC} While TRCCONFIGR.RS is 1, when a Branch with Link instruction is predicted as taken and is traced, the trace unit pushes the following *Address information* to the return stack:

- The instruction address + the instruction size, that is, the return address for the Branch with Link instruction.
- The sub_isa from the instruction set encoding.

R_{ZKTHK} When a return stack push occurs, all existing entries are shifted down one place on the return stack and the new entry is pushed to the top entry of the return stack.

R_{ZSVDQ} While the return stack is full, when a return stack push occurs, the oldest entry on the return stack is discarded.

R_{FFXPW} When a Branch with Link instruction is predicted as taken and traced with an E *Atom element*, when a return stack push occurs, the trace unit pushes to the return stack, even if the prediction is incorrect and is subsequently corrected to an N *Atom element*.

R_{NYHFH} When a Branch with Link instruction is predicted as not taken and traced with an N *Atom element*, the trace unit does not push to the return stack, even if the prediction is incorrect and is subsequently corrected to an E *Atom element*.

R_{GVLKJ} When a Branch with Link instruction is implied by a *Q element*, the trace unit does not push to the return stack.

R_{WRXCW} When a Branch with Link instruction is executed in a branch broadcasting region, the trace unit does not push to the return stack.

R_{FVRPZ} When a Branch with Link instruction is speculatively executed and generates an E *Atom element*, if that *Atom element* is subsequently canceled by a *Cancel element* then any corresponding entry on the trace unit return stack must be popped from the trace unit return stack.

Note

Discarding the entire contents of the trace unit return stack meets this obligation.

R_{QHSBN} When an indirect *P0 instruction* is taken and traced, and the *Address information* in the resultant *Target Address element* matches the address and sub_isa on the top of the return stack, the trace unit performs a return stack pop.

R_{HTKJS} When a return stack pop occurs, both of the following occur:

- The trace unit discards the *Target Address element* that matches the address and sub_isa on the top of the return stack.
- The trace unit removes the top entry of the return stack, and shifts each older entry up one position.

R_{WBCJG} When an indirect *P0 instruction* is implied by a *Q element*, the trace unit does not perform a return stack pop.

I_{BCWSQ} When an indirect *P0 instruction* is taken, it is possible that the target address is predicted incorrectly by the PE.

R_{YMRGB} When the target address of a taken indirect *P0 instruction* is incorrectly predicted, and the incorrect target address is traced with a *Target Address element*, the trace unit corrects the incorrect address by generating a new *Target Address element* with the correct target address, and neither of the target addresses cause a return stack pop.

R_{GBHNP} When the target address of a taken indirect *P0 instruction* is incorrectly predicted, and the incorrect target address matches the top entry of the return stack, the trace unit subsequently generates a *Target Address element* with the correct target address, and neither of the target addresses cause a return stack pop.

R_{ZCCBS} When the final status of the *Atom element* corresponding to an indirect *P0 instruction* is E, including when one or more Mispredict elements change the status of the *Atom element*, the trace unit performs a return stack pop.

Note

A return stack push only occurs if the initial *Atom element* state for the Branch with Link instruction is E. Conversely, a return stack pop only occurs if the final *Atom element* state for the indirect *P0 instruction* is E.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{SLDXR} When an instruction that is both a Branch with Link instruction and an indirect *P0 instruction* is executed, the trace unit performs the following actions on the return stack, in order:

1. Determine whether a return stack push is possible and push if required.
2. Determine whether a return stack pop is possible and pop if required.

Note

Some Arm trace architectures use a different order of operations.

R_{SBZJB} When any of the following occur, the trace unit discards the contents of the return stack:

- The trace unit generates a *Trace Info element*.
- The trace unit generates a *Trace On element*.
- The PE enters a branch broadcasting region.

I_{XRQHQ} A trace unit might discard the contents of the return stack at any time.

I_{DCNGF} When the return stack contents are discarded, there is no requirement for the trace analyzer to be aware that this discard operation has occurred. This is because even though the contents of the trace unit return stack are discarded, there are no adverse consequences if the contents of the trace analyzer return stack are retained, but never used.

R_{GZSSX} After a *Trace Info element*, a *Target Address element* and a *Context element* are required but might not be generated immediately. If the *Target Address element* and the *Context element* are not generated before the next *P0 element*, then any Branch with Link instructions must not push on to the return stack until both the *Target Address element* and the *Context element* have been generated.

Note

This restriction prevents the trace unit from performing return stack pushes for instructions that the trace analyzer cannot analyze, because it is not yet fully synchronized.

D4.5.12.5 Timestamp value compression

I_{GYYNG} The trace analyzer maintains a copy of the last *Timestamp element* value broadcast. The *Timestamp element* value might be compressed relative to the last value and only the bits that have changed need to be encoded.

R_{GPGQQ} When a Trace Info packet is generated, the trace unit sets its maintained value of the last *Timestamp element* to zero, and when the trace unit generates a subsequent Timestamp packet the value is compressed relative to this new zero value. This means that the first Timestamp packet after a Trace Info packet contains all nonzero bits of the Timestamp value.

D4.6 Resource operation

IPKCDG FEAT_ETE has a number of resources that can be used to provide advanced filtering functionality.

RPWBZK The resources operate in one of the following states:

Running
All the resources are active.

Pausing
The resources are progressing to the Paused state.

Paused
All the resources are static and inactive except for External Input Selectors.

Figure D4-16 Resources operation

IHWYYK As described in System behaviors, the trace unit can be disabled by either:

- Setting TRCPRGCTLR.EN to 0.
- Locking the OS Lock, by setting OSLAR_EL1.OSLK to 1.

RJLLVN While the resources are in the Running state, and when any of the following occur, the resources enter the Pausing state:

- The trace unit becomes disabled.
- The trace unit enters the low-power state.
- The PE begins executing in a Trace Prohibited region.

RYWDVJ While the resources are in the Pausing state, the resources enter the Paused state in finite time.

RLYFDT While the trace unit is in the Paused state, when all of the following are true, the resources enter the Running state:

- The trace unit is enabled.
- The trace unit is not in the low-power state.
- The PE is not executing in a Trace Prohibited region.

RTMPZZ A trace unit buffer overflow has no impact on the behavior of the resources.

