The counter counts each snoop counted by DSNP_HIT that hits in a cache at distance 4.

The event is counted by the PE generating the snoop, not the PE being snooped.

The cache distance indicates the relative distance that the return data has traveled. The distance is a relative distance that is defined at the system level, allowing flexibility of use for different systems that may have differing levels of hierarchy.

The interpretation of distance is IMPLEMENTATION DEFINED, and should be the same for all PEs in the base system, and the same for both cache and memory distances.

`0x8431`, ASE_FP_VREDUCE_SPEC, Floating-point operation speculatively executed, Advanced SIMD pairwise or reduction

The counter counts each speculatively executed floating-point treewise reduction or pairwise operation counted by ASE_SVE_FP_VREDUCE_SPEC due to any of the following A64 instructions:

- Advanced SIMD: FADDP, FMAXNMP, FMAXNMV, FMAXP, FMAXV, FMINNMP, FMINNMV, FMINP, or FMINV.

Note

Treewise reduction instructions might be executed and counted as multiple pairwise operations.

`0x8432`, SVE_FP_PREDUCE_SPEC, Floating-point operation speculatively executed, SVE pairwise add step or pairwise reduce step

The counter counts each speculatively executed floating-point pairwise add step or pairwise reduce step operation counted by SVE_FP_VREDUCE_SPEC due to any of the following instructions:

- SVE2: FADDP, FMAXNMP, FMAXP, FMINNMP, or FMINP.

0x8434, DSNP_HITM_N1_RD, Snoop hit in cache at distance 1, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_N1_RD that accesses a previously modified cache location.

0x8435, DSNP_HITM_N2_RD, Snoop hit in cache at distance 2, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_N2_RD that accesses a previously modified cache location.

0x8436, DSNP_HITM_N3_RD, Snoop hit in cache at distance 3, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_N3_RD that accesses a previously modified cache location.

0x8437, DSNP_HITM_N4_RD, Snoop hit in cache at distance 4, demand data read, modified

The counter counts each snoop generated by the PE in response to a demand Memory-read operation counted by DSNP_HIT_N4_RD that accesses a previously modified cache location.

0x8438, DSNP_HITM_N1_WR, Snoop hit in cache at distance 1, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_N1_WR that accesses a previously modified cache location.

0x8439, DSNP_HITM_N2_WR, Snoop hit in cache at distance 2, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_N2_WR that accesses a previously modified cache location.

0x843A, DSNP_HITM_N3_WR, Snoop hit in cache at distance 3, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_N3_WR that accesses a previously modified cache location.

0x843B, DSNP_HITM_N4_WR, Snoop hit in cache at distance 4, demand data write, modified

The counter counts each snoop generated by the PE in response to a demand Memory-write operation counted by DSNP_HIT_N4_WR that accesses a previously modified cache location.

0x843C, DSNP_HITM_N1_RW, Snoop hit in cache at distance 1, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_N1_RW that accesses a previously modified cache location.

0x843D, DSNP_HITM_N2_RW, Snoop hit in cache at distance 2, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_N2_RW that accesses a previously modified cache location.

0x843E, DSNP_HITM_N3_RW, Snoop hit in cache at distance 3, demand data access, modified

The counter counts each snoop generated by the PE in response to a demand Memory-read operation or demand Memory-write operation counted by DSNP_HIT_N3_RW that accesses a previously modified cache location.

0x8480, FP_SP_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is single-precision floating-point

The counter increments by *v* for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the smallest type was single-precision floating-point.

Where *v* is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC or FP_SCALE2_OPS_SPEC.

0x8482, FP_HP_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is half-precision floating-point

The counter increments by *v* for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the smallest type was half-precision floating-point.

Where *v* is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC or FP_SCALE2_OPS_SPEC.

0x8483, FP_BF16_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is BFloat16 floating-point

The counter increments by *v* for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the smallest type was BFloat16 floating-point.

Where *v* is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC or FP_SCALE2_OPS_SPEC.

0x8484, FP_FP8_FIXED_MIN_OPS_SPEC, Non-scalable element arithmetic operations speculatively executed, smallest type is 8-bit floating-point

The counter increments by *v* for each speculatively executed non-scalable element arithmetic operation, due to an instruction where the smallest type was 8-bit floating-point.

Where *v* is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_SCALE_OPS_SPEC or FP_SCALE2_OPS_SPEC.

0x8488, FP_SP_SCALE_MIN_OPS_SPEC, Scalable element arithmetic operations speculatively executed, smallest type is single-precision floating-point

The counter increments by *v* for each speculatively executed scalable element arithmetic operation, due to an instruction where the smallest type was single-precision floating-point.

Where *v* is a value such that $(v \times (VL \div 128))$ is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_FIXED_OPS_SPEC or FP_SCALE2_OPS_SPEC.

0x848A, FP_HP_SCALE_MIN_OPS_SPEC, Scalable element arithmetic operations speculatively executed, smallest type is half-precision floating-point

The counter increments by *v* for each speculatively executed scalable element arithmetic operation, due to an instruction where the smallest type was half-precision floating-point.

Where *v* is a value such that $(v \times (VL \div 128))$ is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_FIXED_OPS_SPEC or FP_SCALE2_OPS_SPEC.

`0x848B`, FP_BF16_SCALE_MIN_OPS_SPEC, Scalable element arithmetic operations speculatively executed, smallest type is BFloat16 floating-point

The counter increments by v for each speculatively executed scalable element arithmetic operation, due to an instruction where the smallest type was BFloat16 floating-point.

Where v is a value such that $(v \times (VL \div 128))$ is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_FIXED_OPS_SPEC or FP_SCALE2_OPS_SPEC.

`0x848C`, FP_FP8_SCALE_MIN_OPS_SPEC, Scalable element arithmetic operations speculatively executed, smallest type is 8-bit floating-point

The counter increments by v for each speculatively executed scalable element arithmetic operation, due to an instruction where the smallest type was 8-bit floating-point.

Where v is a value such that $(v \times (VL \div 128))$ is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_FIXED_OPS_SPEC or FP_SCALE2_OPS_SPEC.

`0x8490`, FP_SP_SCALE2_MIN_OPS_SPEC, Scalable tile arithmetic operations speculatively executed, smallest type is single-precision floating-point

The counter increments by v for each speculatively executed scalable tile arithmetic operation, due to an instruction where the smallest type was single-precision floating-point.

Where v is a value such that $(v \times (VL \div 128)^2)$ is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_FIXED_OPS_SPEC or FP_SCALE_OPS_SPEC.

`0x8492`, FP_HP_SCALE2_MIN_OPS_SPEC, Scalable tile arithmetic operations speculatively executed, smallest type is half-precision floating-point

The counter increments by v for each speculatively executed scalable tile arithmetic operation, due to an instruction where the smallest type was half-precision floating-point.

Where v is a value such that $(v \times (VL \div 128)^2)$ is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_FIXED_OPS_SPEC or FP_SCALE_OPS_SPEC.

`0x8493`, FP_BF16_SCALE2_MIN_OPS_SPEC, Scalable tile arithmetic operations speculatively executed, smallest type is BFloat16 floating-point

The counter increments by v for each speculatively executed scalable tile arithmetic operation, due to an instruction where the smallest type was BFloat16 floating-point.

Where v is a value such that $(v \times (VL \div 128)^2)$ is the number of arithmetic operations carried out by the operation or instruction which causes the counter to increment.

The counter does not count operations that are counted by FP_FIXED_OPS_SPEC or FP_SCALE_OPS_SPEC.

D14.4 Cycle event counting

The CPU_CYCLES event and the cycle counter, PMCCNTR, count cycles. The duration of a cycle is subject to any changes in clock frequency, including clock stopping caused by the WFI and WFE instructions.

It is IMPLEMENTATION SPECIFIC whether CPU_CYCLES and PMCCNTR count when the PE is in WFI or WFE state, even if the clocks are not stopped.

In addition, events such as STALL, STALL_FRONTEND and STALL_BACKEND that are defined to only count cycles that are counted by the CPU_CYCLES event have the same limitation.

D14.4.1 Cycle event counting in multithreaded implementations

Multithreaded implementations can have various forms, some examples of these are:

- *Simultaneous Multithreading* (SMT), where every PE thread is active on every Processor cycle.
- *Fine-grained Multithreading* (FGMT), also known as a Barrel processor, where one PE thread is active on each Processor cycle, and this changes regularly.
- *Switch on Event Multithreading* (SoEMT), also known as *Coarse-grained Multithreading* (CGMT), where high latency events cause the processor to switch the active PE thread.

In the above examples, active means that the PE might execute the instructions. A PE can be active but not executing instructions when no instruction is available or because of limited execution resources.

It is IMPLEMENTATION SPECIFIC whether a thread is active when the thread is in WFE or WFI state. This applies for all forms of multithreaded implementation.

When the PMU implementation supports multithreading, the Effective value of PMEVTYPER<n>.MT bit is 0, and the thread is not in WFE or WFI state, the CPU_CYCLES event only counts Processor cycles when the thread is active. For the example multithreaded implementations, this means that, if the event counter is enabled, event counting is not prohibited, and the thread is not in WFE or WFI state:

- For an SMT implementation, the CPU_CYCLES event counts every Processor cycle.
- For a particular FGMT implementation, that alternates between two threads on each Processor cycle, the CPU_CYCLES event counts every other Processor cycle.
- For a particular SoEMT implementation, that is waiting for a long latency operation, the CPU_CYCLES event does not count Processor cycles, as the PE thread is not active.

It is IMPLEMENTATION SPECIFIC whether CPU_CYCLES event counts Processor cycles when the Effective value of PMEVTYPER<n>.MT bit is 0, the thread is active, and the thread is in WFE or WFI state.

If the Effective value of PMEVTYPER<n>.MT bit is 1 and at least one thread is not in WFE or WFI state, then the CPU_CYCLES event counts each Processor cycle, and can only count a maximum of one for each Processor cycle.

If the Effective value of PMEVTYPER<n>.MT bit is 1, then all of the following apply for events that count PE cycles when a condition applies:

- The event does not count Processor cycles when all threads are in WFE or WFI state.
- If the event counts PE cycles when a stall condition is true and a second condition is true, then the counter counts Processor cycles when the stall condition is true for all of these PEs, and the second condition is true for any of these PEs.
- If the event counts PE cycles when any other condition is true, then the counter counts Processor cycle when the condition is true for any of these PEs.
- Otherwise, the event counts by the sum of the count across all of these PEs.

For the stall events, the stall condition means the applicable condition described by the STALL, STALL_FRONTEND, or STALL_BACKEND event. The second condition is any condition in addition to this. For example, for the STALL_FRONTEND_L1I event, the stall condition is STALL_FRONTEND, and the second condition is when there is a demand instruction miss in the first level of instruction cache. For the STALL, STALL_FRONTEND, and STALL_BACKEND events themselves, the second condition is the null TRUE condition.

Non-Confidential

Note

The cycle counter, PMCCNTR, is not affected by whether the thread is active or inactive. When enabled, PMCCNTR counts every processor cycle.

For more information about when the Effective value of PMEVTYPER<n>_EL0.MT is 0, see:

- MDCR_EL2.MTPME.
- MDCR_EL3.MTPME.
- HDCR.MTPME.
- SDCR.MTPME.

D14.4.2 Time as measured by the Performance Monitors cycle counter

The Performance Monitors cycle counter, accessed through PMCCNTR_EL0 or PMCCNTR, increments from the hardware processor clock, not PE clock cycles.

The relationship between the count recorded by the Performance Monitors cycle counter and the passage of real time is IMPLEMENTATION DEFINED.

See Controlling the PMU counters for information about when the cycle counter does not increment.

Note

- This means that, in an implementation where PEs are multithreaded, when enabled, the cycle counter continues to increment across all PEs, rather than only counting cycles for which the current PE is active.
- Although the architecture requires that direct reads of PMCCNTR_EL0 or PMCCNTR occur in program order, there is no requirement that the count increments between two such reads. Even when the counter is incrementing on every clock cycle, software might need check that the difference between two reads of the counter is nonzero.

  The architecture requires that an indirect write to the PMCCNTR_EL0 or PMCCNTR is observable to direct reads of the register in finite time. The counter increments from the hardware processor clock are indirect writes to these registers.

D14.5 Meaningful combinations of common events

The meaningful combinations listed in this section comprise a numerator event and a denominator event.

In many cases, the definition of the numerator event, <EVENT_NUMERATOR>, is defined such that it counts each event <X> counted by the denominator event, <EVENT_DENOMINATOR>, when some condition <COND> is true.

This means that there is a meaningful ratio between between <EVENT_NUMERATOR> and <EVENT_DENOMINATOR> that describes the proportion of <X> counted by <EVENT_DENOMINATOR> for which <COND> applies.

This does not mean that there is a requirement that if <EVENT_NUMERATOR> is implemented that <EVENT_DENOMINATOR> is also implemented.

A *meaningful combination* means that any microarchitectural conditions that affect the counting of events apply equally to all the events. This typically means that they are counted at the same place in the pipeline, so that, for example, they are equally affected by pipeline flushes to discard speculatively executed operations following a mispredicted branch.

The following tables list the highlighted combinations:

- Refill events and associated access events.
- Latency events.
- Cache hit events and associated data source events.
- Cache line state tracking events.
- TLB events.
- At-retirement events.
- Speculatively executed operation events.
- Bytes loaded and stored events.
- Overall vector utilization events.
- Vector loop efficiency events.

D14.5.1 Refill events and associated access events

I_{GSMLS} The following are meaningful combinations of refill events and associated access events:

Table D14-4 Meaningful combinations of refill events and associated access events

Numerator	Denominator	Ratio
0x0001 L1I_CACHE_REFILL	0x0014 L1I_CACHE	Attributable Level 1 instruction cache refill rate
0x0002 L1I_TLB_REFILL	0x0026 L1I_TLB	Attributable Level 1 instruction TLB refill rate

D14.5.7 Speculatively executed operation events

IRDHPB The number of speculatively executed operations performed on individual scalar values, assuming that all SVE vector elements are Active, can be determined from a pair of event counters. Combined multiply-add and multiply-subtract instructions are counted as two operations per element.

Table D14-10 Meaningful combinations of speculatively executed operation events

Ratio	Meaning
0x80C0, FP_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C1, FP_FIXED_OPS_SPEC	Total number of individual floating-point operations (any precision) performed
0x80C2, FP_HP_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C3, FP_HP_FIXED_OPS_SPEC	Total number of individual half-precision floating-point operations performed
0x80C4, FP_SP_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C5, FP_SP_FIXED_OPS_SPEC	Total number of individual single-precision floating-point operations performed
0x80C6, FP_DP_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C7, FP_DP_FIXED_OPS_SPEC	Total number of individual double-precision floating-point operations performed
0x80C8, INT_SCALE_OPS_SPEC × VL ÷ 128 + 0x80C9 INT_FIXED_OPS_SPEC	Total number of individual integer operations performed
0x80CA, LDST_SCALE_OPS_SPEC × VL ÷ 128 + 0x80CB, LDST_FIXED_OPS_SPEC	Total number of individual load/store accesses performed
0x80CC, LD_SCALE_OPS_SPEC × VL ÷ 128 + 0x80CD, LD_FIXED_OPS_SPEC	Total number of individual load accesses performed

D14.6 Required events

When at least one event counter is implemented, the following common events are implemented:

- `0x0000`, SW_INCR, Instruction architecturally executed, Condition code check pass, software increment.
- `0x0011`, CPU_CYCLES, Cycle.
- When the PE includes a Level 1 data or unified cache:
  - `0x0003`, L1D_CACHE_REFILL, Level 1 data cache refill.
  - `0x0004`, L1D_CACHE, Level 1 data cache access.
- If the implementation includes program-flow prediction:
  - At least one of the following is implemented:
    - `0x0012`, BR_PRED, Predictable branch Speculatively executed.
    - `0x0021`, BR_RETIRED, Instruction architecturally executed, branch.
  - At least one of the following is implemented:
    - `0x0010`, BR_MIS_PRED, Mispredicted or not predicted branch Speculatively executed.
    - `0x0022`, BR_MIS_PRED_RETIRED, Branch instruction architecturally executed, mispredicted.
  - At least one of the following applies:
    - Both BR_PRED and BR_MIS_PRED are implemented.
    - Both BR_RETIRED and BR_MIS_PRED_RETIRED are implemented.

Note

Arm strongly recommends that both BR_RETIRED and BR_MIS_PRED_RETIRED are implemented. If the implementation does not include program-flow prediction, Arm recommends that these events are implemented as described in Common microarchitectural events.

- When FEAT_PMUv3_ICNTR is implemented:
  - `0x0008`, INST_RETIRED, Instruction architecturally executed.
- When FEAT_PMUv3_ICNTR is not implemented, at least one of:
  - `0x0008`, INST_RETIRED, Instruction architecturally executed.
  - `0x001B`, INST_SPEC, Operation Speculatively executed.

Note

Arm strongly recommends that event `0x0008` is implemented.

- When FEAT_PMUv3p1 is implemented:
  - `0x0023`, STALL_FRONTEND, No operation issued due to the frontend.
  - `0x0024`, STALL_BACKEND, No operation issued due to the backend.
- When FEAT_SVE or FEAT_SME is implemented, at least one of:
  - `0x8002`, SVE_INST_RETIRED, SVE instruction architecturally retired.
  - `0x8006`, SVE_INST_SPEC, SVE operation speculatively executed.
- When FEAT_SPE is implemented:
  - `0x4000`, SAMPLE_POP, Statistical Profiling sample population.
  - `0x4001`, SAMPLE_FEED, Statistical Profiling sample taken.
  - `0x4002`, SAMPLE_FILTRATE, Statistical Profiling sample filtered.
  - `0x4003`, SAMPLE_COLLISION, Statistical Profiling sample collision.
- When FEAT_PMUv3p4 is implemented:
  - `0x003C`, STALL, No operation sent for execution.
  - When the PE includes a Level 1 data or unified cache:
    - `0x0039`, L1D_CACHE_LMISS_RD, Level 1 data cache long-latency read miss.
    - `0x0040`, L1D_CACHE_RD, Level 1 data cache read.
  - When the PE includes a Level 1 instruction cache:
    - `0x4006`, L1I_CACHE_LMISS, Level 1 instruction cache long-latency miss.
- When FEAT_SPEv1p2 is implemented:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - 0x812A, SAMPLE_FEED_BR, Statistical Profiling sample taken, branch.
  - 0x812B, SAMPLE_FEED_LD, Statistical Profiling sample taken, load.
  - 0x812C, SAMPLE_FEED_ST, Statistical Profiling sample taken, store.
  - 0x812D, SAMPLE_FEED_OP, Statistical Profiling sample taken, matching operation type.
  - 0x812E, SAMPLE_FEED_EVENT, Statistical Profiling sample taken, matching events.
  - 0x812F, SAMPLE_FEED_LAT, Statistical Profiling sample taken, exceeding minimum latency.
- When FEAT_ETE is implemented:
  - 0x4010, TRCEXTOUT0.
  - 0x4011, TRCEXTOUT1.
  - 0x4012, TRCEXTOUT2.
  - 0x4013, TRCEXTOUT3.
  - If TRCIDR5.NUMEXTINSEL > 0, 0x4018, CTI_TRIGOUT4.
  - If TRCIDR5.NUMEXTINSEL > 1, 0x4019, CTI_TRIGOUT5.
  - If TRCIDR5.NUMEXTINSEL > 2, 0x401A, CTI_TRIGOUT6.
  - If TRCIDR5.NUMEXTINSEL > 3, 0x401B, CTI_TRIGOUT7.
- When FEAT_PMUv3_TH is implemented, the following common events are implemented:
  - 0x003D, STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend.
  - 0x003E, STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend.
  - 0x003F, STALL_SLOT, No operation sent for execution on a Slot.
- When FEAT_PMUv3p9 is implemented and the PE includes a Level 1 instruction cache:
  - 0x0014, L1I_CACHE, Level 1 instruction cache access.
- When FEAT_PMUv3_SS is implemented:
  - 0x8127, PMU_SNAPSHOT, Successful PMU capture event.
- When FEAT_SPE_FDS is implemented:
  - 0x8122, SAMPLE_FEED_DS, Statistical Profiling sample taken, selected Data Source.
- When FEAT_SPEv1p4 is implemented:
  - 0x8123, SAMPLE_BUFFER_FULL, Profiling Buffer full.
- When FEAT_SPE_EFT is implemented:
  - 0x8348, SAMPLE_FEED_FP, Statistical Profiling sample taken, floating-point.
  - 0x8349, SAMPLE_FEED_SIMD, Statistical Profiling sample taken, SIMD.
- When FEAT_SME is implemented:
  - At least one of the following is implemented:
    - 0x835A, SME_INST_RETIRED, Instruction architecturally executed, SME.
    - 0x835E, SME_INST_SPEC, Operation speculatively executed, SME.
  - At least one of the following is implemented:
    - 0x8358, SME_RETIRED, Instruction architecturally executed, SME data processing.
    - 0x835C, SME_SPEC, Operation speculatively executed, SME data processing.

When any of the following common events are implemented, all three of them are implemented:

- 0x003D, STALL_SLOT_BACKEND, No operation sent for execution on a Slot due to the backend.
- 0x003E, STALL_SLOT_FRONTEND, No operation sent for execution on a Slot due to the frontend.
- 0x003F, STALL_SLOT, No operation sent for execution on a Slot.

Arm strongly recommends that the following events are implemented:

- 0x003A, OP_RETIRED.
- 0x003B, OP_SPEC.
- 0x003D, STALL_SLOT_BACKEND.
- 0x003E, STALL_SLOT_FRONTEND.
- 0x003F, STALL_SLOT.

D14.7 IMPLEMENTATION DEFINED event numbers

Arm recommends that implementers establish a standardized numbering scheme for their IMPLEMENTATION DEFINED events, with common definitions, and common event numbers, applied to all of their implementations. In general, the recommended approach is for standardization across implementations with common features. However, Arm recognizes that attempting to standardize the encoding of microarchitectural features across too wide a range of implementations is not productive.

The Arm architecture guarantees not to define any event prefixed with *IMP_* as part of the standard Arm architecture.

Arm strongly recommends that at least the following classes of event are identified in the IMPLEMENTATION DEFINED events:

- Separating each of the STALL_FRONTEND and STALL_SLOT_FRONTEND events to count holes in instruction availability.
- Separating each of the STALL_BACKEND and STALL_SLOT_BACKEND events, to count, for example, cumulative duration of stalls, unavailability of execution resources, or missed superscalar issue opportunities.
- Miss rates for additional levels of caches and TLBs.
- Any external events passed to the PE through an IMPLEMENTATION DEFINED mechanism.
- Cumulative duration of a PSTATE.{A, I, F} interrupt mask set to 1.
- Cumulative occupancy for resource queues, such as data access queues, and entry/exit counts, so that average latencies can be determined, separating out counts for key resources that might exist. An implementation might also provide registers in the IMPLEMENTATION DEFINED space to further extend such counts, for example by specifying a minimum latency for an event to be counted.
- Any other microarchitectural features that the implementer considers are valuable to count.

If FEAT_RME is implemented, IMPLEMENTATION DEFINED events are permitted to count all of:

- *Granule Protection Table* (GPT) accesses.
- For address translations subject to *Granule Protection Checks* (GPC):
  - TLB hits. These are called *GPT-related TLB hits*.
  - TLB misses. These are called *GPT-related TLB misses*.

The range of possible IMPLEMENTATION DEFINED event numbers is described in The PMU event number space and common events.

It is not required that implementations document the behavior of all IMPLEMENTATION DEFINED PMU events, including which PMU event numbers are used for these IMPLEMENTATION DEFINED events. However, Arm strongly recommends that implementations do include and document IMPLEMENTATION DEFINED PMU events. In particular events related to microarchitectural characteristics of the implementation not covered by Common events.

Chapter D15
The System Performance Monitors Extension

This chapter describes the implementation of the Arm System Performance Monitors that are an OPTIONAL non-invasive debug component. It contains the following sections:

- About the System Performance Monitors
- System PMU configuration
- Accessing System PMUs
- Generating System PMU overflow interrupt requests

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D15.1 About the System Performance Monitors

R_{XVHSR} A *System PMU* is a PMU other than the PMU implemented by a PE that is accessible to that PE. For more information on the PMU, see The Performance Monitors Extension.

R_{KGSQX} A System PMU might be accessible to other PEs in the system.

I_{XDHVC} The System Performance Monitors Extension is an OPTIONAL feature of an implementation. The architecture does not require that System PMUs are implemented using FEAT_SPMU. Arm recommends that System PMUs are implemented using FEAT_SPMU or *The CoreSight PMU Architecture*. FEAT_SPMU and *The CoreSight PMU Architecture* share a conceptual model for performance monitors.

I_{DDTRR} The System Performance Monitors Extension supports up to 32 System PMUs.

I_{NYCYF} The basic form of a System PMU is:

- A number of 64-bit event counters, SPMEVCNTR<n>_EL0. Each System PMU can support up to 64 event counters.
- It is IMPLEMENTATION DEFINED whether the event counted by each event counter is fixed or programmable. Event configuration registers, SPMEVTYPER<n>_EL0, SPMEVFILTR<n>_EL0, and SPMEVFILT2R<n>_EL0 are provided for this.
- Controls for:
  - Enabling and resetting counters, in the System PMU control register SPMCR_EL0.
  - If FEAT_SPMU2 is implemented, setting individual counters to zero, in SPMZR_EL0.
  - Count enable set and clear registers, SPMCNTENSET_EL0 and SPMCNTENCLR_EL0, respectively.
  - Counter overflow set and clear registers, SPMOVSSET_EL0 and SPMOVSCLR_EL0, respectively.
  - Interrupt enable set and clear registers, SPMINTENSET_EL1 and SPMINTENCLR_EL1, respectively.
  - System PMU access control registers SPMACCESSR_EL3, SPMACCESSR_EL2, and SPMACCESSR_EL1.
  - If Secure EL1 is implemented, an OPTIONAL Secure state observability control register SPMSCR_EL1.
  - If FEAT_RME is implemented, an OPTIONAL Root and Realm state observability control register SPMROOTCR_EL3.
- Read-only identification registers:
  - Implementation and architecture identification registers, SPMIIDR_EL1 and SPMDEVARCH_EL1, respectively.
  - If the System PMU is accessible to other PEs in the system, then affinity register SPMDEVAFF_EL1.
  - Implementation configuration register SPMCFGR_EL1.
  - If the System PMU implements more than one Counter Group, then Counter Group configuration registers SPMCGCR<n>_EL1.

Non-Confidential

D15.2 System PMU configuration

IXCMGX

A System PMU is identified to software by the following registers:

- SPMIIDR_EL1 uniquely identifies the component implementer and provides a part number code specific to that implementation. This register is OPTIONAL, and if the register is not implemented, it is RAZ.
- SPMDEVARCH_EL1 describes a generic programmers' model for the System PMU that might be shared by multiple implementations. This register is OPTIONAL, and if the register is not implemented, it is RAZ.
- SPMDEVAFF_EL1 describes which PEs the System PMU is shared with, if any.
- SPMCFGR_EL1 describes the capabilities of the System PMU, including, but not limited to, the number and size of counters implemented by the System PMU.
- If SPMCFGR_EL1.NCG indicates the System PMU implements more than one Counter Group, then SPMCGCR<n>_EL1 indicates the number of counters in each Counter Group. Otherwise, SPMCGCR<n>_EL1 are RAZ and all the counters are in the first Counter Group.

When these registers are implemented by a System PMU, software can use these registers along with pre-existing knowledge to determine configuration information about the System PMU, as follows:

1. If software recognizes the identity of the System PMU in SPMIIDR_EL1, it can load a configuration for the System PMU.
2. Otherwise, if software recognizes the architecture in SPMDEVARCH_EL1, it can load a generic configuration for the System PMU.
3. Otherwise, software can use the capabilities described by SPMCFGR_EL1 to define a generic configuration for the System PMU.

The configuration contains, for instance, details of how the event configuration registers SPMEVTYPER<n>_EL0, SPMEVFILTR<n>_EL0, and SPMEVFILT2R<n>_EL0, are programmed, including but not limited to the following IMPLEMENTATION DEFINED information:

- Field assignments.
- Whether additional features are implemented, such as threshold and edge detection.
- Whether an interrupt on counter overflow is implemented.
- Assignment of event codes to events.
- Definitions of events.
- Details of any fixed-function counters.
- Useful metrics derived from events.
- Security policies for allowing access to the System PMU from lower Exception levels.

IYKJXW

A System PMU might statically divide its counters into an IMPLEMENTATION DEFINED number of Counter Groups. The number of Counter Groups is identified to software by SPMCFGR_EL1.NCG. At most 15 Counter Groups can be implemented. If SPMCFGR_EL1.NCG is `0b0000`, then only one Counter Group is implemented, and all counters are in the first Counter Group.

Each Counter Group has an IMPLEMENTATION DEFINED number of counters in that group, from zero to the value *max*. The number of counters in Counter Group <n × 8 + m>, is identified to software by SPMCGCR<n>_EL1.N<m>. The first counter in Counter Group <n> is SPMEVCNTR<n × max>_EL0.

The value *max* depends on the number of Counter Groups implemented, and is defined by the following table:

Table D15-1 Value of max when determining the first counter in a Counter Group

Number of Counter Groups	*max*
2	32
3 or 4	16
Between 5 and 8	8
Between 9 and 15	4

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D15-1 Determining the number of counters in a System PMU

The number of counters in a System PMU can be determined as described in the following example:

- SPMCFGR_EL1.NCG reads as `0b0001`, indicating 2 Counter Groups.
- SPMCGCR0_EL1 reads as `0x0000_0604`, indicating:
  - Group 0 has four counters: SPMEVCNTR0_EL0 to SPMEVCNTR3_EL0.
  - Group 1 has six counters: SPMEVCNTR32_EL0 to SPMEVCNTR37_EL0.
- SPMCFGR_EL1.N reads as `0x09`, indicating 10 counters are implemented overall.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D15.3 Accessing System PMUs

IVXVXK A System PMU <s> is selected by setting SPMSELR_EL0.SYSPMUSEL to <s>, where $0 \leq s \leq 31$. This determines which System PMU is being accessed by the System PMU registers. If enabled, then the System PMUs are always monitoring.

IWYLYL The largest value of SPMSELR_EL0.SYSPMUSEL is identified by ID_AA64DFR1_EL1.SYSPMUID.

IBWTWP Implemented System PMUs might not be contiguously accessible. That is, if System PMU <s> is not implemented, this does not imply System PMU <s+1> is not implemented. Therefore, the value of ID_AA64DFR1_EL1.SYSPMUID does not necessarily indicate the total number of accessible System PMUs.

RJJNZK Accesses to System PMU <s> are controlled by SPMACCESSR_EL1.P<s>, SPMACCESSR_EL2.P<s>, SPMACCESSR_EL3.P<s>, and if implemented by the System PMU, SPMSCR_EL1 and SPMROOTCR_EL3.

IFKZLR FEAT_SPMU does not provide an equivalent of the fine-grained EL0 controls provided for the PE PMU by PMUSERENR_EL0 and PMUACR_EL1.

D15.3.1 Accessing System PMU registers

RNKSGW A System PMU that is shared by multiple PEs implements multi-copy atomicity for writes to the System PMU registers, with each of those PEs being observers of writes to the registers:

- All writes to the same System PMU register are serialized, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a System PMU register does not observe a direct write until all observers observe that direct write.

ITZFBD

Example D15-2 Observing a write to System PMU registers

When observing a write to System PMU registers, this means observing all effects of the write. For example:

- The effect writing to SPMEVCNTR<n>_EL0 is to set the value of the counter to the value that was written.
- The effect writing a 1 to SPMOVSCLR_EL0[n] is to clear both SPMOVSCLR_EL0[n] and SPMOVSSET_EL0[n] to 0.

RTVFHH The System PMU is also an observer of writes to the System PMU registers that makes indirect reads and indirect writes of the registers when counting events.

RXFHMP A direct write to a System PMU register that has been synchronized by a Context synchronization event on the PE performing the direct write will be observable to all observers in finite time.

RBXJVP A `DSB` instruction ordered after a direct write to a System PMU register does not complete until all observers observe the direct write. A Context synchronization event is required to create the order between the direct write and the `DSB` instruction.

IYPSBB Because a direct read from a System register in program order following a direct write to the same System register will observe the write to the register, reading back from that register also guarantees that all observers observe the direct write.

D15.3.2 Accessing System PMU counters

IZWVKD A System PMU counter <n> is selected by setting SPMSELR_EL0.BANK to <n DIV 16>, where $0 \leq n \leq 63$.

IRHHZC There are no mechanisms to trap accesses to individual counters, ranges of counters, or unimplemented counters in a System PMU. If not trapped by a higher priority exception, then accesses to unimplemented counters in a System PMU are RAZ/WI.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D15.3.3 Zeroing System PMU counters

I_{GDKFB} If FEAT_SPMU2 is implemented, then writing 1 to SPMZR_EL0.P<n> sets System PMU counter <n> in System PMU <s> to zero.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D15.4 Generating System PMU overflow interrupt requests

R_{TCYDX} It is IMPLEMENTATION DEFINED whether a System PMU implements a counter overflow flag for each counter SPMEVCNTR<n>_EL0 implemented by the System PMU.

If the System PMU implements a counter overflow flag for SPMEVCNTR<n>_EL0, then all of the following apply:

- When incrementing SPMEVCNTR<n>_EL0 causes an unsigned overflow of the counter, the System PMU sets SPMOVSCLR_EL0[n] to 1.
- SPMOVSCLR_EL0[n] is R/W1C.
- SPMOVSSET_EL0[n] is R/W1S.

Otherwise, SPMOVSCLR_EL0[n] and SPMOVSSET_EL0[n] are RAZ/WI.

Note

If an event can occur multiple times in a single clock cycle, then a counter overflow can occur without the counter registering a value of zero.

R_{NZHDW} The size of each counter implemented by a System PMU is IMPLEMENTATION DEFINED, between 1 and 64 bits. Unimplemented bits in each counter register are RES0.

R_{NBPGV} If a System PMU implements a counter overflow flag for any counter SPMEVCNTR<n>_EL0 implemented by the System PMU, then it is IMPLEMENTATION DEFINED whether the System PMU implements an overflow interrupt request.

I_{NJGBT} Each System PMU that implements an overflow interrupt request has its own interrupt request, and it is IMPLEMENTATION DEFINED whether the interrupts are implemented as a Shared Peripheral Interrupt (SPI) or a Private Peripheral Interrupt (PPI). A System PMU that is not shared with other PEs should use a PPI.

Interrupt IDs are IMPLEMENTATION DEFINED.

R_{PGYZY} When the overflow interrupt request is implemented, software can program SPMINTENSET_EL1 and SPMINTENCLR_EL1 such that an overflow interrupt request is generated when a counter overflow flag is 1.

If the System PMU implements the overflow interrupt request and implements a counter overflow flag for SPMEVCNTR<n>_EL0, then all of the following apply:

- SPMINTENCLR_EL1[n] is R/W1C.
- SPMINTENSET_EL1[n] is R/W1S.

Otherwise, SPMINTENCLR_EL1[n] and SPMINTENSET_EL1[n] are RAZ/WI.

If the overflow interrupt request is implemented as a level-sensitive request, then the System PMU signals an overflow interrupt request when all of the following are true for any implemented counter SPMEVCNTR<n>_EL0:

- SPMCR_EL0.E is 1.
- SPMOVSCLR_EL0[n] is 1.
- SPMINTENCLR_EL1[n] is 1.

For more information, see SPMINTENSET_EL1 and SPMINTENCLR_EL1.

I_{MZGZJ} The architecture does not provide any support for a System PMU interrupt implemented as a message-signaled interrupt (MSI). To support implementing the interrupt as an MSI, additional IMPLEMENTATION DEFINED registers must be defined.

Chapter D16
The Activity Monitors Extension

This chapter describes version 1 of the *Activity Monitor Unit* (AMU) architecture, AMUv1, an optional non-invasive component. It contains the following sections:

- About the Activity Monitors Extension
- Properties and behavior of the activity monitors
- AMU events and event numbers

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D16.1 About the Activity Monitors Extension

The Activity Monitors Extension is an OPTIONAL extension to the Armv8.4 architecture.

The Activity Monitors Extension implements version 1 of the Activity Monitors architecture, AMUv1, and interfaces to the registers defined by AMUv1, the Activity Monitors registers.

Version 1 of the Activity Monitors architecture implements:

- A counter group of four architected 64-bit event counters. The events counted by the architected event counter are fixed and architecturally defined.

  Note

  The Activity Monitors architecture provides space for up to 16 architected event counters. Future versions of the Activity Monitors architecture might use this space to implement additional architected event counters.

- A counter group of up to 16 auxiliary 64-bit event counters. The event counted for each auxiliary event counter can be fixed or programmable, and whether it is fixed or programmable is IMPLEMENTATION DEFINED. When the event counted by an auxiliary event counter is fixed, this event is IMPLEMENTATION DEFINED.
- Controls for enabling and disabling counters.
- When the event counted by an auxiliary event counter is programmable, controls for assigning an event to the counter.
- Controls that determine whether the activity monitor counters continue to count while the PE is halted in Debug state.

The read-only registers AMCFGR and AMCGCR provide information about features supported by the Activity Monitors Extension, the number of counter groups implemented, the total number of counters implemented, the number of counters implemented within each group, and the size of the counters.

The Activity Monitors Extension provides:

- A mandatory System register interface to the Activity Monitors System registers, for both AArch64 and AArch32 states.

  AArch64 Activity Monitors System registers lists the AArch64 Activity Monitors System registers, and AArch32 Activity Monitors System registers lists the AArch32 Activity Monitors System registers. Table K14-3 shows the relationship between the AArch64 and the AArch32 Activity Monitors System registers.
- Controls that allow software to enable or disable access by software running at lower Exception levels to the Activity Monitors registers.
- When FEAT_AMUv1p1 is implemented, and the hypervisor is using AArch64, offset registers that support virtualization of the Activity Monitor event counters.
- An optional external interface providing read-only memory-mapped access to the Activity Monitors registers.

  Alphabetical index of memory-mapped registers lists the Activity Monitors memory-mapped registers. For more information on the recommended external interface, see Recommended External Interface to the Activity Monitors.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D16.2 Properties and behavior of the activity monitors

D16.2.1 Basic characteristics of the activity monitor event counters

Every activity monitor event counter is a 64-bit wrapping counter. When an activity monitor event counter wraps, the counter overflows.

Note

The Activity Monitor architecture does not provide support for overflow status indication or interrupts.

The state of the authentication signals do not affect counting.

Any change in clock frequency, including when a WFI and WFE instruction stops the clock, can affect any counter.

If FEAT_AMUv1p1 is implemented, for the architected event counters 0, 2 and 3, and each auxiliary event counter configured to use an offset, there is an offset register which is used to virtualize the count on a read from EL1 or EL0. At EL2, EL3 or from the memory-mapped view, permitted accesses to the counters use the physical view without any offset. See Virtualization

D16.2.2 Counter configuration and controls

For each architected event counter AMEVCNTR0<n>, there is a corresponding event type register AMEVTYPER0<n> which provides information on the event counted by that counter. The event type registers AMEVTYPER0<n> are read-only.