D4.6.1 Behavior of the resources while in the Running state

SJVYQP The time taken for the resources to operate might vary between different trace unit implementations.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.6.2 Behavior of the resources while in the Pausing state

R_{RDCGC} When the resources enter the Pausing state, the resources perform the following procedure:

1. All resources, except for the Sequencer and any Counters, are driven low as inputs to the Resource Selector logic. The Counters and the Sequencer behave as normal.
2. The states that the inputs were at before they were driven low are propagated through the Resource Selector logic.
3. The states of the Counters and the Sequencer are propagated through the Resource Selector logic one more time. That is, the states of the Counters and the Sequencer are propagated through the Resource Selector logic for the length of time that it takes for the state of a resource to be propagated through the Resource Selector logic.
4. The resources enter the Paused state.

I_{LGWRK} The procedure that the resources perform when the resources are in the Pausing state has the result that, for resource events that are activated by a resource that is not a Counter or a Sequencer, no activity is lost, because all those resource events are updated.

I_{CQNGN} When Counter and Sequencer states are propagated back as resources, so that a loop is created, then the following are true:

- If a Counter at zero resource is being used to activate the Sequencer or a Counter, then that Counter at zero resource might be propagating through the Resource Selector logic at the time when the procedure ends. In this case, the Sequencer state resource or other Counter at zero resource that is activated by that Counter at zero resource might be lost.
- If a Sequencer state resource is being used to activate a Counter, then that Sequencer state resource might be propagating through the Resource Selector logic at the time when the procedure ends. In this case, the Counter at zero resource that is activated by that Sequencer state resource might be lost.

I_{BRZXY} When the trace unit becomes disabled, the behavior of the resources in the Pausing state ensures that the programmers' model provides a consistent view of the state of the trace unit resources. That is, regarding the Counters and the Sequencer, the following are true:

- If the state of the Sequencer propagated back as a resource, then the view of the Sequencer as a resource event and the view of the Sequencer resource state both show the same Sequencer state.
- If the state of a Counter is propagated back as a resource, then the view of the Counter as a resource event and the view of the Counter resource state both show the same Counter state.
  The Counter state might be one of the following:
  — The Counter is at zero.
  — The Counter is not at zero.

D4.6.3 Behavior of the resources while in the Paused state

I_{YXKSQ} The behavior of the resources when the PE enters the low-power state or a Trace Prohibited region differs from other trace architectures defined by Arm.

R_{FHYQW} While the resources are in the Paused state and the trace unit is not disabled, the resources do not lose resource events that are in transition, except those permitted when moving through the Pausing state of the resources. See Behavior of the resources while in the Pausing state for details on the resource events that are permitted to be lost when in the Pausing state.

I_{HZRSS} While the resources are in the Paused state, the resources might not observe resource events that are in transition until after the resources leave the Paused state.

R_{YWQNQ} While the resources are in the Paused state, the resources remain in the state they are in.

R_{BQSMN} While the resources are in the Paused state, the trace unit drives all External Outputs low.

R_{MVZYP} When the trace unit becomes disabled and the resources enter the Paused state, and not before, the trace unit might set TRCSTATR.PMSTABLE to 1.

R_{RWNTS} While TRCSTATR.PMSTABLE is set to 1, all resources and resource events remain in a quiescent state.

I_{ZSHWT} The behavior of the External Input Selectors is detailed in Operation while in Paused state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.6.4 Behavior of resources on a Trace synchronization event

R_{RFSRY} When the following resources have finished calculations for all instructions prior to the previous Context synchronization event, a Trace synchronization event completes:

- Address Comparators.
- Context Identifier Comparators.
- Virtual Context Identifier Comparators.
- Single-shot Comparator Controls.

D4.6.5 Resource organization

I_{NJLRF} There are 2 types of resources:

- Precise resources.
- Imprecise resources.

I_{JCKLL} Each resource has a current state, which is output as a *Resource state*. The Resource state is selected by Resource Selectors, and then used by various trace unit functions as a *Resource event*, see Figure D4-17.

Figure D4-17 Resources organization

D4.6.5.1 Precise resources

I_{QSPKY} The precise resources are used in the evaluation of the ViewInst include/exclude function and the ViewInst start/stop function.

R_{WNGDH} The trace unit evaluates the precise resources for each instruction block. See Instruction block for more details.

R_{NFDCZ} The trace unit maintains execution order of the precise resources.

Figure D4-18 Precise resource path

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.6.5.2 Imprecise resources

I_{NNHSY} If a Resource is not a precise resource, it is an imprecise resource.

Figure D4-19 Imprecise resource path

D4.6.5.3 Selecting a resource or a pair of resources

I_{BRQFW} A resource is selected by using a Resource Selector.

R_{QDJVV} Each Resource Selector uses one of the 30 TRCRSCTLR<n> registers. The trace unit implements Resource Selectors in pairs, so that a maximum of 15 programmable pairs can be implemented.

R_{NRSGN} Resource Selector 0 always provides a FALSE result.

R_{SXSQT} While the resources are in the Running state, Resource Selector 1 provides a TRUE result.

I_{TQVKS} TRCIDR4.NUMRSPAIR indicates how many pairs of Resource Selectors are implemented.

I_{MSHWC} Resource Selectors can be used in pairs or used individually. When a pair of Resource Selectors is used, a Boolean function can be applied to the outputs of the combination of selected resources. See Figure D4-21.

R_{WZVDQ} While TRCRSCTLR<n>.SELECT[m] is 1, the Resource Selector selects the Resource Number m of the group selected by TRCRSCTLR<n>.GROUP as described in Table D4-26.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D4-26 Resource grouping

Group	Resource Number	Resource
0b0000	0-3	External Input Selectors 0-3
	4-15	Reserved
0b0001	0-7	PE Comparator Inputs 0-7
	8-15	Reserved
0b0010	0	Counter 0 at zero
	1	Counter 1 at zero
	2	Counter 2 at zero
	3	Counter 3 at zero
	4	Sequencer state 0
	5	Sequencer state 1
	6	Sequencer state 2
	7	Sequencer state 3
	8-15	Reserved
0b0011	0-7	Single-shot Comparator Control 0-7
	8-15	Reserved
0b0100	0-15	Single Address Comparator 0-15
0b0101	0-7	Address Range Comparator 0-7
	8-15	Reserved
0b0110	0-7	Context Identifier Comparator 0-7
	8-15	Reserved
0b0111	0-7	Virtual Context Identifier Comparator 0-7
	8-15	Reserved
0b1xxx	0-15	Reserved

R_{HVNQG} While TRCRSCTLR<n>.INV is set to 0 and one or more resources in a group are selected, when any of the outputs of the selected resources are high, the Resource Selector fires.