For each auxiliary event counter AMEVCNTR1<n>, there is a corresponding event type register AMEVTYPER1<n> which provides information on the event counted by that counter. When the event counted by an auxiliary event counter is fixed, the corresponding event type register AMEVTYPER1<n> is read-only. When the event counted by an auxiliary event counter is programmable, the corresponding event type register AMEVTYPER1<n> is read/write.

For each counter group, there is a pair of separate controls to enable and disable the counters in that counter group. AMCNTENCLR0 and AMCNTENSET0 are used to disable and enable the architected event counters. AMCNTENCLR1 and AMCNTENSET1 are used to disable and enable the auxiliary event counters.

While the PE is halted in Debug state, AMCR.HDBG controls whether activity monitor counting is halted.

AMUSERENR.EN controls access from EL0 to the Activity Monitor Extension System registers. CPTR_EL2.TAM and HCPTR.TAM control access from EL0 and EL1 to the Activity Monitor Extension System registers. CPTR_EL3.TAM control access from EL0, EL1, and EL2 to the Activity Monitor Extension System registers.

Note

These controls obey the priority order described in Prioritization of Synchronous exceptions taken to AArch64 state and Synchronous exception prioritization for exceptions taken to AArch32 state.

AMUSERENR.EN is configurable at EL1, EL2, and EL3. All other controls, as well as the value of the counters, are configurable only at the highest implemented Exception level.

If FEAT_AMUv1p1 is implemented, AMCG1IDR_EL0 defines which auxiliary counters are implemented, and if virtual offsets are enabled, indicates which of the implemented auxiliary counters have a virtual offset when read from EL0 and EL1.

If FEAT_AMUv1p1 is implemented, AMCR.CG1RZ controls whether the auxiliary event counters read as zero if they are accessed at an Exception level lower than the highest implemented Exception level.

D16.2.3 Power and reset domains

The power domain of the Activity Monitoring Unit is IMPLEMENTATION DEFINED and named the AMU domain.

The reset domain of the Activity Monitoring Unit is IMPLEMENTATION DEFINED and named the AMU reset.

The AMU power domain may be the Core power domain.

When an AMU reset of the AMU power domain occurs, the Activity Monitoring Unit is reset and the counters are reset to zero.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When the PE is not in reset, the Activity Monitoring Unit is available.

D16.2.4 Accuracy and non-invasive behavior

The activity monitors are a non-invasive component which must provide broadly accurate and statistically useful count information.

The implementation of an architecturally required event might create a conflict between the requirement to be non-invasive and the requirement to present an accurate value of the count under normal operating conditions. An implementation might provide an IMPLEMENTATION DEFINED control that disables accurate count of the event to restore performance and document the impact on performance of accurate counting. The expectations for non-invasive behavior and the degree of inaccuracy of the activity monitors are otherwise as described for the Performance Monitors architecture.

Note

For information on the expectations for non-invasive behavior and the degree of inaccuracy of the Performance Monitors, see Non-invasive behavior and A reasonable degree of inaccuracy.

D16.2.5 Virtualization

FEAT_AMUv1p1 supports virtualized access to the Activity Monitors event counters at EL1 and EL0.

The fields HCR_EL2.AMVOFFEN and SCR_EL3.AMVOFFEN enable and disable virtualization. When enabled, the architected event counters 0, 2 and 3 have counter offsets. Architected event counter 1 does not have an offset. The register AMCG1IDR_EL0 indicates which of the implemented auxiliary event counters has implemented counter offsets. An implemented event counter that does not have a defined offset has an effective offset of zero. The offset registers can be accessed only at EL2 or EL3, and affect views of the event counters at EL1 and EL0 from the System register interfaces only.

The AMEVCNTVOFF0<n>_EL2 registers hold the offsets for the implemented and enabled architected event counters.

The AMEVCNTVOFF1<n>_EL2 registers hold the offsets for the implemented and enabled auxiliary event counters.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D16.3 AMU events and event numbers

The Activity Monitors architecture uses the event number space defined by the Performance Monitors architecture to identify events.

The Activity Monitors architecture defines additional events and adds them to the event number space defined by the Performance Monitors architecture for common events.

If the event is counting an IMPLEMENTATION DEFINED event, it must use an event number from the IMPLEMENTATION DEFINED event space.

When an implementation supports monitoring of an event that is assigned a common architectural or microarchitectural event number, Arm strongly recommends that it uses that number for the event.

When a common event is available to both the Performance Monitors architecture and the Activity Monitors architecture within one implementation, both architectures use the same event number.

D16.3.1 Architected event counters

Version 1 of the Activity Monitors architecture, AMUv1, requires four events to be counted by the architected activity monitor event counters.

The events required to be counted are:

`0x0011`**, CPU_CYCLES, Processor frequency cycles**

The counter increments on every cycle when the PE is not in WFI or WFE state. When the PE is in WFI or WFE state, this counter does not increment.

This event is counted by AMEVCNTR0<n>, where n is 0.

`0x4004`**, CNT_CYCLES, Constant frequency cycles**

The counter increments at a constant frequency when the PE is not in WFI or WFE state, equal to the rate of increment of the System counter, CNTPCT_EL0. When the PE is in WFI or WFE state, this counter does not increment.

This event is counted by AMEVCNTR0<n>, where n is 1.

`0x0008`**, INST_RETIRED, Instructions retired**

This event is defined identically to INST_RETIRED in the FEAT_PMUv3 architecture.

This event is counted by AMEVCNTR0<n>, where n is 2.

`0x4005`**, STALL_BACKEND_MEM, Memory stall cycles**

The counter counts cycles in which the PE is unable to dispatch instructions from the frontend to the backend of the PE due to a backend stall caused by a demand data miss in the last level of data or unified cache within the PE clock domain or, if Armv8.7 is implemented, a Non-cacheable data access in progress.

If Armv8.7 is not implemented, it is IMPLEMENTATION DEFINED whether the counter counts backend stall cycles when a Non-cacheable data access is in progress.

This event is counted by AMEVCNTR0<n>, where n is 3.

D16.3.2 Auxiliary event counters

Auxiliary event counters can count events defined by the Performance Monitors architecture and IMPLEMENTATION DEFINED events defined specifically for activity monitoring.

Implementations must not reuse an IMPLEMENTATION DEFINED event number for different hardware events across the Performance Monitors architecture and the Activity Monitors architecture.

Chapter D17
The Statistical Profiling Extension

This chapter describes the Statistical Profiling Extension. It contains the following sections:

- About the Statistical Profiling Extension
- Defining the sample population
- Controlling when an operation is sampled
- Enabling profiling
- Filtering sample records
- The profiling data
- The Profiling Buffer
- Profiling Buffer management
- Synchronization and Statistical Profiling

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.1 About the Statistical Profiling Extension

D_{NLVYX} When the Statistical Profiling Extension is implemented, the PE includes a *Statistical Profiling Unit* (SPU).

I_{WKZFN} When profiling is enabled and not stopped, the SPU does the following:

1. Chooses an operation from a sample population, that can be restricted by Exception level, at a programmable interval that might have some random, or pseudorandom, perturbation.
2. Takes a trace of the sampled operation. This includes the PC, events, timings, and data addresses, related to the sampled operation. This is the profiling operation.
3. If defined, filters out potential sample records generated by the profiling operation by reference to any or all of the following:
   a. The type of operation.
   b. Events.
   c. Latency.
   d. Data source, for loads.
4. Creates a record that contains the traced information. Sample records that meet the criteria of the filter are written to and stored in a memory buffer. These sample records can be processed by software when the memory buffer is full.

R_{JMMZP} After creating the record for the sampled operation, the SPU writes a record to memory sequentially in increasing address order. That is, for each byte in the record, the SPU:

1. If required, translates the current write pointer virtual address to a physical address.
2. If permitted, writes the byte of record data to the write address.
3. If profiling is not stopped, increments the current write pointer.

Profiling Buffer management events are processed as part of this loop. Implementations compliant with the architecture conform with the described behavior of the SPU.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with this specification is the same as a simple sequential model. Although records appear to be written sequentially, the architecture does not require that a record is written sequentially by the SPU.

I_{HXPSC} If FEAT_PMUv3 is implemented, then the SPU also generates PMU events:

- For each operation in the sample population.
- When an operation is chosen for sampling.
- When a sample record is created.

For more information, see PMU Event Descriptions.

D17.1.1 Non-invasive behavior

Statistical Profiling is a non-invasive debug operation:

- While profiling is enabled, the operation and performance of the processing element (PE) must not be significantly impacted between sampled operations, that is, other than for writing out sample records and processing Profiling Buffer management events.
- The performance of the sampled operation and the performance of the PE in general must not be significantly impacted. The sample records are not written to memory until after the sampled operation has finished execution. However, this does not apply if the sample records are physical addresses for data access operations. In this case, the impact is IMPLEMENTATION DEFINED.
- The profiling operation to write sample records must not be excessively impactful on the performance of the sampled operation or the performance of the PE generally.

D17.1.2 Multithreaded implementations

In a multithreaded implementation:

- Statistical Profiling is implemented per-thread.
- The sample interval counter counts only operations for the thread that is being profiled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Latency and other cycle counters count each cycle for the PE for which the thread was active and could issue an operation.

The architecture does not define features for inter-thread profiling and does not support sharing the Profiling Buffer between threads.

Note

An implementation is described as multithreaded when the lowest level of affinity consists of logical processors that are implemented using a multithreading type approach. That is, the performance of processors at the lowest affinity level is interdependent.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.2 Defining the sample population

All samples are taken from a *population of operations*. The population is dynamic rather than static. That is, if a program executes the same operation multiple times (for example, because of loops and subroutines) then that operation appears multiple times in the population.

The operations are one of the following:

- If FEAT_SPE_ArchInst is implemented, architecture instructions.
- If FEAT_SPE_ArchInst is not implemented, IMPLEMENTATION DEFINED microarchitectural operations (micro-ops).

Architecture instruction means a single instruction that is defined by the A-profile instruction set architecture in AArch64 state.

An architecture instruction might create one or more micro-ops at any point in the execution pipeline. The definition of a micro-op is IMPLEMENTATION SPECIFIC. An architecture instruction might create more than one micro-op for each instruction. A micro-op might also be removed or merged with another micro-op in the Execution stream, so an architecture instruction might create no micro-ops for an instruction. Any arbitrary translation of architecture instructions to an equivalent sequence of micro-ops is permitted.

This means that the relationship between a micro-op and an architecturally executed instruction is IMPLEMENTATION DEFINED, and an architectural instruction of one type might be sampled as a micro-op of a different type. See also Information collected for micro-ops. In some implementations, the relationship between architecture instructions and micro-ops might vary over time.

Note

Sampling from architecture instructions does not require that the instruction is architecturally executed.

D17.2.1 Operations that might be excluded from the sample population

It is IMPLEMENTATION DEFINED whether each of the following operations is part of the sample population:

- Operations on misspeculated paths.
- Operations (specifically micro-ops) that do not relate to any architecture instruction.
- Operations that generate non-architectural exceptions.

If the operation is not part of the sample population, the operation does not cause the sample interval counter to decrement, is not counted by the SAMPLE_POP event and therefore is never sampled.

If the operation is part of the sample population, the operation causes the sample interval counter to decrement, is counted by the SAMPLE_POP event, and might be sampled and counted by the SAMPLE_FEED event. However, it is IMPLEMENTATION DEFINED whether the sample record for such a sampled operation is captured in the Profiling Buffer. For more information, see Sample operation records for misspeculated and non-architectural operations and Non-architectural exceptions.

If such a sample record is not captured into the Profiling Buffer, then no packets are output and the sample is not counted by the SAMPLE_FILTRATE event.

Note

If the owning Exception level passes this data to less privileged software for processing, it can set PMSFCR_EL1.FE to 1 and PMSEVFR_EL1[1] to 1 to prevent speculative instructions from being recorded in the Profiling Buffer.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.3 Controlling when an operation is sampled

The sample interval counter, PMSICR_EL1.COUNT controls when an operation is selected for sampling. In some implementations, a secondary sample interval counter, PMSICR_EL1.ECOUNT, is also used.

The following sections describe the operation of the sample interval counters.

Details of the random or pseudorandom number generator used when PMSIRR_EL1.RND is set to 1 are IMPLEMENTATION DEFINED. See Generating random numbers for sampling.

D17.3.1 Operation sampling

A sample operation is as follows:

1. Software writes a sampling interval to PMSIRR_EL1.INTERVAL, and sets PMSICR_EL1 to zero. The interval is measured in operations.
2. The sample interval counter is decremented by hardware for each operation when profiling is enabled.
3. When the sample interval counter reaches zero, then:
   a. If random perturbation is enabled, the PE continues to count for a random number of further operations while profiling is enabled.
   b. An operation is chosen for profiling. The choice of operation around the sampling point is IMPLEMENTATION SPECIFIC, but does not introduce sampling bias.
4. The sample interval counter is reloaded and the process loops to step 2. It is IMPLEMENTATION DEFINED whether the sample interval counter is reloaded before step 3.a) or at step 3.b). That is, before or after counting the random number of further operations.
5. The chosen operation is marked as the sampled operation. The PE collects information about the sampled operation as it executes by a profiling operation.
6. The sample record is created when the sampled operation has finished execution.

D17.3.2 Generating random numbers for sampling

The random number generator is IMPLEMENTATION DEFINED. Implementations might use a pseudorandom number. The random number generator must be reset into a useable state. An implementation might include IMPLEMENTATION DEFINED registers to further configure the random number generator.

It is IMPLEMENTATION DEFINED whether the PE adds the random number to the sample interval counter prior to counting down the interval, or after the counter reaches zero and the counter has been reloaded.

D17.3.3 Initializing the sample interval counters

When the PE moves from a state where profiling is disabled to a state where profiling is enabled:

- If PMSICR_EL1 is nonzero, then sampling restarts from the current values in PMSICR_EL1.
- If PMSICR_EL1 is zero, then it is loaded with an initial value. The behavior depends on PMSIRR_EL1.RND and whether FEAT_SPE_ERnd is implemented.
  - If PMSIRR_EL1.RND is 0:
    - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
    - PMSICR_EL1.COUNT[7:0] is set to `0x00`.
  - If PMSIRR_EL1.RND is 1 and FEAT_SPE_ERnd is not implemented:
    - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
    - PMSICR_EL1.COUNT[7:0] is set to a random or pseudorandom value in the range `0x00` to `0xFF` inclusive.
  - If PMSIRR_EL1.RND is 1 and FEAT_SPE_ERnd is implemented:
    - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
    - PMSICR_EL1.COUNT[7:0] is set to `0x00`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.3.4 Behavior of the sample interval counter while profiling is enabled

While profiling is enabled, the counters control when an operation is selected for sampling. The behavior depends on PMSIRR_EL1.RND and whether FEAT_SPE_ERnd is implemented.

D17.3.4.1 If PMSIRR_EL1.RND is 0

While nonzero, the sample interval counter decrements by 1 for each member of the sample population. When the counter reaches zero:

- A member of the sampling population is selected for sampling.
- The counter is set as follows:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to `0x00`.

Note

Because the counter counts down to zero, when PMSIRR_EL1.RND is 0 the interval between operations being selected for sampling is (*INTERVAL*×256+1).

D17.3.4.2 If PMSIRR_EL1.RND is 1 and FEAT_SPE_ERnd is not implemented

While nonzero, the sample interval counter decrements by 1 for each member of the sample population. When the counter reaches zero:

- A member of the sampling population is selected for sampling.
- The counter is set as follows:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to a random or pseudorandom value in the range `0x00` to `0xFF` inclusive.

Note

When PMSIRR_EL1.RND is 1 and FEAT_SPE_ERnd is not implemented, the mean interval between operations being selected for sampling is (*INTERVAL*×256+128), if the random number generator is uniform.

D17.3.4.3 If PMSIRR_EL1.RND is 1 and FEAT_SPE_ERnd is implemented

While nonzero, the primary sample interval counter decrements by 1 for each member of the sample population. When the primary counter reaches zero:

- The primary sample interval counter is set as follows:
  - PMSICR_EL1.COUNT[31:8] is set to PMSIRR_EL1.INTERVAL.
  - PMSICR_EL1.COUNT[7:0] is set to `0x00`.
- The secondary sample interval counter, PMSICR_EL1.ECOUNT, is set to a random or pseudorandom value in the range `0x00` to `0xFF` inclusive. If this value is zero, then an operation is selected for sampling.
  Otherwise:
  - While the secondary sample interval counter is nonzero, the secondary sample interval counter decrements by 1 for each member of the sample population. The primary sample interval counter also continues to decrement because it is also nonzero.
  - When the secondary sample interval counter reaches zero, an operation is selected for sampling.

Note

When PMSIRR_EL1.RND is set to 1 and FEAT_SPE_ERnd is implemented, the mean interval between operations being selected for sampling is (*INTERVAL*×256+1), if the random number generator is uniform.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.3.5 Behavior of the sample interval counter while profiling is disabled

When profiling is disabled:

- No operations are selected for sampling.
- No sample records are collected.
- The sample interval counters retain their values and do not decrement.

D17.3.6 Where operations are sampled

The exact point in the sampled lifespan of operations at which operations are chosen for profiling is IMPLEMENTATION DEFINED.

Note

Arm recommends that the point at which operations are sampled is linked to the definition of the Performance Monitors Extension (PMU) STALL_FRONTEND and STALL_BACKEND events, so that sampling records information for STALL_BACKEND stalls.

D17.3.7 Sample collisions

R_{QWTQB} The maximum number of sampled operations that a PE can support simultaneously is IMPLEMENTATION DEFINED.

I_{QYCRM} If the maximum number of simultaneous sampled operations has been reached at the point when a new operation must be sampled, the new sample is said to have collided with a previous sampled operation.

The PE records the fact that a sampled operation has collided with another sampled operation. Software can also count the number of collisions and gauge the impact of the collisions.

I_{DBJXM} On a sample collision:

- The PMU event SAMPLE_COLLISION is generated.
- PMBSR_ELx.COLL is set to 1, where ELx is the value in the *Other event* column of Table D17-7. The other fields in PMBSR_ELx and the other PMBSR_ELy registers are unchanged.
- The new operation is not sampled.

I_{RCCQG} Sample collisions are likely to increase with shorter sampling intervals. Samples might not be representative of the overall workload if statistically significant numbers of sample collisions occur.

R_{LTMKQ} When all of the following are true, the direct read **C** of PMBSR_ELx.COLL will return 1:

- An instruction or operation **A** is selected for sampling.
- A sample collision occurs for sampled operation **A**.
  The PE sets PMBSR_ELx.COLL to 1. This is an indirect write to PMBSR_ELx.
- A Context synchronization event **B** is in program order after **A**.
- A direct read **C** of PMBSR_ELx is in program order after **B**.

ELx is the value in the *Other event* column of Table D17-7. The other fields in PMBSR_ELx and the other PMBSR_ELy registers are unchanged. For more information, see Synchronization and Statistical Profiling.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.4 Enabling profiling

R_{TWFRY} If and only if any of the following are true, then profiling is *stopped*:

- PMBSR_EL1.S is 1.
- FEAT_SPE_EXC is implemented and all of the following are true:
  - EL2 is implemented and any of the following applies:
    - The Effective value of SCR_EL3.NS is 1.
    - The Effective value of SCR_EL3.{NS, EEL2} is {0, 1}.
  - EL3 is not implemented or MDCR_EL3.PMSEE is not `0b00`.
  - PMSCR_EL2.EE is either `0b10` or `0b11`.
  - PMBSR_EL2.S is 1.
- FEAT_SPE_EXC is implemented and all of the following are true:
  - EL3 is implemented.
  - MDCR_EL3.PMSEE is either `0b10` or `0b11`.
  - PMBSR_EL3.S is 1

The pseudocode function `SPEProfilingStopped()` shows this.

R_{WXXFL} When all of the following are true, profiling is *enabled*:

- The PE is in AArch64 state.
- PMBLIMITR_EL1.E is 1. The Profiling Buffer is *enabled*.
- Profiling is not stopped.
- The PE is executing at either the Profiling Buffer owning Exception level or any lower Exception level.
- Either the Profiling Buffer owning Exception level is EL2 or the Effective value of HCR_EL2.TGE is 0.
- The PE is executing in the Profiling Buffer owning Security state.
- The PE is in Non-debug state.
- PMSCR_EL1.{E1SPE, E0SPE} and PMSCR_EL2.{E2SPE, E0HSPE} enable profiling at the current Exception level.

Otherwise, profiling is *disabled*.

The pseudocode function `StatisticalProfilingEnabled()` show this.

I_{BRTKK} When the Profiling Buffer is disabled or profiling is stopped:

- Any sample records that have been collected but not written to memory are discarded.
- PMBPTR_EL1 and PMSICR_EL1 are not updated by the SPU.

Note

The owning Security state is controlled by MDCR_EL3.{NSPBE, NSPB} and the owning Exception level is controlled by MDCR_EL2.E2PB. See The owning translation regime.

I_{SBQVZ} If the Profiling Buffer is enabled and the PE is in Non-debug state and using AArch64 state, Table D17-1 defines the valid combinations of the following that define when profiling is enabled:

- The Effective value of SCR_EL3.NSE.
- The Effective value of SCR_EL3.NS.
- The Effective value of SCR_EL3.EEL2.
- The Effective value of MDCR_EL3.NSPBE.
- The Effective value of MDCR_EL3.NSPB.
- The Effective value of MDCR_EL2.E2PB.
- The Effective value of HCR_EL2.TGE.

In Table D17-1:

D	Disabled.
E2SPE	Enabled if PMSCR_EL2.E2SPE == 1, disabled otherwise.
E1SPE	Enabled if PMSCR_EL1.E1SPE == 1, disabled otherwise.
E0HSPE	Enabled if PMSCR_EL2.E0HSPE == 1, disabled otherwise.
E0SPE	Enabled if PMSCR_EL1.E0SPE == 1, disabled otherwise.

D17.5 Filtering sample records

After the sampled operation has finished execution, the Statistical Profiling Unit might discard the sample records generated by the profiling operation.

PMSFCR_EL1 controls filtering of sample records, as described in the following sections. If multiple filters are enabled, a packet is discarded if it is discarded by any of the enabled filters. These controls combine together as a logical AND.

Example D17-1 Collection of sampled operations

If PMSFCR_EL1.FE is 1, PMSFCR_EL1.FnE is 0, PMSFCR_EL1.FT is 1, and PMSFCR_EL1.FL is 1, then only sampled operations that meet all of the following criteria are recorded and written to the Profiling Buffer:

- The sampled operation is one of the selected operation types.
- The operation has all of the events in the filter set.
- The total latency is equal to or greater than the minimum latency.

This is described in the pseudocode function `SPECollectRecord()`.

D17.5.1 Filtering by operation type

I_{BWNKX} PMSFCR_EL1.FT enables filtering by operation type. When enabled PMSFCR_EL1.{ST, LD, B, FP, SIMD, STm, LDm, Bm, FPm, SIMDm} define the collected types.

I_{ZZTZL} When FEAT_SPE_EFT is implemented, the following values are defined:

- PMSFCR_EL1.{SIMD, FP, ST, LD, B} are the operation type filter controls, `ctrl`.
- PMSFCR_EL1.{SIMDm, FPm, STm, LDm, Bm} are the operation type filter mask, `mask`.
- `flags` is a five bit value {SIMD, FP, B, LD, ST} that defines the type of the sampled operation.

R_{NYZKJ} When FEAT_SPE_EFT is not implemented:

- PMSFCR_EL1.{ST, LD, B} are the operation type filter controls, `ctrl`.
- The operation type filter mask, `mask`, is zero.
- `flags` is a three bit value {ST, LD, B} that defines the type of the sampled operation.

Filtering by SIMD&FP types is not supported.

D_{DSNMB} The operation types are defined as follows:

ST Means a sampled store operation, including all atomic operations. That is, an operation counted by ST_SPEC.

LD Means a sampled load operation, including atomic operations that return a value to a register. That is, an operation counted by LD_SPEC.

B Means a sampled branch operation, including direct and indirect branches and exception returns. That is, an operation counted by PC_WRITE_SPEC, including branches which are not taken, but excluding `BRK`, `SVC`, `HVC`, `SMC`, and UNDEFINED instructions which generate exceptions. It is IMPLEMENTATION DEFINED whether `ISB` is sampled as a branch operation.

FP Means a sampled floating-point operations including all of the following:

- Floating-point data-processing operations, including scalar, Advanced SIMD, SVE, and SME floating-point data-processing operations. That is, operations counted by FP_SPEC.
- Scalar load/store of a SIMD&FP register or pair of SIMD&FP registers, excluding loads/stores of Q registers, load and replicate, and structure loads/stores.

Only supported when FEAT_SPE_EFT is implemented.

SIMD Means a sampled SIMD operation, including all of the following:

- Advanced SIMD, SVE, or SME SIMD data-processing operations.
- Structure load/store of one or more SIMD&FP registers.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Load and replicate to one or more SIMD&FP registers.
- Scalar load/store of a SIMD&FP Q register or pair of Q registers.
- SVE or SME load/store.

That is, an operation counted by SIMD_INST_SPEC.

Only supported when FEAT_SPE_EFT is implemented.

I_{ZWMZT} An operation might be more than one type, in which case the `flags` field has all applicable bits set. For example:

- A scalar load of a single SIMD&FP register has both the `FP` and `LD` bits set.
- An Atomic operation that returns a value to the PE has both the `LD` and `ST` bits set.

R_{YGCFK} When FEAT_SPE_EFT is implemented and PMSFCR_EL1.FT is 1, all of the following apply:

- The sampled operation is discarded if the following is true:

```
(!IsZero(ctrl AND NOT mask) && IsZero(flags AND (ctrl AND NOT mask)))
```

  That is, the SPU applies a Boolean-OR filter based on each of the operation type filter controls where the corresponding operation type filter mask bit is 0:
  - If all the operation type filter mask bits are 1, then no operations are discarded by this part of the filter.
  - Otherwise, for the operation type bits for which corresponding mask bit is 0:
    - If all these bits are 0, then no operations are discarded by this part of the filter.
    - Otherwise, operations that match any of these bits are selected, and other operations are discarded.
- The sampled operation is discarded if the following is true:

```
(flags AND mask) != (ctrl AND mask)
```

  That is, the SPU applies a Boolean-AND filter based on the remaining operation type filter controls where the corresponding operation type filter mask bit is 1:
  - If all the operation type filter mask bits are 0, no operations are discarded by this part of the filter.
  - Otherwise, only operations that exactly match all of these bits are selected, and other operations are discarded.

R_{LVCZH} When FEAT_SPE_EFT is not implemented, if PMSFCR_EL1.FT is 1 and the following expression is true, then the sampled operation is discarded:

```
IsZero(flags AND ctrl)
```

That is, only operations that match any of the types selected in the operations type filter controls are selected, and other operation types are discarded.

I_{XNXRN} When micro-op sampling is implemented, filtering is based on the micro-op type. See Defining the sample population.

D17.5.2 Filtering by the contents of the Events packet

PMSFCR_EL1.FE enables filtering by events, Streaming mode, and Transactional mode bits that are defined by PMSEVFR_EL1. When PMSFCR_EL1.FE is 1, only sampled operations with all the events in the filter set to 1 are recorded and written to the Profiling Buffer.

If FEAT_SPE_FnE is implemented, PMSFCR_EL1.FnE enables filtering by events, Streaming mode, and Transactional mode bits that are defined by PMSNEVFR_EL1. When PMSFCR_EL1.FnE is 1, only sampled operations with all the events in the filter set to 0 are recorded and written to the Profiling Buffer.

D17.5.3 Filtering by latency

PMSFCR_EL1.FL enables filtering by total latency. PMSLATFR_EL1.MINLAT defines the minimum latency. When PMSFCR_EL1.FL is 1, only sampled operations with a total latency greater than or equal to the minimum latency are recorded and written to the Profiling Buffer.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.5.4 Filtering by data source

If FEAT_SPE_FDS is implemented, PMSFCR_EL1.FDS enables filtering by a data source mask defined by PMSDSFR_EL1. When PMSFCR_EL1.FDS is 1, sampled load operations with a Data Source packet value `DS` are recorded only if PMSDSFR_EL1[UInt(DS[5:0])] is 1. Load operations without a Data Source and other sampled operations are not affected by PMSFCR_EL1.FDS and PMSDSFR_EL1.

D17.5.5 Discard mode

When Discard mode is implemented and enabled, all sampled operations to be discarded and not written to the Profiling Buffer. Discard mode is enabled when PMBLIMITR_EL1.FM is `0b10`, and has all of the following effects:

- All profiling data is discarded after filtering.
- The PMBLIMITR_EL1.LIMIT and PMBPTR_EL1 fields are ignored. PMBPTR_EL1 does not increment for each sampled operation.
- The restrictions on setting PMBLIMITR_EL1.LIMIT and PMBPTR_EL1 do not apply, see Restrictions on the current write pointer.
- Buffer management events are not generated.

Discard mode is implemented when FEAT_SPEv1p2 is implemented.

Other profiling behaviors are unchanged, including:

- The discarding of profiling data occurs after SAMPLE_FILTRATE and other PMU events are counted.
- Sample collisions will still set PMBSR_ELx.COLL to 1. See Sample collisions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.6 The profiling data

Unless otherwise stated, all sample records that are generated by a profiling operation contain:

- A timestamp, if enabled. This is one of:
  - Physical time.
  - Offset physical time.
  - Virtual time.

  It is IMPLEMENTATION DEFINED how this timestamp relates to the sampled operation. It might be the time when the sampled operation was taken or any later time during the lifetime of the sampled operation, that is, up to the time when the sampled operation finishes execution.

  If the Generic Timer system counter is disabled and timestamps are enabled, then it is IMPLEMENTATION DEFINED whether:
  - The SPU behaves as if timestamps are disabled.
  - The timestamp that is collected in the sample record is UNKNOWN.

  Note

  This behavior describes when CNTCR.EN is 0, the Generic Timer system counter is disabled. This behavior does not apply when the Generic Timer system counter is enabled but not accessible at the current Exception level.

- The context, if enabled, which is one or more of:
  - CONTEXTIDR_EL1.
  - CONTEXTIDR_EL2.
  - The Exception level.
  - The Security state.
- Information about whether the sampled operation generated an exception:
  - The target address for an exception generating operation is not collected.
- Information about whether the sampled operation was Architecturally executed.

If the sampled operation is Architecturally executed and does not generate an exception, the sample record also contains:

- The PC virtual address for the sampled operation.
- Information about whether the sampled operation is a branch, a load, a load atomic, a store, or other.
- Information about whether the sampled operation is conditional, conditional select, or not.
- The total latency, a cycle count from the start of the sampled operation up to the point where the operation has finished execution and is no longer capable of stalling any instruction that consumes its output.
- The issue latency, a count of cycles when the operation is waiting to be issued. A sampled operation might be delayed, for example, because the input operands were not available.

If the sampled operation is not Architecturally executed or generates an exception, it is UNPREDICTABLE whether the record contains all or any of this information and the other information about the operation listed in this section and the following subsections. For information on exceptions being taken in sampled operations, see Exceptions.

The architecture defines a set of additional data that is collected in the sample record for each sampled operation. This is described in the following subsections, and comprises:

- Events, which are required to be implemented consistently with PMU Events. For more information, see Statistical Profiling Extension Sample Record Specification and The Performance Monitors Extension.
- Cycle counters. Cycle count values as described in this architecture, which, for a particular implementation, are fixed with an IMPLEMENTATION DEFINED value, might be omitted from the sample record.
- Addresses.

In addition, the architecture permits IMPLEMENTATION DEFINED events, counters, and addresses to be collected.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.6.1 Asynchronous operation

IPXWXV If an operation executes asynchronously to the main PE, such that the cycles are not main CPU cycles, then the PE might count the cycles recorded in a Counter packet in one of the following ways:

- The Counter packet counts elapsed cycles in the main CPU clock domain. For example, the asynchronous execution unit signals start and stop events to the CPU clock domain and the cycles are counted in the CPU clock domain.
- When FEAT_SPE_SME is implemented, for operations executed in Streaming SVE mode, the Counter packet counts elapsed cycles in the SMCU clock domain. Counter packet.INDEX and PMSIDR_EL1.ALTCLK indicate that the Streaming Mode Compute Unit clock value is recorded.
  This option is not supported for the Total latency Counter packet.
- The Counter packet counts elapsed cycles in a clock domain other than an architecturally defined clock domain. Counter packet.INDEX indicates an IMPLEMENTATION DEFINED counter value.
  This option is not supported for the Total latency Counter packet.

For example, an operation is executed by a separate Streaming Mode Compute Unit.

D17.6.2 Information collected for micro-ops

Because architectural instructions might create zero, one, or more micro-ops, micro-ops might have different characteristics from the architectural instructions they are created from. The data collected for each micro-op is IMPLEMENTATION DEFINED. The PE collects the subset of data appropriate to the micro-op.

However, in order for the profile information to be meaningful to the user of the profile, Arm recommends that the sampled micro-op is recorded as a type appropriate to the instruction when the recorded properties of the micro-op correlate with the properties of the instruction.

Example D17-2 Sampling of micro-ops

If an architectural load instruction is split into an address generation micro-op and a load micro-op, then when generating the sample record and filtering based on operation type:

- If the address generation micro-op is sampled, the sampled operation is treated as *other*.
- If the load micro-op is sampled, the sampled operation is treated as a load.

D17.6.3 Additional information for each profiled branch or exception return

For an Architecturally executed sampled branch or exception return operation, the profiling operation records:

- The sampled operation type as an unconditional branch or a conditional branch. Sampled exception returns are treated as unconditional branches by the Statistical Profiling Extension.
- If the branch is taken, the target virtual address of the branch. The target virtual address includes the Exception level and Security state of the target. If the sampled operation is an illegal exception return, it is CONSTRAINED UNPREDICTABLE whether the context information recorded in the target virtual address is the actual target context, or the target context that is described by the SPSR.
- If the PE implements branch prediction, whether the branch was correctly predicted or mispredicted.
- Whether the branch was taken or not taken.
- Whether the branch was direct or indirect.
- If the branch is not taken, a target virtual address might be recorded. Software must treat this value if present as UNKNOWN.
- If FEAT_SPE_PBT is implemented, the target address of the most recently executed branch that was taken and retired in program order before the sampled operation.
- If FEAT_SPE_CRR is implemented, whether the branch was a branch with link, a procedure return, or neither of these.

If an operation executes both a Branch and a Guarded Control Stack data access, then all of the following apply:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Operation Type packet for the operation is Branch.
- The information for both the branch and the load or store is collected.
- The operation is treated as both a branch and a load or store for the purposes of filtering. See Filtering sample records.

A sampled operation that generates an exception is not treated as a branch.

It is IMPLEMENTATION DEFINED whether an ISB instruction is treated as a branch to the next instruction.

D17.6.3.1 Previous branch target

FEAT_SPE_PBT adds the capability to record a packet for each event that provides the target address of the previous taken branch. PMSIDR_EL1.PBT describes whether this feature is implemented.

When implemented, the profiling operation records the target address of the most recent branch that was taken and retired in program order before the sampled operation.

It is IMPLEMENTATION DEFINED whether or not the profiling operation records the target address of the most recently taken branch instruction in the following cases:

- The sampled operation is not a sampled retired taken branch operation.
- The most recently taken branch instruction was a Context synchronization operation, exception-generating instruction, or exception return.
- No branch instruction has been retired, prior to the sampled operation, since the most recent Context synchronization operation or taken exception.
- No branch instruction has been retired recently, prior to the sampled operation. The definition of *recently* is IMPLEMENTATION SPECIFIC, but should be such that this does not apply for most compiled code.

The profiling operation does not record the target address of the most recently taken branch instruction in the following cases:

- The most recently taken branch instruction was executed when profiling was disabled or prohibited.
- Either the most recently taken branch instruction or the sampled operation is still speculative.

D17.6.4 Additional information for each profiled memory access operation

For an Architecturally executed sampled load, store, or atomic operation that does not generate an exception, the profiling operation records:

- The data virtual and, if enabled, physical addresses being accessed.
  - If the applicable Top Byte Ignore (TBI) bit is set to one, the virtual address includes any top-byte tag.
  - The physical address is the address the PE accesses in the physical address space, and so includes the Secure address space identifier.
- The sampled operation type, which includes:
  - Whether the sampled operation is a load, store, or atomic.
  - When FEAT_SPEv1p3 and FEAT_MTE are implemented, whether the sampled operation is a Tag load or store.
  - When FEAT_NV2 is implemented, whether the sampled operation is a System register access transformed into a memory access.
  - When FEAT_SPEv1p3 and FEAT_MOPS are implemented, whether the sampled operation is a Memory Copy or Memory Set load or store.
  - Whether the sampled operation is Load-Exclusive, Store-Exclusive or Load-acquire, Store-release.
  - Whether the sampled operation accesses the general-purpose or SIMD&FP registers.
- The translation latency. The count of cycles when at least one part of the operation is waiting for the MMU to complete an address translation. It is IMPLEMENTATION DEFINED whether a cycle is counted if a part of the operation is accessing memory, having completed an address translation for that part of the operation. For more information, see Additional information for each profiled memory access operation.
- Whether the sampled operation accessed the Level 1 data cache and the result.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Whether the sampled operation accessed the data TLB and the result.
- An optional record of whether the sampled operation accessed Last Level data cache and the result.
- An optional record of whether the sampled operation accessed *another socket* in a multi-socket system.
- An optional, IMPLEMENTATION DEFINED, indicator of the data source for a load. If the sampled operation makes multiple accesses, it is IMPLEMENTATION DEFINED whether this indicator combines information for all parts of the load or applies only for a chosen part of the load.
- If FEAT_SPEv1p1 is implemented, an optional indication that the sampled memory operation is non-optimal for the access size. For more information, see Data Alignment Flag.
- If FEAT_SPEv1p2 is implemented, all of the following:
  - An optional record of whether the sampled operation accessed the Level 2 data cache, and the result.
  - An optional record of whether the sampled operation accessed the modified data in a cache, and whether the sampled operation accessed a recently fetched cache line.
  - An optional record of whether the sampled operation snooped data from a cache outside of the cache hierarchy of this PE.
- If FEAT_GCS is implemented, whether the operation includes a Guarded Control Stack data access.

For each of the cache and another socket indicators, it is IMPLEMENTATION DEFINED and might be UNPREDICTABLE whether this information is present for store accesses.

For more information, see Events packet.

Note

A store might be marked as not accessing a cache or another socket because it microarchitecturally finished before doing so. For example, the write was placed into a write buffer. This behavior is IMPLEMENTATION DEFINED and might change from time to time, and such events must be interpreted with care.

It is IMPLEMENTATION DEFINED whether a sampled `DC ZVA`, `DC GVA`, `DC GZVA` operation is recorded as a store operation targeting unspecified registers or a cache maintenance operation. The behavior if the sampled operation is recorded as a data cache maintenance operation is described in Additional information for other operations. Arm recommends that these operations are recorded as store operations.

If the sampled load, store, or atomic operation performs multiple accesses, it is IMPLEMENTATION DEFINED whether the implementation chooses to profile all or a chosen part of the access.

If the implementation profiles part of the access:

- It is IMPLEMENTATION DEFINED how the PE chooses the part of the access, while avoiding introducing systematic bias.

  Note

  For an example of inadvertent systematic bias, consider an implementation where a multiple-register load operation is split into multiple accesses. If the PE systematically chooses the first operation at the lower address for sampling translation latency and data source indicator, and the operation is executed in a loop with an incrementing address, then the first access has better spatial locality with preceding accesses than later accesses and is more likely to both:

  - Hit in the TLB, giving a shorter translation latency.
  - Return data from the Level 1 data cache.