R_{WFGMY} While TRCRSCTLR<n>.INV is set to 1, when none of the outputs of the selected resources are high, the Resource Selector fires.

I_{SZZMP} Figure D4-20 summarizes the process of resource selection.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure D4-20 A Resource Selector

D4.6.5.4 A Resource Selector pair

I_{DLRMJ} The Resource Selectors are arranged in pairs, and the result of each of a pair of Resource Selectors can be combined using a Boolean function and used to drive other resources and events in the trace unit.

R_{KTNJM} For each TRCRSCTLR<n> register which is the lower register for a pair of Resource Selectors, the TRCRSCTLR<n> register has the TRCRSCTLR<n>.PAIRINV field.

I_{QKTSJ} For example:

- TRCRSCTLR2 and TRCRSCTLR3 constitute a Resource Selector pair. In this case:
  - TRCRSCTLR2 is the lower register.
  - TRCRSCTLR2.PAIRINV optionally inverts the result of the Boolean function that is applied to the outputs of the combination of selected resources.
  - TRCRSCTLR3 is the upper register.
  - TRCRSCTLR3.PAIRINV is RES0.

This means that, when a Resource Selector pair is used, the following scenario is possible:

- One TRCRSCTLR<n> might select only one resource within the group.
- The other TRCRSCTLR<n> might select more than one resource from the group, so that the result is a logical OR of the selected resources.
- A Boolean function, for example a logical AND, might be applied to the outputs of the combination of selected resources.
- The result of that Boolean function might be inverted by using PAIRINV.

I_{LPJXK} In Figure D4-21, the Boolean function is selected by using the INV field for each Resource Selector, with the PAIRINV field for each Resource Selector pair, see Table D4-27.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure D4-21 A Resource Selector pair

Table D4-27 Selecting a Boolean function

Function	PAIRINV	Resource A INV	Resource B INV
A AND B	0b0	0b0	0b0
NOT(A AND B)	0b1	0b0	0b0
Reserved	0b0	0b0	0b1
NOT(A) OR B	0b1	0b0	0b1
NOT(A) AND B	0b0	0b1	0b0
Reserved	0b1	0b1	0b0
NOT(A) AND NOT(B)	0b0	0b1	0b1
A OR B	0b1	0b1	0b1

D4.6.6 Address comparators

I_{LGGVG} An ETE trace unit provides between 0 and 16 *Single Address Comparators* (SACs), each of which compares the instruction address with a user-programmed value.

R_{YCRNP} The trace unit implements SACs in pairs, so that a trace unit implementation contains an even number of SACs.

I_{MNTCY} TRCIDR4.NUMACPAIRS indicates how many pairs of SACs are implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{YMVDZ} When the PE executes instructions in Debug state, Address Comparators do not match.

R_{YPWLR} When the PE executes instructions in a Trace Prohibited region, Address Comparators do not match.

I_{WDJPG} Address Comparators might match on Speculative execution.

D4.6.6.1 Single Address Comparators

I_{SSHHT} A SAC can be used in the following ways:

- As inputs to the ViewInst start/stop function in the ViewInst function. For more information, see ViewInst start/stop function filtering.
- As an individual resource.
- The comparator can be programmed so that, whenever the PE is in a specific Security state, the comparator only matches in certain Exception levels.

R_{DKCFF} An SAC only matches on Exception levels and Security states as indicated by TRCACATR<n>.

$$\text{SAC_EL}_i[n] = \begin{cases} \neg\text{TRCACATR<n>.EXLEVEL_S_EL0} & \text{Secure EL0} \\ \neg\text{TRCACATR<n>.EXLEVEL_S_EL1} & \text{Secure EL1} \\ \neg\text{TRCACATR<n>.EXLEVEL_S_EL2} & \text{Secure EL2} \\ \neg\text{TRCACATR<n>.EXLEVEL_S_EL3} & \text{EL3} \\ \neg\text{TRCACATR<n>.EXLEVEL_NS_EL0} & \text{Non-secure EL0} \\ \neg\text{TRCACATR<n>.EXLEVEL_NS_EL1} & \text{Non-secure EL1} \\ \neg\text{TRCACATR<n>.EXLEVEL_NS_EL2} & \text{Non-secure EL2} \\ \neg(\text{TRCACATR<n>.EXLEVEL_RL_EL0} \oplus \text{TRCACATR<n>.EXLEVEL_NS_EL0}) & \text{Realm EL0} \\ \neg(\text{TRCACATR<n>.EXLEVEL_RL_EL1} \oplus \text{TRCACATR<n>.EXLEVEL_NS_EL1}) & \text{Realm EL1} \\ \neg(\text{TRCACATR<n>.EXLEVEL_RL_EL2} \oplus \text{TRCACATR<n>.EXLEVEL_NS_EL2}) & \text{Realm EL2} \end{cases}$$

R_{QFNSK} An SAC only matches on the context indicated by TRCACATR<n>.CONTEXT and TRCACATR<n>.CONTEXTTYPE.

$$m = \text{TRCACATR<n>.CONTEXT}$$
$$\text{type} = \text{TRCACATR<n>.CONTEXTTYPE}$$

$$\text{SAC_CONTEXT}_i[n] = \begin{cases} 1 & \text{type is 0} \\ \text{CIDCOMP}[m] & \text{type is 1} \\ \text{VMIDCOMP}[m] & \text{type is 2} \\ \text{CIDCOMP}[m] \wedge \text{VMIDCOMP}[m] & \text{type is 3} \end{cases}$$

R_{PYMZV} When an instruction is executed, and the address of the lowest byte of the instruction exactly matches the programmed address of an SAC, the SAC matches.

$$\text{SAC_ADDR}_i[n] = (\text{ThisInstrAddr()}_i \equiv \text{TRCACVR<n>.ADDRESS})$$

I_{SPFXX} For example, for a 4-byte instruction at address `0x1000`:

- The lowest byte of the instruction is at `0x1000`.
- The second byte of the instruction is at `0x1001`.
- The third byte of the instruction is at `0x1002`.
- The highest byte of the instruction is at `0x1003`.