  In this case, or if the PE systematically chooses the last access at the higher address, then sampling would be biased.

- If the accesses are architecturally contiguous, it is further IMPLEMENTATION DEFINED whether the recorded data virtual address is the lowest virtual address that is accessed by the sampled operation or applies to the chosen part of the access.
- If the accesses are not architecturally contiguous, the recorded data virtual address applies for the chosen part of the access.
- It is IMPLEMENTATION DEFINED whether the events and total operation latency apply to the whole operation or the chosen part of the operation.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The translation latency applies to the chosen part of the operation, and is the count of cycles for which the chosen part of the operation is waiting for the MMU to complete an address translation.

Arm recommends that if the implementation chooses to profile a chosen part of the access, then the recorded addresses, events, and total operation latency apply to the chosen access. That is, the PE behaves as if the chosen part of the access is the sampled operation.

If the sampled load, store, or atomic operation performs a single access, or the implementation chooses to profile all parts of a multiple access:

- If the accesses are architecturally contiguous, the recorded data virtual addresses is the lowest virtual address that is accessed by the sampled operation.
- If the accesses are not architecturally contiguous, the recorded data virtual addresses apply for the chosen part of the access.
- The events and total operation latency apply to the whole operation. For example, when recording whether the sampled operation accessed the Level 1 data cache, the PE records whether any part of the access accessed the Level 1 data cache, and the result, and the total operation latency applies from the issue of the operation to the completion of all parts of the operation.
- The translation latency is an IMPLEMENTATION DEFINED choice between:
  - The count of cycles for which at least one part of the operation is waiting for the MMU to complete an address translation, and no part of the operation is accessing memory.
  - The count of cycles for which at least one part of the operation is waiting for the MMU to complete an address translation.

The sampled data physical address packet is not output if any of the following are true:

- The sampled operation operates on a virtual address and any of the following are true:
  - The PE does not translate the address, for example because it does not perform the access.
  - The sampled data virtual address packet is not output.
- Sampling of physical addresses is prohibited by System register controls.

If `AArch64_ExclusiveMonitorsPass()` or `AArch32_ExclusiveMonitorsPass()` returns FALSE for a Store-Exclusive instruction, it is IMPLEMENTATION DEFINED whether or not the physical address packet is output when permitted by the above rules.

If a sampled virtual address packet is not output, or the PE does not perform the access, then all of the following apply:

- It is IMPLEMENTATION DEFINED whether the Translation latency Counter packet for the access is either not recorded, or recorded with a value of zero. If the access does not occur and the address is not translated, the packet is not recorded.
- It is IMPLEMENTATION DEFINED whether the bits corresponding to the access in the Events packet are recorded or always zero. If the access does not occur, these bits are zero.

D17.6.4.1 Additional effects when FEAT_MTE is implemented

If profiling is enabled, each Allocation Tag covers multiple locations in a Tag Granule. It is IMPLEMENTATION DEFINED whether the implementation treats each Allocation Tag access as an access to the data location addressed in the operation, or the whole Tag Granule. That is, whether the data virtual address associated with the sampled access or chosen part of the access is the address of the location being accessed, or the lowest address covered by the same Allocation Tag or Allocation Tags.

An instruction that loads or stores an Allocation Tag is treated as a load or store for the purpose of Statistical Profiling.

When a sampled data access virtual address is from a context using Memory Tagging with Address tagging disabled, the TAG byte in the Address packet payload holds bits[63:56] of the address.

If the operation is an access to an Allocation Tag or multiple Allocation Tags, the sampled data physical address has two possibilities:

- The address generated from translating the sampled data virtual address.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The address generated from translating the lowest address covered by the same Allocation Tag or Allocation Tags.

If the two possibilities have different values, it is IMPLEMENTATION DEFINED which one is used as the sampled data physical address. Otherwise, the sampled data physical address is the address generated from translating the sampled data virtual address.

If FEAT_SPEv1p3 is implemented, instructions that load or store Allocation Tags are sampled using a dedicated Operation Type packet subclass, (Tags load/store). See Operation Type packet payload (Load/store, general).

Note

Operations that store both Tags and data are recorded as store operations targeting the general-purpose registers or targeting an unspecified registers subclass.

For more information, see The Memory Tagging Extension.

D17.6.4.2 Additional effects when FEAT_NV2 is implemented

When the sampled operation is a System register access transformed into a memory access by the mechanism described in Enhanced support for nested virtualization, the operation is recorded as an `MRS` or `MSR` operation at EL1 transformed into a load/store. If Statistical Profiling is disabled at EL2, the virtual address for the memory access is not recorded.

D17.6.4.3 Additional effects when FEAT_MOPS is implemented

Memory Copy and Memory Set instructions are sampled as retired if they have started processing. This is true even if the execution is not completed at the time of sampling, for example, due to an interrupt.

Memory Copy operations `CPY` and `CPYF` are sampled using Operation Type packet subclass (Memory Copy load/store), and Memory Set operations `SET` and `SETG` are sampled using Operation Type packet subclass (Memory Set load/store).

If a sampled Memory Copy operation performs both a load and a store, then the following are true:

- The sampled data virtual address is:
  - The corresponding one of load and store addresses if the filter controls are set to sample only one of load and store operations, respectively.
  - An unbiased sampling of one of load and store addresses if the filter controls are set to sample both load and store operations.
- The value of the LDST bit in the Operation Type packet is 0 if the source address is sampled, and 1 if the destination address is sampled.

D17.6.4.4 Additional effects when FEAT_LS64, FEAT_LS64_V, and FEAT_LS64_ACCDATA are implemented

FEAT_LS64, FEAT_LS64_V, and FEAT_LS64_ACCDATA add the `LD64B`, `ST64B`, `ST64BV`, and `ST64BV0` instructions. For SPE:

- `LD64B` is treated as a load.
- `ST64B`, `ST64BV`, and `ST64BV0` are treated as stores. `ST64BV` and `ST64BV0` are store with status result instructions and might have performance properties similar to a Device memory load. Sampled `ST64BV` and `ST64BV0` instructions might have the following additional behaviors normally associated with sampled loads:
  - A Data Source packet is generated. This is optional for these instructions. For example, if the Data Source packet can only describe Normal memory sources, then they are not relevant for these instructions.
  - The total latency counter for the sampled operation preferably includes cycles to the point where the return value is returned to the PE.

Note

These behaviors are optional. The information in these packets might not be available or relevant for all implementations.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.6.4.5 Additional effects when FEAT_GCS is implemented

If a sampled operation from `GCSSS2` instruction performs both a load and a store, then the following is true:

- The sampled data virtual address is:
  - The corresponding one of load and store addresses if the filter controls are set to sample only one of load and store operations, respectively.
  - An unbiased sampling of one of load and store addresses if the filter controls are set to sample both load and store operations.
- The value of the LDST bit in the Operation Type packet payload depends on the address sampled:
  - If the source address is sampled, the value is 0.
  - If the destination address is sampled, the value is 1.

For an operation executing both a Branch and the Guarded Control Stack data access, if one of the branch and load or store is filtered out, the sampled operation will continue to record the information for both operations. For example, the Total latency packet or Issue latency packet includes the latencies of both the branch and the load or store operations.

D17.6.4.6 Data Alignment Flag

If FEAT_SPEv1p1 is implemented Events packet.E[11] is set to 1 for a sampled memory operation if the address alignment is non-optimal for the access size.

Address alignment is defined as *non-optimal* if that access incurs an additional performance penalty only because of the address alignment, and is unrelated to whether the access is architecturally misaligned for the access size.

Example D17-3 Data Alignment Flag operation

- A 32-bit word access that is not word aligned is architecturally misaligned, but (if Alignment faults are disabled) might not incur an additional penalty because of this alignment unless the word also happens to span a cache-line boundary.
- A contiguous load operation that loads a vector that is the length of two cache lines is optimally aligned if it has cache-line alignment, even though the operation makes two cache line accesses.
- A non-contiguous SVE load operation that makes a sequence of access is optimal only if all of the access are optimal.

The definition of non-optimal is IMPLEMENTATION DEFINED and support for the Alignment Flag is OPTIONAL.

D17.6.5 Additional information for each profiled conditional instruction

For an Architecturally executed sampled conditional operation that finishes execution, the profiling operation records:

- That the sampled operation was conditional.
- Whether the condition passed or failed.

Only operations where the conditionality is controlled by PSTATE.{N, Z, C, V} are treated as conditional operations. Predicated SVE and SME operations are not treated as conditional operations, because the conditionality of the operation is controlled by a predicate

For each of the following operations, it is IMPLEMENTATION DEFINED whether it is treated as a conditional operation:

- Conditional select, both integer and floating-point.
- Conditional select increment.
- Conditional select negation.
- Conditional select inversion.
- Conditional compare, both integer and floating-point.
- Conditional compare negative.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Arm recommends that all operations where the conditionality is controlled by PSTATE.{N, Z, C, V} are treated as conditional operations.

Micro-ops might have different characteristics from the architectural instructions they are created from. See Information collected for micro-ops for more information.

Note

If the implementation samples architectural instructions, for some alias instructions, the alias specifies the opposite condition to the machine instruction that they alias. For example, CSET and CSETM. The event as captured by SPE always captures the result of the machine instruction, not the alias.

For conditional branches, see Additional information for each profiled branch or exception return.

D17.6.6 Additional information for each profiled SVE and SME operation

ICKWPL When FEAT_SPEv1p1 is implemented, SVE and SME operations are sampled as described in this section.

DWRNLK This section uses the following terms:

Maximum implemented SVE vector length

- The *Maximum implemented Streaming SVE vector length* means the implemented width of the SVE scalable vector registers in Streaming SVE mode.
- The *Maximum implemented Non-streaming SVE vector length* means the implemented width of the SVE scalable vector registers in Non-streaming SVE mode.

See Maximum implemented SVE vector lengths.

Effective SVE vector length (VL)

Means the current SVE vector length, `SVL` or `NSVL`:

- The *Effective Streaming SVE vector length (SVL)* is less than or equal to the Maximum implemented Streaming SVE vector length.
- The *Effective Non-streaming SVE vector length (NSVL)* is less than or equal to the Maximum implemented Non-streaming SVE vector length.

See Configurable SVE vector lengths.

Effective tile size

Means the tile size of the current instruction, determined by `SVL` and the element size used by the instruction. The Effective tile size is less than or equal to the square of the Maximum implemented Streaming SVE vector length, divided by the element size.

Sampled SVE SIMD operation

Means a sampled operation that reads from or writes to the SVE vector or predicate registers but not the SME ZA storage, and that is not a non-SIMD SVE instruction or operation. This includes instructions with scalar inputs or outputs. Non-SIMD SVE instructions are defined by Definition of terms. For example, the following instructions are in this category:

- `ADD Z0.S, P7/M, Z0.S, Z1.S.`
- `FMLALB Z2.S, Z3.H, Z4.H.`
- `TBL Z5.H, { Z6.H }, Z7.H.`
- `LASTA W0, P6, Z8.S.`
- `LUTI4 {Z8.H-Z9.H}, ZT0, Z10[2].`
- `FMAX {Z0.H-Z1.H}, {Z2.H-Z3.H}, {Z4.H-Z5.H}.`

Sampled SME vector SIMD operation

Means a sampled operation reading from or writing to SME ZA array vectors or tile slices, which is not reading from or writing to a 2D ZA tile. For example, the following instructions are in this category:

- `ADD ZA.S[W8, 3, VGx2], {Z0.S-Z1.S}, {Z2.S-Z3.S}.`
- `FMLAL ZA.S[W9, 4:5, VGx4], {Z4.H-Z7.H}, {Z8.H-Z11.H}.`
- `MOVA Z11.S, P3/M, ZA0H.S[W12,1].`
- `LD1W {ZA1V.S[W13,0]}, P4/Z, [X1,X2,LSL 2].`

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Sampled SME tile SIMD operation

Means a sampled operation reading from or writing to a 2D ZA tile or multiple ZA tiles. For example, the following instructions are in this category:

- `SMOPA ZA0.S, P0/M, P1/M, Z2.B, Z3.B`.
- `ZERO {ZA1.H}`.

Sampled effective vector length

Means the length in bits of the vector or vectors operated on by a Sampled SVE SIMD operation or a Sampled SME vector SIMD operation. That is, the number of elements in the vector multiplied by the element size.

In cases where the Sampled effective vector length for the input operands of the sampled operation and the Sampled effective vector length for the output operand of the sampled operation differ, the Sampled effective vector length of the output operand is used.

For a Sampled SVE SIMD operation or a Sampled SME vector SIMD operation which reads or writes only SVE predicate registers, the Sampled effective vector length is:

- The length in bits of the predicate operated on multiplied by 8, when predicate-as-mask encoding is used.
- The VL, when predicate-as-counter encoding is used.

Sampled effective tile size

Means the size in bits of the ZA tile or tiles operated on by a Sampled SME tile SIMD operation. That is, the number of elements in the ZA tile or tiles multiplied by the element size.

Sampled predicated operation

Means a Sampled SVE SIMD operation, Sampled SME vector SIMD operation, or Sampled SME tile SIMD operation that is one of:

- An operation that writes to one or more SVE scalable vector registers or ZA tile slices under a Governing predicate or predicates using either zeroing or merging predication.
- A predicated store of a one or more SVE scalable vector registers or ZA tile slices.

For an implementation that samples micro-operations, an SVE or SME instruction might be split up into one or more micro-operations, some of which are predicated and some of which are not predicated.

Note

Sampled predicated operation excludes operations that do not write a vector register, or do so but not using zeroing or merging predication, and applies to machine instructions rather than aliases. For example, the following instructions are not predicated SVE instructions under this definition:

- `CNTP`, `LASTA`, and `PTRUE` do not write to vector registers.
- `FADDV` and `SMAXV` write scalar values to SIMD&FP registers.
- `COMPACT` and `SEL` (vectors) write to vector registers, and have a predicate operand, but do not use that predicate as a Governing predicate for zeroing or merging predication.
- `MOV` (vector, predicated) appears to be a predicated SVE instruction because it specifies merging predication through the `<PG>/M` operand, but it is actually an alias for the `SEL` (vectors) instruction. However, `MOV` (scalar, predicated) is an alias for the predicated SVE instruction, `CPY` (scalar).

IXYGNN

In some implementations, a SIMD instruction might be split into one or more micro-operations, each operating on only a part of the vector or tile specified by the instruction. When such an operation is sampled by the Statistical Profiling Unit (SPU), the Sampled effective vector length or Sampled effective tile size might be smaller than the Effective vector length or Effective tile size specified by `SVL` or `NSVL`.

Furthermore, some instructions might not affect the whole vector or tile specified by the instruction. For example, a predicated operation or an instruction such as `ZERO` (tiles) that specifies a mask in the instruction. This might affect how an individual micro-operation functions, and, for an implementation that samples operations, how the micro-operation is described by the SPU when sampled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D17-4 Vector length

To support a vector length of 1024 bits, an implementation might split all instructions into four micro-operations on 256-bit vector paths. The implementation must, however, implement 1024-bit wide vector registers.

This behavior might vary based on operation type. For example, an implementation that has a full-width data-path for most operations might choose to break certain complex operations, such as non-contiguous load or stores, into shorter vectors.

Example D17-5 Effective SVE vector length less-than the Maximum implemented

To support an Effective SVE vector length less-than the Maximum implemented SVE vector length, an implementation might choose to execute all operations at the Maximum implemented SVE vector length and discard the results above the Effective SVE vector length. Discarded results, arising from difference between Maximum implemented SVE vector length and Effective vector length, do not form part of the sampled operation and the Sampled effective SVE vector length does not include any discarded portions of the vector.

Results discarded because of predication are part of the sampled operation.

I_{DDCQB}

If an implementation samples micro-operations, then, because any arbitrary translation of architecture instructions to an equivalent sequence of micro-ops is permitted, it is IMPLEMENTATION SPECIFIC, and might vary between operation types, whether an operation due to a SIMD SVE, SME, or Advanced SIMD instruction is treated as an equivalent Sampled SVE SIMD data-processing operation, a Sampled SME vector SIMD operation, a sampled Advanced SIMD operation, or a sampled scalar operation. This includes SIMD load and store operations.

For example, when all of the following are true, a sampled micro-op generated by a SIMD SVE instruction might be recorded as a sampled Advanced SIMD operation:

- The Sampled effective vector length is 128 bits.
- The operation is unpredicated, and does not have a predicate register as an input or output.
- The operation has an equivalent Advanced SIMD operation.

This might be because the properties of the instruction are not preserved in the micro-ops after the instruction has been decoded, and so the PE cannot determine the classification of the original instruction at the point where an operation is sampled.

Arm recommends that a SIMD micro-op is sampled as a type appropriate for the SIMD instruction which generated the micro-op. See also Information collected for micro-ops.

R_{LMHHC}

The division of instructions into micro-operations must be fixed prior to sampling to guarantee consistently accurate statistical sampling.

R_{MDBYZ}

A Sampled SVE SIMD data-processing operation generates a Data processing, SVE vector format Operation Type packet, and:

- If FEAT_SPE_SME is implemented, then the Operation Type packet.EVL field records the upper bound of the Sampled effective vector length multiplied by the number of vectors operated on by the sampled operation. If the result is greater than 2048 bits, then the Operation Type packet.EVL field is set to `0b111`.
- If FEAT_SPE_SME is not implemented, then the Operation Type packet.EVL field records the upper bound of the Sampled effective vector length.

If FEAT_SPE_SME is not implemented, then it is IMPLEMENTATION DEFINED whether any of the following Sampled SVE SIMD data-processing operations generate an Other or a Data processing, SVE vector format Operation Type packet:

- A data-processing operation which involves the ZT registers.
- A data-processing operation with a multi-vector operand which accesses only SVE scalable vector registers.

R_{MZJMH}

If FEAT_SPE_SME is implemented, then a Sampled SME tile SIMD operation generates a Data processing, SME array format Operation Type packet, and:

- If the operation operates on the whole ZA array at once, then the Operation Type packet.ETS field is set to `0b1111`.
- Otherwise, the Operation Type packet.ETS field records an upper bound of the Sampled effective tile size for the sampled operation.

If FEAT_SPE_SME is not implemented, then a Sampled SME tile SIMD operation generates an Other format Operation Type packet.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The Data processing, SME array format does not record whether the Sampled SME tile SIMD operation was predicated, or not.

R_{CYBGV} If FEAT_SPE_SME is implemented, then a Sampled SME vector data-processing operation generates a Data processing, SME array format Operation Type packet, and the Operation Type packet.ETS field records an upper bound of the Sampled effective vector length multiplied by the number of vectors operated on by the sampled operation.

If FEAT_SPE_SME is not implemented, then a Sampled SME vector data-processing operation generates an Other format Operation Type packet.

Note

The Data processing, SME array format does not record whether the Sampled SME vector data-processing operation was predicated, or not.

R_{LQXZR} A Sampled SVE vector load/store operation generates a Load/store, SVE or SME format Operation Type packet.

R_{MJQCL} If FEAT_SPE_SME is implemented, then a Sampled SME vector load/store operation generates a Load/store, SVE or SME format Operation Type packet.

If FEAT_SPE_SME is not implemented, then it is IMPLEMENTATION DEFINED whether a Sampled SME vector load/store operation generates a Load/store, SVE or SME format or an Unspecified load/store format Operation Type packet.

R_{JCLMP} If FEAT_SPE_SME is implemented and a Sampled SME vector load/store operation or Sampled SVE SIMD load/store operation generates a Load/store, SVE or SME format Operation Type packet, then the Operation Type packet.EVL field records the upper bound of the Sampled effective vector length multiplied by the number of vectors loaded or stored by the sampled operation. If this product is greater than 2048 bits, then the Operation Type packet.EVL field is set to `0b111`.

If FEAT_SPE_SME is not implemented and a Sampled SME vector load/store operation or Sampled SVE SIMD load/store operation generates a Load/store, SVE or SME format Operation Type packet, then the Operation Type packet.EVL field records the upper bound of the Sampled effective vector length.

R_{BHKSC} For a sampled SVE cache prefetch operation:

- The profiling operation captures an IMPLEMENTATION DEFINED subset of the information captured for an SVE load instruction.
- The profiling operation treats the operation type as Other when generating the sample records and filtering based on operation.
- It is IMPLEMENTATION DEFINED whether the operation is treated as a Sampled SVE SIMD operation:
  - If treated as a Sampled SVE SIMD operation, then the Operation Type packet format is Data processing, SVE vector payload.
  - If not treated as a Sampled SVE SIMD operation, then the Operation Type packet format is Other payload.

R_{MYPFF} For a sampled non-contiguous SVE load or store operation that makes multiple memory accesses, the sampled data virtual address is the address accessed by a random one of the load or store operations chosen from the Sampled predicated operation. If the chosen load or store operation is for an Inactive element, the data virtual address packet is not output.

For more information, see Additional information for each profiled memory access operation.

R_{NHSYR} For a sampled contiguous SVE load or store operation that makes multiple memory accesses, the sampled data virtual address is an IMPLEMENTATION DEFINED choice of:

- The address accessed for the lowest element in the Sampled predicated operation.
- The address used for the access containing the lowest Active element in the Sampled predicated operation.

If the corresponding element is an Inactive element, it is IMPLEMENTATION DEFINED whether the data virtual address packet is output.

D17.6.7 Sample operation records for misspeculated and non-architectural operations

It is IMPLEMENTATION DEFINED whether each of the following operations is part of the sample population:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Operations on misspeculated paths.
- Operations that do not relate to any architecture instruction.

If the operation is part of the sample population, it is further IMPLEMENTATION DEFINED whether the sample record for the sampled operation is captured in the Profiling Buffer. For more information, see Operations that might be excluded from the sample population.

If such an operation is part of the sample population and the sample record is captured in the Profiling Buffer, then some information for the operation might not be present. However, the Events packet and either the End packet or the Timestamp packet is always output. Neither event 0 (generated exception) nor event 1 (architecturally retired) will be set in the Events packet.

The record must not contain or infer values that cannot be accessed or used by the sampled operation, as defined by Restrictions on the effects of speculation.

For example:

- An address that is not permitted to be used by the sampled operation, such as might be recorded in an Address packet.
- A condition code or predicate value that is not permitted to be used by the sampled operation, such as might be inferred from the Mispredicted, Partial or empty predicate, or Empty predicate bits in the Events packet.
- A branch target address predicted in a way that is prohibited, such as might be recorded in an Address packet.

D17.6.8 Additional information for other operations

For a sampled operation that does not use any of the Operation Type packet formats defined in the previous sections, it will use the Other format Operation Type packet. This indicates:

- Whether the instruction was conditional or not. See Additional information for each profiled conditional instruction.
- If FEAT_SPE_FPF is implemented, whether the operation is Advanced SIMD or scalar.
- If FEAT_SPE_FPF is implemented, whether the operation is floating-point or not floating-point.

For cache maintenance operations by virtual address, cache prefetch other than SVE cache prefetch, or address translation instructions, the profiling operation:

- Generates an Other format Operation Type packet.
- Captures an IMPLEMENTATION DEFINED subset of the information captured for a load instruction. See Additional information for each profiled memory access operation.
- Is not treated as a load or a store when filtering based on operation type. See Filtering sample records.

D17.6.9 Controlling the data that is collected

Certain data in sample records is collected only if permitted by one or both of EL1 and EL2. This is to restrict exposure of data to a lower Exception level or to Non-secure state.

CONTEXTIDR_EL1 is collected only if PMSCR_EL1.CX is set to 1, the PE is executing at EL1 or EL0 and any of the following are true when an operation is sampled:

- EL2 is not implemented.
- FEAT_SEL2 is implemented and EL2 is disabled for the current Security state.
- The Effective value of HCR_EL2.TGE is 0.

CONTEXTIDR_EL2 is collected only if the Effective value of PMSCR_EL2.CX is 1 and EL2 is implemented and enabled for the current Security state.

This is described in the pseudocode functions `CollectContextIDR1()` and `CollectContextIDR2()`.

Timestamps are collected only if one of the following is true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- PMSCR_EL1.TS is set to 1 and the Profiling Buffer is owned by EL1.
- PMSCR_EL2.TS is set to 1 and the Profiling Buffer is owned by EL2.

The timestamp is a choice between:

- Physical time, which is defined by the physical count value returned by `PhysicalCountInt()`.
- If FEAT_ECV is implemented, offset physical time, which is defined as the value of `PhysicalCountInt()` minus a physical offset.
- Virtual time, which is defined as the value of `PhysicalCountInt()` minus a virtual offset.

Table D17-3 summarizes the choice of value for the Timestamp packet when FEAT_ECV is implemented and `StatisticalProfilingEnabled()` is TRUE. In Table D17-3:

Owning EL This is the Exception level that owns the Profiling Buffer. This is returned by the function `ProfilingBufferOwner()`. If EL2 is disabled in the current Security state, this is always EL1.

EL2 enabled This is TRUE when EL2 is enabled in the current Security state. When EL2 is disabled in the current Security state, this is FALSE.

Virtual offset The virtual offset is treated as zero if a read of CNTVCT_EL0 at the current Exception level would treat the virtual offset as zero. Therefore if any of the following are true, the virtual offset is zero:

- EL2 is not implemented.
- The Effective value of HCR_EL2.E2H is 1, and the sampled operation was executed at EL2.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, and the sampled operation was executed at EL0.

Otherwise the virtual offset is the value of CNTVOFF_EL2.

Physical offset If any of the following are true, the physical offset is zero:

- EL2 is not implemented.
- FEAT_ECV_POFF is not implemented.
- CNTHCTL_EL2.ECV is 0.
- EL3 is implemented and SCR_EL3.ECVEn is 0.

Otherwise the physical offset is the value of CNTPOFF_EL2.

Table D17-3 Recorded timestamp when FEAT_ECV is implemented

EL2 enabled	Owning EL	PMSCR_EL2		PMSCR_EL1		Recorded timestamp
		PCT[1:0]	TS	PCT[1:0]	TS	
x	EL1	xx	x	xx	0	None
				`0b00`	1	`PhysicalCountInt()` - virtual offset
FALSE	EL1	xx	x	`0b01`	1	`PhysicalCountInt()`
				`0b11`	1	`PhysicalCountInt()` - physical offset
TRUE	EL1	`0b00`	x	xx	1	`PhysicalCountInt()` - virtual offset
		`0b01`	x	`0b01`	1	`PhysicalCountInt()`
				`0b11`	1	`PhysicalCountInt()` - physical offset
		`0b11`	x	`0b01`	1	`PhysicalCountInt()` - physical offset
				`0b11`	1	`PhysicalCountInt()` - physical offset
	EL2	xx	0	xx	x	None

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EL2 enabled	Owning EL	PMSCR_EL2		PMSCR_EL1		Recorded timestamp
		PCT[1:0]	TS	PCT[1:0]	TS	
		0b00	1	xx	x	PhysicalCountInt() - virtual offset
		0b01	1	xx	x	PhysicalCountInt()
		0b11	1	xx	x	PhysicalCountInt() - physical offset

If EL2 is not implemented, see the register descriptions of PMSCR_EL1.PCT and PMSCR_EL2.PCT for details of their behavior. This behavior is described by the pseudocode function `CollectTimeStamp()`.

Physical data addresses are collected only if one of the following is true:

- The Effective value of PMSCR_EL1.PA is 1, the Effective value of PMSCR_EL2.PA is 1, and the Profiling Buffer is owned by EL1.
- The Effective value of PMSCR_EL2.PA is 1 and the Profiling Buffer is owned by EL2.

If EL2 is not implemented or is disabled for the owning Security state, then the Effective value of PMSCR_EL2.PA is 1.

Physical data address collection is described by the pseudocode function `CollectPhysicalAddress()`.

Enabling collection of the physical data addresses has an IMPLEMENTATION DEFINED impact on the sampled operation.

D17.6.10 Exceptions

All sample records written to the Profiling Buffer contain the Events packet and either the End packet or the Timestamp packet.

If the sampled operation generates an exception condition, it is UNPREDICTABLE whether the sample record contains any other information. This includes operations that generate faults or other exception conditions but do not generate exceptions. For example:

- An instruction on a misspeculated path.
- A load operation that is part of a Non-fault load instruction or is not the First active element of a First-fault load instruction that generates an MMU fault or watchpoint.
- An address translation operation or prefetch instruction that generates an MMU fault.

Where a sampled operation generates an exception and the type of exception means that a particular item is not calculated by the sampled operation, that information is not collected by the profiling operation. For more information, see Synchronization and Statistical Profiling.

Example D17-6 Translation Faults

If a sampled operation generates a Translation Fault, the physical address for the sampled operation was not generated by the MMU and cannot be recorded.

D17.6.10.1 Non-architectural exceptions

It is IMPLEMENTATION DEFINED whether operations that generate non-architectural exceptions are part of the sample population. If such an operation is part of the sample population, it is further IMPLEMENTATION DEFINED whether the sample record for a sampled operation that generates a non-architectural exception is captured in the Profiling Buffer. For more information, see Operations that might be excluded from the sample population.

If such an operation is part of the sample population and the sample record is captured in the Profiling Buffer, then the sample might record handling of the non-architectural exception. If the sample record does not record handling of the non-architectural exception, then the sampled operation is not Architecturally executed because of the non-architectural exception and it is recorded using E[1] == 0 (operation is not architecturally executed) in the Events packet. Bit E[0] (operation generated an exception) might be used to indicate the operation did not complete because of the non-architectural exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.7 The Profiling Buffer

I_{LSYJL} When the SPU is not in Discard mode, profile data is collected in a memory *Profiling Buffer*. The Profiling Buffer is defined by:

- PMBPTR_EL1, the current write pointer.
- PMBLIMITR_EL1, the write limit pointer.

R_{KLGPG} The Profiling Buffer starts at the current write pointer and extends to the current limit pointer minus one. The write limit pointer must be aligned to the smallest implemented translation granule size. The alignment of the current write pointer is IMPLEMENTATION DEFINED.

I_{JXFJK} If the Effective value of PMBLIMITR_EL1.nVM is 0, then address translation for the Profiling buffer in the owning translation regime is enabled. See Behavior when address translation is enabled.

If the Effective value of PMBLIMITR_EL1.nVM is 1, then address translation for the Profiling buffer in the owning translation regime is disabled. See Behavior when address translation is disabled.

R_{PSLVX} If FEAT_SPE_nVM is not implemented or all of the following apply, then the Effective value of PMBLIMITR_EL1.nVM is 0:

- EL2 is implemented and enabled in the owning Security state.
- The owning Exception level is EL1.
- The Effective value of PMSCR_EL2.EnVM is 0.

D17.7.1 Behavior when address translation is enabled

R_{LWHSF} If the Effective value of PMBLIMITR_EL1.nVM is 0, then PMBLIMITR_EL1 and PMBPTR_EL1 are virtual addresses in the stage 1 translation regime of the owning translation regime.

R_{VGJHQ} If the Effective value of PMBLIMITR_EL1.nVM is 0, other than as described in this section, then the stage 1 translation process for translating virtual addresses and checking for MMU faults is identical to that for any other virtual address in the owning translation regime. For example, PMBPTR_EL1[63:56] are ignored by address translation if the respective TBI bit is set to 1.

I_{TDKDL} If ELx stage 1 translates an address and stage 1 Indirect permissions are used, then the Statistical Profiling Unit indirectly reads PIR_ELx.

R_{FXNVL} The effect of PSTATE.PAN is not applied to the stage 1 Base permissions.

R_{QJZGB} The effect of FEAT_S1POE stage 1 Overlay permissions and POR_ELx are not applied to the access.

D17.7.2 Behavior when address translation is disabled

R_{RPSLW} If the Effective value of PMBLIMITR_EL1.nVM is 1, then the write limit pointer and current write pointer are:

- Physical address in the owning Security state if the owning translation regime has no stage 2 translation.
- Intermediate physical addresses (IPAs) in the owning Security state if the owning translation regime has stage 2 translations.

These addresses are output directly by stage 1 without any address translation. Stage 1 translation is disabled for writes to the Profiling Buffer made by the *Statistical Profiling Unit*.

The pseudocode function `AArch64_S1Enabled()` shows this.

R_{SDWFC} If the Effective value of PMBLIMITR_EL1.nVM is 1, PMBMAR_EL1 defines:

- The memory type.
- And as applicable, the following attributes:
  - Cacheability.
  - Shareability.
  - Device type.

The pseudocode function `AArch64_S1DisabledOutput()` shows this.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{FRCPH} If the Effective value of PMBLIMITR_EL1.nVM is 1, the values of SCTLR_ELx.{C, M} for the owning translation regime are ignored for the purposes of determining the Profiling Buffer Cacheability attributes.

I_{DJRBT} If the Effective value of PMBLIMITR_EL1.nVM is 1, it is possible to generate mismatched attributes for a location from within stage 1 of the owning translation regime using PMBMAR_EL1.

Software must be aware of the consequences of and permitted behaviors when accessing a memory location with mismatched attributes. For more information, see Mismatched memory attributes.

R_{QJNFT} If the Effective value of PMBLIMITR_EL1.nVM is 1, `OAMax` is greater than or equal to `AArch64_PAMax()`, and PMBPTR_EL1[`OAMax:AArch64_PAMax()`] is nonzero, a stage 1 Address Size fault is generated when the *Statistical Profiling Unit* attempts to write to memory, where:

- If FEAT_D128 is implemented, then `OAMax` is 55.
- Otherwise, if FEAT_LPA is implemented or FEAT_LPA2 is implemented , then `OAMax` is 51.
- Otherwise, `OAMax` is 47.

For more information, see Implemented physical address size.

R_{XBFCM} If the Effective value of PMBLIMITR_EL1.nVM is 1 and PMBPTR_EL1[`63:(OAMax+1)`] is nonzero when the *Statistical Profiling Unit* attempts to write to the Profiling Buffer, then one of the following CONSTRAINED UNPREDICTABLE behaviors apply:

- A stage 1 Address Size fault is generated.
- PMBPTR_EL1[`63:(OAMax+1)`] are ignored and treated as zero.

The value of `OAMax` is as defined by R_{QJNFT}.

D17.7.3 Effect of stage 2 translation

R_{DQTTB} If the owning translation regime has stage 2 translations, the stage 2 process of the following is identical to that for any other intermediate physical address generated by the owning translation regime:

- Translating the stage 1 output intermediate physical addresses.
- Translating the stage 1 attributes to a physical address and attributes.
- Checking for MMU faults.

R_{MXRVQ} If stage 2 translates an address and stage 2 Overlay permissions are used, then the effect of FEAT_S2POE stage 2 Overlay permissions apply to the memory access and the Statistical Profiling Unit indirectly reads S2POR_EL1.

Example D17-7

The intermediate physical addresses are translated to physical addresses by stage 2 translation, and checked for stage 2 MMU faults.

- If the Effective value of PMBLIMITR_EL1.nVM is 1, meaning stage 1 translation is disabled, and the resulting IPA is translated by a stage 2 Block or Page descriptor with the AssuredOnly attribute set to 1, then the access translated by that descriptor generates a stage 2 Permission fault. See R_{WWYDL} in Assured translation.
- The attributes from stage 1 are combined with the attributes from the stage 2 translation to generate the physical memory attributes.
- If the Effective value of HCR_EL2.DC in the owning translation regime is 1, then stage 1 translation is disabled and the memory type produced by stage 1 is Normal Non-shareable, Inner Write-Back Cacheable Read-Allocate Write-Allocate, Outer Write-Back Cacheable Read-Allocate Write-Allocate, regardless of the values of SCTLR_EL1.C and PMBMAR_EL1.

D17.7.4 Restrictions on the current write pointer

This section describes the software rules on setting the current write pointer, PMBPTR_EL1. The rules in this section do not apply when Discard mode is enabled. See Discard mode.

R_{PGGHS} If software violates the restrictions in R_{HXSYK} and R_{HLXGD}, then the behavior is CONSTRAINED UNPREDICTABLE, and the PE might do any of the following at any point after profiling is enabled:

- The value of PMBPTR_EL1 becomes UNKNOWN.
- Write sample records to any address in memory that is writable by a privileged access in the owning translation regime. These addresses are:
  - Virtual addresses in the owning translation regime, if the Effective value of PMBLIMITR_EL1.nVM is 0.
  - Intermediate physical addresses in the owning Security state, if the Effective value of PMBLIMITR_EL1.nVM is 1, and the owning translation regime has stage 2 translations.
  - Physical addresses in the owning Security state, if the Effective value of PMBLIMITR_EL1.nVM is 1, and either the owning translation regime has no stage 2 translation or stage 2 translation is disabled.
- Generate a Profiling Buffer management event, with or without indicating data loss, for one of the following reasons:
  - A Buffer full buffer management event. See Buffer full event.
  - An Access not allowed buffer management event. See Access not allowed.
  - Any MMU Fault. See Faults and watchpoints.
  - An IMPLEMENTATION DEFINED buffer management event. See Implementation defined reason.

  If FEAT_SPE_EXC is implemented, then the management event is recorded as described by R_{HJXHT}.
- Silently discard all profiling data without writing it to memory.
- Behave as if profiling is disabled.
- Generate the SAMPLE_BUFFER_FULL PMU event.

R_{HXSYK} When profiling becomes enabled, all the following must be true:

- The current write pointer must be at least one sample record size below the write limit pointer. That is: `UInt`(PMBPTR_EL1.PTR) <= `UInt`(PMBLIMITR_EL1.LIMIT:`Zeros`(12)) - $2^{\text{PMSIDR_EL1.MaxSize}}$.
- PMBPTR_EL1.PTR[63:56] must equal PMBLIMITR_EL1.LIMIT[63:56].

If profiling becomes enabled due to a Context synchronization event, then these conditions apply for the values of these System registers after the Context synchronization event.

R_{HLXGD} When the Profiling Buffer is first configured, PMBPTR_EL1.PTR must be aligned to PMBIDR_EL1.Align. That is, if PMBIDR_EL1.Align is nonzero, PMBPTR_EL1.PTR [`UInt`(PMBIDR_EL1.Align)-1:0] must be all zeros.

However, the current write pointer and write limit pointer can usually be restored to the saved write pointer and saved write limit pointer values that were in the System registers when profiling was disabled, providing a `PSB` and a Context synchronization event were executed before reading the System registers.

Following a management event and executing a `PSB` and a Context synchronization event:

- If PMBSR_ELx.{EA, DL} are not {0, 0}, indicating an External abort and/or data loss occurred, then profiling cannot be restarted using the saved write pointer and saved write limit pointer.
- Otherwise, if PMBSR_ELx.S is 0, indicating no Profiling Buffer management event was signaled, then profiling can be restarted from the saved write pointer and saved write limit pointer.
- Otherwise, if software clears PMBSR_ELx.S to 0 before restarting profiling, then the following apply:
  - If the Profiling Buffer management event was caused by an MMU fault, then profiling can be restarted from the saved write pointer.

    Note

    If the MMU fault has not been corrected, then the SPU will generate a MMU fault Profiling Buffer management event when it next tries to write a sample record.

  - If the Profiling Buffer management event was caused by a buffer full event, then profiling cannot be restarted from the saved write pointer and saved limit pointer, as the saved write pointer will not be at least one sample record below the saved limit pointer. However, software can extend the Profiling Buffer by changing PMBLIMITR_EL1, and then profiling can be restarted from the saved write pointer.
- Otherwise, profiling is restarted with PMBSR_ELx.S set to 1, meaning profiling is stopped and there are no constraints on the values of the current write pointer and write limit pointer.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If software restarts profiling with a new current write pointer and new write limit pointer, then the restrictions on the current write pointer when first enabling profiling apply.