If an SAC is programmed with `0x1000`, then it always matches on that instruction at address `0x1000`.

I_{JZXFJ} It is IMPLEMENTATION DEFINED whether an SAC matches when its programmed address matches any byte of an instruction which is not the lowest byte of the instruction.

I_{VSFSS} The Arm architecture supports disabling `IT` instructions on more than one subsequent instruction, using the ITD bits in the SCTLR, HSCTLR, and SCTLR_EL1 System registers. If any of the ITD bits are set to 1 and are affecting `IT`

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

operation, and a SAC is programmed to match on the address of the instruction that is immediately after an `IT` instruction, when the instruction immediately after the `IT` instruction is executed it is CONSTRAINED UNPREDICTABLE whether that comparator matches.

S_{TFYFT} If any of the ITD bits are set to 1, Arm recommends that a SAC is programmed to match on the address of the `IT` instruction, instead of the instruction immediately after the `IT` instruction.

S_{MLDYK} To avoid unexpected behavior from an SAC, Arm recommends that the SAC is always programmed with an address that is for the lowest byte of an instruction.

I_{MCKFH} When the instruction immediately after a `MOVPRFX` instruction executes, if a SAC is programmed to match on the address of this instruction, then it is CONSTRAINED UNPREDICTABLE whether that comparator matches.

S_{FPTHL} Arm recommends that a SAC is programmed to match on the address of the `MOVPRFX` instruction, instead of the instruction immediately after the `MOVPRFX` instruction.

I_{TBNTJ} The operation of a SAC is as follows:

$$\mathrm{SAC}_i[n] = \begin{cases} 0 & \text{When Prohibited} \\ 0 & \text{When in Debug State} \\ \mathrm{SAC_ADDR}_i[n] \wedge \mathrm{SAC_EL}_i[n] \wedge \mathrm{SAC_CONTEXT}_i[n] & \text{Otherwise} \end{cases}$$

D4.6.6.2 Address Range Comparators

I_{HDFQM} Pairs of SACs are arranged to form one *Address Range Comparator* (ARC). An ARC is programmed with an address range, so that whenever any address in that range is accessed, the ARC matches. A trace unit contains between zero and eight ARCs. ARCs can be used in the following ways:

- Selected for the ViewInst include/exclude function in the ViewInst function. See ViewInst include/exclude function filtering.
- As individual resources.

An ARC is programmed by programming the SACs as follows:

- The first SAC is programmed with the start address of the instruction range.
- The second SAC is programmed with the end address of the instruction range.

S_{WFSPV} The address that the second SAC is programmed with must be greater than or equal to the address that the first SAC is programmed with, that is, the end address must be greater than or equal to the start address.

R_{MXCGD} While the start address of an ARC is greater than the end address, the behavior of the ARC is CONSTRAINED UNPREDICTABLE, that is, at any time the ARC might do one of the following:

- Match.
- Not match.

R_{XYJLC} While the TRCACATR<n> registers for the SACs in an ARC are programmed to different values, the behavior of the ARC is CONSTRAINED UNPREDICTABLE.

R_{LLQPL} While an ARC is programmed with an instruction address range, when the PE executes an instruction at an address in the following range, the ARC matches:

$$\begin{aligned} \text{start_address} &= \text{TRCACVR<n>.ADDRESS} \\ \text{end_address} &= \text{TRCACVR<n+1>.ADDRESS} \\ \mathrm{ARC_ADDR}_i[n/2] &= (\text{ThisInstrAddr()}_i \geq \text{start_address}) \wedge (\text{ThisInstrAddr()}_i \leq \text{end_address}) \end{aligned}$$

R_{YYXSQ} When an instruction is executed, and the address of the lowest byte of the instruction is within the programmed address range of an ARC, the ARC matches.

I_{RPFWZ} When an instruction is executed and the programmed address range of an ARC contains addresses for one or more bytes of the instruction, but does not contain the address for the lowest byte of the instruction, it is IMPLEMENTATION SPECIFIC whether the ARC matches.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{RZFPT} For example, for a 4-byte instruction at address `0x1000`:

- The lowest byte of the instruction is at `0x1000`.
- The second byte of the instruction is at `0x1001`.
- The third byte of the instruction is at `0x1002`.
- The highest byte of the instruction is at `0x1003`.

If the programmed address range contains `0x1000`, then the ARC always matches. However, if the programmed address range starts at either `0x1001`, `0x1002`, or `0x1003`, then it is IMPLEMENTATION SPECIFIC whether the ARC matches.

S_{HSFTQ} To avoid unexpected behavior from an ARC, Arm recommends that the ARC is always programmed with an address range that starts with an address for the lowest byte of an instruction.

I_{VRRHS} The Arm architecture supports disabling `IT` instructions on more than one subsequent instruction, using the ITD bits in the SCTLR, HSCTLR, and SCTLR_EL1 System registers. If any of the ITD bits are set to 1 and are affecting `IT` operation, and an ARC is programmed to include the address of the instruction that is immediately after an `IT` instruction but not include the `IT` instruction, when the instruction immediately after the `IT` instruction is executed then it is CONSTRAINED UNPREDICTABLE whether that comparator matches.

S_{DMHQH} If any of the ITD bits are set to 1, Arm recommends that an ARC is programmed to include both the `IT` instruction and the instruction immediately after the `IT` instruction.

I_{PBKPJ} When the instruction immediately after a `MOVPRFX` instruction is executed, if an ARC is programmed to include the address of the instruction that is after the `MOVPRFX` instruction but not the `MOVPRFX` instruction, then it is CONSTRAINED UNPREDICTABLE whether that comparator matches.

S_{HVTHL} Arm recommends that an ARC is programmed to include both the `MOVPRFX` instruction and the instruction immediately after the `MOVPRFX` instruction.