ELx is defined by R_{HJXHT}.

For more information, see Synchronization and Statistical Profiling and Profiling Buffer management.

D17.7.5 The owning translation regime

R_{WWFKZ} The owning translation regime is defined by the owning Security state and the owning Exception level.

R_{BWRVP} When the Profiling Buffer is enabled, the owning Security state is:

- Non-secure state if and only if one of the following is true:
  - EL3 is not implemented and the PE executes in Non-secure state.
  - FEAT_RME is not implemented, EL3 is implemented, and MDCR_EL3.NSPB is either `0b10` or `0b11`.
  - FEAT_RME is implemented and MDCR_EL3.{NSPBE, NSPB} is either {`0b0`, `0b10`} or {`0b0`, `0b11`}.
- Secure state if and only if one of the following is true:
  - EL3 is not implemented and the PE executes in Secure state.
  - FEAT_RME is not implemented, EL3 is implemented, and MDCR_EL3.NSPB is either `0b00` or `0b01`.
  - FEAT_RME is implemented, Secure state is implemented, and MDCR_EL3.{NSPBE, NSPB} is either {`0b0`, `0b00`} or {`0b0`, `0b01`}.
- Realm state if and only if all of the following are true:
  - FEAT_RME is implemented.
  - MDCR_EL3.{NSPBE, NSPB} is either {`0b1`, `0b10`} or {`0b1`, `0b11`}.

R_{KFMHR} When the Profiling Buffer is enabled, the owning Exception level is:

- EL1 if and only if at least one of the following is true:
  - EL2 is not implemented in the owning Security state.
  - EL2 is disabled in the owning Security state.
  - MDCR_EL2.E2PB is either `0b10` or `0b11`.
- EL2, if and only if all of the following are true:
  - EL2 is implemented and enabled in the owning Security state.
  - MDCR_EL2.E2PB is `0b00`.

R_{TDHBH} When the Profiling Buffer is enabled and the owning Exception level is EL1, all of the following apply:

- The owning translation regime is EL1&0.
- If the Effective value of PMBLIMITR_EL1.nVM is 0, the Profiling Buffer addresses are virtual addresses in the EL1&0 translation regime using the current ASID from TTBRx_EL1.
- If the Effective value of PMBLIMITR_EL1.nVM is 1, the Profiling Buffer addresses are intermediate physical addresses.
- Intermediate physical addresses (whether from the output of stage 1, or the pointers, as applicable) are subject to stage 2 translation using the current VMID if EL2 is implemented and enabled and HCR_EL2.VM is 1.
- Profiling is disabled at the following Exception levels:
  - EL3.
  - EL2.
  - EL0, if EL2 is implemented and enabled and HCR_EL2.TGE is 1.

R_{KRVDC} When the Profiling Buffer is enabled and the owning Exception level is EL2, all of the following apply:

- If the Effective value of HCR_EL2.E2H is 0, the owning translation regime is EL2.
- If the Effective value of HCR_EL2.E2H is 1, the owning translation regime is EL2&0.
- If the Effective value of HCR_EL2.E2H is 0 and the Effective value of PMBLIMITR_EL1.nVM is 0, the Profiling Buffer addresses are virtual addresses in the EL2 translation regime.
- If the Effective value of HCR_EL2.E2H is 1 and the Effective value of PMBLIMITR_EL1.nVM is 0, the Profiling Buffer addresses are virtual addresses in the EL2&0 translation regime using the current ASID from TTBRx_EL2.
- If the Effective value of PMBLIMITR_EL1.nVM is 1, the Profiling Buffer addresses are physical addresses.
- Profiling is disabled at EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IYCDWQ When the Profiling Buffer is enabled, all of the following apply:

- If the owning Security state is Non-secure state, profiling is disabled in Secure and Realm states.
- If the owning Security state is Secure state, profiling is disabled in Non-secure and Realm states.
- If the owning Security state is Realm state, profiling is disabled in Non-secure and Secure states.

D17.7.5.1 Summary of the owning translation regime

IYZHFG Table D17-4 summarizes the owning translation regime. In this table:

E is the value of PMBLIMITR_EL1.E.

NSE is the Effective value of SCR_EL3.NSE.

NS is the Effective value of SCR_EL3.NS.

EEL2 is the Effective value of SCR_EL3.EEL2.

NSPBE is the Effective value of MDCR_EL3.NSPBE.

NSPB is the Effective value of MDCR_EL3.NSPB.

E2PB is the Effective value of MDCR_EL2.E2PB.

E2H is the Effective value of HCR_EL2.E2H.

Table D17-4 Summary of owning translation regime (for all Exception levels using AArch64 state)

Controls								Owning translation regime
E	NSE	NS	EEL2	NSPBE	NSPB	E2PB	E2H	
0b0	x	x	x	x	x	x	x	Disabled
0b1	0b0	0b0	0b0	0b0	0b0x	x	x	Secure EL1&0
			0b1	0b0	0b0x	0b1x	x	Secure EL1&0
						0b00	0b0	Secure EL2
							0b1	Secure EL2&0
			x	0b0	0b1x	x	x	Disabled in Secure state
		0b1	x	0b0	0b1x	0b1x	x	Non-secure EL1&0
						0b00	0b0	Non-secure EL2
							0b1	Non-secure EL2&0
					0b0x	x	x	Disabled in Non-secure state
	0b1	0b1	x	0b1	0b1x	0b1x	x	Realm EL1&0
						0b00	0b0	Realm EL2
							0b1	Realm EL2&0
					0b0x	x	x	Disabled in Non-secure state
x	x	x	x	0b1	0b0x	x	x	Reserved

D17.7.6 Memory access types and coherency

Writes to any Device memory type by the SPU occur once.

The memory type and attributes that are used for a write by the SPU to the Profiling Buffer is taken from the translation table entries for the virtual address being written to. That is:

- The writes are treated as coming from an observer that is coherent with all observers in the Shareability domain that is defined by the translation tables.
- There is no requirement to manage coherency for observers in the same Shareability domain but coherency for other observers in the system might require explicit management.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information, see Synchronization and Statistical Profiling.

If FEAT_MTE2 is implemented, a PE will generate a Tag Unchecked access for each access to the Profiling Buffer as part of writing a sample record.

For more information on FEAT_MTE2, see The Memory Tagging Extension.

Writes to the Profiling Buffer are made as privileged writes within the owning translation regime. However, the value of PSTATE.PAN and the FEAT_S1POE stage 1 Overlay permissions are ignored for these writes and treated as zero, see Faults and watchpoints.

This means that if FEAT_E0PD is implemented, the values of TCR_ELx.E0PDy, where ELx is the owning Exception level, do not apply to accesses to the Profiling Buffer made by the SPU.

D17.7.7 Memory access and crossing page boundaries

A memory access from the SPU that crosses a page boundary to a memory location that has a different memory type or Shareability attribute results in CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- Each memory access generated by the SPU uses the memory type and Shareability attribute associated with its own address.
- The access generates an Alignment fault caused by the memory type:
  - If only the stage 1 translation generated the mismatch, or there is only one stage of translation in the owning translation regime, the resulting Buffer Management event is a stage 1 Data Abort.
  - If only the stage 2 translation generated the mismatch, the resulting Buffer Management event is a stage 2 Data Abort.
  - If both stages of translation generate the mismatch, the resulting Buffer Management event is either a stage 1 Data Abort or a stage 2 Data Abort.
- Some or all of the data is discarded. The write pointer is either updated by the amount of data written not including the discarded data or the amount of data written including the discarded data.

A memory access from the SPU to Device memory that crosses a boundary corresponding to the smallest translation granule size of the implementation causes CONSTRAINED UNPREDICTABLE behavior. In this case, the implementation performs one of the following behaviors:

- All memory accesses generated by the SPU are performed as if the boundary has no effect on the memory accesses.
- All memory accesses generated by the SPU are performed as if the boundary has no effect on the memory accesses except that there is no guarantee of ordering between memory accesses.
- The access generates an Alignment fault caused by the memory type:
  - If only the stage 1 translation causes the boundary to be crossed, or there is only one stage of translation in the owning translation regime, the resulting Buffer Management event is a stage 1 Data Abort.
  - If only the stage 2 translation causes the boundary to be crossed, the resulting Buffer Management event is a stage 2 Data Abort.
  - If both stages of translation cause the boundary to be crossed, the resulting Buffer Management event is either a stage 1 Data Abort or a stage 2 Data Abort.
- Some or all of the data is discarded. The write pointer is either updated by the amount of data written not including the discarded data or the amount of data written including the discarded data.

Note

The boundary referred to is between two Device memory regions that are both:

- Of the size of the smallest implemented translation granule.
- Aligned to the size of the smallest implemented translation granule.

If PMSIDR_EL1.MaxSize indicates the same value as PMBIDR_EL1.Align, then records are a fixed power-of-two size and never cross a page boundary.

D17.7.8 Cache and TLB operations

TLB maintenance operations that affect the TLB of the PE also affect any TLB caching translations for the SPU of that PE.

Cache maintenance operations that affect the caches of the PE also affect data caching by the SPU of that PE.

This means that the completion of any cache or TLB maintenance instruction includes its completion on all SPUs for PEs that are affected by both the instruction and the `DSB` operation that is required to guarantee visibility of the maintenance instruction.

See also:

- Completion and endpoint ordering.
- Synchronization and Statistical Profiling.

D17.7.9 Effect on the exclusive monitors

If a Load-exclusive instruction or an operation between Load-exclusive and Store-exclusive instructions is sampled, and the sample record is written to an unrelated address, then to avoid a probe effect, Arm recommends that the Store-exclusive does not systematically fail on account of the sampled operation.

If a Store-exclusive instruction is sampled, and the sample record is written to an unrelated address, then the Store-exclusive must not systematically fail on account of the instruction having been sampled.

D17.7.10 Statistical Profiling and MEC

R_{DFFVT} If FEAT_MEC is implemented, accesses made by the Statistical Profiling Unit to the Profiling Buffer are associated with a MECID that is determined by the owning translation regime, owning Security state, and owning Exception level, as defined in Memory Encryption Contexts extension.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.8 Profiling Buffer management

R_{FJDLW} A Profiling Buffer management event occurs:

- On a fault, see Faults and watchpoints.
- On an External abort, see External aborts.
- When the Profiling Buffer fills, see Buffer full event.
- When the access is not allowed for other reasons, see Access not allowed.
- For IMPLEMENTATION DEFINED reasons, see Implementation defined reason.

I_{QRJYF} The Profiling Buffer management event behavior differs from that of the FEAT_TRBE trace buffer management event.

R_{NXZXG} On a Profiling Buffer management event:

- The service bit, PMBSR_ELx.S, is set to 1.
- The data loss bit, PMBSR_ELx.DL, is set as described in the event description.
- Additional syndrome for the event is written to PMBSR_ELx.MSS.

The value of ELx depends on the type of event, and is defined by R_{HJXHT}. Unless otherwise stated in the event description, other fields in PMBSR_ELx and the other PMBSR_ELx registers are unchanged.

R_{WVKFM} The following Profiling Buffer management events are reported synchronously:

- Buffer full events.
- If FEAT_SPEv1p5 is not implemented, Alignment fault and MMU fault events.

If FEAT_SPEv1p3 is not implemented, it is IMPLEMENTATION DEFINED whether External aborts are reported to the Statistical Profiling Unit synchronously or asynchronously.

Reported synchronously means that profiling is disabled before the Statistical Profiling Unit samples further operations. The interrupt or Profiling exception resulting from recording the Profiling Buffer management event is an asynchronous exception.

When FEAT_SPEv1p5 is implemented, the Statistical Profiling Unit is permitted to sample further operations after the sampled operation that generates the Alignment fault or MMU fault Profiling Buffer management event. This means that one or more samples might be discarded because of the Alignment fault or MMU fault Profiling Buffer management event.

R_{THGCR} The SPU never writes past the PMBLIMITR_EL1 limit pointer.

I_{QRKCL} Software cannot assume that:

- The PE has not modified memory between the current PMBPTR_EL1 write pointer and the PMBLIMITR_EL1 limit pointer minus one.
- The data between the current PMBPTR_EL1 write pointer and the PMBLIMITR_EL1 limit pointer minus one is valid.
- If PMBSR_ELx.DL is set to 1 on a Profiling Buffer management event, that there is any valid data between the end of the last complete sample record and the current PMBPTR_EL1 write pointer. The value of ELx depends on the type of event. See R_{HJXHT}.
- *Any* valid data has been written to the Profiling Buffer if an External abort is reported asynchronously to the SPU. For more information, see The External abort generates a MMU fault.

I_{VJVKZ} The Statistical Profiling Unit generates PMU events and CTI trigger events when a sampled operation completes.

If writing records to the Profiling Buffer generates an MMU fault, one or more of these events might have been generated for one or more sampled operations that are discarded because of the MMU fault.

R_{HJXHT} If FEAT_SPE_EXC is implemented, then when a Profiling Buffer management event is generated:

- If EL3 is implemented and any of the following are true, then the management event is recorded in PMBSR_EL3:
  - MDCR_EL3.PMSEE is `0b11`.
  - MDCR_EL3.PMSEE is `0b10` and the management event is due to a fault on a write to the Profiling Buffer that would generate a Data Abort exception taken to EL3 if generated by a store instruction executed at the owning Exception level. That is, any of the following faults on a write to the Profiling Buffer:
    - Granule Protection Check (GPC) faults, other than Granule Protection Faults (GPFs). For more information, see Granule Protection Check faults.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

        - If SCR_EL3.GPF is 1, GPFs.
        - If SCR_EL3.EA is 1, External aborts. See also I_{FDVRZ}.
    - MDCR_EL3.PMSEE is `0b10` and the management event is an IMPLEMENTATION DEFINED buffer management event that the implementation elects to record in PMBSR_EL3.
- Otherwise, if all of the following are true, then the management event is recorded in PMBSR_EL2:
    - EL3 is not implemented or MDCR_EL3.PMSEE is not `0b00`.
    - EL2 is implemented and any of the following are true:
        - The Effective value of SCR_EL3.NS is 1.
        - The Effective value of SCR_EL3.{NS, EEL2} is {0, 1}.

        This applies even when the current Exception level is EL3.
    - One of the following is true:
        - PMSCR_EL2.EE is `0b11`.
        - PMSCR_EL2.EE is `0b10` and the management event is due to any fault on a write to the Profiling Buffer that would generate a Data Abort exception taken to EL2 if generated by a store instruction executed at the owning Exception level.
          If the owning Exception level is EL2, this means any fault on a write to the Profiling Buffer.
          If the owning Exception level is EL1, this means any of the following faults on a write to the Profiling Buffer:
            - Stage 2 faults.
            - If HCR_EL2.GPF is 1, GPFs.
            - If HCR_EL2.TEA is 1, External aborts. See I_{FDVRZ}.
        - PMSCR_EL2.EE is `0b10` and the management event is due to a GPC fault other than a GPF.
        - PMSCR_EL2.EE is `0b10` and the management event is an IMPLEMENTATION DEFINED buffer management event that the implementation elects to record in PMBSR_EL2.
- Otherwise, the management event is recorded in PMBSR_EL1.

If FEAT_SPE_EXC is not implemented, then the management event is recorded in PMBSR_EL1.

The pseudocode function `ReportSPEEvent()` shows this.

I_{FDVRZ} When FEAT_SPEv1p3 is implemented, External aborts are not reported on writes to the trace buffer. However, External aborts on translation table walks, translation table updates, and GPT walks can be reported as MMU faults. See Faults and watchpoints.

I_{JVQRY} Table D17-5, Table D17-6, and Table D17-7 show which PMBSR_ELx register used to record the syndrome for each type of Profiling Buffer management event.

Each column in the left side of the tables refers to the Effective value of a field in a System register.

Each column in the right side of the tables represents a Profiling Buffer management event:

Other event

Means a Profiling Buffer management event recorded with the EC value `0b000000`.

Stage 1 (GPF)

Means a Profiling Buffer management event for a Granule Protection Fault (GPF) reported as a stage 1 abort on a write to the buffer, recorded with the EC value of `0b100100` and an FSC value indicating a GPF.

Stage 1 (External abort)

Means a Profiling Buffer management event for an External abort reported as a stage 1 abort on a write to the buffer, recorded with the EC value of `0b100100` and an FSC value indicating an External abort.

Stage 1 (Other abort)

Means a Profiling Buffer management event for any other stage 1 abort on a write to the buffer, recorded with the EC value `0b100100`.

Stage 2 (GPF)

Means a Profiling Buffer management event for a GPF reported as a stage 2 abort on a write to the buffer, recorded with the EC value of `0b100101` and an FSC value indicating a GPF.

Stage 2 (External abort)

Means a Profiling Buffer management event for an External abort reported as a stage 2 abort on a write to the buffer, recorded with the EC value of `0b100101` and an FSC value indicating an External abort. That is, a synchronous External abort on a stage 2 translation table walk or translation table update.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Stage 2 (Other abort)

Means a Profiling Buffer management event for any other stage 2 abort on a write to the buffer, recorded with the EC value `0b100101`.

GPC fault

Means a Profiling Buffer management event for a Granule Protection Check fault, other than a GPF, on a write to the buffer, recorded with the EC value `0b011110`.

The values in these cells denotes which PMBSR_ELx register is updated for that combination of control register values and Profiling Buffer management event type.

Table D17-5 SPE Profiling Buffer management event reporting (Granule Protection Checks)

0b10	0b0X	XX	EL1	EL1	EL1
0b10	0b10	0b00	EL2	EL2	EL1
0b10	0b10	0b1X	EL1	EL2	EL1
0b10	0b11	XX	EL2	EL2	EL2
0b11	XX	XX	EL3	EL3	EL3

R_{MYXZK} When a write to the Profiling Buffer by the Statistical Profiling Unit generates an Alignment fault or MMU fault, the PE sets PMBPTR_EL1 to the faulting address.

The last byte of the last complete sample record, including any padding bytes after the record, is at most $2^{(\text{PMSIDR_EL1.MaxSize})}$ bytes below PMBPTR_EL1.

If PMBPTR_EL1 does not point to the first byte after the last complete record, including any padding after the record, then PMBSR_ELx.DL is set to 1. Otherwise, PMBSR_ELx.DL is set to an IMPLEMENTATION DEFINED choice of 0 and 1.

ELx is defined by R_{HJXHT}. See also Table D17-6.

R_{YZJQX} When FEAT_SPE_EXC is implemented and any of the following are true, then the SPE Profiling exception is *enabled* and pending:

- All of the following are true:
  - EL3 is implemented.
  - MDCR_EL3.PMSEE is 0b10 or 0b11.
  - PMBSR_EL3.S is 1.

  In this case:
  - The target Exception level is EL3.
  - If all of the following are true, then the SPE Profiling exception is *unmasked*:
    - The PE is executing at EL2, EL1, or EL0.
    - The PE is in Non-debug state.
- All of the following are true:
  - EL3 is not implemented or MDCR_EL3.PMSEE is not 0b00.
  - EL2 is implemented and enabled in the current Security State.
  - PMSCR_EL2.EE is 0b10 or 0b11.
  - PMBSR_EL2.S is 1.

  In this case:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- — The target Exception level is EL2.
- — If the PE is executing in the owning Security state, the PE is in Non-debug state, and any of the following are true, then the SPE Profiling exception is unmasked:
  - — The PE is executing at EL1 or EL0.
  - — The PE is executing at EL2, PMSCR_EL2.EE is `0b11`, PMSCR_EL2.KE is 1, and PSTATE.PM is 0.

- All of the following are true:
  - — EL3 is not implemented or MDCR_EL3.PMSEE is not `0b00`.
  - — EL2 is not implemented, or EL2 is disabled in the current Security State, or PMSCR_EL2.EE is not `0b00`.
  - — PMSCR_EL1.EE is `0b11`.
  - — PMBSR_EL1.S is 1.

  In this case:
  - — The target Exception level is EL2 if the Effective value of HCR_EL2.TGE is 1, and EL1 otherwise.
  - — If the PE is executing in the owning Security state, the PE is in Non-debug state, and any of the following are true, then the SPE Profiling exception is unmasked:
    - — The PE is executing at EL0.
    - — The PE is executing at EL1, PMSCR_EL1.KE is 1, and PSTATE.PM is 0.

When none of the above apply, the SPE Profiling exception is *disabled* and not pending.

When the SPE Profiling exception is enabled and unmasked, the SPE Profiling exception will be taken to the *target Exception level*.

When the SPE Profiling exception is enabled and not unmasked, then the SPE Profiling exception is *masked*. The SPE Profiling exception is always masked at EL3.

The pseudocode function `CheckForSPEException()` shows this.

IGMBMC

Table D17-8, Table D17-9, and Table D17-10 show the SPE Profiling exception enable and masking for each Exception level, for the Effective values of each of the PMBSR_EL1.S, PMBSR_EL2.S, and PMBSR_EL3.S bits respectively.

Each column in the left side of the table refers to the Effective value of a field in a System register or PSTATE. If FEAT_SPE_EXC is not implemented, then the Effective values of PMBSR_EL2.S and PMBSR_EL3.S are 0.

In Table D17-8, the IRQ column represents the state of the **PMBIRQ** signal. Table D17-8 does also apply when FEAT_SPE_EXC is disabled. In these cells for each row representing a combination of control bits:

HIGH
: Means the SPE Profiling exception is disabled and the SPE interrupt request is enabled and asserted.

LOW
: Means the SPE interrupt request is not asserted.

The other columns in the right side of the table represent an Exception level the exception is taken from. In each cell for each of these columns for each row representing a combination of control bits:

None
: Means the exception is disabled. For Table D17-9 and Table D17-10 this means that the PMBSR_EL3.S or PMBSR_EL2.S bit (as applicable) is ignored.

B
: Means the exception is enabled and masked by PSTATE.PM. The exception remains pending.

C
: Means the exception is enabled and masked regardless of the value of PSTATE.PM. The exception remains pending.

ELx
: Means the exception is enabled, is not masked, and is taken to ELx.

n/a
: Not applicable. The PE cannot be executing at this Exception level for the specified value of HCR_EL2.TGE.

0b10	0b1	EL3	n/a	EL3	C
0b11	0b0	EL3	EL3	EL3	C
0b11	0b1	EL3	n/a	EL3	C

I_{SFJPD} When FEAT_SPE_EXC is implemented, the target Exception level might be the same as the owning Exception level, or a higher Exception level, or a lower Exception level. For example:

- The owning Exception level is EL1, but EL2 triages all SPE Profiling exceptions and so programs PMSCR_EL2.EE to 0b11.
- The owning Exception level is EL2, because EL2 has mapped the Profiling Buffer in the EL2 translation regime, but EL1 can handle all non-MMU management events, and so EL2 programs PMSCR_EL2.EE to 0b10.

R_{YMRRB} When FEAT_SPE_EXC is implemented, SPE Profiling exceptions are taken asynchronously and precisely.

R_{NXPMV} When FEAT_SPE_EXC is implemented, if an SPE Profiling exception is enabled and unmasked, and all of the following are true, then the SPE Profiling exception will be taken before an instruction **C** completes execution:

- Instruction **A** is one of the following:
  - A direct read of the corresponding PMBSR_ELx register that observes that the S bit is 1.
  - A direct write of the corresponding PMBSR_ELx register that sets the S bit to 1.
  - A `PSB CSYNC` instruction that synchronizes a profiling operation that causes a Profiling Buffer management event that sets the corresponding PMBSR_ELx.S bit to 1. For more information, see Synchronization and Statistical Profiling.
- **C** follows in program order immediately after a Context synchronization event **B**.
- **B** is in program order after **A**.

Otherwise, the SPE Profiling exception is taken in finite time.

R_{TSJRP} If any of the following are true, then the SPE interrupt request (**PMBIRQ**) is enabled and driven from PMBSR_EL1.S:

- FEAT_SPE_EXC is not implemented.
- EL3 is implemented and MDCR_EL3.PMSEE is 0b00.
- EL2 is implemented, PMSCR_EL2.EE is 0b00, and any of the following are true:
  - The Effective value of SCR_EL3.NS is 1.
  - The Effective value of SCR_EL3.{NS, EEL2} is {0, 1}.

  This applies even when the current Exception level is EL3.
- PMSCR_EL1.EE is 0b00.

Otherwise, if FEAT_SPE_EXC is implemented, then the SPE interrupt request is disabled and driven LOW (inactive). The pseudocode function `SPEInterruptEnabled()` shows this.

I_{GRLRX} When the **PMBIRQ** is enabled:

- A direct write that sets PMBSR_EL1.S to 1 causes the interrupt to be asserted.
- **PMBIRQ** will remain asserted until software clears PMBSR_EL1.S to 0.

I_{SMLLS} If a Generic Interrupt Controller (GIC) is implemented, **PMBIRQ** must be configured as a Private Peripheral Interrupt (PPI) in a multiprocessor system. **PMBIRQ** is signaled by the PE that implements the SPU.

Note

A standard PPI number is allocated by the *Arm® Base System Architecture* (BSA).

D17.8.1 Prioritization of Profiling Buffer management events

R_{DTGVZ} Where multiple synchronous Profiling Buffer management events occur on writing a sample record, the PE prioritizes them as follows (from highest to lowest priority):

1. Synchronous fault.
2. Synchronous External abort.
3. Buffer full event.

I_{XQRTS} Asynchronous External aborts are not prioritized with respect to other events.

I_{CTRLW} When a Profiling Buffer management event generates an SPE interrupt request, the priority of the SPE interrupt request is separately managed by the interrupt controller. Do not confuse the prioritization of Profiling Buffer management events with the prioritization of SPE interrupt requests by an interrupt controller.

D17.8.2 Buffer full event

If, after writing a sample record, there is not sufficient space in the Profiling Buffer for a sample record of the size indicated by PMSIDR_EL1.MaxSize, and PMBSR_ELx.S is 0, a Profiling Buffer management event is generated:

- PMBSR_ELx.S is set to 1.
- PMBSR_ELx.EC is set to `0b000000`, other buffer management event.
- The BSC field of PMBSR_ELx.MSS is set as follows:
  - PMBSR_ELx.BSC is set to `0b000001`, buffer filled.
- PMBPTR_EL1 is set to the first byte after the last complete sample record, which can include any padding that the implementation uses to force alignment. PMBSR_ELx.DL is unchanged.
- The other fields in PMBSR_ELx and the other PMBSR_ELx registers are unchanged.
- The SAMPLE_BUFFER_FULL PMU event is generated.

ELx is defined by R_{HJXHT}. See also Table D17-7.

That is, the Profiling Buffer management event is generated when the PE writes past the write limit pointer minus $2^{(PMSIDR_EL1.MaxSize)}$. The SPU never writes beyond the write limit pointer.

For more information, see Restrictions on the current write pointer.

D17.8.3 Faults and watchpoints

Table D17-11 lists the faults that might be generated by a write to the Profiling Buffer by the SPU.

Writes to the Profiling Buffer never generate watchpoints.

Table D17-11 Faults

Fault	Conditions
Translation	The translation of a virtual address to a physical address might generate a Translation fault.
Address Size	The translation of a virtual address to a physical address might generate an Address Size fault.
Alignment	If PMBPTR_EL1 is not aligned to an IMPLEMENTATION DEFINED minimum alignment, the behavior is UNPREDICTABLE and a write to the Profiling Buffer by the SPU might generate an Alignment fault. For more information, see Restrictions on the current write pointer.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Fault	Conditions
Permission	Writes to the Profiling Buffer are made as privileged writes. If the write does not have write permission, a Permission fault is generated. The value of PSTATE.PAN is treated as zero and the FEAT_S1POE stage 1 Overlay permissions are ignored. If the SPU does not manage the dirty state in translation tables, then accesses ignore the Dirty Bit Modifier bit in Page and Block descriptors and an access might as a result generate a Permission fault. For more information, see Hardware management of the dirty state.[a]
Access flag	If the SPU does not manage the Access flag in translation tables or hardware management of the Access flag state is disabled for the owning translation regime, then any access to a Page or Block with the Access Flag bit set to 0 in a descriptor will generate an Access Flag fault. For more information, see The Access flag.[a]
TLB Conflict fault	IMPLEMENTATION DEFINED.
Unsupported atomic hardware update fault	If hardware update of the translation tables is not guaranteed atomic in regard to other agents that access the memory, the translation of a virtual address to a physical address might generate an Unsupported atomic hardware update fault.
External abort on translation table walk, translation table update, or GPT walk	The translation of a virtual address to a physical address might generate an External abort on the translation table walk, translation table update, or GPT walk, and be treated as a synchronous MMU fault. For more information, see External aborts.
Granule Protection Check	The translation of a virtual address to a physical address might generate a GPC fault.

a. PMBIDR_EL1.F defines whether the SPU manages the Access flag and dirty state in the translation tables.

If a write to the Profiling Buffer generates an Alignment fault or MMU fault, including a Granule Protection Check (GPC) fault, and PMBSR_ELx.S is 0, then all of the following occur:

- A Profiling Buffer management event is generated. This sets PMBSR_ELx.S is set to 1.
- PMBSR_ELx.EC is set to one of:
  - `0b011110`, GPC fault, other than a Granule Protection Fault (GPF), on write to the Profiling Buffer.
  - `0b100100`, stage 1 Data Abort on write to the Profiling Buffer.
  - `0b100101`, stage 2 Data Abort on write to the Profiling Buffer.

  A GPF on translation table walk or update is reported as either a stage 1 or stage 2 Data Abort, as appropriate. Other GPFs are reported as a stage 1 Data Abort.
- The FSC field of PMBSR_ELx.MSS is set as follows:
  - PMBSR_ELx.FSC is set to indicate the type of the fault.
- If FEAT_THE is implemented, then PMBSR_ELx.TopLevel is set as follows:
  - 1, for a stage 2 Permission fault due to a TopLevel check.
  - 0, otherwise.
- If FEAT_THE is implemented, then PMBSR_ELx.AssuredOnly is set as follows:
  - 1, for a stage 2 Permission fault due to the AssuredOnly attribute.
  - 0, otherwise.
- PMBPTR_EL1 is set to the address that generated the fault.
- If PMBPTR_EL1 is not the address of the first byte after the last complete sample record, written by the SPU and including any padding used to force alignment, then PMBSR_ELx.DL is set to 1. Otherwise, PMBSR_ELx.DL is unchanged.

If the MMU fault is an External abort on a translation table walk, translation table update, or GPT walk, then it is IMPLEMENTATION DEFINED whether PMBSR_ELx.EA is set to 1 or unchanged.

The value of ELx depends on the type of event, and is defined by R_{HJXHT}. The other fields in PMBSR_ELx and the other PMBSR_ELx registers are unchanged.

Note

Each of these faults causes a Profiling Buffer management event, not an actual MMU fault exception. The ESR and FAR registers are unchanged.

For more information, see MMU fault-checking sequence.

D17.8.3.1 Hardware management of dirty state and the Access flag by the Statistical Profiling Extension

If FEAT_SPEv1p3 is implemented, address translations performed by the SPU manage dirty state and the Access flag in Block and Page descriptors. Otherwise, it is IMPLEMENTATION DEFINED whether address translations performed by the SPU manage dirty state and the Access flag. This is discoverable by software using PMBIDR_EL1.F. See Hardware management of the dirty state and Hardware management of the Access flag.

If the SPU manages dirty state and hardware management of dirty state is enabled for the owning translation regime, then the SPU can speculatively update the Translation Table descriptor for any Page or Block in the Statistical Profiling buffer before writing data to it, if the write is otherwise permitted. This includes the case where a buffer management event means the SPU stops writing data before the page or block is written to. For more information, see The Profiling Buffer.

If FEAT_HAFT is implemented and the SPU manages dirty state, for an architecturally executed memory access that is translated by a translation stage with Table descriptor Access flag hardware management enabled, the SPU sets the Access flag to 1 in all Table descriptors accessed during the translation table walk for that access that have the Access flag set to 0.

D17.8.4 External aborts

R_{JFYNW} When a write to the Profiling Buffer generates an External abort, including an External abort on a translation table walk, translation table update, or GPT walk, the permitted IMPLEMENTATION DEFINED behaviors are:

- The External abort is ignored.
- The External abort generates an SError exception.
- For an External abort on a translation table walk, translation table update, or GPT walk only, the External abort generates a MMU fault.
- If FEAT_SPEv1p3 is not implemented, the External abort is reported to the SPU. The SPU generates a Profiling Buffer management event.

I_{KDMQG} PMBIDR_EL1.EA indicates to software the mechanism used by the SPU when a write to memory generates an External abort that does not generate a MMU fault.

Note

The originator of the abort might additionally take other actions. For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

D17.8.4.1 The External abort is ignored

I_{VPLMK} If the External abort is ignored, this has the same visible behavior as when a write does not generate any External abort. PMBSR_ELx is not modified.

D17.8.4.2 The External abort generates an SError exception

I_{ZGGXW} If a write to the Profiling Buffer generates an External abort that is taken as an SError exception, the PE takes the SError exception as normal, and PMBSR_ELx fields are unchanged.

D17.8.4.3 The External abort generates a MMU fault

I_{QNXKH} When an External abort on a translation table walk, translation table update, or GPT walk generates a MMU fault, the behavior is as described by Faults and watchpoints.

D17.8.4.4 The External abort is reported to the SPU

I_{TCPLL} The behavior in this section is not permitted if FEAT_SPEv1p3 is implemented.

R_{BPFPN} If a write to the Profiling Buffer generates an External abort that is reported to the SPU:

- The External abort bit, PMBSR_ELx.EA, is set to 1.
- The SPU stops writing sample records to the Profiling Buffer. It is IMPLEMENTATION DEFINED whether an External abort on a write to the Profiling Buffer is reported as synchronous or asynchronous:
  - The External abort is reported as *synchronous* if PMBPTR_EL1 is set to the address that was externally aborted.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— The External abort is reported as *asynchronous* if PMBPTR_EL1 is not guaranteed to be set to the address that was externally aborted.

- If the External abort is reported as asynchronous or PMBPTR_EL1 is not the address of the first byte of the sample record being written by the SPU, then PMBSR_ELx.DL is set to 1. Otherwise, PMBSR_ELx.DL is unchanged.

Note

Following an External abort reported asynchronously to the SPU, software must not assume that any valid data has been written to the Profiling Buffer.

- If PMBSR_ELx.S is 0, a buffer management event is generated:
  — PMBSR_ELx.S is set to 1.
  — PMBSR_ELx.EC is set to one of:
    — If the External abort is on a GPT fetch, `0b011110`, Granule Protection Check fault on write to Profiling Buffer, other than Granule Protection Fault (GPF).
    — If the External abort is on a stage 2 translation table access, `0b100101`, stage 2 Data Abort on write to buffer.
    — Otherwise, `0b100100`, stage 1 Data Abort on write to buffer.
  — PMBSR_ELx.MSS is set as follows:
    — PMBSR_ELx.FSC is set to indicate a synchronous or asynchronous External abort.

ELx is defined by R_{HJXHT}. See also Table D17-6. Other fields in PMBSR_ELx and the other PMBSR_ELx registers are unchanged.

I_{XPWQC} If External aborts are reported as asynchronous:

- The External abort might not be received until after a first Profiling Buffer management event has set PMBSR_ELx.S to 1.
- Writes to the buffer might generate a second Profiling Buffer management event after the External abort has set PMBSR_ELx.S to 1.

D17.8.5 Access not allowed

An SPU might detect that a write to the Profiling Buffer cannot occur, usually because software has created an architecturally UNPREDICTABLE situation. In these cases, when profiling data is generated, the SPU might discard the data and generate a Profiling Buffer management event:

- If PMBSR_ELx.S is 0, then all of the following occur:
  — PMBSR_ELx.S is set to 1.
  — PMBSR_ELx.DL is set to 1.
  — PMBSR_ELx.EC is set to `0x00`, other buffer management event.
  — PMBSR_ELx.BSC is set to `0b000000`, access not allowed.
- The other fields in PMBSR_ELx and the other PMBSR_ELx registers are unchanged.

ELx is defined by R_{HJXHT}. See also Table D17-7.

D17.8.6 Implementation defined reason

An implementation might include support for generating Profiling Buffer events for IMPLEMENTATION DEFINED reasons. These should normally be disabled unless enabled by IMPLEMENTATION DEFINED controls. The PMBSR_ELx.EC code `0x1F` is reserved for this purpose.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D17.9 Synchronization and Statistical Profiling

I_{RRBSZ} The profiling operation of the SPU:

- Makes indirect reads and indirect writes of System registers.
- Writes to memory.
- Makes further indirect writes to PMBPTR_EL1 as a result of an External abort on a write to memory.

I_{WZSLB} The indirect reads of the PMSCR_EL1.{E1SPE, E0SPE} and PMSCR_EL2.{E2SPE, E0HSPE} controls when determining whether to select an operation for profiling are treated as indirect reads made by the instruction being executed, and subject to the standard requirements for synchronization.

Otherwise, although the profiling operation is generated by a sampled operation, the profiling operation executes independently of the instructions that are executed on the PE.

I_{NRNSL} A `DSB` instruction guarantees that all memory transactions that are made by the PE are observable by writes made by a profiling operation relating to a sampled operation in program order after the `DSB` instruction.

I_{NDWCG} A Context Synchronization event guarantees that a direct write to a System register made by the PE in program order before the Context synchronization event are observable by indirect reads and indirect writes of the same System register made by a profiling operation relating to a sampled operation in program order after the Context synchronization event.

R_{TRDTK} To synchronize previous profiling operations, software must execute a `PSB` Buffer Synchronization instruction.

Note

The `PSB CSYNC` instruction is not defined in the AArch32 instruction set architecture.

I_{MLGHW} Following a Context synchronization event, a `PSB` instruction is guaranteed to synchronize the profiling operations for all instructions that are executed in program order before the Context synchronization event.

Synchronized by the `PSB` instruction means:

- A direct read of a System register in program order following a `PSB` instruction requires explicit synchronization to observe an indirect write to the same System register made by a profiling operation synchronized by the `PSB` instruction.
- An indirect write to a System register made by a profiling operation synchronized by a `PSB` instruction does not affect a direct write to the same System register made in program order following the `PSB` instruction.
- A direct write to a System register in program order following a `PSB` instruction is not allowed to affect an indirect read of the same System register made by a profiling operation synchronized by the `PSB` instruction.
- A `DSB` instruction in program order following a `PSB` instruction does not complete before the writes to the Profiling Buffer of sample records for profiling operations synchronized by the `PSB` instruction have completed. The `DSB` instruction must apply to both loads and stores.

For the indirect write to PMBSR_ELx that is made as a result of an External abort on a write of a sample record to memory, the synchronization rules apply only after the write has completed. Completion of the write includes reporting any Profiling Buffer management event due to an Alignment fault or MMU fault.

Note

If profiling is not disabled when the Context synchronization event occurs, further profiling operations might be generated that are not guaranteed to be synchronized by the `PSB` instruction.
If the PE takes an exception to an Exception level where profiling is disabled, no new operations are selected for sampling. Profiling is always disabled if the owning Exception level is a lower Exception level than the current Exception level.

I_{VKDVF} In the absence of a Context synchronization event, a `PSB` instruction is not required to execute in program order with respect to sampled operations.