I_{HTXLT} It might be possible for multiple matches to occur simultaneously. The definition of when matches occur simultaneously is IMPLEMENTATION SPECIFIC, and might vary because of runtime conditions. However, an example of when multiple matches might occur simultaneously is when multiple instructions are observed in the same processor clock cycle, so that multiple comparisons take place with each address in the programmed range. In this case, any of the following might occur:

- An address in the range is matched more than once.
- More than one address in the range is matched simultaneously.

R_{HMYMX} When multiple ARC matches occur simultaneously for one ARC, both of the following are true:

- The ARC signals a match at least once.
- The ARC does not signal more matches than the number of instructions that are executed with an address that matches an address in the programmed range.

I_{CTBDN} Each ARC can be used with one, or a combination of, the following:

- A Context Identifier Comparator.
- A Virtual Context Identifier Comparator.

R_{TMCJX} An ARC only matches on Exception levels and Security states as indicated by TRCACATR<2n>.

$$\text{ARC_EL}_i[n] = \begin{cases} \neg\text{TRCACATR<2n>.EXLEVEL_S_EL0} & \text{Secure EL0} \\ \neg\text{TRCACATR<2n>.EXLEVEL_S_EL1} & \text{Secure EL1} \\ \neg\text{TRCACATR<2n>.EXLEVEL_S_EL2} & \text{Secure EL2} \\ \neg\text{TRCACATR<2n>.EXLEVEL_S_EL3} & \text{EL3} \\ \neg\text{TRCACATR<2n>.EXLEVEL_NS_EL0} & \text{Non-secure EL0} \\ \neg\text{TRCACATR<2n>.EXLEVEL_NS_EL1} & \text{Non-secure EL1} \\ \neg\text{TRCACATR<2n>.EXLEVEL_NS_EL2} & \text{Non-secure EL2} \\ \neg(\text{TRCACATR<2n>.EXLEVEL_RL_EL0} \oplus \text{TRCACATR<2n>.EXLEVEL_NS_EL0}) & \text{Realm EL0} \\ \neg(\text{TRCACATR<2n>.EXLEVEL_RL_EL1} \oplus \text{TRCACATR<2n>.EXLEVEL_NS_EL1}) & \text{Realm EL1} \\ \neg(\text{TRCACATR<2n>.EXLEVEL_RL_EL2} \oplus \text{TRCACATR<2n>.EXLEVEL_NS_EL2}) & \text{Realm EL2} \end{cases}$$

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{VSBJF} An ARC only matches on the context indicated by TRCACATR<2n>.CONTEXT and TRCACATR<2n>.CONTEXTTYPE.

$$m = \text{TRCACATR<2n>.CONTEXT}$$
$$\text{type} = \text{TRCACATR<2n>.CONTEXTTYPE}$$

$$\text{ARC_CONTEXT}_i[n] = \begin{cases} 1 & \text{type is 0} \\ \text{CIDCOMP}[m] & \text{type is 1} \\ \text{VMIDCOMP}[m] & \text{type is 2} \\ \text{CIDCOMP}[m] \wedge \text{VMIDCOMP}[m] & \text{type is 3} \end{cases}$$

R_{RTXJN} The operation of an ARC is as follows:

$$\text{ARC}_i[n] = \begin{cases} 0 & \text{When Prohibited} \\ 0 & \text{When in Debug State} \\ \text{ARC_ADDR}_i[n] \wedge \text{ARC_EL}_i[n] \wedge \text{ARC_CONTEXT}_i[n] & \text{Otherwise} \end{cases}$$

D4.6.7 Context Identifier Comparator

I_{KDSNY} An ETE trace unit provides between zero and eight Context Identifier Comparators. Each Context Identifier Comparator can be used in any of the following ways:

- Associated with a SAC.
- Associated with an ARC.
- As an individual resource.

R_{DCCBY} While a Context Identifier Comparator is associated with either an SAC or an ARC, only while the PE is executing with the Context identifier that the Context Identifier Comparator is programmed with and when an address is accessed which the SAC or ARC is programmed to match on, the SAC or ARC signals a match.

R_{BKQKQ} While a Context Identifier Comparator is used as an individual resource, when an instruction block is executed with the Context identifier that the Context Identifier Comparator is programmed with, the Context Identifier Comparator matches.

I_{PBXRH} When using a Context Identifier Comparator as an independent resource to activate a resource event, the time that the resource event is activated relative to the time that the Context Identifier Comparator becomes active might be imprecise.

I_{RBLYL} It might be possible for multiple matches of a Context Identifier Comparator to occur simultaneously. The definition of when matches occur simultaneously is IMPLEMENTATION SPECIFIC, and might vary because of runtime conditions. However, an example of when multiple matches might occur simultaneously is when multiple instructions are observed in the same processor clock cycle, so that multiple comparisons take place.

R_{MPJBW} When multiple Context Identifier Comparator matches occur simultaneously for one Context Identifier Comparator, all of the following are true:

- The Context Identifier Comparator signals a match at least once.
- The Context Identifier Comparator does not signal more matches than the number of instructions that are executed with the Context identifier that the Context Identifier Comparator is programmed with.

I_{HDCJK} A Context Identifier Comparator might match on Speculative execution, that is, a Context Identifier Comparator might match if the PE speculatively changes the Context identifier.

R_{MCYYC} When the PE executes instructions in Debug state, Context Identifier Comparators do not match.

R_{SRZGJ} When the PE executes instructions in a Trace Prohibited region, Context Identifier Comparators do not match.

I_{GKDRL} The Context identifier might change at points that are not Context synchronization events, for example when a System instruction is used to write to the current Context identifier register. In these scenarios, the Context Identifier Comparator might compare against the old or new Context identifier value for any instruction after the *P0 element* before the System instruction, up to the Context synchronization event after the System instruction.

$$m = \begin{cases} \text{TRCCIDCCTLR0.COMP0} & n \equiv 0 \\ \text{TRCCIDCCTLR0.COMP1} & n \equiv 1 \\ \text{TRCCIDCCTLR0.COMP2} & n \equiv 2 \\ \text{TRCCIDCCTLR0.COMP3} & n \equiv 3 \\ \text{TRCCIDCCTLR1.COMP4} & n \equiv 4 \\ \text{TRCCIDCCTLR1.COMP5} & n \equiv 5 \\ \text{TRCCIDCCTLR1.COMP6} & n \equiv 6 \\ \text{TRCCIDCCTLR1.COMP7} & n \equiv 7 \end{cases}$$

$$v = \text{TRCCIDCVR<n>.VALUE}$$

$$\text{cid} = \text{CONTEXTIDR_EL1.PROCID}$$

$$\text{CIDCOMP}[n] = \begin{cases} 0 & \text{When Prohibited} \\ 0 & \text{When in Debug State} \\ \prod_{j=0}^{7} \left((v[8j+7:8j] \equiv \text{cid}[8j+7:8j]) \vee \text{m}[j] \right) & \text{Otherwise} \end{cases}$$

D4.6.8 Virtual Context Identifier Comparators

I_{BXVPG} An ETE trace unit provides between zero and eight Virtual Context Identifier Comparators. Each Virtual Context Identifier Comparator can be used in any of the following ways:

- Associated with a SAC.
- Associated with an ARC.
- As an individual resource.

R_{RTRBM} While a Virtual Context Identifier Comparator is associated with either an SAC or an ARC, only while the PE is executing with the Virtual context identifier that the Virtual Context Identifier Comparator is programmed with and when an address is accessed which the SAC or ARC is programmed to match on, the SAC or ARC signals a match.

R_{VWYMY} While a Virtual Context Identifier Comparator is used as an individual resource, when an instruction block is executed with the Virtual context identifier that matches the Virtual Context Identifier Comparator value, the Virtual Context Identifier Comparator matches.

R_{FLXQL} While TRFCR_EL2.CX indicates that Virtual Context Identifier Comparators cannot match, Virtual Context Identifier Comparators do not match.

R_{LPKBR} When the PE executes instructions in Debug state, Virtual Context Identifier Comparators do not match.

R_{WZWLT} When the PE executes instructions in a Trace Prohibited region, Virtual Context Identifier Comparators do not match.

I_{SCPJP} When using a Virtual Context Identifier Comparator as an independent resource to activate a resource event, the time at which the resource event is activated relative to the time at which the Virtual Context Identifier Comparator becomes active might be imprecise.

R_{LJRPW} A Virtual Context Identifier Comparator is associated with an SAC by programming TRCACATR<n>.CONTEXT for the SAC.

I_{GJCRG} It might be possible for multiple matches of a Virtual context identifier to occur simultaneously. The definition of when matches occur simultaneously is IMPLEMENTATION SPECIFIC, and might vary because of runtime conditions. However, an example of when multiple matches might occur simultaneously is when multiple instructions are observed in the same processor clock cycle, so that multiple comparisons take place.

R_{JNNDL} When multiple Virtual Context Identifier Comparator matches occur simultaneously for one Virtual Context Identifier Comparator, both of the following are true:

- The Virtual Context Identifier Comparator signals a match at least once.
- The Virtual Context Identifier Comparator does not signal more matches than the number of instructions that are executed with the Virtual context identifier that the Virtual Context Identifier Comparator is programmed with.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{NPPCF} A Virtual Context Identifier Comparator might signal a match on Speculative execution, that is, a Virtual Context Identifier Comparator might signal a match when the PE speculatively changes the Virtual context identifier.

I_{PPWXT} The Virtual context identifier might change at points which are not Context synchronization events, for example when a System instruction is used to write to CONTEXTIDR_EL2. In these scenarios, the Virtual Context Identifier Comparator might compare against the old or new Virtual context identifier value for any instruction after the *P0 element* before the System instruction, up to the Context synchronization event after the System instruction.

$$m = \begin{cases} \text{TRCVMIDCCTLR0.COMP0} & n \equiv 0 \\ \text{TRCVMIDCCTLR0.COMP1} & n \equiv 1 \\ \text{TRCVMIDCCTLR0.COMP2} & n \equiv 2 \\ \text{TRCVMIDCCTLR0.COMP3} & n \equiv 3 \\ \text{TRCVMIDCCTLR1.COMP4} & n \equiv 4 \\ \text{TRCVMIDCCTLR1.COMP5} & n \equiv 5 \\ \text{TRCVMIDCCTLR1.COMP6} & n \equiv 6 \\ \text{TRCVMIDCCTLR1.COMP7} & n \equiv 7 \end{cases}$$

$$\text{VMID} = \text{CONTEXTIDR_EL2.PROCID}$$

$$v = \text{TRCVMIDCVR<n>.VALUE}$$

$$\text{VMIDCOMP}[n] = \begin{cases} 0 & \text{When Prohibited} \\ 0 & \text{When in Debug State} \\ \prod_{j=0}^{7} \Big((v[8j+7:8j] \equiv \text{VMID}[8j+7:8j]) \vee \text{m}[j] \Big) & \text{Otherwise} \end{cases}$$

D4.6.9 Counters

I_{NCCBM} The Counters that are employed by the ETE architecture are all decrement counters.

The ETE architecture enables a trace unit to connect Counter outputs to resource events, so that a Counter at zero state can be used as a resource to activate a resource event. For example, a Counter at zero state might be used to assert an External Output or to make ViewInst active.

An ETE trace unit provides up to four 16-bit Counters. TRCIDR5.NUMCNTR indicates how many Counters are implemented. For each Counter, the following can be specified:

- The initial counter value. This can be programmed using TRCCNTVR<n>.
- The reload value. This can be programmed using TRCCNTRLDVR<n>.
- The resource event that causes the Counter to reload with the reload value. This resource event is called RLDEVENT. In addition, if required, the Counter can be programmed so that it automatically reloads whenever it reaches zero.
- The resource event that enables the Counter to decrement. This resource event is called CNTEVENT. The Counter decrements whenever CNTEVENT is active.

R_{RBMQM} The processor clock clocks the Counters in the trace unit.

R_{PZQGV} While the PE is stalled, the Counters continue to count.

R_{FHFMP} While the resources are in the Paused state, the Counters do not count.

R_{LFVYH} When a Counter value is changed by anything other than a direct write to TRCCNTVR<n>, the trace unit considers the change to be an indirect write to TRCCNTVR<n>.VALUE.