D17.9.1 UNPREDICTABLE behavior

R_{PVRNK} In the absence of correct Context synchronization events, it is UNPREDICTABLE whether an indirect read of a System register made by a profiling operation will return the old or the new values.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{SXWCP} If the indirect reads mean that `ProfilingBufferEnabled()` returns FALSE when a sample record or records are about to be written to memory, then it is further CONSTRAINED UNPREDICTABLE whether the sample record or records:

- Are written to memory.
- Are silently discarded and not written to memory.
- Are discarded and not written to memory, and an Access Not Allowed Profiling Buffer management event is generated.

R_{VCYWL} If SCR_EL3.{NSE, NS} does not match the owning Security state, then it is CONSTRAINED UNPREDICTABLE whether the sample record or records:

- Are written to memory using an address formed using the identity of the owning translation regime.
- Are written to memory using an address formed using the Effective values of SCR_EL3.{NSE, NS}.
- Are silently discarded and not written to memory.
- Are discarded and not written to memory, and an Access Not Allowed Profiling Buffer management event is generated.

R_{QJWVQ} When FEAT_RME is implemented and MDCR_EL3.{NSPB, NSPBE} selects a reserved value, then it is CONSTRAINED UNPREDICTABLE whether the sample record or records:

- Are written to memory using an address formed using any implemented Security state.
- Are silently discarded and not written to memory.
- Are discarded and not written to memory, and an Access Not Allowed Profiling Buffer management event is generated.

I_{PDDCL} Software must execute a `PSB` instruction to force any sample records to be written to the Profiling Buffer before changing context.

Chapter D18
Statistical Profiling Extension Sample Record Specification

This chapter describes the sample records generated by the Statistical Profiling Extension. It contains the following sections:

- About the Statistical Profiling Extension sample records
- Alphabetical list of Statistical Profiling Extension packets

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D18.1 About the Statistical Profiling Extension sample records

The Statistical Profiling Extension sample record format version is identified by PMSIDR_EL1.Format. The architecture currently defines only version 0.

Note

Armv8.7 defines the SPE sample record format version, allowing future architecture updates to extend or change the record format. PMSIDR_EL1.Format was previously a res0 field in a read-only register. Software that reads and checks PMSIDR_EL1.Format on any implementation prior to Armv8.7 that includes SPE will read a value indicating format version 0 is supported.

The sample record format version 0 is self-describing and extensible. This format allows software to parse profile data even when that profile data contains extended information.

The Statistical Profiling Extension writes a series of sample records to memory, each record consisting of a sequence of packets, and each packet consisting of:

- One or two header bytes.
- Zero, 1, 2, 4, or 8 payload bytes.

D18.1.1 Headers

The first header byte encodes the number of payload bytes:

`0x00` - `0x1F` Single byte header, no payload.

`0x20` - `0x3F` First byte of extended header. Second byte encodes the payload length.

`0x40` - `0x4F`, `0x80` - `0x8F`, `0xC0` - `0xCF`

Header with an 8-bit payload.

`0x50` - `0x5F`, `0x90` - `0x9F`, `0xD0` - `0xDF`

Header with a 16-bit payload.

`0x60` - `0x6F`, `0xA0` - `0xAF`, `0xE0` - `0xEF`

Header with a 32-bit payload.

`0x70`-`0x7F`, `0xB0`-`0xBF`, `0xF0`-`0xFF`

Header with a 64-bit payload.

D18.1.2 Records

A record consists of multiple packets. A record comprises, in ascending address order:

- A sequence of headers, each followed by their payload byte or bytes.
- Either:
  - An End packet header.
  - A Timestamp packet.

Figures in this chapter show each packet as a sequence of bytes. Figure D18-1 shows how bytes are stored in memory in increasing addresses from left to right.

Non-Confidential

First byte	1	2	3	4	Last Byte
Header (16-bit data)	Data		Header (8-bit data)	Data	0x01 End Packet
	LSB	MSB			

First Byte	1	2	3	4	5	6	...	12	Last Byte
Header (16-bit data)	Data		Header (8-bit data)	Data	0x71 Timestamp Packet	TS [7:0]	...	TS [55:48]	TS [63:56]
	LSB	MSB							

Figure D18-1 Convention for packet description

In some sections, the figures are split into separate figures for the header byte and payload bytes. For instance, where the number of payload bytes varies according to a field in the header.

The header bytes and payload bytes are described in ascending memory address order. Within a payload value, values are in little-endian byte order.

The size of the access granule for writes to the Profiling Buffer by the Statistical Profiling Unit is IMPLEMENTATION DEFINED, up to a maximum of 2KB. The size of the access granule can vary from time to time.

D18.1.3 Protocol framing packets and forwards compatibility

The padding header, Timestamp packet, and end packet are protocol framing packets that frame the records created by the Statistical Profiling Unit. Only padding headers are permitted between records.

Note

PMBIDR_EL1.Align defines a minimum alignment for records. However, implementations must nevertheless create a valid protocol stream that can be parsed without knowledge of the minimum alignment.

The packet types are described in the following sections. Software must ignore unknown packets, using the size field encoded in the header. This includes packets containing reserved values in fields.

The following sections give an overview of the Statistical Profiling Unit packets output to a memory-mapped Profiling Buffer or Device memory:

- Statistical Profiling Extension protocol packet headers

D18.1.4 Statistical Profiling Extension protocol packet headers

D18.1.4.1 8-bit headers

For Address packets and Counter packets, the 8-bit header format is described as the *Short format*.

Table D18-1 8-bit header encodings

[7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]	Description
0	0	0	0	0	0	0	0	Padding

D18.2 Alphabetical list of Statistical Profiling Extension packets

This section lists every SPE packet and their description.

D18.2.1 Address packet

Purpose

Provides an address value for the record. Addresses are always 64 bits.

Attributes

Multi-part packet comprising:

- 8 or 16-bit header.
- 64-bit payload.

Address packet header

7	6	5	4	3	2	1	0
0	0	1	0	0	0	INDEX[4:3]	
1	0	SZ 1	1	0	INDEX[2:0]		

Figure D18-2 Address packet header (Extended format)

7	6	5	4	3	2	1	0
1	0	SZ 1	1	0	INDEX		

Figure D18-3 Address packet header (Short format)

Byte 1 bits [7:6], when Extended format; byte 0 bits [7:6], when Short format

This field reads as `0b10`.

SZ, byte 1 bits [5:4], when Extended format; byte 0 bits [5:4], when Short format

Payload size.

SZ	Description
`0b11`	Doubleword.

This field reads as `0b11`.

Byte 1 bit [3], when Extended format; byte 0 bit [3], when Short format

This bit reads as `0b0`.

INDEX, byte 0 bits [1:0], byte 1 bits [2:0], when Extended format; byte 0 bits [2:0], when Short format

Identifies the address value.

INDEX	Description
`0b00000`	Instruction virtual address (PC). The virtual address of the sampled operation.
`0b00001`	Branch target address. The target virtual address of a sampled branch operation.
`0b00010`	Data access virtual address. The virtual address accessed by a sampled data memory accessing operation.
`0b00011`	Data access physical address. The physical address accessed by a sampled data memory accessing operation.
`0b00100`	Previous branch target address. The target virtual address of the most recently taken branch operation in program order before the sampled operation. This value is defined only if FEAT_SPE_PBT is implemented, and reserved otherwise.
`0b0011x`	IMPLEMENTATION DEFINED address.
`0b1xxxx`	IMPLEMENTATION DEFINED address.

All other values are reserved.

In the Short format header, INDEX[4:3] are zero.

Byte 0 bits [7:5], when Extended format

This field reads as `0b001`.

Byte 0 bits [4:2], when Extended format

This field reads-as-zero.

Address packet payload (instruction virtual address or branch target address)

7	6	5	4	3	2	1	0

ADDR[47:40]							
ADDR[55:48]							
NS	EL		NSE	0	0	0	0

Figure D18-4 Address packet payload

NS, byte 7 bit [7]

Non-secure state.

For an instruction virtual address (PC) this is the Security state the instruction was executed in. For a branch target address, this is the Security state at the target of the branch.

Note

For an Exception Return, the Security state at the target of the branch might be different to the Security state the instruction was executed in.

When FEAT_RME is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

With the NSE bit, indicates the Security state associated with the address.

NSE	NS	Description
0b0	0b0	Secure state. This value is defined only if FEAT_Secure is implemented, and reserved otherwise.
0b0	0b1	Non-secure state.
0b1	0b1	Realm state.

All other values are reserved.

Note

There is no encoding for Root because records are not generated at EL3.

When EL3 is implemented

The Security state associated with the address.

NS	Description
0b0	Secure state.
0b1	Non-secure state.

When FEAT_Secure is implemented

The Security state associated with the address. This bit reads-as-zero.

Otherwise

The Security state associated with the address. This bit reads-as-one.

EL, byte 7 bits [6:5]

Exception level. The Exception level associated with the address. For an instruction virtual address (PC) this is the Exception level the instruction was executed in. For a branch target address, this is the Exception level at the target of the branch.

EL	Description
0b00	EL0.
0b01	EL1.
0b10	EL2. This value is defined only if EL2 is implemented, and reserved otherwise.
0b11	EL3. This value is defined only if EL3 is implemented, and reserved otherwise.

Note

For an Exception Return, the Exception level at the target of the branch might be different to the Exception level the instruction was executed in.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSE, byte 7 bit [4]

Security state.

When FEAT_RME is implemented

Together with the NS bit, indicates the Security state associated with the address.

Otherwise

This bit reads-as-zero.

Byte 7 bits [3:0]

This field reads as `0b0000`.

ADDR, bytes <6:0>

Address. Bits [55:0] of the instruction virtual address or branch target address.

Address packet payload (data access virtual address)

7	6	5	4	3	2	1	0
ADDR[7:0]							
ADDR[15:8]

ADDR[39:32]							
ADDR[47:40]							
ADDR[55:48]							
TAG							

Figure D18-5 Address packet payload

TAG, byte <7>

Top-byte tag.

If the applicable TBI bit is 1, then a data access virtual address includes the top-byte tag, and this field holds bits [63:56] of the address.

Otherwise, it is IMPLEMENTATION DEFINED whether this field reads as zero or holds bits [63:56] of the address.

ADDR, bytes <6:0>

Address. Bits [55:0] of the data access virtual address.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Address packet payload (data access physical address)

7	6	5	4	3	2	1	0

ADDR[47:40]							
ADDR[55:48]							
NS	CH	0	NSE	LAT			

Figure D18-6 Address packet payload

NS, byte 7 bit [7]

Physical address space identifier.

When FEAT_RME is implemented

With the NSE bit, indicates the physical address space of the physical address.

NSE	NS	Description
`0b0`	`0b0`	Secure physical address space. This value is defined only if FEAT_Secure is implemented, and reserved otherwise.
`0b0`	`0b1`	Non-secure physical address space.
`0b1`	`0b1`	Realm physical address space.

All other values are reserved.

Note

There is no encoding for Root because records are not generated at EL3.

When EL3 is implemented

The physical address space of the physical address.

NS	Description
`0b0`	Secure physical address space.
`0b1`	Non-secure physical address space.

When FEAT_Secure is implemented

The physical address space of the physical address. This bit reads-as-zero.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise

The physical address space of the physical address. This bit reads-as-one.

CH, byte 7 bit [6]

Tag Checked.

When FEAT_MTE2 is implemented

Indicates whether the access was checked against an Allocation Tag in memory.

CH	Description
`0b0`	Access not checked.
`0b1`	Access checked against an Allocation Tag in memory.

If FEAT_MTE_CANONICAL_TAGS is implemented and a sampled data access physical address is Canonically Tagged, then the value of this bit is 0.

Otherwise, if Tag Check Faults are configured to be ignored by SCTLR_EL*x*.TCF or SCTLR_EL*x*.TCF0, then it is IMPLEMENTATION DEFINED whether this bit is 1 or 0 on a Tag Checked access.

Otherwise

This bit reads-as-zero.

Byte 7 bit [5]

This bit reads as `0b0`.

NSE, byte 7 bit [4]

Physical address space.

When FEAT_RME is implemented

Together with the NS bit, indicates the physical address space associated with the address.

Otherwise

This bit reads-as-zero.

LAT, byte 7 bits [3:0]

Logical Address Tag.

When FEAT_MTE2 is implemented

Logical Address Tag for a checked access. If the access is not checked then this field reads as an IMPLEMENTATION DEFINED choice between `0b0000` and the Logical Address Tag used to perform the access.

Otherwise

This field reads-as-zero.

ADDR, bytes <6:0>

Address. Bits [55:0] of the data access physical address.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D18.2.2 Context packet

Purpose

Provides context information for the record.

Attributes

Multi-part packet comprising:

- 8-bit header.
- 32-bit payload.

Context packet header

7	6	5	4	3	2	1	0
0	1	SZ 1	SZ 0	0	1	INDEX	

Figure D18-7 Context packet header

Byte 0 bits [7:6]

D18.2.3 Counter packet

Purpose

Count of cycles the operation spent performing all or part of its behavior. The counter value occupies the least significant bits of the payload. The remaining bits are set to zero.

Attributes

Multi-part packet comprising:

- 8 or 16-bit header.
- 16-bit payload.

Counter packet header

7	6	5	4	3	2	1	0
0	0	1	0	0	0	INDEX[4:3]	
1	0	SZ 0	SZ 1	1	INDEX[2:0]		

Figure D18-9 Counter packet header (Extended format)

7	6	5	4	3	2	1	0
1	0	SZ 0	SZ 1	1	INDEX		

Figure D18-10 Counter packet header (Short format)

Byte 1 bits [7:6], when Extended format; byte 0 bits [7:6], when Short format

This field reads as `0b10`.

SZ, byte 1 bits [5:4], when Extended format; byte 0 bits [5:4], when Short format

Payload size.

SZ	Description
`0b01`	Halfword.

This field reads as `0b01`.

Byte 1 bit [3], when Extended format; byte 0 bit [3], when Short format

This bit reads as `0b1`.

INDEX, byte 0 bits [1:0], byte 1 bits [2:0], when Extended format; byte 0 bits [2:0], when Short format

Identifies the counter value.

INDEX	Description
`0b00000`	Total latency. The count of cycles from the operation being dispatched for issue to the operation being complete. Included for all operations.
`0b00001`	Issue latency. The count of cycles when the operation is waiting to be issued.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

INDEX	Description
0b00010	Translation latency. The count of cycles when at least one part of the operation is waiting for the MMU to complete an address translation. It is IMPLEMENTATION DEFINED whether a cycle is counted if another part of the operation is accessing memory, having completed an address translation for that part of the operation, while the at least one part is still waiting for translation to complete. For more information, see Additional information for each profiled memory access operation.
0b00100	Alternate clock issue latency. As *issue latency*, but counts cycles in the clock domain specified by PMSIDR_EL1.ALTCLK. This value is defined only if FEAT_SPE_ALTCLK is implemented, and reserved otherwise.
0b0011x	IMPLEMENTATION DEFINED counter value.
0b1xxxx	IMPLEMENTATION DEFINED counter value.

All other values are reserved.

In the Short format header, INDEX[4:3] are zero.

Dispatched for issue means:

- The operation has been decoded.
- The operation might not be ready to start execution because it is waiting for input values. The operation might be put into a queue.

Issued for execution means the operation is ready to start executing.

For a sampled operation, complete means:

- The operation has completed execution and is no longer capable of stalling any instruction that consumes its output.
- It is IMPLEMENTATION DEFINED whether the operation has committed its results to the architectural state of the PE.
- For example:
  - For an arithmetic, FP or SIMD operation with variable timing, such as divide the results of the operation are available.
  - For load and atomic operations that return data, all data have been returned from memory.
  - For store and atomic operations that do not return data, it is not required that the store has reached its end point for it to be complete.
  - For branch operations, the branch has been resolved as taken or not taken.
  - For barrier operations, the barrier has completed.

For `WFE` and `WFI` operations, it is IMPLEMENTATION DEFINED whether:

- The instruction is complete before the PE enters a low-power state or when the PE wakes from the low-power state.
- Counters count in the low power state.
- Sampling an operation is itself a wakeup event.

Byte 0 bits [7:5], when Extended format

This field reads as `0b001`.

Byte 0 bits [4:2], when Extended format

This field reads-as-zero.

COUNT[7:0]							
COUNT[15:8]							

Figure D18-12 Counter packet payload (16-bit counters are implemented)

Byte 1 bits [7:4], when 12-bit counters are implemented

This field reads as `0b0000`.

COUNT, byte 1 bits [3:0], byte <0>, when 12-bit counters are implemented; bytes <1:0>, when 16-bit counters are implemented

The counter value occupies the least significant bits of the payload. The remaining bits are set to zero. The counters are:

- Unsigned numbers.
- 12 or 16 bits.
- Saturating.

PMSIDR_EL1.CountSize indicates the size of counter implemented, and:

- If 12-bit counters are implemented, the value `0xFFF` indicates the count has saturated.
- If 16-bit counters are implemented, the value `0xFFFF` indicates the count has saturated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D18.2.4 Data Source packet

Purpose

If the implementation includes support for indicating the loaded data source, then the Data Source packet indicates where the data returned for a load operation was sourced. It might also include other information, such as the state of the data at the source. It is IMPLEMENTATION SPECIFIC whether this is included for load and atomic operations that generate an External Abort. It is IMPLEMENTATION DEFINED whether this is included for atomic operations that do not return data to a PE register. Included for all other load and atomic operations.

Attributes

Multi-part packet comprising:

- 8-bit header.
- 8 or 16-bit payload.

Data Source packet header

7	6	5	4	3	2	1	0
0	1	SZ		0	0	1	1

D18.2.6 Events packet

Purpose

Indicates events generated by the sampled operation. If the sampled operation generates one of the specified events, then the corresponding field is set to `0b1`. Otherwise, the corresponding field is set to `0b0`. Where applicable, a corresponding PMU event is defined for each event in the packet.

Attributes

Multi-part packet comprising:

- 8-bit header.
- 8, 16, 32, or 64-bit payload.

Events packet header

7	6	5	4	3	2	1	0

E[63:56]							

Figure D18-21 Events packet payload (SZ == 0b11)

E[63:48], bytes <7:6>, when SZ == `0b11`

Events 63 to 48. IMPLEMENTATION DEFINED.

Bytes <5:4>, when SZ == `0b11`

This field reads-as-zero.

E[31:26], byte 3 bits [7:1], when SZ == `0b10` or SZ == `0b11`

Events 31 to 26.

When FEAT_SPEv1p4 is implemented

This field reads-as-zero.

Otherwise

This field reads as an IMPLEMENTATION DEFINED value.

E[25], byte 3 bit [1], when SZ == `0b10` or SZ == `0b11`

Shared resource.

When (FEAT_SPE_SME is implemented or FEAT_SPEv1p5 is implemented), and an SMCU or other shared resource is implemented

Indicates whether the sampled operation was executed on a Streaming Mode Compute Unit (SMCU) or other shared resource.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E[25]	Description
0b0	Operation did not execute on an SMCU or other shared resource.
0b1	Operation executed on an SMCU or other shared resource.

A shared resource means a resource that is shared between PEs for the execution of instructions. It is IMPLEMENTATION DEFINED which instructions can be executed on a shared resource.

When FEAT_SPEv1p4 is implemented or FEAT_SPE_SME is implemented

This bit reads-as-zero.

Otherwise

This bit reads as an IMPLEMENTATION DEFINED value.

E[24], byte 3 bit [0], when SZ == 0b10 or SZ == 0b11

Streaming SVE mode.

When FEAT_SPE_SME is implemented

Indicates whether the PE was in Streaming SVE mode when the sampled operation was executed.

E[24]	Description
0b0	Operation executed when PE is in Non-streaming SVE mode.
0b1	Operation executed when PE is in Streaming SVE mode.

When FEAT_SPEv1p4 is implemented

This bit reads-as-zero.

Otherwise

This bit reads as an IMPLEMENTATION DEFINED value.

E[23], byte 2 bit [7], when SZ == 0b10 or SZ == 0b11

Data snooped.

When FEAT_SPEv1p4 is implemented

Indicates whether the sampled operation hit in a cache outside of the cache hierarchy of this PE.

E[23]	Description
0b0	Operation was not a load, or did not access a cache outside the cache hierarchy of this PE.
0b1	Load operation that snooped data from a cache outside the cache hierarchy of this PE.

This event is optional. If this event is not implemented, then this bit reads-as-zero.

If this event and FEAT_PMUv3 are implemented, then this event is implemented consistently with DSNP_HIT_RD.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise

This bit reads-as-zero.

E[22], byte 2 bit [6], when SZ == `0b10` or SZ == `0b11`

Recently fetched.

When FEAT_SPEv1p4 is implemented

Indicates whether the sampled operation hit a recently-fetched cache line.

E[22]	Description
`0b0`	Operation was not a load, or did not hit a recently-fetched cache line.
`0b1`	Load operation hit a recently-fetched cache line.

This event is optional. If this event is not implemented, then this bit reads-as-zero.

If this event and FEAT_PMUv3 are implemented, then this event is implemented consistently with L1D_LFB_HIT_RD, L2D_LFB_HIT_RD, and LL_LFB_HIT_RD.

Otherwise

This bit reads-as-zero.

E[21], byte 2 bit [5], when SZ == `0b10` or SZ == `0b11`

Cache data modified.

When FEAT_SPEv1p4 is implemented

Indicates whether the sampled operation accessed modified data from the cache.

E[21]	Description
`0b0`	Operation was not a load, or did not access modified data.
`0b1`	Load operation accessed modified data in a cache.

It is IMPLEMENTATION DEFINED whether this bit is valid for a cache hit (L<*n*>D_CACHE_HITM_RD), a snoop hit (DSNP_HITM_RD), or both.

This event is optional. If this event is not implemented, then this bit reads-as-zero.

If this event and FEAT_PMUv3 are implemented, then this event is implemented consistently with DSNP_HITM_RD, L1D_CACHE_HITM_RD, L2D_CACHE_HITM_RD, and LL_CACHE_HITM_RD.

Otherwise

This bit reads-as-zero.

E[20], byte 2 bit [4], when SZ == `0b10` or SZ == `0b11`

Level 2 data cache miss.

When FEAT_SPEv1p4 is implemented

Indicates whether the sampled operation accessed and missed in the level 2 data or unified cache. This excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E[20]	Description
`0b0`	Operation was not a load, or did not miss in the level 2 data or unified cache.
`0b1`	Load operation accessed and missed in the level 2 data or unified cache.

This event is optional. If this event is not implemented, then this bit reads-as-zero.

If this event and FEAT_PMUv3 are implemented, then this event is implemented consistently with L2D_CACHE_LMISS_RD.

Otherwise

This bit reads-as-zero.

E[19], byte 2 bit [3], when SZ == `0b10` or SZ == `0b11`

Level 2 data cache access.

When FEAT_SPEv1p4 is implemented

Indicates whether the sampled operation accessed the level 2 data or unified cache.

E[19]	Description
`0b0`	Operation was not a load, or did not access level 2 data or unified cache.
`0b1`	Load operation caused a cache access to at least the level 2 data or unified cache.

This event is optional. If this event is not implemented, then this bit reads-as-zero.

If this event and FEAT_PMUv3 are implemented, then this event is implemented consistently with L2D_CACHE_RD.

Otherwise

This bit reads-as-zero.

E[18], byte 2 bit [2], when SZ == `0b10` or SZ == `0b11`

Empty predicate.

When FEAT_SPEv1p1 is implemented and (FEAT_SVE is implemented or FEAT_SME is implemented)

Indicates whether all elements in the Governing predicate for the sampled operation were FALSE.

E[18]	Description
`0b0`	Operation was neither an SVE nor an SME operation, was not predicated, or at least one element in the Governing predicate or predicates was TRUE.
`0b1`	SVE or SME operation and all elements in the Governing predicate or predicates were FALSE.

For a sampled SVE operation, it is IMPLEMENTATION DEFINED whether this field is valid or reads as zero when the PRED field in the Operation Type packet is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

For outer product instructions which are widening, predication is considered with respect to the input element size.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with SME_PRED2_EMPTY_SPEC and SVE_PRED_EMPTY_SPEC.

Otherwise

This bit reads-as-zero.

E[17], byte 2 bit [1], when SZ == `0b10` or SZ == `0b11`

Partial or empty predicate.

When FEAT_SPEv1p1 is implemented and (FEAT_SVE is implemented or FEAT_SME is implemented)

Indicates whether at least one element in the Governing predicate for the sampled operation was FALSE.

E[17]	Description
`0b0`	Operation was neither an SVE nor an SME operation, was not predicated, or all elements in the Governing predicate or predicates were TRUE.
`0b1`	SVE or SME operation and at least one element in the Governing predicate or predicates was FALSE.

For a sampled SVE operation, it is IMPLEMENTATION DEFINED whether this field is valid or reads as zero when the PRED field in the Operation Type packet is 0.

Note

For outer product instructions which are widening, predication is considered with respect to the input element size.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with SME_PRED2_NOT_FULL_SPEC and SVE_PRED_NOT_FULL_SPEC.

Otherwise

This bit reads-as-zero.

Byte 2 bit [0], when SZ == `0b10` or SZ == `0b11`

This bit reads-as-zero.

E[15:12], byte 1 bits [7:4], when SZ == `0b01`, SZ == `0b10`, or SZ == `0b11`

Events 15 to 12. IMPLEMENTATION DEFINED.

E[11], byte 1 bit [3], when SZ == `0b01`, SZ == `0b10`, or SZ == `0b11`

Misalignment.

When FEAT_SPEv1p1 is implemented

Indicates whether the sampled operation incurred additional latency due to the address being accessed not being optimally aligned for the size of data being accessed.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E[11]	Description
0b0	Operation was not a load/store, or a load/store operation that was optimally aligned for the size of data being accessed.
0b1	Load/store operation that was not optimally aligned for the size of data being accessed.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with LDST_ALIGN_LAT.

Otherwise

This bit reads-as-zero.

E[10], byte 1 bit [2], when SZ == 0b01, SZ == 0b10, or SZ == 0b11

Remote access. Indicates whether the sampled operation accessed a device that does not contain the PE. This includes each data memory access that accesses another socket in a multi-socket system, including those that do not return data.

E[10]	Description
0b0	Operation was not a load/store, or did not make a remote access.
0b1	Load/store operation caused a remote access.

This event is optional. If this event is implemented, then it is further IMPLEMENTATION SPECIFIC whether a store can finish execution before this event is generated, meaning that, for stores, this event is not recorded and this bit reads-as-zero. If this event is not implemented, then this bit reads-as-zero.

If this event and FEAT_PMUv3 are implemented, then this event is implemented consistently with REMOTE_ACCESS or REMOTE_ACCESS_RD.

E[9], byte 1 bit [1], when SZ == 0b01, SZ == 0b10, or SZ == 0b11

Last-level cache miss. Indicates whether the sampled operation accessed in the last-level cache but was not completed by the last-level cache. That is, each:

- Load operation that does not return data from the last-level cache.
- Store operation that does not update the last-level cache.

E[9]	Description
0b0	Operation was not a load/store, or did not miss the last-level cache.
0b1	Load/store operation caused an access to at least the last-level cache but is not completed by the last-level cache.

This event reads as zero for operations that are completed by a cache above the last-level cache.

This event is optional. If this event is implemented, then it is further IMPLEMENTATION SPECIFIC whether a store can finish execution before this event is generated, meaning that, for stores, this event is not recorded and this bit reads-as-zero. If this event is not implemented, then this bit reads-as-zero.

If this event and FEAT_PMUv3 are implemented, then this event is implemented consistently with LL_CACHE_MISS or LL_CACHE_MISS_RD.

E[8], byte 1 bit [0], when SZ == 0b01, SZ == 0b10, or SZ == 0b11

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Last-level cache access. Indicates whether the sampled operation accessed the last-level cache.

E[8]	Description
0b0	Operation was not a load/store, or did not access the last-level data or unified cache.
0b1	Load/store operation caused a cache access to at least the last-level data or unified cache.

This event is optional. If this event is implemented, then it is further IMPLEMENTATION SPECIFIC whether a store can finish execution before this event is generated, meaning that, for stores, this event is not recorded and this bit reads-as-zero. If this event is not implemented, then this bit reads-as-zero.

If this event and FEAT_PMUv3 are implemented, then this event is implemented consistently with LL_CACHE or LL_CACHE_RD.

E[7], byte 0 bit [7]

Mispredicted. Indicates whether the sampled operation was a branch that was mispredicted, causing a correction to the predicted program flow.

E[7]	Description
0b0	Operation was not a branch, or was correctly predicted.
0b1	Branch that was mispredicted.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with BR_MIS_PRED or BR_MIS_PRED_RETIRED.

E[6], byte 0 bit [6]

Not taken. Indicates whether the sampled operation failed its condition code check, if applicable.

E[6]	Description
0b0	Operation was not a conditional operation, or did not fail its condition code check.
0b1	A conditional instruction that failed its condition code check.

Failing the condition code check means:

- For a conditional branch or compare-and-branch instruction, the branch was not taken.
- For a conditional select, the first operand was not written to the result.
- For a conditional compare, the condition flags were set to the immediate value and not the result of the compare.

If the implementation samples micro-operations, the condition result is the result condition of the micro-op. This might not match the condition that was specified in the instruction as the mapping from instructions to operations is IMPLEMENTATION DEFINED. This means that software should be careful interpreting this field, and, without a prior knowledge of this mapping, treat the value as UNKNOWN.

If the implementation samples architectural instructions, then note that for some alias instructions, the operation specifies the opposite condition to the machine instruction that they alias. For example, `CSET` and `CSETM`. The event as captured by SPE always captures the result of the underlying instruction, not the alias.

This field is valid only if the Operation Type packet defines this as either a Conditional Branch or a Conditional operation, and reads as zero otherwise.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E[5], byte 0 bit [5]

TLB miss. Indicates whether the sampled operation accessed and missed in at least the first level of data or unified TLB, causing a translation table walk involving at least one translation table access. This includes each complete or partial translation table walk that causes an access to memory or caches, including translation table walk caches.

E[5]	Description
0b0	Operation was not a load/store, or did not miss in the data or unified TLB and did not cause a TLB walk.
0b1	Load/store operation that missed in the data or unified TLB and caused a TLB walk.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with DTLB_WALK.

E[4], byte 0 bit [4]

TLB access. Indicates whether the sampled operation accessed at least the first level of data or unified TLB.

E[4]	Description
0b0	Operation was not a load/store that accessed the data or unified TLB.
0b1	Load/store operation caused an access to at least the first level of data or unified TLB.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with L1D_TLB.

E[3], byte 0 bit [3]

Level 1 data cache refill or miss.

When FEAT_SPEv1p4 is implemented

Indicates whether the sampled operation accessed and caused a refill of the level 1 data or unified cache. This excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

E[3]	Description
0b0	Operation was not a load/store, or did not miss in the level 1 data or unified cache.
0b1	Load/store operation accessed and missed in the level 1 data or unified cache.

It is IMPLEMENTATION SPECIFIC whether a store can finish execution before this event is generated, meaning that, for stores, this event is not recorded and this bit reads-as-zero.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with L1D_CACHE_MISS or L1D_CACHE_MISS_RD.

Otherwise

Indicates whether the sampled operation accessed and caused a refill of the level 1 data or unified cache. This excludes accesses that do not cause a new cache refill but are satisfied from refilling data of a previous miss.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E[3]	Description
0b0	Operation was not a load/store, or did not cause a level 1 data cache refill.
0b1	Load/store operation caused a refill of at least the first level of data or unified cache.

It is IMPLEMENTATION SPECIFIC whether a store can finish execution before this event is generated, meaning that, for stores, this event is not recorded and this bit reads-as-zero.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with L1D_CACHE_REFILL or L1D_CACHE_REFILL_RD.

This event is 1 for each data memory access that causes a refill from outside the cache.

E[2], byte 0 bit [2]

Level 1 data cache access. Indicates whether the sampled operation accessed the level 1 data or unified cache.

E[2]	Description
0b0	Operation was not a load/store, or did not access the level 1 data or unified cache.
0b1	Load/store operation accessed at least the level 1 data or unified cache.

It is IMPLEMENTATION SPECIFIC whether a store can finish execution before this event is generated, meaning that, for stores, this event is not recorded and this bit reads-as-zero.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with L1D_CACHE or L1D_CACHE_RD.

E[1], byte 0 bit [1]

Retired.

When the PE supports sampling of speculative instructions

Indicates whether the sampled operation was architecturally executed. This includes instructions on the architecturally-executed path that generated a synchronous exception which was taken.

E[1]	Description
0b0	Operation did not retire and did not generate a synchronous architectural exception that was taken.
0b1	Operation retired or generated a synchronous exception that was taken.

Note

A conditional instruction can retire even if it fails its condition code check.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with INST_RETIRED.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise

This bit reads-as-one.

E[0], byte 0 bit [0]

Generated exception. Indicates whether the sampled operation generated a synchronous exception.

E[0]	Description
`0b0`	Operation did not generate an exception.
`0b1`	Operation generated a synchronous exception.

If E[1] in the same Events packet is 0, then the meaning of this bit is IMPLEMENTATION DEFINED.

If FEAT_PMUv3 is implemented, then this event is implemented consistently with EXC_TAKEN.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D18.2.7 Operation Type packet

Purpose

Defines the type of operation sampled. Included for all operations.

Attributes

Multi-part packet comprising:

- 8-bit header.
- 8-bit payload.

Operation Type packet header

7	6	5	4	3	2	1	0
0	1	SZ		1	0	CLASS	
		0	0				

Figure D18-22 Operation Type packet header

Byte 0 bits [7:6]

This field reads as `0b01`.

SZ, byte 0 bits [5:4]

Payload size.

SZ	Description
`0b00`	Byte.

This field reads as `0b00`.

Byte 0 bits [3:2]

This field reads as `0b10`.

CLASS, byte 0 bits [1:0]

Top-level operation class.

CLASS	Description
`0b00`	The payload is one of the following and the SUBCLASS field in the payload encodes which: • Other. • Data processing, SVE vector. • Data processing, SME array.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CLASS	Description
`0b01`	Load, store, or atomic. The payload is one of the following and the SUBCLASS field in the payload encodes which: • Load/store, general. • Load/store, extended. • Load/store, SVE or SME. • Load/store, Memory Copy. • Load/store, Memory Set. • Load/store, GCS.
`0b10`	Branch or exception return.

All other values are reserved.

Operation Type packet payload (Other)

Figure D18-23 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Describes the operation type.

SUBCLASS	Description
`0b00000xxx`	Other operation. Bits [2:0] are further defined as the ASE, FP, and COND fields.

Other values are either defined by other payload types for CLASS==`0b00` or reserved.

This field reads as `0b00000xxx`.

ASE, byte 0 bit [2]

Advanced SIMD.

When FEAT_SPE_FPF is implemented

ASE	Description
`0b0`	Not an Advanced SIMD operation.
`0b1`	Advanced SIMD operation.

Otherwise

This bit reads-as-zero.

FP, byte 0 bit [1]

Floating-point.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SPE_FPF is implemented

FP	Description
`0b0`	Not a floating-point operation.
`0b1`	Floating-point operation.

Otherwise

This bit reads-as-zero.

COND, byte 0 bit [0]

Conditional.

COND	Description
`0b0`	Unconditional operation.
`0b1`	Conditional select or conditional compare operation.

Operation Type packet payload (Data processing, SVE vector)

Configurations

Defined only if all of the following are true:

- FEAT_SVE is implemented.
- FEAT_SPEv1p1 is implemented.

Figure D18-24 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Describes the operation type.

SUBCLASS	Description
`0b0xxx1xx0`	SVE vector operation. Bits [6:4,2:1] are further defined as the EVL, PRED, and FP fields.

Other values are either defined by other payload types for CLASS==`0b00` or reserved.

This field reads as `0b0xxx1xx0`.

EVL, byte 0 bits [6:4]

Sampled Effective Vector Length.

Describes the size in bits of the vector or vectors operated on by the sampled SVE SIMD operation. That is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For a sampled SVE multi-vector SIMD operation, the number of elements in each vector, multiplied by the number of vectors, multiplied by the element size.
- For other sampled SVE SIMD operations, the number of elements in the vector multiplied by the element size.

EVL	Description
`0b000`	32 bits.
`0b001`	64 bits.
`0b010`	128 bits.
`0b011`	256 bits.
`0b100`	512 bits.
`0b101`	1024 bits.
`0b110`	2048 bits.
`0b111`	More than 2048 bits. This value is defined only if FEAT_SPE_SME is implemented, and reserved otherwise.

If the sampled effective vector length for the input operands of the sampled SVE SIMD operation and the sampled effective vector length for the output operand of the sampled SVE SIMD operation differ, then the sampled effective vector length of the output operand is used.

The Effective SVE vector length is always a power of two. However, the sampled effective vector length can be any size down to the smallest element size.

If the sampled effective vector length is not a power of two, or is less than 32 bits, then the value is rounded up before it is encoded in this field.

PRED, byte 0 bit [2]

Predicated SVE operation.

PRED	Description
`0b0`	Not predicated.
`0b1`	Predicated SVE data-processing operation. This includes operations which result in no effective change in architectural state due to all predicates being FALSE.

Predicated SVE data-processing operation means an SVE data-processing operation that writes to one or more SVE Z vector destination registers under a Governing predicate using either zeroing or merging predication.

It is IMPLEMENTATION DEFINED whether this includes data-processing operations due to instructions with a single Governing predicate operand that determines the Active elements, which do not write to any SVE Z vector destination registers using either zeroing or merging predication. For example, `INCP` and `SEL` (predicates).

FP, byte 0 bit [1]

Floating-point operation.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FP	Description
0b0	Not a floating-point operation.
0b1	Floating-point operation.

Operation Type packet payload (Data processing, SME array)

Configurations

Defined only if FEAT_SPE_SME is implemented.

Figure D18-25 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Describes the operation type.

SUBCLASS	Description
0b1xxx1xx0	SME tile operation. Bits [6:4,2:1] are further defined as the ETS and FP fields. This value is defined only if FEAT_SPE_SME is implemented, and reserved otherwise.

Other values are either defined by other payload types for CLASS==0b00 or reserved.

This field reads as 0b1xxx1xx0.

ETS, byte 0 bits [6:4,2]

Sampled Effective vector length or Tile Size.

Describes the size in bits of the portion of the ZA array operated on by the sampled SME vector or tile SIMD operation. That is:

- For a sampled SME tile SIMD operation, the number of elements in the ZA tile or tiles multiplied by the element size.
- For a sampled SME multi-vector SIMD operation, the number of elements in each vector, multiplied by the number of vectors, multiplied by the element size.
- For other sampled SME vector SIMD operations, the number of elements in the vector multiplied by the element size.

ETS	Description
0b0000	128 bits.
0b0001	256 bits.
0b0010	512 bits.
0b0011	1024 bits.
0b0100	2048 bits.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ETS	Description
0b0101	4096 bits.
0b0110	8192 bits.
0b0111	16384 bits.
0b1000	32768 bits.
0b1001	65536 bits.
0b1010	131072 bits.
0b1011	262144 bits.
0b1111	Whole ZA array.

All other values are reserved.

If the sampled effective vector length or tile size for the input operands of the sampled SME SIMD operation and the sampled effective vector length or tile size for the output operand of the sampled SME SIMD operation differ, then the sampled effective vector length or tile size of the output operand is used.