I_{MLDXC} Each Counter operates in one of the two following possible modes:

- Normal mode.
- Self-reload mode.

R_{SBQPN} While the Counter is in Normal mode, when the Counter reaches zero, the Counter remains at zero until the reload resource event, RLDEVENT, occurs.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{HYLGG} While the Counter is in Normal mode, the Counter-at-zero resource is active for the whole of the time that the Counter is at zero.

R_{YLYPH} While the Counter is in Self-reload mode, when the Counter reaches zero, when the decrement resource event is next active, the trace unit reloads the Counter with the reload value.

R_{VGJNL} While the Counter is in Self-reload mode, when the Counter value is zero, the decrement resource event is active and the reload resource event is not active, the Counter-at-zero resource is active for one cycle.

I_{KTRXV} The following examples show various operating scenarios for a single Counter. Each Counter is programmed with a reload value of `0x3`.

Figure D4-22 Counter Example 1, Normal mode

Figure D4-23 Counter Example 2, Normal mode

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure D4-24 Counter Example 3, Self-reload mode

Figure D4-25 Counter Example 4, Self-reload mode

Figure D4-26 Counter Example 5, Self-reload mode

R_{KXLKC} While the decrement resource event is inactive, the Counters do not decrement.

R_{DDCDK} The trace unit prioritizes the reload resource event over the count decrement resource event.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D4.6.9.1 Counter Operation in Normal mode

IBRLYH This table describes the counter operation in Normal mode.

RLDEVENT	dec_action	Counter value	Action	Resource Active	Notes
Inactive	x	0	Stable	Yes	Resource is active while Counter is at zero and remains at zero
Inactive	0	> 0	Stable	No	No activity
Inactive	1	> 0	Decrement	No	Decrement when not zero
Active	x	0	Reload	Yes	Reload, but resource is active because Counter is at zero
Active	x	> 0	Reload	No	Reload

D4.6.9.2 Counter Operation in Self-reload mode

ISHWBT This table describes the counter operation in Self-reload mode:

RLDEVENT	dec_action	Counter value	Action	Resource Active	Notes
Inactive	0	x	Stable	No	No activity, resource is not active even if the Counter is at zero
Inactive	1	0	Reload	Yes	Reload because dec_action is active and the Counter is at zero, resource is active only in this cycle
Inactive	1	> 0	Decrement	No	Decrement when not zero
Active	x	x	Reload	No	Reload regardless of decrement action and the value of the Counter, resource is never active

D4.6.9.3 Forming a larger Counter from two separate Counters

ITYLSH Some Counters can be chained together to form a larger counter, so that every time one Counter reloads, another Counter decrements.

IMMDRW The following example shows an operating scenario for 2 Counters chained together. Counter 0 is programmed with a reload value of `0x2`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Figure D4-27 Chained Counter Example 1

R_{WPWQD} Only certain Counters can be programmed to be chained together, as follows:

- Counter 1 can be programmed to decrement when Counter 0 reloads.
- Counter 3 can be programmed to decrement when Counter 2 reloads.

R_{QHZFW} The decrement resource event for the higher Counter n is active when either of the following occurs:

- The lower Counter reloads due to one of the following:
  - The reload resource event that is selected by TRCCNTCTLR<n-1>.RLDEVENT.
  - The Self-reload mechanism that is controlled by TRCCNTCTLR<n-1>.RLDSELF.
- The decrement resource event that is selected by TRCCNTCTLR<n>.CNTEVENT is active.

R_{BDPDN} While two Counters are chained together to form a larger counter, the larger counter appears as a 32-bit counter without any tearing of the values between the two Counters.

I_{FTDHL} For example, if Counter 0 is in Self-reload mode and has a value of `0x0000` and a reload value of `0xFFFF`, and Counter 1 is in Normal mode and has a value of `0x1234`, then when a decrement resource event occurs on Counter 0, Counter 0 reloads to `0xFFFF`. The reload of Counter 0 causes Counter 1 to decrement, resulting in a value of `0x1233`. Therefore the sequence on the Counters on consecutive cycles is `0x1234_0000` and `0x1233_FFFF`.

I_{BCMGM} For Counters 1 and 3, TRCCNTCTLR<n>.CNTCHAIN is an RW field that determines whether the Counter is chained. For Counters 0 and 2, TRCCNTCTLR<n>.CNTCHAIN is RES0.

Note

The CounterAtZero resource might not be asserted at the same time that the Counter is at zero. For example, this could happen if the trace unit implementation pipelines some logic.

I_{KJSDV} The CounterAtZero resource might not be asserted at the same time that the Counter is at zero. For example, this could happen if the trace unit implementation pipelines some logic.

D4.6.9.4 Pseudocode

D4.6.9.4.1 EvalAllCounters()

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
// The counter-at-zero resources
var CounterAtZero : array[[4]] of boolean;

//
// EvalAllCounters() is called each clock cycle
//

func EvalAllCounters()
begin
    var reload : array[[4]] of boolean;
    for i = 0 to UInt(TRCIDR5().NUMCNTR) - 1 do
        if (i == 1) || (i == 3) then
            reload[[i]] = EvalCounter(i, reload[[i-1]]);
        else
            reload[[i]] = EvalCounter(i, FALSE);
        end;
    end;
    return;
end;

//
// EvalCounter() is called for each counter
//

func EvalCounter(index : integer, lower_reloads : boolean) => boolean
begin
    var dec_action : boolean;
    var resource_active : boolean;
    var reload : boolean;
    var decrement : boolean;

    // A dec_action signal is constructed which indicates whether the counter
    // decrements. This is based on TRCCNTCTLR(n).CNTEVENT and, for counters
    // which support chaining, on TRCCNTCTLR(n).CNTCHAIN and on whether or not
    // the lower counter is reloading.
    dec_action = (IsEventActive(TRCCNTCTLR(index).CNTEVENT) ||
                  ((TRCCNTCTLR(index).CNTCHAIN == '1') && lower_reloads));

    // The counter-at-zero resource is active if the counter is
    // currently at zero and is either in Normal mode or in
    // Self-Reload mode and dec_action is active and the reload
    // event is not active.
    resource_active = ((TRCCNTVR(index).VALUE == Zeros{16}) &&
                       ((TRCCNTCTLR(index).RLDSELF=='0') ||
                        (dec_action && !IsEventActive(TRCCNTCTLR(index).RLDEVENT))));