If the sampled effective vector length or tile size is not a power of two, or is less than 128 bits, then the value is rounded up before it is encoded in this field.

The 0b1111 value is used when the whole ZA array is operated on at once by the sampled instruction or operation. For example the ZERO (tiles) instruction writes to the whole ZA array, and might use this encoding even if the instruction specifies a mask that prevents part of the ZA array being updated.

FP, byte 0 bit [1]

Floating-point operation.

FP	Description
0b0	Not a floating-point operation.
0b1	Floating-point operation.

Operation Type packet payload (Load/store, general)

0	0	0	1	0	0	0	LDST

SUBCLASS

Figure D18-30 Operation Type packet payload (Unspecified load/store)

SUBCLASS, byte <0>

Second-level operation class. Indicates the load/store type.

SUBCLASS	Description
`0b0000000x`	A load/store targeting the general-purpose registers, other than an atomic operation, load-acquire, store-release, or exclusive.
`0b0000010x`	A load/store targeting the SIMD&FP registers, or, if FEAT_SPEv1p1 is not implemented, the SVE registers.
`0b0001000x`	A load/store targeting unspecified registers. This value is defined only if FEAT_SPEv1p1 is implemented, and reserved otherwise.
`0b0001010x`	A load/store of an Allocation Tag or multiple Allocation Tags. This value is defined only if all of the following are true: • FEAT_SPEv1p3 is implemented. • FEAT_MTE is implemented. This value is reserved otherwise.
`0b0011000x`	An `MRS` or `MSR` operation at EL1 transformed to a load/store when the Effective value of HCR_EL2.NV2 is 1. This value is defined only if FEAT_NV2 is implemented, and reserved otherwise.

Other values are either defined by other payload types for CLASS==`0b01` or reserved.

Bit [0] is further defined as the LDST field.

LDST, byte 0 bit [0]

Store not load.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

LDST	Description
0b0	Memory-reading instruction. That is, a load, a swap, or an atomic that returns a value to the PE.
0b1	Not a memory-reading instruction. That is, a store or an atomic that does not return a value to the PE.

Memory-reading instruction and Memory-writing instruction are defined in Definitions.

Operation Type packet payload (Load/store, extended)

Figure D18-31 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Indicates the load/store type.

SUBCLASS	Description
0b000xxx1x	An atomic operation, load-acquire, store-release, or exclusive. Bits [4:2,0] are further defined as the AT, EXCL, AR, and LDST fields.

Other values are either defined by other payload types for CLASS==0b01 or reserved.

This field reads as 0b000xxx1x.

AR, byte 0 bit [4]

Acquire/Release.

AR	Description
0b0	Load/store/atomic without Acquire or Release semantics.
0b1	Load/store/atomic with Acquire or Release semantics.

EXCL, byte 0 bit [3]

Exclusive.

EXCL	Description
0b0	Load/store/atomic without Exclusive.
0b1	Load/store with Exclusive.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AT, byte 0 bit [2]

Atomic load/store.

AT	Description
`0b0`	Not atomic.
`0b1`	Atomic.

LDST, byte 0 bit [0]

Store not load.

LDST	Description
`0b0`	Memory-reading instruction. That is, a load, a swap, or an atomic that returns a value to the PE.
`0b1`	Not a memory-reading instruction. That is, a store or an atomic that does not return a value to the PE.

Memory-reading instruction and Memory-writing instruction are defined in Definitions.

Operation Type packet payload (Load/store, SVE or SME)

Configurations

Defined only if all of the following are true:

- Any of the following are true:
  - FEAT_SME is implemented.
  - FEAT_SVE is implemented.
- FEAT_SPEv1p1 is implemented.

Figure D18-32 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Indicates the load/store type.

SUBCLASS	Description
`0bxxxx1x0x`	A load/store targeting the SVE or SME registers. Bits [7:4,2,0] are further defined as the PRED, EVL, SG, and LDST fields.

Other values are either defined by other payload types for CLASS==`0b01` or reserved.

This field reads as `0bxxxx1x0x`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SG, byte 0 bit [7]

Gather/scatter SVE load/store.

SG	Description
0b0	Neither gather load nor scatter store.
0b1	Gather load or scatter store.

EVL, byte 0 bits [6:4]

Sampled Effective Vector Length.

Describes the size in bits of the vector or vectors operated on by the sampled SVE or SME SIMD load/store operation.

If FEAT_SPE_SME is implemented, then the EVL field records the upper bound of the sampled effective vector length multiplied by the number of vectors loaded or stored by the sampled operation. If the sampled effective vector length for the sampled operation is greater than 2048 bits, then EVL is set to 0b111.

Otherwise, the EVL field records an upper bound of the sampled effective vector length for a single vector loaded or stored by the sampled operation.

EVL	Description
0b000	32 bits.
0b001	64 bits.
0b010	128 bits.
0b011	256 bits.
0b100	512 bits.
0b101	1024 bits.
0b110	2048 bits.
0b111	More than 2048 bits. This value is defined only if FEAT_SPE_SME is implemented, and reserved otherwise.

All other values are reserved.

The Effective SVE vector length is always a power of two. However, the sampled effective vector length can be any size down to the smallest element size.

If the sampled effective vector length is not a power of two, or is less than 32 bits, then the value is rounded up before it is encoded in this field.

PRED, byte 0 bit [2]

Predicated SVE or SME load/store.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PRED	Description
0b0	Not predicated.
0b1	The operation is one of the following: • If FEAT_SPEv1p2 is implemented, a predicated SVE or SME load operation that writes to one or more vector destination registers under a Governing predicate using zeroing predication. • A predicated SVE or SME store of one or more vector registers. This includes operations which result in no effective change in architectural state due to all predicates being FALSE.

LDST, byte 0 bit [0]

Store not load.

LDST	Description
0b0	Load.
0b1	Store.

Operation Type packet payload (Load/store, Memory Copy)

Configurations

Defined only if all of the following are true:

- FEAT_SPEv1p3 is implemented.
- FEAT_MOPS is implemented.

Figure D18-33 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Indicates the load/store type.

SUBCLASS	Description
0b0010000x	A load/store from a Memory Copy operation. Bit [0] is further defined as the LDST field.

Other values are either defined by other payload types for CLASS==0b01 or reserved.

This field reads as 0b0010000x.

LDST, byte 0 bit [0]

Store not load.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

LDST	Description
0b0	Load. The sampled virtual address is the source address.
0b1	Store. The sampled virtual address is the destination address.

Operation Type packet payload (Load/store, Memory Set)

Configurations

Defined only if all of the following are true:

- FEAT_SPEv1p3 is implemented.
- FEAT_MOPS is implemented.

Figure D18-34 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Indicates the load/store type.

SUBCLASS	Description
0b00100101	A store from a Memory Set operation.

Other values are either defined by other payload types for CLASS==0b01 or reserved.

This field reads as 0b00100101.

Operation Type packet payload (Load/store, GCS)

Configurations

Defined only if all of the following are true:

- FEAT_SPEv1p4 is implemented.
- FEAT_GCS is implemented.

Figure D18-35 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Indicates the load/store type.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SUBCLASS	Description
`0b01000x0x`	A load/store from a GCS operation. Bits [2,0] are further defined as the COMM and LDST fields.

Other values are either defined by other payload types for CLASS==`0b01` or reserved.

This field reads as `0b01000x0x`.

COMM, byte 0 bit [2]

Common. Indicates whether or not the sampled load/store operation is from a Branch with link or Procedure return instruction.

COMM	Description
`0b0`	Branch with link or Procedure return.
`0b1`	Neither a Branch with link nor a Procedure return.

LDST, byte 0 bit [0]

Store not load.

LDST	Description
`0b0`	Load or swap that returns a value to the PE.
`0b1`	Store.

Operation Type packet payload (Branch)

Figure D18-36 Operation Type packet payload

SUBCLASS, byte <0>

Second-level operation class. Describes the operation type.

SUBCLASS	Description
`0b000xxxxx`	Branch. Bits [4:0] are further defined as the CR, GCS, IND, and COND fields.

Other values are reserved.

This field reads as `0b000xxxxx`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CR, byte 0 bits [4:3]

Call Return. Indicates whether the branch was a subroutine call, a subroutine return instruction, or neither of these.

CR	Description
0b00	Whether the sampled branch operation is a Branch with link or a Procedure return operation is not recorded.
0b01	Branch with link.
0b10	Procedure return.
0b11	Neither Branch with link nor Procedure return.

If FEAT_SPE_CRR is not implemented, then the only permitted value is 0b00.

If FEAT_SPE_CRR is implemented, then the value of 0b00 is not permitted.

GCS, byte 0 bit [2]

Guarded control stack data access.

When FEAT_SPEv1p4 is implemented

Indicates whether the sampled branch operation generated a Guarded control stack data access.

GCS	Description
0b0	No Guarded control stack data access.
0b1	Guarded control stack data access.

If FEAT_GCS is not implemented, then the only permitted value is 0.

Otherwise

This bit reads-as-zero.

IND, byte 0 bit [1]

Indirect.

IND	Description
0b0	Direct branch.
0b1	Indirect branch.

COND, byte 0 bit [0]

Conditional.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

COND	Description
`0b0`	Unconditional branch.
`0b1`	Conditional branch.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D18.2.8 Padding

Purpose

Allows the PE to create alignment in the protocol buffer.

Attributes

8-bit packet.

Field descriptions

7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0

Figure D18-37 Padding

Byte <0>

This field reads as `0b00000000`.

Non-Confidential

D18.2.9 Timestamp packet

Purpose

The 64-bit timestamp value when the operation was sampled. The Timestamp packet must come at the end of the record. If the Timestamp packet is not present, an End packet must come at the end of the record.

Attributes

Multi-part packet comprising:

- 8-bit header.
- 64-bit payload.

Timestamp packet header

7	6	5	4	3	2	1	0
0	1	SZ		0	0	0	1
		1	1				

Figure D18-38 Timestamp packet header

Byte 0 bits [7:6]

This field reads as `0b01`.

SZ, byte 0 bits [5:4]

Payload size.

SZ	Description
`0b11`	Doubleword.

This field reads as `0b11`.

Byte 0 bits [3:0]

This field reads as `0b0001`.

Timestamp packet payload

7	6	5	4	3	2	1	0
TS[7:0]

TS[55:48]							
TS[63:56]							

Figure D18-39 Timestamp packet payload

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TS, bytes <7:0>

Timestamp value when the operation was sampled. The value depends on the result of `CollectTimeStamp()`:

- If `TimeStamp_Virtual`, the value of `PhysicalCountInt()` - CNTVOFF_EL2.
- If `TimeStamp_Physical`, the value of `PhysicalCountInt()`.
- If `TimeStamp_OffsetPhysical`, the value of `PhysicalCountInt()` - CNTPOFF_EL2. Only supported when FEAT_ECV is implemented.

If `CollectTimeStamp()` returns `TimeStamp_None`, then the Timestamp packet is not included and an End packet must come at the end of the record.

However, if the Generic Timer System counter is disabled and `CollectTimeStamp()` returns a value other than `TimeStamp_None`, then it is IMPLEMENTATION DEFINED which of the following occurs:

- The Statistical Profiling Unit behaves as if `CollectTimeStamp()` returns the value `TimeStamp_None`.
- The value of this field in the record is UNKNOWN.

Note

This set of behaviors is only permitted when the actual System counter is disabled, that is, when CNTEN.EN is `0b0`. It does not apply when the System counter is enabled but not accessible at the current Exception level.

Chapter D19
The Branch Record Buffer Extension

This chapter describes the *Branch Record Buffer Extension* (BRBE). It contains the following sections:

- About the Branch Record Buffer Extension
- Branch record filtering
- Branch record buffer operation
- Branch record buffer
- Programmers' model

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D19.1 About the Branch Record Buffer Extension

I_{LQHFJ} The Branch Record Buffer Extension provides control path information for compiling and optimizing software. These directed optimizations extract information about hotspots and common control paths in the code.

FEAT_BRBE provides a mechanism for capturing control path history in a low-cost manner.

FEAT_BRBEv1p1 extends FEAT_BRBE to enable branch recording at EL3.

D19.1.1 Branch records

I_{JBTBH} Each *Branch record* consists of 3 registers:

- BRBINF<n>_EL1.
- BRBSRC<n>_EL1.
- BRBTGT<n>_EL1.

I_{GBCQW} Taken branch instructions, as defined by Branches, Exception generating, and System instructions, generate a Branch record.

I_{LFVJR} Exceptions generate a Branch record.

R_{RPVXK} A *Half-source Branch record* has BRBINF<n>_EL1.VALID set to `0b10`.

R_{LPLYK} A *Half-target Branch record* has BRBINF<n>_EL1.VALID set to `0b01`.

R_{GSMRH} A *Full Branch record* has BRBINF<n>_EL1.VALID set to `0b11`.

R_{XRHTY} BRBINF<n>_EL1.VALID indicates the validity of a Branch record:

- If BRBINF<n>_EL1.VALID is `0b00`, the Branch record is invalid.
- Otherwise, the Branch record is valid.

R_{MLGCF} When a Branch record is generated for any branch or exception which does not transition between a BRBE Prohibited region and a BRBE Non-prohibited region, the Branch record is a *Full Branch record*.

See Branch records for exceptions and Branch records for exception returns for more details on when a Half-source Branch record or a Half-target Branch record is generated.

I_{ZCHRF} When an Instruction Synchronization Barrier instruction causes a Context synchronization event which synchronizes an update to one or more System registers which are indirectly read when generating a Branch record, the synchronization of those register updates occurs before the registers are indirectly read. Such order is generally consistent with indirect reads of System registers performed by events which cause a Context synchronization event.

R_{ZHDCC} When an exception or exception return instruction causes a Context synchronization event which synchronizes an update to one or more System registers which are used to determine whether the source of the Branch record is from a BRBE Prohibited region, indirect reads of those System registers are permitted to occur before the Context synchronization event. Specifically, the registers indirectly read by `BranchRecordAllowed()`. All other indirect reads of System registers used for creation of a Branch record occur after the Context synchronization event, including those for determining whether the Branch record is filtered or not, and those used for determining whether Branch recording is prohibited at the target.

R_{TWYWS} Where an operation such as an exception or exception return causes a Context synchronization event and that synchronizes a System register update which permits a BRBE freeze event to occur, and the same operation also changes the PE state to prevent a BRBE freeze event from occurring, it is IMPLEMENTATION SPECIFIC whether the BRBE freeze event occurs.

R_{CBHRY} The reason for the *Branch record* is captured in BRBINF<n>_EL1.TYPE.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D19.1.2 Cycle counting

I_{RRBFF} Each Branch record contains a cycle count value which is representative of the time taken between each Branch record being generated. The cycle count value can be used to determine the relative performance of the program between each Branch record. For large cycle count values, the value stored in each Branch record is encoded to use less storage, with a small loss of precision in the value.

R_{HQXNW} The size of the cycle counter used to generate cycle count values is IMPLEMENTATION DEFINED, from one of the sizes indicated in BRBIDR0_EL1.CC.

R_{KVRBB} Each Branch record contains a cycle count value which indicates the number of PE clock cycles that occurred between the previous Branch record being generated and this Branch record being generated.

R_{SBXCF} In a multithreaded implementation, the cycle counter only counts cycles on which the thread was active.

I_{VPPYW} The Branch record counts cycles in the same way as the CPU_CYCLES PMU event counts cycles when PMEVTYPER<n>_EL0.MT is 0. For more information, see Cycle event counting.

R_{PGXMB} For the purposes of the cycle count, a Branch record is generated only when the corresponding branch instruction or exception is guaranteed to be architecturally executed and the target address has been calculated. Arm recommends that the Branch record is generated as soon after this point as possible.

I_{KBDLR} When a branch target address contains an address tag, the target address captured in the Branch record is the virtual address with the address tag removed.

R_{MJDLC} The cycle count value in a Branch record is Branch cycle count unknown when any of the following are true:

- If EL2 is implemented, BRBCR_EL2.CC is 0.
- BRBCR_EL1.CC is 0.
- This is the first Branch record after the PE exited a BRBE Prohibited region.
- This is the first Branch record after cycle counting has been enabled.
- This is the first Branch record after BRBFCR_EL1.PAUSED is cleared from 1 to 0.
- This is the first Branch record after execution of a BRB IALL instruction.

Note

This applies even when EL2 is disabled in the current Security state.

R_{PBJTJ} When the cycle count value in a Branch record is Branch cycle count unknown:

- BRBINF<n>_EL1.CCU has the value 1.
- BRBINF<n>_EL1.CC contains a value which is all zeros.

The number of cycles indicated by this Branch record is UNKNOWN.

R_{XGSSZ} If the cycle count value in a Branch record would exceed the maximum value of the cycle counter, then:

- BRBINF<n>_EL1.CCU has the value 0.
- BRBINF<n>_EL1.CC contains a value which is all ones.

R_{JZWPG} If the cycle count value in a Branch record is not UNKNOWN and would not exceed the maximum value of the cycle counter, then:

- BRBINF<n>_EL1.CCU has the value 0.
- BRBINF<n>_EL1.CC contains the cycle count value, encoded as defined in BRBINF<n>_EL1.CC.

D19.1.3 Mispredicted branches

I_{QHGFW} Each Branch record generated for a branch instruction contains an indication of whether the branch was correctly or incorrectly predicted by the PE. Branch prediction behavior is IMPLEMENTATION DEFINED and this is an indication of whether such prediction succeeded, or not.

R_{XHWRB} For a Branch record of a branch instruction, one of the following occurs:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If EL2 is implemented and BRBCR_EL2.MPRED is 0, then BRBINF<n>_EL1.MPRED is set to 0.
- Else if BRBCR_EL1.MPRED is 0, then BRBINF<n>_EL1.MPRED is set to 0.
- Otherwise:
  — BRBINF<n>_EL1.MPRED is 0 for a correctly predicted branch.
  — BRBINF<n>_EL1.MPRED is 1 for an incorrectly predicted branch.

Note: This applies even when EL2 is disabled in the current Security state.

R_{DHNPJ} For a Branch record of an exception, BRBINF<n>_EL1.MPRED has the value 0.

R_{LBRGV} An incorrectly predicted branch is when any of the following is true:

- The direction of a conditional branch was incorrectly predicted at least once during the execution of the instruction.
- The target of a branch was incorrectly predicted at least once during the execution of the instruction.
- The branch was not predicted by a branch predictor.

R_{RDLQF} A correctly predicted branch is one that is not incorrectly predicted.

D19.1.4 BRBE Prohibited regions

I_{NVWPM} An executable program might contain regions of code that are prohibited to generate Branch records, and these regions are called BRBE Prohibited regions. These regions are usually associated with a different Security state or Exception level.

I_{DMPQZ} BRBE Prohibited regions are controlled by the following:

- BRBCR_EL1.E0BRE.
- BRBCR_EL1.E1BRE.
- BRBCR_EL2.E0HBRE.
- BRBCR_EL2.E2BRE.
- MDCR_EL3.SBRBE.

I_{HPZWM} While executing outside a BRBE Prohibited region, Branch records might not be generated because the Branch Record Buffer Extension has a number of filtering functions.

R_{FHGJN} Execution in AArch32 state is a BRBE Prohibited region.

R_{LPYBQ} Execution in Debug state is a BRBE Prohibited region.

R_{JWWFY} When FEAT_BRBEv1p1 and EL3 are implemented:

- When MDCR_EL3.{E3BREC, E3BREW} is {`0b0`, `0b1`} or MDCR_EL3.{E3BREC, E3BREW} is {`0b1`, `0b0`}, self-hosted EL3 branch recording is enabled.
- When MDCR_EL3.{E3BREC, E3BREW} is {`0b0`, `0b0`} or MDCR_EL3.{E3BREC, E3BREW} is {`0b1`, `0b1`}, self-hosted EL3 branch recording is disabled.

R_{GLKGW} Execution at EL3 is a BRBE Prohibited region when any of the following are true:

- FEAT_BRBEv1p1 is not implemented.
- Self-hosted EL3 branch recording is disabled.

R_{SFZQD} Execution at EL2 is a BRBE Prohibited region when any of the following are true:

- BRBCR_EL2.E2BRE is 0.
- MDCR_EL3.SBRBE is `0b00`.
- MDCR_EL3.SBRBE is `0b01` and the PE is in Secure state.

R_{YPHYG} Execution at EL1 is a BRBE Prohibited region when any of the following are true:

- BRBCR_EL1.E1BRE is 0.
- MDCR_EL3.SBRBE is `0b00`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- MDCR_EL3.SBRBE is `0b01` and the PE is in Secure state.

R_{DBPCP} Execution at EL0 is a BRBE Prohibited region when any of the following are true:

- EL2 is disabled in the current Security state or HCR_EL2.TGE is 0, and BRBCR_EL1.E0BRE is 0.
- EL2 is enabled in the current Security state and HCR_EL2.TGE is 1, and BRBCR_EL2.E0HBRE is 0.
- MDCR_EL3.SBRBE is `0b00`.
- MDCR_EL3.SBRBE is `0b01` and the PE is in Secure state.

R_{YGGSC} While the PE is executing code from a BRBE Prohibited region, no data is captured in Branch records that might provide information about execution in the BRBE Prohibited region.

D19.1.5 Branch records for exceptions

R_{YSKQK} When an exception is taken from a BRBE Prohibited region to a BRBE Prohibited region, no Branch record is generated.

R_{KRJQC} When an exception is taken from a BRBE Non-prohibited region, or an exception is taken to a BRBE Non-prohibited region:

- If the target Exception level is EL1, a Branch record is generated only if BRBCR_EL1.EXCEPTION is 1.
- If the target Exception level is EL2, a Branch record is generated only if BRBCR_EL2.EXCEPTION is 1.
- If the target Exception level is EL3, a Branch record is generated only if FEAT_BRBEv1p1 is implemented and self-hosted EL3 branch recording is enabled.

R_{YBJDJ} When a Branch record is generated for an exception:

- If the exception is taken from a BRBE Prohibited region, then a Half-target Branch record is generated.
- If the exception is taken from a BRBE Non-prohibited region to a BRBE Prohibited region, then a Half-source Branch record is generated.
- If the exception is taken from a BRBE Non-prohibited region to a BRBE Non-prohibited region, then a *Full Branch record* is generated.

I_{MZNRY} When a Half-source Branch record or a *Full Branch record* is generated for an Illegal Execution state exception, the source information in the *Branch record* indicates where the exception was taken from, in the same way as all other exceptions.

R_{BZCRW} A Branch record for an exception which contains a valid source address has the source address set to the preferred exception return address for the exception.

R_{FYLTC} A Branch record for an exception which contains a valid target address has the target address set to the address of the exception vector.

D19.1.6 Branch records for exception returns

R_{LMXHS} When an exception return instruction is executed in a BRBE Prohibited region and branches to a BRBE Prohibited region, no Branch record is generated.

R_{ZSHDL} When an exception return instruction is executed in a BRBE Non-prohibited region, or an exception return instruction branches to a BRBE Non-prohibited region:

- If the exception return instruction is executed at EL3, a Branch record is generated only if FEAT_BRBEv1p1 is implemented and self-hosted EL3 branch recording is enabled.
- If the exception return instruction is executed at EL2, a Branch record is generated only if BRBCR_EL2.ERTN is 1.
- If the exception return instruction is executed at EL1, a Branch record is generated only if BRBCR_EL1.ERTN is 1.

R_{ZTGMW} When a Branch record is generated for an exception return instruction:

- If the exception return instruction is executed in a BRBE Prohibited region, then a Half-target Branch record is generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the exception return instruction is executed in a BRBE Non-prohibited region and branches to a BRBE Prohibited region, then a Half-source Branch record is generated.
- If the exception return instruction is executed in a BRBE Non-prohibited region and branches to a BRBE Non-prohibited region, then a *Full Branch record* is generated.

I_{NGWPR} When a Half-target Branch record or a *Full Branch record* is generated for an exception return instruction which is an illegal return or a legal return which sets PSTATE.IL to 1, the target information in the Branch record indicates the target of the branch:

- BRBTGT<n>_EL1.ADDRESS contains the target of the branch.
- BRBINF<n>_EL1.EL contains the value that is loaded in to PSTATE.EL.

I_{JCYHD} When a Half-target Branch record or a *Full Branch record* is generated for an exception return instruction which is an illegal return or a legal return which sets PSTATE.IL to 1, for the purposes of determining whether the target is a BRBE Prohibited region the value that is loaded in to PSTATE.EL is used as the target Exception level.

PSTATE.EL is unchanged on an illegal return, so the current Exception level is the target of the illegal return, regardless of where the return was attempting to return to.

D19.1.7 Branch records for Debug state

R_{LLCTG} When entering Debug state:

- If the entry is from a BRBE Prohibited region, no Branch record is generated.
- If the entry is from a BRBE Non-prohibited region, then a Half-source Branch record is generated.

R_{XJKJB} When a Branch record is generated for entry to Debug state, it is recorded with the type Debug halt. See BRBINF<n>_EL1.TYPE for more details.

R_{RBCFP} When exiting from Debug state:

- If the exit is to a BRBE Prohibited region, no Branch record is generated.
- If the exit is to a BRBE Non-prohibited region, then a Half-target Branch record is generated.

D19.1.8 PE speculation

R_{KXTKS} The Branch records only contain information for a branch, exception, or exception return that is architecturally executed.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D19.2 Branch record filtering

INZWBP For Branch records generated outside a BRBE Prohibited region, it is useful to reduce the number of records that are generated to match their use. Table D19-1 lists some different use cases.

Table D19-1 Example use cases for filtering

Use case	Description
Control path	• All branches • Subroutine returns • Exceptions • Exception returns
Call path	• Branch with link instructions • Subroutine returns
Kernel calls	• Exceptions • Exception returns

D19.2.1 Filtering on type

IFSNVG The Branch records can be filtered by independently enabling the generation of the following types:

- Exception.
- Exception return.
- Direct Branch with link.
- Indirect Branch with link.
- Return from subroutine.
- Indirect Branches.
- Conditional Direct Branches.
- Unconditional Direct Branches.

RLYGJZ Control of when Branch records for exceptions are generated is controlled by BRBCR_EL1.EXCEPTION and BRBCR_EL2.EXCEPTION. See Branch records for exceptions for details.

Table D19-2 Exception mapping for exceptions taken to AArch64 state

Reason	Type
Branch Target exception	Inst fault
Breakpoint	Inst debug
Exceptions due to SME functionality	Trap
EXLOCK exception	Inst fault
FIQ	FIQ
GPC exception due to data access	Data fault
GPC exception due to instruction access	Inst fault
Guarded Control Stack Data Check exception	Data fault
HVC	Call

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Reason	Type
IRQ	IRQ
Illegal execution state	Trap
Instruction Abort	Inst fault
Instruction or event trapped by a control bit	Trap
MemCpy or MemSet	Trap
Misaligned PC	Alignment

R_{VBGTZ} Each of the indirect branch with link instructions only generates a Branch record when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:

- BRBFCR_EL1.INDCALL is 1 and BRBFCR_EL1.EnI is 0.
- BRBFCR_EL1.INDCALL is 0 and BRBFCR_EL1.EnI is 1.

Table D19-5 A64 indirect branch with link instructions

Instruction	Description
BLR	Branch with link to register
BLRAA	Authenticate and branch with link
BLRAAZ	Authenticate and branch with link
BLRAB	Authenticate and branch with link
BLRABZ	Authenticate and branch with link

R_{CKNBH} Each of the return from subroutine instructions only generates a Branch record, when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:

- BRBFCR_EL1.RTN is 1 and BRBFCR_EL1.EnI is 0.
- BRBFCR_EL1.RTN is 0 and BRBFCR_EL1.EnI is 1.

Table D19-6 A64 return from subroutine instructions

Instruction	Description
RET	Return From subroutine
RETAA	Authenticate and function return
RETAASPPC	Authenticate and function return
RETAASPPCR	Authenticate and function return
RETAB	Authenticate and function return
RETABSPPC	Authenticate and function return
RETABSPPCR	Authenticate and function return

R_{KKLDV} Unless covered by other rules, each of the indirect branch instructions only generates a Branch record when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:

- BRBFCR_EL1.INDIRECT is 1 and BRBFCR_EL1.EnI is 0.
- BRBFCR_EL1.INDIRECT is 0 and BRBFCR_EL1.EnI is 1.

Instruction	Description
BRABZ	Authenticate and branch

R_{BBNSZ} Unless covered by other rules, each of the conditional direct branch instructions only generates a Branch record when the instruction is taken, is executed in a BRBE Non-prohibited region, and if any of the following are true:

- BRBFCR_EL1.CONDDIR is 1 and BRBFCR_EL1.EnI is 0.
- BRBFCR_EL1.CONDDIR is 0 and BRBFCR_EL1.EnI is 1.

Table D19-8 A64 conditional direct branch instructions

Instruction	Description
B.cond	Conditional Branch
BC.cond	Branch Consistent conditionally
CB<cc> (immediate)	Compare register with immediate and branch
CB<cc> (register)	Compare registers and branch
CBB<cc>	Compare bytes and branch
CBH<cc>	Compare halfwords and branch
CBZ or CBNZ	Compare with zero and branch
TBZ or TBNZ	Test and branch

Note: `BC.cond` and `B.cond` instructions with the `AL` or `NV` condition code are considered conditional.

R_{FJYVT} Unless covered by other rules, each of the unconditional direct branch instructions only generates a Branch record when the instructions are executed in a BRBE Non-prohibited region and if any of the following are true:

- BRBFCR_EL1.DIRECT is 1 and BRBFCR_EL1.EnI is 0.
- BRBFCR_EL1.DIRECT is 0 and BRBFCR_EL1.EnI is 1.

Table D19-9 A64 unconditional direct branch instructions

Instruction	Description
B	Unconditional Branch

R_{FJYDC} It is IMPLEMENTATION DEFINED whether Branch records are generated for each of the following taken unconditional direct branch instructions when the instruction is executed in a BRBE Non-prohibited region and if any of the following are true:

- BRBFCR_EL1.DIRECT is 1 and BRBFCR_EL1.EnI is 0.
- BRBFCR_EL1.DIRECT is 0 and BRBFCR_EL1.EnI is 1.

Table D19-10 Optional A64 unconditional direct branch instructions

Instruction	Description
ISB	Instruction Synchronization Barrier

S_{XZRTW} Writing a value of `0b0000_0001` to the filter controls, BRBFCR_EL1<23:16>, ensures Branch records are generated for all branch instructions.

D19.3 Branch record buffer operation

R_{LKWNB} The Branch Record Buffer Extension operation is controlled by the BRBCR_EL1, BRBCR_EL2, and BRBFCR_EL1 registers.

R_{PYBRZ} Generation of Branch records is *paused* when BRBFCR_EL1.PAUSED is 1.

R_{YDZNK} When generation of Branch records is paused, Branch records are not generated.

R_{NXCWF} If EL2 is implemented, a BRBE freeze event occurs when all of the following are true:

- BRBCR_EL1.FZP is 1.
- Generation of Branch records is not paused.
- PMOVSCLR_EL0[(MDCR_EL2.HPMN-1):0] is nonzero.
- The PE is in a BRBE Non-prohibited region.

R_{GXGWY} If EL2 is implemented, a BRBE freeze event occurs when all of the following are true:

- BRBCR_EL2.FZP is 1.
- Generation of Branch records is not paused.
- PMOVSCLR_EL0[(PMCR_EL0.N-1):MDCR_EL2.HPMN] is nonzero.
- The PE is in a BRBE Non-prohibited region.

This applies even when EL2 is disabled in the current Security state.

R_{PKTXQ} If EL2 is not implemented, a BRBE freeze event occurs when all of the following are true:

- BRBCR_EL1.FZP is 1.
- Generation of Branch records is not paused.
- PMOVSCLR_EL0[(PMCR_EL0.N-1):0] is nonzero.
- The PE is in a BRBE Non-prohibited region.

R_{LDMVK} If FEAT_PMUv3_ICNTR is implemented, then a BRBE freeze event occurs when all of the following are true:

- BRBCR_EL1.FZP is 1.
- Generation of Branch records is not paused.
- PMOVSCLR_EL0.F0 is 1.
- The PE is in a BRBE non-Prohibited Region.

R_{LBQZR} If FEAT_PMUv3_SS is implemented, on a successful Capture event, then a BRBE freeze event occurs when all of the following are true:

- FEAT_BRBE is implemented.
- BRBCR_EL1.FZPSS is 1.
- Either EL2 is not implemented or BRBCR_EL2.FZPSS is 1.
  This applies even when EL2 is disabled in the current Security state.
- Generation of Branch records is not paused.
- The PE is in a non-Prohibited Region.

I_{YTVCC} Where a branch instruction, exception, or Debug state entry or exit causes a change to whether execution is in a Prohibited region and this change results in the conditions for a BRBE freeze event to be met, it is IMPLEMENTATION SPECIFIC whether the instruction, exception, Debug state entry or exit generates a Branch record before the BRBE freeze event occurs, or does not generate a Branch record because the BRBE freeze event has already occurred and branch record generation is paused.

This means the Branch record might or might not be captured before the BRBE freeze occurs.

R_{BHYTD} On a BRBE freeze event:

- BRBFCR_EL1.PAUSED is set to 1.
- The current timestamp is captured in BRBTS_EL1.

R_{QKQZL} The source of value of the timestamp captured in BRBTS_EL1 is selected by the combination of programming of BRBCR_EL2.TS and BRBCR_EL1.TS. See Table D19-11 and `BRBETimeStamp()`.

The timestamp is a choice between:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Physical time, which is defined by the physical count value returned by `PhysicalCountInt()`.
- If FEAT_ECV is implemented, offset physical time, which is defined as the value of `PhysicalCountInt()` minus a physical offset.
  If any of the following are true, the physical offset is zero:
  — EL2 is not implemented.
  — FEAT_ECV_POFF is not implemented.
  — CNTHCTL_EL2.ECV is 0.
  — EL3 is implemented and SCR_EL3.ECVEn is 0.
  Otherwise the physical offset is the value of CNTPOFF_EL2.
- Virtual time, which is defined as the value of `PhysicalCountInt()` minus a virtual offset.
  If any of the following are true, the virtual offset is zero:
  — EL2 is not implemented.
  Otherwise, the virtual offset is always CNTVOFF_EL2, including when a read of CNTVCT_EL0 at the current Exception level would treat the virtual offset as zero.

Table D19-11 Captured timestamp

BRBCR_EL2.TS	BRBCR_EL1.TS	Captured timestamp
`0b00` (delegate)	`0b01` (virtual)	`PhysicalCountInt()` - virtual offset
	`0b10` (offset physical)	`PhysicalCountInt()` - physical offset
	`0b11` (physical)	`PhysicalCountInt()`
`0b01` (virtual)	`0bxx`	`PhysicalCountInt()` - virtual offset
`0b10` (offset physical)	`0bxx`	`PhysicalCountInt()` - physical offset
`0b11` (physical)	`0bxx`	`PhysicalCountInt()`

If EL2 is not implemented, the Effective value of BRBCR_EL2.TS is `0b00`.

R_{GWMZV} When a valid Branch record is captured in the Branch record buffer storage, the BRB_FILTRATE event is generated.

R_{GMCHN} When BRB_FILTRATE is generated for an exception or an exception return, it is an Exception-related event. For more information on PMU event filtering, see Exception-related events.

I_{WGZSC} It is CONSTRAINED UNPREDICTABLE whether a BRB_FILTRATE event is generated after a `BRB INJ` causes a Branch record to be injected.

I_{SJDRW} It is expected that the Branch record buffer storage is in a BRBE Prohibited region during software context switches.
During software context switches, if the PMU event counters are not prohibited from counting events, it is expected that event counters set to count the BRB_FILTRATE event are prohibited from counting.

I_{RMGDV} The architecture does not define when PMU events are counted relative to the instructions that caused the event. Events generated by an instruction might be counted before or after the instruction becomes architecturally executed, and events might be counted for operations that do not become architecturally executed. This means that events can be counted speculatively and/or out-of-order regarding the simple sequential execution of the program. Events might also be counted simultaneously by other event counters when the overflow occurs, including events from different instructions. In addition, multiple instances of an event might occur simultaneously, meaning that an event counter unsigned overflow can yield a nonzero value in the event counter.
Furthermore, the Branch records are generated only for architecturally executed operations. See R_{KXTKS}.
These properties mean that, unless otherwise stated, on a BRBE freeze event, it is CONSTRAINED UNPREDICTABLE whether the branches that define the basic block containing the instruction causing that event are captured in the Branch record buffer.
An exception to this relaxation applies for the BRB_FILTRATE event.

S_{JCHLT} If a direct read of PMOVSCLR_EL0 returns a nonzero value for a subset of the overflow flags, such that one of R_{NXCWF}, R_{GXGWY}, or R_{PKTXQ} means that a BRBE freeze event should occur, then a direct read of BRBFCR_EL1 ordered after the direct read of PMOVSCLR_EL0 will return BRBFCR_EL1.PAUSED is 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{QNBDV} Direct reads of System registers require explicit synchronization for following direct reads of other System registers to be ordered after the first direct read. For more information, see General behavior of accesses to the AArch64 System registers.

R_{SRJND} If a direct read of BRBFCR_EL1.PAUSED returns 1, then no operations ordered after the direct read will generate further Branch records until BRBFCR_EL1.PAUSED is cleared by software.

Note: The subsequent operations can be ordered by a Context synchronization event.

D19.4 Branch record buffer

I_{FBHCC} The Branch record buffer can contain:

- 8 Branch records.
- 16 Branch records.
- 32 Branch records.
- 64 Branch records.

This is known as the Branch record buffer storage.

R_{KSLSM} The Branch record buffer storage has a maximum number of Branch records as defined by BRBIDR0_EL1.NUMREC.

I_{PPBZP} The Branch record buffer provides System registers to access the Branch records stored in the Branch record buffer storage. These System registers provide access to up to 32 Branch records without the need for explicit synchronization between each System register read. When more than 32 Branch records are implemented, the Branch record buffer provides a banking mechanism to provide access to multiple banks, each bank containing up to 32 Branch records. BRBFCR_EL1.BANK controls which bank is currently selected, and updates to BRBFCR_EL1.BANK require explicit synchronization before accessing the bank.

R_{WLSWP} Accessing Branch records 0-31 is performed by setting BRBFCR_EL1.BANK to `0b00`.

R_{WRJLW} Accessing Branch records 32-63 is performed by setting BRBFCR_EL1.BANK to `0b01`.

R_{TJGLK} The Branch record with index `0` is the youngest captured branch.

R_{HTRNR} The Branch record with index `n` is younger than *Branch record* with index `n+1`.

R_{DTPDK} On the generation of a new Branch record, if the Branch record buffer storage is full, then the oldest *Branch record* is lost.

R_{SQLCX} When the buffer contains `M` valid Branch records, where `M > 0` and `M` is less than the maximum number of *Branch records*, all of the following are true:

- Branch records with index `0` to `M-1` are all valid.
- All other Branch records are invalid.

R_{PGDLX} The creation of a Branch record is considered an indirect write to BRBTGT<n>_EL1, BRBSRC<n>_EL1 and BRBINF<n>_EL1, and therefore requires explicit synchronization before being read.

I_{SFFNF} The generation of Branch records performs indirect reads and indirect writes of System registers.

I_{KFYTV} Synchronization requirements for AArch64 System registers defines the synchronization requirements for direct reads, direct writes, indirect reads, and indirect writes of System registers made by instructions and external agents.

D19.4.1 Invalidating the record buffer

R_{LLHYN} Execution of `BRB IALL` causes all Branch records to be invalidated.

R_{PFRNW} A Branch record, **R**, is invalidated by the instruction `BRB IALL`, **W**, if all of the following are true:

- **R** is caused by a branch operation or exception, **B**.
- **B** is either:
  - In program order before a *Context synchronization event*, **CSE**.
  - Is the *Context synchronization event*.
- **CSE** is in program order before **W**.

R_{LWPKR} A Branch record **R** is not invalidated by the instruction `BRB IALL`, **W**, if all of the following are true:

- **R** is caused by a branch operation or exception, **B**.
- **B** is in program order after a *Context synchronization event*, **CSE**.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- **CSE** is in program order after **W**.

R_{WMZKF} It is CONSTRAINED UNPREDICTABLE whether a Branch record **R** is invalidated by the instruction `BRB IALL`, **W**, if all of the following are true:

- CSE_1 is in program order before **W**.
- **R** is caused by a branch operation or exception, **B**.
- **B** is in program order after a *Context synchronization event*, CSE_1
- **B** is either:
  - In program order before a *Context synchronization event*, CSE_2.
  - Is the *Context synchronization event*, CSE_2.
- CSE_2 is in program order after **W** and there are no other CSEs between CSE_1 and CSE_2.

If a Branch record is invalidated, all older Branch records are invalidated.

R_{JSCWK} When a Branch record has been invalidated, it remains invalid until it is overwritten by any of the following:

- A new Branch record is created.
- A Branch record is injected using the `BRB INJ` instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D19.5 Programmers' model

R_{BNGTH} Reads from an unimplemented Branch record return the value zero.

R_{PKZCF} All Branch records captured while generation of Branch records is not paused, must represent a continuous block of execution for all BRBE Non-prohibited regions.

I_{XSBPR} The captured Branch records might not represent a continuous block if generation of Branch records is paused at any time. To avoid this non-continuous nature, the `BRB IALL` instruction can be used to invalidate all Branch records while generation is paused.

R_{PMRRL} If a Branch record cannot be captured for a branch instruction or exception that is not prohibited and has been selected to generate a record, then all the Branch records must be invalidated. The reasons for a PE being unable to capture a Branch record are IMPLEMENTATION DEFINED and Arm recommends that such reasons are rare.

I_{QJFSV} When a process is migrated to a PE with a smaller number of Branch records implemented then the information from the older Branch records will be lost.

I_{BDKJJ} When FEAT_BRBE is implemented, the following fields are provided in System registers to control access to the Branch record buffer functionality:

- When EL2 is implemented:
  - HDFGRTR_EL2.nBRBIDR.
  - HDFGRTR_EL2.nBRBCTL.
  - HDFGWTR_EL2.nBRBCTL.
  - HDFGRTR_EL2.nBRBDATA.
  - HDFGWTR_EL2.nBRBDATA.
  - HFGITR_EL2.nBRBINJ.
  - HFGITR_EL2.nBRBIALL.
- When EL3 is implemented:
  - MDCR_EL3.SBRBE.

S_{GCYTK} When self-hosted EL3 branch recording is enabled, the following registers must be programmed:

- BRBCR_EL1 and BRBCR_EL2. Software must program these registers to control the following:
  - Recording of exceptions taken to EL1 and EL2.
  - Recording of exception returns from EL1 and EL2.
  - Branch recording at EL0, EL1, and EL2.
  - Occurrence of BRBE freeze events on PMU overflows.
  - Timestamp source.
  - Misprediction information.
  - Cycle count information.
- BRBFCR_EL1. Software must program this register to control the following:
  - Selection of Branch record buffer bank.
  - Selection of branch types to record at all Exception levels.
  - Pausing of Branch recording.

Software should also consider how MDCR_EL3.SBRBE should be programmed to either allow or prohibit access to the captured branch records from lower Exception levels. Even if self-hosted EL3 branch recording is not being used, software should consider whether a `BRB IALL` instruction should be executed before executing software at lower Exception levels.

S_{YLMQQ} Software must invalidate the Branch records after a PE reset to ensure that details of execution before the reset event are not leaked.

I_{FPJPQ} MDCR_EL3.E3BREC resets to 0 on a Cold reset, and MDCR_EL3.E3BREW resets to 0 on a Warm reset. This allows software to program MDCR_EL3.E3BREC and MDCR_EL3.E3BREW such that the BRBE continues recording after Warm reset, or stops recording at Warm reset.

I_{NZMWQ} When FEAT_BRBEv1p1 is implemented, certain fields in the following registers are reset to an architecturally UNKNOWN value on a Cold reset and unchanged on a Warm reset:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- BRBCR_EL1.
- BRBCR_EL2.
- BRBFCR_EL1.

D19.5.1 Manual injection of Branch records

I_{DXNLX} The Branch Record Buffer Extension supports the ability to manually create Branch records and inject them in to the Branch record buffer storage. The primary purpose of the injection functionality is to support the restore of the Branch record buffer storage contents, particularly during software context switch events, including migration of software between PEs. The Branch record buffer storage contents are read out using direct reads of BRBSRC<n>_EL1, BRBTGT<n>_EL1, and BRBINF<n>_EL1.

R_{FYXNL} The Branch Record Injection data registers are:

- BRBSRCINJ_EL1.
- BRBTGTINJ_EL1.
- BRBINFINJ_EL1.

I_{FJHMP} Branch record injection consists of creating a single Branch record using direct writes to the Branch Record Injection data registers, then injecting the record into the Branch record buffer storage using `BRB INJ`. This process injects a single Branch record as the youngest entry in the Branch record buffer storage. This process is repeated for each Branch record to be added to the Branch record buffer storage.

I_{BCZRK} When `BRB INJ` is executed outside of a BRBE Prohibited region, it is CONSTRAINED UNPREDICTABLE whether a Branch record is injected and it is CONSTRAINED UNPREDICTABLE whether the cycle count value in the next Branch record to be generated is Branch cycle count unknown.

R_{XVDNN} When `BRB INJ` is executed inside a BRBE Prohibited region, the contents of the Branch Record Injection data registers are used to create a Branch record which is added to the Branch record buffer storage as the youngest entry.

R_{SMBVK} When a `BRB INJ` instruction is executed inside a BRBE Prohibited region and the contents of the Branch Record Injection data registers indicates an invalid record, it is CONSTRAINED UNPREDICTABLE whether a Branch record is injected to the Branch record buffer. An invalid record is one with BRBINFINJ_EL1.VALID set to `0b00`.

R_{HNCSX} For a `BRB INJ` instruction, it is CONSTRAINED UNPREDICTABLE whether a Branch record is injected to the Branch record buffer when all of the following are true:

- The `BRB INJ` instruction is executed inside a BRBE Prohibited region.
- The contents of the Branch Record Injection data registers indicates a valid record.
- The other contents of the Branch Record Injection data registers indicate an incorrectly formatted record.

If a Branch record is injected, then the contents of the Branch record are CONSTRAINED UNPREDICTABLE.

I_{JLVPS} An example of an incorrectly formatted record is one where BRBINFINJ_EL1.VALID is `0b01` and BRBINFINJ_EL1.MPRED is `0b1`.

R_{PWKFJ} Execution of `BRB INJ` does not require explicit synchronization to use the result of direct writes to the Branch Record Injection data registers in program order before `BRB INJ`.

I_{TVDMK} The creation of a Branch record as a result of execution of `BRB INJ` does not use the result of direct writes to the Branch Record Injection data registers in program order after `BRB INJ`. Explicit synchronization is not required to ensure this ordering. For more information, see Synchronization requirements for AArch64 System registers.

R_{LKDTJ} After the execution of `BRB INJ`, the contents of the Branch Record Injection data registers are UNKNOWN.

I_{CPBKF} Changes to the BRB registers are subject to the rules for synchronization for System registers. See Synchronization requirements for AArch64 System registers.

Chapter D20
RAS PE Architecture

This chapter describes the RAS Extension PE Architecture. It contains the following sections:

- About the RAS Extension
- PE error handling
- Generating error exceptions
- Taking error exceptions
- Error synchronization event
- Virtual SError exceptions and delegated SError exceptions
- Error records in the PE

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D20.1 About the RAS Extension

I_{LBKPL} The RAS Extension extends the exception syndrome registers to include fields that allow the PE to report a PE error state when an Error exception is taken.

I_{THGHB} The RAS Extension defines System registers that are specific to RAS, including to access optional Error records defined by the RAS System Architecture. The format of the error record registers is defined in Error record System register view.

R_{YWXWL} The RAS Extension does not prescribe the level of reliability, availability, and serviceability in the PE. The RAS features that the system and PE include, for example to detect, correct, contain, or defer errors, are IMPLEMENTATION DEFINED. The RAS Extension defines a framework for building RAS features in a PE.

Example D20-1 Minimal implementation of RAS Extension

For systems without a requirement for high reliability and availability, a minimal approach to RAS might include:

- There is no error detection. ERRIDR_EL1.NUM is zero, indicating that no error records are implemented. See Error record System register view.
- Any error signaled to the PE generates an asynchronous SError exception, and on taking the SError exception:
  - The PE error state is recorded as Uncontainable (UC).
    - If FEAT_RASv2 is implemented, then ESR_ELx.VFV is set to 0, meaning FAR_ELx is UNKNOWN and not valid. If FEAT_RASv2 is not implemented, then FAR_ELx is always UNKNOWN and not valid on taking an SError exception.
  - FEAT_PFAR is not implemented, meaning ESR_ELx.PFV is set to 0.

  See Taking error exceptions.
- The `ESB` instruction is implemented as `NOP`.
  See also ESB and virtual SError exceptions and ESB and delegated SError exceptions.

Example D20-2 Minimal implementation of RAS Extension

For systems without a requirement for high reliability and availability, a minimal approach to RAS might include:

- There is no error detection. ERRIDR_EL1.NUM is zero, indicating that no error records are implemented. See Error record System register view.
- Any error signaled to the PE generates an asynchronous SError exception, and on taking the SError exception the PE error state is recorded as Uncontainable (UC).
  See Taking error exceptions.
- The `ESB` instruction is implemented as `NOP`.
  See also ESB and virtual SError exceptions and ESB and delegated SError exceptions.

Example D20-3 Common error handling for RAS features

For a system with a requirement for high reliability and error containment:

- When errors are detected, they are recorded in error records. This includes both correctable and uncorrectable errors. Error correction and detection logic exists on all significant memory structures, and might include other non-memory structures.
- Most uncorrectable errors generate poison values to defer the error.
- On consuming poison from the memory system, a load instruction that would corrupt PE state generates a synchronous External Abort exception, regardless of the memory type. For systems where the performance impact of this approach might be an issue, the controls defined by FEAT_ANERR and FEAT_ADERR are provided.
- On taking error exceptions, the PE error state is Recoverable state (UER).
- FEAT_PFAR is implemented, and the PE makes a best effort attempt to record the faulting physical address in PFAR_ELx or MFAR_ELx, setting ESR_ELx.PFV to 1.

Non-Confidential

D20.2 PE error handling

D20.2.1 PE error detection

I_{KRYQW} When a PE accesses memory or other state, an error might be detected in that memory or state, and corrected, deferred, or signaled to the PE as a Detected error with an in-band error response.

Note:

- An error that is deferred might be signaled to the PE with an in-band error response.
- An error might also be signaled to a PE by means other than an in-band error response.

I_{SLYLK} The response from memory or other state is defined by Detecting and consuming errors. For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

I_{DWWQJ} When an error is detected by a component on a read or a cache maintenance operation from the PE:

- If the error can be corrected, it is corrected and corrected data is returned.
- If the error cannot be corrected and can be deferred, it is deferred. For example, on a load by poisoning the PE state, if this is supported by the PE implementation.
- If the error cannot be corrected and if implemented and enabled at the component, the Detected error is signaled to the PE as an in-band error response.

I_{BKVQP} When an error is detected by a component consuming a write from the PE:

- If the error can be corrected, it is corrected.
- If the error cannot be corrected and can be deferred, it is deferred to the consumer. For example, by poisoning the location being written.
- If the error cannot be corrected and if implemented and enabled at the component, the Detected error is signaled to the PE as an in-band error response.

I_{PDDNB} The component might record the Detected error and generate a Fault handling interrupt and/or Error recovery interrupt.

I_{VRYFF} If the component implements the RAS System Architecture, its behavior is defined by the RAS System Architecture, and depends on the nature of the error and IMPLEMENTATION DEFINED properties of the component. In each of these cases, the component might be a part of the processor, such as a cache, or might be outside of the processor.

The component might also report the error to a RAS System Architecture node, which records the error and might generate one or more of a Fault handling interrupt, Error recovery interrupt, or Critical Error interrupt depending on the features and configuration of the node.

See also Other errors.

I_{FLXTY} An in-band error response is sometimes referred to as an *External abort*. To avoid confusion with the External abort *exception*, the RAS sections in this Manual use in-band error response to describe the response to the PE for a memory access.

For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

R_{WLTPV} The size of the protection granule for any implemented error detection mechanism in memory is IMPLEMENTATION DEFINED and might vary from moment to moment and instruction to instruction.

For example, the size of the protection granule might depend on one or more of the following:

- The physical address of the Location being accessed.
- Whether a copy of the Location held in a cache is being accessed, and the cache it is held in.
- The type of access being made.
- If FEAT_SME is implemented, whether the PE is in Streaming SVE mode or is not in Streaming SVE mode.

I_{JJJGW} A system might implement multiple error detection mechanisms with differing protection granule sizes.

I_{YBRSM} For a Deferred error, Clearing Deferred errors from poisoned Locations describes mechanisms to remove poison and clear the error. The architecture also permits IMPLEMENTATION DEFINED mechanisms for clearing an error or poison from memory.

D20.2.2 PE error propagation

I_{NTXKV} The program-visible architectural state of the PE, referred to as the PE state, includes:

- General-purpose, SIMD&FP, and SVE registers.
- SME and SME2 registers.
- System registers.
- Special-purpose registers.
- PSTATE.

R_{XMBNW} An error is consumed by the PE by any of the following:

- An instruction commits the corruption into the PE state.
- The error is on an instruction fetch and the corrupt instruction is committed for execution.
- The error is on a translation table walk for a committed load, store, or instruction fetch.

I_{HVFKW} For a PE, Error propagation applies to the propagation of Detected error by the PE between the PE state, and any other PE state or memory.

Note: *Memory* includes structures that cache the contents of memory, such as an instruction cache, data cache, or TLB.

R_{VGXBJ} An error is propagated by the PE by one or more of the following occurring that would not have been permitted to occur had the fault not been activated:

- Consumption of the corrupt value by any instruction, propagating the error to the target(s) of the instruction. This includes:
  - A store of a corrupt value.
  - A write of a corrupt value to a System register, Special-purpose register, or PSTATE. Infecting a System register state might mean that the PE generates transactions that would not otherwise be permitted.
- Any operation occurring that should not have occurred, including:
  - A load, translation table walk, or instruction fetch that would not have been permitted, including those from hardware speculation or prefetching.
  - A store to an incorrect address, or a store that would not have been made or not permitted.
  - A direct or indirect write to a Special-purpose or System register that would not have been made or not permitted.
  - Assertion of any signal, such as an interrupt, that would not have been asserted.
- Any operation not occurring that should have occurred.
- Causing the PE to take an imprecise exception, other than an Error exception in response to the error itself. For more information, see Definition of a precise exception and imprecise exception.
- The PE discarding data that it holds in a modified state.
- Any other loss of required uniprocessor semantics, ordering, or coherency.

I_{RMZNK} In R_{VGXBJ}, *not have been permitted to occur* means that the observable behavior of the PE is a deviation from the correct service of the PE, as defined by the architecture. Deviations from the normal behavior of the PE implementation that would otherwise be permitted by the architecture are not deviations from correct service.

Example D20-4

A PE takes an Error exception asynchronously as follows, in program order:

1. A load returns a corrupt value from a first location to a general-purpose register.
2. The PE suppresses a store of the register to a second memory location. In particular, the location is not updated and so retains its previous value.
3. The Error exception is taken.
4. At the point when the Error exception is taken, the ordering constraints imposed by the architecture have not been violated, in particular those relating to the observability of the store at step 2.

Although the error has not been propagated, the PE state is not consistent with the PE having executed all of the instructions up to the point when the Error exception is taken, and so it would be unlikely that software would be able to recover execution.

R_{NQDWB} An error propagated by the PE is silently propagated by the PE only if all of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

1. The propagation is not part of the required operation of the PE in taking an Error exception generated by the error.
2. The propagation is not part of the required operation of the PE executing an `ESB` instruction that synchronizes the error.
3. The error is not signaled to the consumer as a Detected error or Deferred error.
4. Any of the following are true:
   - The corrupt value is held in other than the general-purpose, SIMD&FP, SVE, SME, and SME2 registers.
   - The error is propagated by an instruction in program order before either taking an Error exception generated by the error or executing an `ESB` instruction that synchronizes the error, and is propagated to outside of the general-purpose, SIMD&FP, SVE, SME, and SME2 registers.
   - The error is propagated other than by an instruction that consumes the corrupt value as an input operand but otherwise behaves correctly.

IBRBFF In R_{NQDWB}, item 4 means that after taking the Error exception generated by the error, or an `ESB`, propagating an error by, for example, storing the corrupt value to memory, is not considered as silent propagation of the error by the PE.

Example D20-5

A PE takes an Error exception in response to a load that returns a corrupt value to a general-purpose register. The error is not silently propagated to outside of the general-purpose registers before the Error exception is taken.

Neither of the following are considered silent propagation of the error by the PE:

- Taking the Error exception causes the ESR_ELx, ELR_ELx, and SPSR_ELx registers to be updated. This is part of the required operation of the PE.
- After taking the Error exception, software stores the contents of the general-purpose register to memory, and this is not signaled to memory as a Deferred error. This happens in program order after the exception is taken.

The error is not silently propagated by the PE.

Example D20-6

Further to Example D20-4, if either of the following example additional operations occur between 2 and 3, then the PE has silently propagated the error:

- A second store to a third location is performed by the PE, and the architecture requires that the first store is ordered-before the second store. For example, the second store is a store-release operation. In this case, the PE violates the external ordering constraints for the two stores, and the error is silently propagated to any observer of the second store.
- A second load from the second location returns the previous value, and a second store writes that value to a third location. In this case, the PE violates the requirements of the Coherence-before relation because the second load cannot be Coherence-before the first store. The error silently propagates to any observer of the second store.

If instead of the PE suppressing the store at 2, the PE poisons the second memory location, and in the second example propagates that poison through the second load and second store, then the error is not silently propagated.

RDTRFQ The features that a PE includes to prevent silent propagation of an error are IMPLEMENTATION DEFINED.

Example D20-7

An implementation ensures that a corrupt value in a general-purpose, SIMD&FP, SVE, or SME register is not silently propagated, by signaling a Deferred error on any write of data to any memory location, such that the memory location is poisoned.

D20.2.3 Clearing Deferred errors from poisoned Locations

D20.2.3.1 Poison-atomicity of Memory Write Effects

DYQQLJ A Memory Write Effect is *poison-atomic* if the Memory Write Effect removes a Deferred error (poison) at all Locations written to by the Memory Write Effect.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{XVFDG} For each store instruction with Explicit Memory Write Effects, it is IMPLEMENTATION DEFINED whether the Memory Write Effects are poison-atomic for a region of physical memory. This includes the `DC ZVA` and/or `DC GZVA` instructions.

R_{QSBKL} If a Location in a region of physical memory supports the poison-atomic property for a store instruction, then all Locations in the same naturally-aligned region support this for the same store instruction, where the size of the region is the largest translation granule that the PE supports.

I_{CSJLP} Support for the poison-atomic property for a store instruction is a property of both the PE as well as the system. That is, if the system includes a PE that supports the poison-atomic property for the instruction, then both the PE and the system support this instruction such that it is guaranteed to be poison-atomic.

For example, the system should not split cache line writes of data to be smaller than the poison granule of the downstream component in order to preserve poison-atomicity of a `DC {G}ZVA` instruction.

I_{ZRSSM} There is no architected means to discover the poison-atomic property for `DC ZVA` or `DC GZVA` for any region of physical memory.

I_{NXNTY} When a Memory Write Effect to a Location is not poison-atomic, the Memory Write Effect propagates a Deferred error previously at the Location to the new value being written.

Example D20-8

A region of physical memory uses Error Correction Codes (ECC) to provide error detection and correction. The protection granule for this region of memory is the size of a range covered by a single ECC. The ECC is also used to encode a poison value. This means the poison granule is the same size as the protection granule, for this region of physical memory.

A write that is smaller than the protection granule to this region of physical memory must read the protection granule containing the Location being written in order to calculate a new ECC for the protection granule. If the protection granule contains poison, then a poisoned value is written back, meaning the write is not poison-atomic.

If a write overwrites the entire protection granule, then the system can calculate a new ECC for the protection granule without reading the previous contents, meaning the write can be poison-atomic.

I_{GLFCV} A system might require software to stop using the protection granule until the Deferred error can be removed.

For example, by not using the physical page containing the granule until the system is reset. The architecture does not set any limit on the size of a protection granule, and it might be larger than a translation granule.

I_{HPJFJ} The size of the poison granule is IMPLEMENTATION DEFINED and might vary from moment to moment, instruction to instruction, and by Location. The size of the poison granule might be the same as the size of the protection granule, but this is not guaranteed. See also R_{WLTPV}.

I_{CBCMK} The regions of physical memory that support the poison-atomic property are IMPLEMENTATION DEFINED. Systems might have multiple physical memory types, including multiple physical memory regions used for bulk memory.

D20.2.3.2 Removing poison

I_{VZRKL} For guidance on mechanisms that software can use to remove poison from a Location, see Use of the RAS Extension.

I_{PSLGW} In order to test that poison has been removed from a Location, after the Location has been overwritten by a known-good value, software must be able to read back the Location from physical memory to check that the poison has been removed and the error is not persistent.

To do this, software must ensure that the Location has been cleaned and invalidated from all caches, so that the read returns a value from the Point of Physical Storage for the Location, and not any intermediate cache.

The Point of Coherency might be before a transparent unified cache, meaning that it might be before the Point of Physical Storage for a Location.

For more information on the Point of Physical Storage, see A64 Cache maintenance instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D20.2.4 Other errors

I_{KRQMR} The RAS Extension deals mostly with errors detected by components outside of the PE, such as memory, and consumed by the PE.

Other errors might be detected from within the processor that implements the PE. If the error is not an error in the PE state then the error might be treated as an error detected by another component.

In the following examples, the *component* reports these errors to a RAS System Architecture node that implements Error records and records the errors, and might generate one or more of a Fault handling interrupt, Error recovery interrupt, or Critical Error interrupt depending on the features and configuration of the node.

Example D20-9

A processor cache can be treated as a component outside the PE.

The cache detects an error in the cache state that cannot be corrected:

- If the error is detected in dirty cache data being evicted from the cache when the PE makes an access, then the error might be deferred by the cache writing poison in the evicted cache data.
- If the PE is performing a partial write that does not completely overwrite the protection granule, then the error might be deferred by the cache writing poisoned to the cache location, and/or evicting the cache line with poison. Deferring the error means the error is not consumed by the PE.

Otherwise, the cache component generates the in-band error response to the PE.

Example D20-10

A processor memory interface can be treated as a component outside the PE.

A processor detects a corrupt or poisoned value being returned on the interface that is not being signaled as an in-band error response and cannot be corrected or deferred. For example, in response to a non-cacheable read or a cache refill.

The memory interface component generates the in-band error response to the PE.

I_{VNTWD} An implementation might include error detection logic within the PE state itself. When the PE detects an error in the PE state, the instruction that uses that state consumes the error, and the PE generates an IMPLEMENTATION DEFINED Error exception, taken as an SError exception. See R_{FNVVJ}.

In this case, the processor that implements the PE includes a RAS System Architecture node that implements Error records that record these errors.

I_{JRQDM} An implementation might support poisoning within the PE state. When the PE consumes a Deferred error, for example a poisoned value, from memory into the PE state, the PE state becomes poisoned. Subsequent operations that read the poisoned value can continue to defer the error by poisoning the result of the operation.

However, if the PE attempts to execute an operation that reads the poisoned value and cannot defer the error further, the PE generates an IMPLEMENTATION DEFINED Error exception, taken as an SError exception. See R_{FNVVJ}.

In this case, the processor that implements the PE includes a RAS System Architecture node that implements Error records that record these errors.

I_{JHQVK} Components outside of the PE might detect errors that are not consumed by the PE. These components might report such errors to a PE using Error recovery interrupts.

R_{XJNNT} For implementations that include the Statistical Profiling Extension, the Statistical Profiling Extension behaves like a separate component.

I_{MJQQZ} Errors from software faults are outside the scope of the RAS Extension. For more information, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

D20.3 Generating error exceptions

R_{VJRKF} An Error exception is generated when a detected error is signaled to the PE as an in-band error response to an architecturally-executed memory access or cache maintenance operation. This includes any explicit data access, instruction fetch, translation table walk, or hardware update to the translation tables made by an architecturally-executed instruction.

I_{PJHZS} An Error exception is taken as an asynchronous SError exception, a synchronous External Data Abort exception, or a synchronous External Instruction Abort exception.

R_{MBNBH} It is IMPLEMENTATION DEFINED whether an Error exception can be generated for an error that is consumed by hardware speculation or prefetching by a PE, but that is not committed to the architecturally visible state of the PE.

R_{SHKJB} It is IMPLEMENTATION DEFINED whether an Error exception can be generated for a detected error that is deferred.

R_{GVWJD} It is IMPLEMENTATION DEFINED whether an Error exception can be generated for a detected error that is corrected.

R_{FNVVJ} An Error exception can also be generated for IMPLEMENTATION DEFINED causes. An Error exception generated for an IMPLEMENTATION DEFINED cause is taken as an SError exception.

Example D20-11

An error is detected and neither corrected nor deferred to the PE, and signaled to the PE by means other than an in-band error response, such as a wired SError exception pin. Asserting the SError exception pin causes the PE to generate an SError exception.

Example D20-12

An error is detected by the PE in the PE state, or in the result of a calculation performed by the PE. The detected error generates an SError exception.

I_{ZXHDP} See also:

- Exceptions.
- Taking error exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D20.4 Taking error exceptions

R_{VXFYS} For an error signaled on a non-speculative instruction fetch or a translation table walk or hardware update of translation tables for an instruction fetch:

- If FEAT_DoubleFault is implemented, then the Error exception is taken as a synchronous Instruction Abort exception.
- Otherwise, it is IMPLEMENTATION DEFINED whether an Error exception on these accesses is taken as a synchronous External Abort exception or as an asynchronous SError exception.

R_{HWVPC} Other than for the IMPLEMENTATION SPECIFIC cases described below, if FEAT_ANERR is implemented and the Effective value of SCTLR2_ELx.EnANERR is `0b0`, an error signaled on a load from Normal memory is handled precisely and synchronously.

It is IMPLEMENTATION SPECIFIC whether SCTLR2_ELx.EnANERR applies to memory reads generated by each of the following:

- If FEAT_LSE is implemented, `LD<OP>`, `SWP`, and `CAS{P}` atomic instructions that return a value to the PE.
- If FEAT_LS64_V is implemented, `LD64B` and `ST64BV{0}` instructions that return a value to the PE.
- If FEAT_SME is implemented:
  - SIMD&FP register loads when the PE is in Streaming SVE mode.
  - SVE register loads when the PE is in Streaming SVE mode.
  - SME register loads.
- If FEAT_THE is implemented, `RCW*` instructions that return a value to the PE.
- If FEAT_NV2 is implemented, a memory read that is generated as a result of HCR_EL2.NV2 transforming an `MRS` or `MRRS` instruction to a load, and the target memory type is not Normal Inner and Outer Write-back cacheable.

This applies to exceptions taken from both AArch64 and AArch32 Execution states.

R_{SYQGN} Other than for the IMPLEMENTATION SPECIFIC cases described below, if FEAT_ADERR is implemented and the Effective value of SCTLR2_ELx.EnADERR is `0b0`, an error signaled on a load from Device memory is handled precisely and synchronously.

It is IMPLEMENTATION SPECIFIC whether SCTLR2_ELx.EnADERR applies to memory reads generated by each of the following:

- SIMD&FP register loads.
- If FEAT_LSE is implemented, `LD<OP>`, `SWP`, and `CAS{P}` atomic instructions that return a value to the PE.
- IF FEAT_SVE is implemented, SVE register loads.
- If FEAT_LS64_V is implemented, `LD64B` and `ST64BV{0}` instructions that return a value to the PE.
- If FEAT_SME is implemented, SME register loads.
- If FEAT_THE is implemented, `RCW*` instructions that return a value to the PE.
- If FEAT_NV2 is implemented, a memory read that is generated as a result of HCR_EL2.NV2 transforming an `MRS` or `MRRS` instruction to a load.

This applies to exceptions taken from both AArch64 and AArch32 Execution states.

I_{YRSKT} For an error signaled on a fetch of GPT information to check an access, the Error exception generates a synchronous External abort on GPT fetch, which is taken as a GPC exception. For more information see GPC faults.

R_{VLFTP} Unless otherwise stated, it is IMPLEMENTATION DEFINED whether an Error exception is handled precisely and synchronously, or handled asynchronously for each non-speculative:

- Explicit memory access made by an instruction.
- Cache maintenance operation.
- If FEAT_MTE is implemented, access to an Allocation Tag in memory made by an instruction.
- Translation table walk or hardware update of translation tables for a memory access made by an instruction.

D_{TSYLW} In this section, *Handled precisely and synchronously* means:

- If an access is due to any Active element of an SVE non-fault vector load instruction, or an Active element that is not the First active element of an SVE First-fault vector load instruction, then the error is reported in the FFR.
- Otherwise, the error generates a precise synchronous Data Abort exception.

D_{NBSFD} In this section, *Handled asynchronously* means:

- If an access is due to any Active element of an SVE non-fault vector load instruction or an Active element that is not the First active element of an SVE First-fault vector load instruction, then the error is not reported in the FFR.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The error generates an asynchronous SError exception.

R_{CLFJM} All Error exceptions generated by speculative memory accesses are taken as an asynchronous SError exception.

R_{WFNJG} When an Error exception is taken as an asynchronous SError exception, the exception is taken in finite time.

R_{BCXKN} When any of the following exceptions are taken, the PE records the PE error state in the exception syndrome register:

- A synchronous External abort taken to AArch64 state.
- An SError exception taken to either AArch32 or AArch64 state.

R_{TYVYR} When a synchronous External abort is taken to AArch32 state, the PE does not record the PE error state.

I_{GGCQQ} The exception type and target Execution state determine the set of PE error state values the PE can record.

I_{WSYXB} The recorded PE error state informs software whether software can recover execution and, if so, whether any action by the recovery software to locate and repair the error is necessary first.

I_{TRWXF} Other than as described by I_{WBVYC}, the PE error state recorded in the exception syndrome register describes the recovery of the PE state only. For example, the PE state might be recoverable when the state of system is such that system-level recovery is not possible. See also I_{ZQRGL}.

I_{NFDSM} Software is only able to successfully recover execution and make progress from a restart address for the exception by executing an Exception Return instruction to branch to the instruction at this restart address if all of the following are true:

- The error has not been silently propagated by the PE.
- At the point when the Exception Return instruction is executed, the PE state and memory system state are consistent with the PE having executed all of the instructions up to but not including the instruction at the restart address, and none afterwards. That is, at least one of the following restart conditions is true:
  - The error has been not architecturally consumed by the PE and infected the PE state.
  - Executing the instruction at the restart address will not consume the error and will correct any corrupt state by overwriting it with the correct value or values.

R_{DCKHJ} On taking an Error exception, the PE determines that software is able to recover execution at the point where the exception is taken, with no additional action from software, if and only if all of the following are true:

- The error has not been silently propagated by the PE.
- The restart conditions are met because all of the following are true:
  - Either the error does not remain latent or executing the instruction at the restart address will not consume the error and will correct any corrupt PE state.
  - The restart address is the preferred return address for the exception.
- The PE has not elected to determine that software is not able to recover execution, and has not elected to determine that software is able to recover execution if software takes action to locate and repair the error.

R_{JBHWY} On taking an Error exception, the PE determines that software is able to recover execution if software takes action to locate and repair the error, to get the PE state and memory system state into this consistent state before attempting recovery, if and only if all the following are true:

- The error has not been silently propagated by the PE.
- The restart conditions can be met because the restart address is the preferred return address for the exception and at least one of the following is true:
  - The error remains latent and executing the instruction at the restart address will access the corrupt state. If the error is removed then executing the instruction at the restart address will correct any corrupt PE state and/or corrupt memory state. For example, the instruction at the restart address is a load that will consume the error and corrupts PE state.
  - The error does not remain latent and the PE has elected to determine that software is able to recover execution if software takes action to locate and repair the error.
  - Executing the instruction at the restart address will not consume the error and the PE has elected to determine that software is able to recover execution if software takes action to locate and repair the error.
- The PE has not elected to determine that software is not able to recover execution.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{GJQWN} On taking an Error exception, the PE determines that software is not able to recover execution if and only if one or more of the following are true:

- The error has been silently propagated by the PE.
- The restart conditions cannot be met even if software takes action to locate and repair the error. This is because at least one of the following is true:
  - The error remains latent and executing the instruction at the restart address will consume the error and corrupt PE state. Either the error cannot be removed or executing the instruction at the restart address will not correct any corrupt PE state.
  - The restart address is not the preferred return address for the exception.
- The PE has elected to determine that software is not able to recover execution.

I_{XMCCR} That the PE determines that software is able to recover execution if software takes action to locate and repair the error does not mean that software can locate and repair the error. For example, the error in memory might be one which cannot be located or cannot be repaired. See I_{ZQRGL}.

Error recovery software might instead make the PE state and memory system state consistent with an *alternative execution* of the program.

Example D20-13

An Error exception is generated by a load from a location in a clean page of memory that is infected by an error. Software might be able to repair the error by:

- Reloading the page from a backing store. This makes the memory system state consistent with the uncorrupted view. Executing the instruction at the restart address will load the uncorrupted value into the PE state.
- Invalidating the clean page and marking it page as inaccessible. Executing the instruction at the restart address will result in a Translation fault being generated when the program tries to access the page. The target of the load will contain an UNKNOWN value, which is permitted by the architecture. The MMU fault handler can then reload the page from the backing store, as it would for a page that has not been previously accessed or has been paged out.

Either approach might result in the virtual address to physical address mapping for the page being changed by software, meaning the memory system state is not consistent with the previously executed instructions. However, the memory system state is consistent with a valid alternative view of the execution of the program that allows software to recover execution.

This recovery is only possible if the error can be isolated to a location.

I_{RHPPV} A PE might include additional IMPLEMENTATION DEFINED mechanisms to aid software locate and repair the error.

If software has to use IMPLEMENTATION DEFINED mechanisms to locate and repair the error, then the PE reports that it has determined that software is not able to recover execution. The PE might use IMPLEMENTATION DEFINED additional syndrome registers to report that software is able to recover execution if software takes action to locate and repair the error using the IMPLEMENTATION DEFINED mechanisms.

I_{RLQVJ} See also:

- PE error state recording in the exception syndrome.
- PE error state classification.

D20.4.1 PE error state recording in the exception syndrome

R_{WPKYM} When an asynchronous SError exception is taken to AArch64 state, the PE records the PE error state in the ESR_ELx exception syndrome register as the applicable one of:

- Uncontainable (UC).
- Unrecoverable state (UEU).
- Recoverable state (UER).
- Restartable state (UEO).
- Corrected (CE).
- Uncategorized error.
- IMPLEMENTATION DEFINED syndrome.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{SDDLL} When an asynchronous SError exception is taken to AArch64 state:

- Uncategorized error is recorded by setting ESR_ELx.ISS to zero. This includes setting ESR_ELx.IDS and ESR_ELx.DFSC to zero.
- IMPLEMENTATION DEFINED syndrome is recorded by setting ESR_ELx.IDS to `0b1`. The remainder of the ESR_ELx.ISS syndrome is IMPLEMENTATION DEFINED.

Other values for the PE error state are recorded in ESR_ELx.AET, by setting ESR_ELx.IDS to `0b0` and ESR_ELx.DFSC to the applicable nonzero fault status code, indicating ESR_ELx.AET is valid.

R_{ZSKKG} If FEAT_RASv2 is implemented and any of the following are true, then an error exception is taken as an SError exception:

- The error has been silently propagated by the PE.
- The PE determines that software is not able to recover execution from the preferred return address of the exception.

R_{FKHHF} When a synchronous External abort exception is taken to AArch64 state, the PE records the PE error state in ESR_ELx.SET as the applicable one of the following:

- If FEAT_RASv2 is not implemented, Uncontainable (UC).
- Recoverable state (UER).
- Restartable state (UEO).

Other values for the PE error state are not supported by synchronous External abort exceptions taken to AArch64 state.

R_{PWKBL} When an asynchronous SError exception is taken to AArch32 state, the PE records the PE error state in DFSR.AET or HSR.AET as appropriate, as the applicable one of:

- Uncontainable (UC).
- Unrecoverable state (UEU).
- Recoverable state (UER).
- Restartable state (UEO).

Other values for the PE error state are not supported by asynchronous SError exceptions taken to AArch32 state.

I_{QVVSM} Table D20-1 summarizes the supported PE error state syndrome values for each type of Error exception.

Table D20-1 Summary of Error exception types and supported PE error state syndrome values

PE error state	External abort to AArch64 state	SError exception to AArch64 state	External abort to AArch32 state	SError exception to AArch32 state
Recorded in:	ESR_ELx.SET	ESR_ELx.AET	No syndrome	DFSR.AET
Uncategorized error	No	Yes (ISS==0)	-	No
IMPLEMENTATION DEFINED syndrome	No	Yes (IDS==1)	-	No
Uncontainable (UC), FEAT_RASv2 implemented	No	Yes (`0b000`)	-	Yes (`0b00`)
Uncontainable (UC), FEAT_RASv2 not implemented	Yes (`0b10`)	Yes (`0b000`)	-	Yes (`0b00`)
Unrecoverable state (UEU)	No	Yes (`0b001`)	-	Yes (`0b01`)
Recoverable state (UER)	Yes (`0b00`)	Yes (`0b011`)	-	Yes (`0b11`)
Restartable state (UEO)	Yes (`0b11`)	Yes (`0b010`)	-	Yes (`0b10`)

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PE error state	External abort to AArch64 state	SError exception to AArch64 state	External abort to AArch32 state	SError exception to AArch32 state
Deferred (DE)	No	No	-	No
Corrected (CE)	No	Yes (`0b110`)	-	No

D20.4.2 PE error state classification

I_{CCKWK} The PE determines which PE error state to record based on the following criteria:

- The PE error state syndrome values supported by the type of Error exception being taken. See PE error state recording in the exception syndrome.
- The following IMPLEMENTATION SPECIFIC properties and behaviors of the PE on taking the exception:
  - Whether the error has been silently propagated by the PE.
  - Whether the PE determines that software is able to recover execution at the point where the exception is taken.
  - If the PE determines that software can recover execution, whether software needs locate and repair the error before attempting to recover. If software does not locate and repair the error, then attempting to recover execution might cause the Error exception to be generated again.
  - If the PE determines that software cannot recover execution, whether the error is a synchronizable error.
- Whether the implementation elects to record the PE error state as another state. The PE only does this when the criteria for the other, recorded state are met. The conditions under which the PE elects to record the PE error state as another state are IMPLEMENTATION DEFINED.