    // The counter reloads if the reload event is active or the self-reload
    // mechanism causes a reload.
    reload = (IsEventActive(TRCCNTCTLR(index).RLDEVENT) ||
              ((TRCCNTCTLR(index).RLDSELF == '1') &&
                dec_action && TRCCNTVR(index).VALUE == Zeros{16}));

    // The counter only decrements if it is nonzero and does not reload and
    // dec_action is active.
    decrement = !reload && (TRCCNTVR(index).VALUE != Zeros{16}) && dec_action;

    // Determine the next value of the counter
    if reload then
        TRCCNTVR(index).VALUE = TRCCNTRLDVR(index).VALUE;
    elsif decrement then
        TRCCNTVR(index).VALUE = (UInt(TRCCNTVR(index).VALUE) - 1)[15:0];
    else
        TRCCNTVR(index).VALUE = TRCCNTVR(index).VALUE;
    end;
```

```
    CounterAtZero[[index]] = resource_active;
    return reload;
end;
```

D4.6.10 Sequencer

I_{BGGRG} An ETE trace unit can contain a Sequencer state machine that has four states.

Figure D4-28 Sequencer state machine

I_{PTVBH} TRCIDR5.NUMSEQSTATE indicates whether the state machine is implemented.

R_{QYNJH} If the Sequencer state machine is implemented, it has four states, numbered 0 to 3.

R_{TQWHX} When the trace unit leaves the Disabled state, the Sequencer state machine starts in the state programmed in TRCSEQSTR.STATE.

I_{SYCBV} The Sequencer can be connected to resource events, so that the Sequencer transitions from one state to another when certain resource events occur. The TRCSEQEVR<n> registers can be used to specify which resource events cause the state machine to transition.

Each register can be used to specify the following:

- A resource event that causes the state machine to progress to the next state.
- A resource event that causes the state machine to transition backwards to the previous state.

Different resource events can be chosen to cause the Sequencer to transition between different states. For example, a particular resource event might cause an F0 transition from state 0 to state 1 on one processor clock cycle, whereas a different resource event might cause an F1 transition from state 1 to state 2 on the next processor clock cycle. A third independent resource event might cause a B1 transition backwards from state 2 to state 1 on the third clock cycle.

R_{NPVRQ} The trace unit prioritizes forward transitions over backward transitions in the Sequencer state machine. That is, when two resource events occur that result in a forward transition conflicting with a backward transition in the same processor clock cycle, the trace unit gives priority to the forward transition and ignores the backward transition.

I_{QNFJZ} The Sequencer can progress through multiple states in a single processor clock cycle. For example, if the Sequencer is in state 0 and the resource events that cause an F0 and F1 transition to take place both become active in one clock cycle, then the Sequencer progresses from state 0 to state 2.

I_{DMZGJ} The Sequencer can be reset to state 0 from any other state. TRCSEQRSTEVR can be used to specify a resource event to reset the Sequencer.

R_{HQBBF} When a resource event that causes an RST transition occurs, the Sequencer finishes the clock cycle in state 0 and does not progress to another state until the next clock cycle.

R_{KVSXC} The trace unit prioritizes RST transitions over all other transitions. That is, when a resource event that causes an RST transition is active in the same clock cycle as resource events that cause other transitions, the trace unit gives priority to the RST transition and ignores all other transitions.

R_{JDPYL} The following table defines all of the possible state transitions.

1	RST | (B0 & !F1 & !F0)	(!B0 | F0) & !F1	F1 & !F2	F1 & F2
2	RST | (B0 & B1 & !F2 & !F1 & !F0)	B1 & (!B0 | F0) & !F1 & !F2	(!B1 | F1) & !F2	F2
3	RST | (B0 & B1 & B2 & !F2 & !F1 & !F0)	B2 & B1 & (!B0 | F0) & !F2 & !F1	B2 & (!B1 | F1) & !F2	!B2 | F2

I_{YQZGV} If multiple resource events that cause transitions become active in one processor clock cycle, there is no guarantee that the order of these resource events becoming active is observed. For example, you might program:

- F0 to be active on an instruction Address Comparator at address `0x1000`.
- F1 to be active on an instruction Address Comparator at address `0x1004`.

If the instruction at `0x1000` and the instruction at `0x1004` are executed in the same processor clock cycle, then the transition from state 0 to state 2 occurs regardless of the program order of the two instructions.

R_{VDTDP} When the Sequencer state is changed by anything other than a direct write to TRCSEQSTR, the trace unit considers the change to be an indirect write to TRCSEQSTR.STATE.

I_{WYFZH} The ETE architecture provides each Sequencer state as a resource, so that states can be used to trigger other resource events in the trace unit.

Figure D4-29 Sequencer operation

R_{HQHFT} When the Sequencer progresses through multiple states in a single processor clock cycle, for each state that it passes through, the resource state that the Sequencer triggers is active for that cycle.

I_{DCFMF} For example, if the Sequencer is in state 0, and in one processor clock cycle it moves to state 3, then the resource events that state 1 and state 2 are connected to must be active for that clock cycle. The same rule applies if the Sequencer is transitioning backwards, so that if it is in state 3, and in one processor clock cycle B2 and B1 cause it move to state 1, then the resource event that state 2 is connected to must be active for that clock cycle.

The exception to this is when an RST transition causes the Sequencer to return to state 0. For example, if the Sequencer is in state 3, and in one processor clock cycle it moves to state 0, then the resource events that state 2 and stage 1 are connected to must not become active.

Figure D4-30 Example of State Transitions

D4.6.10.1 Pseudocode

D4.6.10.1.1 EvalSequencer()

```
// The sequencer state resources
var SequencerState : array[[4]] of boolean;

    end;
end;
```

D4.6.11 Single-shot Comparator Controls

I_{QSKXC} If a trace unit is exposed to speculative execution when Address Comparators are used to activate resource events in the trace unit, then those resource events might be activated when speculative execution occurs:

- A Single Address Comparator might signal a match on speculative execution.
- An Address Range Comparator might signal a match on speculative execution.