The recorded PE error state is defined by the rules in this section.

R_{QKZLB} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Uncontainable (UC):

- One or more of the following are true:
  - The error has been silently propagated by the PE.
  - The PE determines that software is not able to recover execution from the preferred return address of the exception and the error is not a synchronizable error.
  - The PE determines that software is not able to recover execution from the preferred return address of the exception and the Error exception is taken as a synchronous External abort to AArch64 state. (That is, the type of Error exception does not support reporting the PE error state as Unrecoverable state (UEU).)
  - The implementation has elected to record the PE error state as Uncontainable (UC).
- The Error exception is not taken as a synchronous External abort to AArch32 state.
- Either FEAT_RASv2 is not implemented, or the Error exception is not taken as a synchronous External abort to AArch64 state.
- The implementation has not elected to record the PE error state as IMPLEMENTATION DEFINED syndrome or Uncategorized error, or the type of Error exception does not support reporting the PE error state as IMPLEMENTATION DEFINED syndrome or Uncategorized error.

R_{QGNYD} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Unrecoverable state (UEU):

- The error has not been silently propagated by the PE.
- The Error exception is taken as an SError exception.
- One or more of the following are true:
  - The PE determines that software is not able to recover execution from the preferred return address of the exception and the error is a synchronizable error.
  - The implementation has elected to record the PE error state as Unrecoverable state (UEU).
- The implementation has not elected to record the PE error state as Uncontainable (UC), IMPLEMENTATION DEFINED syndrome, or Uncategorized error.

I_{FJCZP} Error synchronization event defines synchronizable error.

R_{JHNVT} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Recoverable state (UER):

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The error has not been silently propagated by the PE.
- The Error exception is not taken as a synchronous External abort to AArch32 state.
- The PE determines that software is able to recover execution from the preferred return address of the exception.
- One or more of the following are true:
  - The PE determines that software must take action to locate and repair the error to successfully recover execution. This might be because the exception was taken before the error was architecturally consumed by the PE, at the point when the PE was not be able to make correct progress without either consuming the error or otherwise making the state of the PE unrecoverable.
  - The implementation has elected to record the PE error state as Recoverable state (UER).
- The implementation has not elected to record the PE error state as Unrecoverable state (UEU), Uncontainable (UC), IMPLEMENTATION DEFINED syndrome, or Uncategorized error.

R_{MBVCF} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Restartable state (UEO):

- The error has not been silently propagated by the PE.
- The Error exception is not taken as a synchronous External abort to AArch32 state.
- The PE determines that software can recover execution from the preferred return address of the exception without the need for software to take action to locate and repair the error first.
- One or more of the following are true:
  - The error is an uncorrected error. This includes a deferred error.
  - The error is a corrected error and the Error exception is not taken as an SError exception taken to AArch64 state.
  - The implementation has elected to record the PE error state as Restartable state (UEO).
- The implementation has not elected to record the PE error state as any of Recoverable state (UER), Unrecoverable state (UEU), Uncontainable (UC), IMPLEMENTATION DEFINED syndrome, or Uncategorized error.

R_{LFXRD} If and only if all of the following are true, then on taking an Error exception the PE error state is recorded as Corrected (CE):

- The error has been corrected and not silently propagated by the PE.
- The Error exception is taken as an SError exception taken to AArch64 state.
- Software can recover execution from the preferred return address of the exception. Because the error has been corrected, software does not need to take action to locate and repair the error.
- The implementation has not elected to record the PE error state as any other type.

I_{BWPJZ} Arm strongly recommends that a corrected error that is not silently propagated does not generate any Error exception at the PE. The producer of the data that corrected the error might still record the error in a RAS error record, and generate a fault handling interrupt, as described in the *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

R_{NZYRP} If and only if all the following are true, then on taking an Error exception the PE error state is recorded as an Uncategorized error:

- The Error exception is taken as an asynchronous SError exception taken to AArch64 state.
- The implementation has elected to record the PE error state as an Uncategorized error.

R_{VHWHD} If and only if all the following are true, then on taking an Error exception the PE error state is recorded as an IMPLEMENTATION DEFINED syndrome:

- The Error exception is taken as an asynchronous SError exception taken to AArch64 state.
- The implementation has elected to record the PE error state as an IMPLEMENTATION DEFINED syndrome.

I_{SRPJD} The IMPLEMENTATION DEFINED syndrome type might provide additional IMPLEMENTATION DEFINED syndrome recorded in the exception syndrome register. Software might be able to determine the state of the PE from this syndrome, or other IMPLEMENTATION DEFINED syndrome registers.

I_{WLZRP} Uncategorized error and IMPLEMENTATION DEFINED syndrome are defined for backward compatibility with previous versions of the architecture. Arm does not recommend use of these PE error state values in new implementations that include other RAS features.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IVKMZB The PE error states for an Error exception generated when the PE consumes an uncorrected error are summarized by Figure D20-1. Figure D20-1 assumes the type of Error exception supports the resulting PE error state, that the error was neither corrected nor deferred, and the PE never elects to record an error as a different PE error state when permitted, an Uncategorized error syndrome, or an IMPLEMENTATION DEFINED syndrome.

Figure D20-1 PE error states

IZQRGL If the PE error state reports that software can recover execution, or that software isolation might be possible because the error is a synchronizable error, then this does not necessarily mean that the error can be recovered from because the error in the system might be one which does not allow software to recover the operation. Rather, software *might* be able to recover if it can repair the error and continue.

Example D20-14

A component detects an error when accessed by a PE, and records in a RAS System Architecture node that the error is uncontainable at the component, meaning the system has to be shut down to avoid catastrophic failure.

The component signals the error with an in-band error response to a PE, which does not report the severity of the error. The recorded PE error state refers only to the PE, not the system error state.

IWBVYC If the in-band error response can signal the severity of the error to the PE, then the PE might use this information to elect to report the PE error state as the severity of error reported to it, if permitted by the preceding rules.

However, this is not required, and software must not rely on this behavior and should determine from the system whether the error is recoverable at the system level.

Example D20-15

A processor cache detects an uncontainable tag RAM error, and the PE reports the PE error state as Uncontainable (UC), even though the state of the PE itself is Recoverable state (UER). RQKZLB allows this.

ITXFMY An SError exception that is masked when it is generated remains pending until taken later when no longer masked.

In these cases, the PE error state is also unlikely to be *Restartable* or *Recoverable*, and if FEAT_RASv2 is implemented, is reported with ESR_ELx.ELS cleared to 0.

D20.4.2.1 Using the PE error state classification

S_{XSKNS} When the PE error state is recorded as Uncontainable (UC):

- The error handling software must assume that either:
  - The error has been silently propagated by the PE.
  - Software is not able to recover execution from the preferred return address of the exception and the error was not a synchronizable error.
- If the error handling software cannot isolate the error to an application or VM, or both, by other means, then the system must be shut down by software to avoid catastrophic failure.

S_{HYWFL} When the PE error state is recorded as Unrecoverable state (UEU):

- The error handling software can assume the error has not been silently propagated by the PE.
- The error handler cannot safely recover execution from the preferred return address of the exception, even if it takes action to locate and repair the error. The state of the affected software is unrecoverable. However, if the software includes Error synchronization events, the error handler can use the properties of the Error synchronization event to determine which software is affected by the error.
- The affected software cannot continue and must be isolated by the error handling software.

S_{LSFYM} When the PE error state is recorded as Recoverable state (UER):

- The uncorrected error might remain latent in the system.
- If the error handling software takes action to locate and repair the uncorrected error, then the error handler can safely recover execution from the preferred return address of the exception. Otherwise on restart of the affected software the PE might attempt to consume the error again, causing a further Error exception. If the error handler cannot locate and repair the error, then the affected software must be isolated by the error handling software.

S_{GLPZY} When the PE error state is recorded as Restartable state (UEO):

- The error might remain latent in the system.
- The error handling software might take action to locate and repair the error before it is consumed. However, the affected software can be safely restarted by the error handler without software taking any action to locate and repair the error.

For example, the error was signaled when the PE speculatively accessed corrupt data.

S_{GRZQS} When the PE error state is recorded as IMPLEMENTATION DEFINED syndrome or Uncategorized error, if the error handling software is not able to determine the actual state of the PE and memory, it should treat IMPLEMENTATION DEFINED syndrome and Uncategorized error as Uncontainable (UC).

D20.4.2.2 Recording the physical address

D_{LVGRB} When FEAT_PFAR is implemented, the address written to PFAR_ELx.PA or MFAR_EL3.PA on taking a synchronous External Abort or SError exception can be any address within a naturally-aligned fault granule that contains the faulting physical address.

R_{THPSG} The fault granule size is IMPLEMENTATION DEFINED and no larger than the size of the range of values permitted to be recorded in FAR_ELx.

Note

To aid with data recovery, it is recommended that the fault granule is no larger than the error protection granule used in the system.

R_{JZCNK} When FEAT_PFAR is implemented, Execution at EL0 makes PFAR_EL1 become UNKNOWN, and Execution at EL1 or EL0 makes PFAR_EL2 become UNKNOWN.

D20.4.3 Multiple SError exceptions

I_{CPJLW} Multiple physical and/or virtual SError exception conditions might be pending together. The architecture does not define relative priorities for asynchronous exceptions.

R_{DHKQZ} If multiple physical and/or virtual SError exception conditions are pending, then it is IMPLEMENTATION DEFINED whether the multiple pending SError exception conditions are taken as a single SError exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{JBQSC} On taking an SError exception for more than one SError condition:

- If the exception is taken to AArch64 state and one or more pending SError conditions would be reported as IMPLEMENTATION DEFINED syndrome or Uncategorized error, then the syndrome recorded in ESR_ELx.ISS is IMPLEMENTATION DEFINED.
- Otherwise, the recorded PE error state applies recorded by combined effect of the errors.

I_{GNHXJ} Any pending SError conditions that are not taken with other SError exceptions as a single SError exception remains pending after the SError exception is taken.

D20.4.4 Target Exception level for External abort and SError exceptions taken to AArch64 state

D_{FWSVH} This section is included for completeness. It repeats the definitions from this Manual and so is *non-normative*.

These definitions also apply to synchronous External abort exceptions and SError exceptions taken from AArch32 state to AArch64 state.

I_{NRZXZ} The default target Exception level for synchronous External abort exceptions taken to AArch64 state is:

- EL1, if taken from EL0 or EL1.
- EL2, if taken from EL2.
- EL3, if taken from EL3.

The default target Exception level for SError exceptions taken to AArch64 state is EL1.

However:

- If EL3 is implemented and SCR_EL3.EA is `0b1`, then the target Exception level for all SError exceptions and synchronous External abort exceptions is EL3.
- Otherwise, if EL2 is implemented and enabled in the current Security state, then:
  - If HCR_EL2.AMO is `0b1` or HCR_EL2.TGE is `0b1`, then the target Exception level for SError exceptions is EL2.
  - If HCR_EL2.TEA is `0b1` or HCR_EL2.TGE is `0b1`, then the target Exception level for synchronous External abort exceptions taken from EL0 and EL1 is EL2.

When executing in AArch64 state at a higher Exception level than the target Exception level for SError exceptions, SError exceptions are implicitly masked and not taken.

I_{BPGXV} See also The AArch64 System Level Programmers' Model.

D20.4.5 Target Exception level for External abort and SError exceptions taken to AArch32 state

D_{WFQWP} This section is included for completeness. It repeats the definitions from this Manual and so is *non-normative*.

I_{BMBXM} The default target mode for SError and synchronous External abort exceptions taken to AArch32 state is:

- Abort mode, if taken from EL0, EL1 or EL3, including from Monitor mode.
- Hyp mode, if taken from EL2.

However:

- If EL3 is implemented, EL3 is using AArch32, and SCR.EA is `0b1`, then the target mode for SError exceptions and synchronous External abort exceptions is Monitor mode.
- Otherwise, if EL2 is implemented, EL2 is using AArch32, and the PE is in Non-secure state:
  - If HCR.AMO is `0b1` or HCR.TGE is `0b1`, then the target mode for SError exceptions taken from EL0 and EL1 is Hyp mode, using vector offset `0x14`.
  - If HCR.TEA is `0b1` or HCR.TGE is `0b1`, then the target mode for synchronous External abort exceptions taken from EL0 and EL1 is Hyp mode, using vector offset `0x14`.

Unless otherwise stated, vector offset `0x10` is used for SError exceptions and synchronous Data Abort exceptions, and vector offset `0x0C` is used for Prefetch Abort exceptions.

I_{CCPMY} See also The AArch32 System Level Programmers' Model.

Non-Confidential

D20.5 Error synchronization event

R_{GRJVN} An Error synchronization event is generated by any of the following:

- Executing an ESB instruction.
- When FEAT_IESB is implemented, and one of the following is true, taking an exception in Non-debug state to an Exception level, ELx, using AArch64:
  - The Effective value of the applicable SCTLR_ELx.IESB bit is 0b1.
  - FEAT_DoubleFault is implemented, the Exception level is EL3, and SCR_EL3.NMEA is 0b1.
- When FEAT_IESB is implemented, and one of the following is true, executing an exception return instruction in Non-debug state at an Exception level, ELx, using AArch64:
  - The appropriate SCTLR_ELx.IESB bit is 0b1.
  - FEAT_DoubleFault is implemented, the exception level is EL3, and SCR_EL3.NMEA is 0b1.

R_{RKWPZ} SCTLR_ELx.IESB is ignored in Debug state and treated as zero.

I_{XKTLD} Because SError exceptions are masked in Debug state, and the effects of an implicit Error synchronization barrier could happen at any time regardless of the value of SCTLR_ELx.IESB, an implementation that honors SCTLR_ELx.IESB in Debug state is compliant with R_{RKWPZ}.

I_{PMGVM} In addition to generating an Error synchronization event, the ESB instruction might additionally record and then clear a masked pending asynchronous SError exception. This is also referred to as deferring the pending asynchronous SError exception.

R_{WPPWC} A synchronizable error is one of a subset of errors specific to the implementation that are synchronized by Error synchronization events, generated by an instruction executed on the same PE as the Error synchronization events.

Note: Synchronizable error must not be confused with a synchronous error exception. An Error exception for a synchronizable error might be taken asynchronously.

R_{BZPTV} If the Error exception for a synchronizable error is taken in program order after the Error synchronization event completes, and either physical SError exceptions are unmasked when the Error synchronization event occurs or the Error exception is taken synchronously, then all of the following are true:

- The instruction that generated the synchronizable error is in program order after the Error synchronization event.
- On completion of the Error synchronization event, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the Error synchronization event.

R_{ZRHDD} If the Error exception for a synchronizable error is taken asynchronously as an SError exception, physical SError exceptions are masked when the Error synchronization event occurs, and the SError exception is not pending when the Error synchronization event completes, then all of the following are true:

- The instruction that generated the synchronizable error is in program order after the Error synchronization event.
- On completion of the Error synchronization event, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the Error synchronization event.

The SError exception is not pending when the Error synchronization event completes if a subsequent read of ISR_EL1.A or ISR.A returns 0b0.

R_{YCJTN} If the Error exception for a synchronizable error is taken asynchronously as an SError exception, the Error synchronization event is generated by an ESB instruction executed when physical SError exceptions are masked, and the ESB instruction does not set DISR_EL1.A or DISR.A to 0b1, then all of the following are true:

- The instruction that generated the synchronizable error is in program order after the ESB.
- On completion of the ESB, the PE state and memory system state are consistent with the PE having executed all instructions in program order before the ESB.

R_{NFKMQ} Taken in program order after the Error synchronization event completes means:

- For an Error synchronization event generated by an ESB instruction, the exception is taken in program order after the instruction.
- For an Error synchronization event generated by an exception return instruction when FEAT_IESB implemented, the exception is taken in program order after the instruction.
- For an Error synchronization event generated by an exception entry when FEAT_IESB is implemented, one of the following is true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— The exception is taken in program order strictly after the first instruction of the exception handler at the exception vector address.

— The exception is taken from the first instruction of the exception handler at the exception vector address and the ESR_ELx.IESB syndrome bit is recorded as `0b0`.

I_{QZSHG} The definition of synchronizable error means that if the error that is a synchronizable error is generated by an instruction in program order before the Error synchronization event, then either the Error exception is taken before the Error synchronization event, or on executing the Error synchronization event the following apply:

- If physical SError exceptions are unmasked or the Error exception is taken synchronously, then the Error synchronization event ensures that the Error exception is not taken in program order after the Error synchronization event. This allows isolation of the software affected by the error.
- If physical SError exceptions are masked and the Error exception is taken asynchronously, then:
  — If the Error synchronization event was generated by an `ESB`, then the error is recorded in DISR_EL1 or DISR. Software can use the PE error state recorded in DISR_EL1 or DISR to determine what recovery is possible.
  — Otherwise, the Error exception is pending when the Error synchronization event completes.

The SError exception might have been pending before or made pending by the Error synchronization event.

The definition does not mean that if the error is generated by a instruction in program order after the Error synchronization event, then the Error exception will only be taken after the Error synchronization event. The Error exception might be taken before the Error synchronization event, if the PE speculated past the Error synchronization event and speculatively executed the instruction that generated the error. This might cause software to generate a false failure. Error synchronization events are not speculation barriers.

I_{SQCFG} The criteria for the PE error state mean that if the PE reports the PE error state as one of the following, then the error must be either explicitly or implicitly a synchronizable error:

- Unrecoverable state (UEU).
- Recoverable state (UER).
- Restartable state (UEO).

This is because whether the error is a synchronizable error is a criterion for Unrecoverable state (UEU), and the criteria for Recoverable state (UER) and Restartable state (UEO) satisfy the definition of synchronizable error.

For other physical errors:

- An error that has been silently propagated by the PE and is not reported as either IMPLEMENTATION DEFINED syndrome or Uncategorized error must be reported as Uncontainable (UC) and is not containable even if the error is a synchronizable error. Software must assume the error has been silently propagated even if the error is a synchronizable error.
- It is IMPLEMENTATION SPECIFIC whether an error reported with an ESR_ELx.ISS syndrome that is IMPLEMENTATION DEFINED syndrome or Uncategorized error is a synchronizable error.
- The following errors have not been consumed by the PE:
  — A *Deferred error*.
  — A *Corrected error*.
  — An Error exception from a read by hardware speculation that does not corrupt the state of the PE.

  Software can recover execution from these errors regardless of whether the error is a synchronizable error.
- An implementation might have other IMPLEMENTATION DEFINED Error exception and other sources of SError exception, see R_{FNVVJ}. If an IMPLEMENTATION DEFINED SError exception is generated by a level-sensitive interrupt signal, then the SError exception cannot be a synchronizable error.

I_{VFFYW} An Error synchronization event might operate as follows:

1. The PE ensures that any synchronizable error generated by an instruction in program order before the Error synchronization event has caused a physical SError exception to become pending.
2. If a physical SError exception is pending for a synchronizable error and generated by an instruction in program order before the Error synchronization event, and physical SError exceptions are not masked at the current Exception level, then the physical SError exception is taken before completion of the Error synchronization event. The SError exception might have been made pending by the Error synchronization event, or might have been pending before the Error synchronization event.

R_{NPPGJ} If a physical SError exception for a synchronizable error is pending after completing the Error synchronization event generated by an `ESB` instruction, and physical SError exceptions are masked at the current Exception level, then the `ESB` instruction performs the following steps:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

1. The pending physical SError exception is recorded in DISR_EL1 or DISR. This includes the PE error state that the pending Error exception would record if taken.
2. The DISR_EL1.A bit or DISR.A bit is set to `0b1`.
3. The pending state of the physical SError exception is cleared.

The SError exception might have been made pending by the Error synchronization event, or might have been pending before the Error synchronization event.

I_{BLRTM} The criteria for `ESB` recording the PE error state in DISR_EL1 or DISR are the same as for that for recording the PE error state in ESR_ELx or DFSR when an SError exception taken to the current execution state.

R_{KNWBN} If an SError exception is taken as part of an Error synchronization event generated by an `ESB` instruction, then the `ESB` instruction address is the *preferred return address* of the exception.

For the definition of the *preferred return address* for an exception, see Preferred return address.

R_{SFHDS} On executing an `ESB` instruction when SError exceptions are masked, any pending SError exception generated by an error that is not a synchronizable error:

- Remains pending after completion of the Error synchronization event.
- Does not update DISR_EL1 or DISR.

I_{CQKXL} The Error recovery interrupt, Fault handling interrupt, and Critical Error interrupt interrupts described by RAS System Architecture are asynchronous interrupts, and so are not synchronizable errors.

I_{BBGXN} If multiple SError exception conditions are pending, then an Error synchronization event synchronizes all errors that are synchronizable errors.

S_{VFHGT} Software must be aware that an SError exception taken at an Error synchronization event or recorded in the DISR_EL1 or DISR register by an `ESB` instruction might have been generated by hardware speculation of an instruction in program order after the Error synchronization event.

D20.5.1 ESB and virtual SError exceptions

R_{LLLVR} If all of the following are true, then an `ESB` instruction executed at EL0 or EL1 synchronizes a pending virtual SError exception:

- EL2 is implemented and enabled in the current Security state.
- Any of the following are true:
  - EL2 is using AArch64, HCR_EL2.TGE is `0b0`, HCR_EL2.VSE is `0b1` and either:
    - HCR_EL2.AMO is `0b1`.
    - FEAT_DoubleFault2 is implemented and the Effective value of HCRX_EL2.TMEA is `0b1`.
  - EL2 is using AArch32, HCR.AMO is `0b1`, HCR.TGE is `0b0`, and HCR.VA is `0b1`.
- The VSESR_EL2 and, if implemented, VDFSR registers are writable.

In these cases, a virtual SError exception is pending, and the following occur when an `ESB` instruction is executed at EL0 or EL1:

- If the virtual SError exception is unmasked at the current Exception level, then the exception is taken before the completion of the `ESB` instruction.
- If the virtual SError exception is masked at the current Exception level, then all the following occur:
  - HCR_EL2.VSE or HCR.VA cleared to `0b0`.
  - The virtual SError exception syndrome from VSESR_EL2 or VDFSR is recorded in VDISR_EL2 or VDISR respectively.
  - VDISR_EL2.A or VDISR.A is set to `0b1` to indicate the virtual SError exception was pending prior to the execution of the `ESB` instruction.

R_{GXHYX} If all of the following are true, then it is IMPLEMENTATION DEFINED whether or not an `ESB` instruction executed at EL0 or EL1 synchronizes a pending virtual SError exception:

- EL2 is implemented and enabled in the current Security state.
- Any of the following are true:
  - EL2 is using AArch64, HCR_EL2.TGE is `0b0`, HCR_EL2.VSE is `0b1` and either:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

    - HCR_EL2.AMO is 0b1.
    - FEAT_DoubleFault2 is implemented and the Effective value of HCRX_EL2.TMEA is 0b1.
  - EL2 is using AArch32, HCR.AMO is 0b1, HCR.TGE is 0b0, and HCR.VA is 0b1.
- VSESR_EL2 and, if implemented, VDFSR registers are implemented as RAZ/WI.

In these cases, a virtual SError exception is pending. If the IMPLEMENTATION DEFINED choice is that the ESB instruction synchronizes a pending virtual SError exception, then the following occur when an ESB instruction is executed at EL0 or EL1:

- If the virtual SError exception is unmasked at the current Exception level, then the exception is taken before the completion of the ESB instruction.
- If the virtual SError exception is masked at the current Exception level, then all the following occur:
  - HCR_EL2.VSE or HCR.VA cleared to 0b0.
  - The virtual SError exception syndrome in VDISR_EL2 or VDISR is set to zero.
  - VDISR_EL2.A or VDISR.A is set to 0b1 to indicate the virtual SError exception was pending prior to the execution of the ESB instruction.

If the IMPLEMENTATION DEFINED choice is that the ESB instruction does not synchronize a pending virtual SError exception, then an ESB instruction executed at EL0 or EL1 ignores the pending virtual SError exception and the virtual SError exception stays pending.

See also Syndrome registers.

I_{VKQGL} If both a virtual SError exception and a physical SError exception are pending as described in R_{LLLVR} and Error synchronization event, then the physical SError exception is not masked at the current Exception level, because this is not possible when a virtual SError exception is pending. This means that:

- If the virtual SError exception is masked at the current Exception level, then the physical SError exception will be taken before the ESB instruction completes and HCR_EL2.VSE, HCR.VA, VDISR_EL2, and VDISR are unchanged.
- If the virtual SError exception is not masked at the current Exception level, then it is IMPLEMENTATION DEFINED which of the virtual SError or physical SError exceptions is taken before the ESB instruction completes. If the virtual SError exception is taken and, after taking the exception to EL1, the physical SError exception is still pending, then the physical SError exception is still not masked and will be taken.

A virtual SError exception injected using HCR_EL2.VSE has priority over a delegated SError exception injected using SCR_EL3.DSE when both are synchronized by ESB.

D20.5.2 ESB and delegated SError exceptions

R_{KKPVY} If all of the following are true, then an ESB instruction executed at EL0, EL1, or EL2 synchronizes a pending delegated SError exception:

- FEAT_E3DSE is implemented.
- SCR_EL3.{EnDSE, DSE} is {0b1, 0b1}.
- VSESR_EL3 is writable.

In this case, a delegated SError exception is pending, and the following occur when an ESB instruction is executed at EL0, EL1, or EL2:

- If the delegated SError exception is unmasked at the current Exception level, then the exception is taken before the completion of the ESB instruction.
- If the delegated SError exception is masked at the current Exception level, then all the following occur:
  - SCR_EL3.DSE is cleared to 0b0.
  - The delegated SError exception syndrome from VSESR_EL3 is recorded in VDISR_EL3.
  - VDISR_EL3.A is set to 0b1 to indicate the delegated SError exception was pending prior to the execution of the ESB instruction.

R_{GGVCW} If all of the following are true, then it is IMPLEMENTATION DEFINED whether or not an ESB instruction executed at EL0, EL1, or EL2 synchronizes a pending delegated SError exception:

- FEAT_E3DSE is implemented.
- SCR_EL3.{EnDSE, DSE} is {0b1, 0b1}.
- The VSESR_EL3 register is implemented as RAZ/WI.

In this case, a delegated SError exception is pending. If the IMPLEMENTATION DEFINED choice is that the ESB instruction synchronizes a pending delegated SError exception, then the following occur when an ESB instruction is executed at EL0, EL1, or EL2:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the delegated SError exception is unmasked at the current Exception level, then the exception is taken before the completion of the ESB instruction.
- If the delegated SError exception is masked at the current Exception level, then all the following occur:
  - SCR_EL3.DSE is cleared to 0b0.
  - The delegated SError exception syndrome in VDISR_EL3 is set to zero.
  - VDISR_EL3.A is set to 0b1 to indicate the delegated SError exception was pending prior to the execution of the ESB instruction.

If the IMPLEMENTATION DEFINED choice is that the ESB instruction does not synchronize a pending delegated SError exception, then an ESB instruction executed at EL1 or EL2 ignores the pending delegated SError exception and the delegated SError exception stays pending.

See also Syndrome registers.

I_{VYGVB} If both a delegated SError exception and a physical SError exception are pending as described in R_{KKPVY} and Error synchronization event, then the physical SError exception is not masked at the current Exception level, because this is not possible when a delegated SError exception is pending. This means that:

- If the delegated SError exception is masked at the current Exception level, then the physical SError exception will be taken before the ESB instruction completes and SCR_EL3.DSE and VDISR_EL3 are unchanged.
- If the delegated SError exception is not masked at the current Exception level, then it is IMPLEMENTATION DEFINED which of the delegated SError or physical SError exceptions is taken before the ESB instruction completes. If the delegated SError exception is taken and, after taking the exception to EL1 or EL2, the physical SError exception is still pending, then the physical SError exception is still not masked and will be taken.

A virtual SError exception injected using HCR_EL2.VSE has priority over a delegated SError exception injected using SCR_EL3.DSE when both are synchronized by ESB.

D20.5.3 Extension for synchronization at exception entry and return

D_{DPSJR} The rules in this section apply when FEAT_IESB is implemented.

I_{WDSBL} An implicit Error synchronization event has no effect on DISR_EL1 or VDISR_EL2.

R_{KJWNS} When FEAT_DoubleFault is implemented, the PE is in Non-debug state, and the Effective value of SCR_EL3.NMEA is 1, then the Effective value of SCTLR_EL3.IESB is 1.

R_{HLVWK} When FEAT_DoubleFault2 is implemented and the PE is in Non-debug state, all of the following apply:

- If the Effective value of SCTLR2_EL1.NMEA is 1, then the Effective value of SCTLR_EL1.IESB is 1.
- If the Effective value of SCTLR2_EL2.NMEA is 1, then the Effective value of SCTLR_EL2.IESB is 1.

D20.5.3.1 Synchronization on exception entry

R_{RNZWY} For each value of ELx in EL1, EL2, EL3, if all of the following are true, then each exception that is taken to ELx generates an Error synchronization event:

- ELx is using AArch64.
- The Effective value of SCTLR_ELx.IESB is 0b1.

R_{JQSKQ} If an SError exception is taken to the Exception level ELy as a result of the Error synchronization event generated on exception entry by the FEAT_IESB mechanism, then all the following occur:

- The PE sets the ESR_ELy.IESB bit in the SError exception syndrome to 0b1.
- The preferred return address for the SError exception is the exception vector address for the original exception.

Note: ELy might be the same Exception level as ELx.

I_{FWZHV} If SError exceptions are masked at ELx, then any SError exception made pending by the Error synchronization event stays pending.

I_{MMVJW} The prioritization of asynchronous exceptions is IMPLEMENTATION DEFINED. This means that an implementation might choose to behave as if the SError exception made pending by the Error synchronization event was taken before the implicit Error synchronization event, if the SError exception was not masked, taking the SError exception in place of the original exception, unless the original exception is also an SError exception.

In this case, ESR_ELy.IESB is cleared to 0 and the reported PE error state correctly indicates, for instance, whether software can recover execution from the preferred return address for the SError exception in ELR_ELy.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{BVBKS} Arm recommends that, when enabled, an implicit Error synchronization event is inserted before taking an exception other than an SError exception. In particular, Arm recommends that:

- When FEAT_DoubleFault is implemented, an implicit Error synchronization event is inserted before taking the exception to EL3.
- When FEAT_DoubleFault2 is implemented, an implicit Error synchronization event is inserted before taking the exception to the target Exception level of an SError exception.

D20.5.3.2 Synchronization on exception return

R_{SKRCR} For each value of ELx in EL1, EL2, EL3, if all of the following are true, then executing an exception return instruction at ELx generates an Error synchronization event:

- The instruction does not generate any exception.
- ELx is using AArch64.
- The Effective value of SCTLR_ELx.IESB is `0b1`.

I_{GPPXQ} On an illegal return event, the exception return instruction sets PSTATE.IL to `0b1`, which causes the next instruction to generate an Illegal State exception. The exception return instruction does not generate the exception.

R_{GXQYD} Any SError exception taken as part of the Error synchronization event terminates execution of the instruction.

R_{LPKVM} If an SError exception is taken to an Exception level, ELy, as a result of the Error synchronization event generated on exception return by the FEAT_IESB mechanism, then all the following occur:

- The PE sets the ESR_ELy.IESB bit in the SError exception syndrome to an IMPLEMENTATION DEFINED choice of `0b0` or `0b1`.
- The preferred return address for the SError exception is the address of the `ERET` instruction.

S_{MHCTH} R_{JQSKQ} and R_{LPKVM} describe how ESR_ELy.IESB records that an SError exception was taken because of an implicit Error synchronization event generated by the FEAT_IESB mechanism.

When ESR_ELy.IESB is 1, software can compare the value in ELR_ELy with the value of VBAR_ELx, where ELx is the Exception level the SError exception was taken from, to confirm whether this is due to the exception entry or the exception return case.

If the error is also reported as a synchronizable error, then:

- In the exception entry case:
  - ESR_ELy.IESB == 1 indicates that the error was generated by an instruction in program order before the exception was taken.
  - ELR_ELy will contain the address of an exception vector. See Exception vectors.
  - Software can determine the Exception level the exception was taken from the value recorded in SPSR_ELx, where ELx is the Exception level the SError was taken from.
- In the exception return case, software can ignore the value of ESR_ELy.IESB:
  - The value 1 indicates that the error was generated by an instruction in program order before the exception return.
  - However, this is indistinguishable from an SError taken before the exception return was executed. Hence the value of ESR_ELy.IESB is IMPLEMENTATION SPECIFIC in this case.

If ID_AA64MMFR4_EL1.EIESB indicates to software that implicit Error synchronization events are inserted before exceptions taken to ELy, then software can ignore the value in ESR_ELy.IESB, as it would only ever be set for the exception return case.

I_{JZHDB} If SError exceptions are masked at ELx, then any SError exception made pending by the Error synchronization event stays pending.

D20.5.4 Error synchronization barriers in a minimal implementation

I_{GQQCK} Error synchronization events and the `ESB` instruction can be implemented as no-ops if all of the following apply:

- Either there are no sources of SError exceptions, or all SError exceptions are reported as Uncategorized error and are not synchronizable errors.
- Either EL2 is not implemented, or VSESR_EL2 and VDFSR are implemented as RES0.

This allows for a very low cost implementation of the RAS Extension.

Such an implementation might include FEAT_IESB, meaning the SCTLR_ELx.IESB controls have no effect.

I_{HSHJG} See also Syndrome registers.

D20.6 Virtual SError exceptions and delegated SError exceptions

I_{LSSCN} EL2 provides a virtual SError exception.

For more information, see:

- Virtual asynchronous exceptions
- Virtual exceptions when an implementation includes EL2.

I_{YLSLH} When FEAT_E3DSE is implemented, EL3 provides delegated SError exceptions. For more information, see Delegated SErrors.

I_{ZXMPL} FEAT_RAS provides:

- Mechanisms to allow a hypervisor to specify the syndrome value reported to a guest Operating System on taking a virtual SError exception.
- Mechanisms to allow firmware to specify the syndrome value reported to a hypervisor or guest Operating System on taking a delegated SError exception.
- Support for EL0 or EL1 to isolate a virtual SError exception and for EL0, EL1, or EL2 to isolate a delegated SError exception as if it was a physical SError exception. See ESB and virtual SError exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D20.7 Error records in the PE

I_{KMMPK} A component that records detected errors is called a node by the RAS System Architecture. Each node implements one or more Error records.

R_{VNLPC} It is IMPLEMENTATION DEFINED whether the processor that implements a PE implements any nodes.

R_{XKDRX} A PE implementing the RAS Extension might implement the System register interface to nodes.

I_{SCVSB} The System register interface to nodes is not restricted to accessing only PE nodes.

I_{ZRKKQ} When an error is recorded by a PE node, one or more of the following might be generated, according to the configuration of the node:

- A Fault handling interrupt.
- An Error recovery interrupt.
- A Critical Error interrupt.
- An in-band error response.

D20.7.1 Error record System register view

I_{SLVDW} If the System register interface to a node is implemented, then software can access the Error records of the node using Error record System registers.

R_{BYLZQ} The number of Error records that can be accessed using the System registers is IMPLEMENTATION DEFINED, and might be zero. The ERRIDR_EL1 and ERRIDR registers indicate the highest numbered index of the Error records that can be accessed using System registers, plus one.

I_{NWBNQ} The AArch64 Error record System registers are those registers with an ERX*_EL1 mnemonic.
The AArch32 Error record System registers are those registers with an ERX* mnemonic.

I_{BJNDF} The following tables describe the AArch32 and AArch64 Error record System registers.
The descriptions in this section apply whether the Error record is accessed through the indirection mechanism, as described in Table D20-2 and Table D20-3, or as memory-mapped registers. For more information on the RAS memory-mapped registers, see *Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture* (ARM IHI 0100).

Table D20-2 Using AArch32 System registers, System register map

Use	To Access	Access	Description
ERXADDR	ERR<n>ADDR[31:0]	RW	Error Record <*n*> Address Register
ERXADDR2	ERR<n>ADDR[63:32]	RW	Error Record <*n*> Address Register
ERXCTLR	ERR<n>CTLR[31:0]	RW	Error Record <*n*> Control Register
ERXCTLR2	ERR<n>CTLR[63:32]	RW	Error Record <*n*> Control Register
ERXFR	ERR<n>FR[31:0]	RO	Error Record <*n*> Feature Register
ERXFR2	ERR<n>FR[63:32]	RO	Error Record <*n*> Feature Register
ERXMISC0	ERR<n>MISC0[31:0]	RW	Error Record <*n*> Miscellaneous Register 0
ERXMISC1	ERR<n>MISC0[63:32]	RW	Error Record <*n*> Miscellaneous Register 0
ERXMISC2	ERR<n>MISC1[31:0]	RW	Error Record <*n*> Miscellaneous Register 1
ERXMISC3	ERR<n>MISC1[63:32]	RW	Error Record <*n*> Miscellaneous Register 1
ERXMISC4[a]	ERR<n>MISC2[31:0]	RW	Error Record <*n*> Miscellaneous Register 2

Use	To Access	Access	Description
ERXMISC5[a]	ERR<n>MISC2[63:32]	RW	Error Record <*n*> Miscellaneous Register 2
ERXMISC6[a]	ERR<n>MISC3[31:0]	RW	Error Record <*n*> Miscellaneous Register 3
ERXMISC7[a]	ERR<n>MISC3[63:32]	RW	Error Record <*n*> Miscellaneous Register 3
ERXSTATUS	ERR<n>STATUS	RW	Error Record <*n*> Primary Status Register

a. If FEAT_RASv1p1 is implemented.

Table D20-3 Using AArch64 System registers, System register map

Use	To Access	Access	Description
ERXADDR_EL1	ERR<n>ADDR	RW	Error Record <*n*> Address Register
ERXCTLR_EL1	ERR<n>CTLR	RW	Error Record <*n*> Control Register
ERXFR_EL1	ERR<n>FR	RO	Error Record <*n*> Feature Register
ERXMISC0_EL1	ERR<n>MISC0	RW	Error Record <*n*> Miscellaneous Register 0
ERXMISC1_EL1	ERR<n>MISC1	RW	Error Record <*n*> Miscellaneous Register 1
ERXMISC2_EL1[a]	ERR<n>MISC2	RW	Error Record <*n*> Miscellaneous Register 2
ERXMISC3_EL1[a]	ERR<n>MISC3	RW	Error Record <*n*> Miscellaneous Register 3
ERXPFGCDN_EL1	ERR<n>PFGCDN	RW	Error Record <*n*> Pseudo-fault Generation Countdown Register
ERXPFGCTL_EL1	ERR<n>PFGCTL	RW	Error Record <*n*> Pseudo-fault Generation Control Register
ERXPFGF_EL1	ERR<n>PFGF	RO	Error Record <*n*> Pseudo-fault Generation Feature Register
ERXSTATUS_EL1	ERR<n>STATUS	RW	Error Record <*n*> Primary Status Register
ERXGSR_EL1[b]	ERRGSR{<n>}	RO	Error Group Status Register

a. If FEAT_RASv1p1 is implemented.
b. If FEAT_RASv2 is implemented.

R_{ZBCFZ} If FEAT_RASv1p1 is implemented, then all Error records accessible through System registers implement RAS System Architecture version 1.1.

R_{MBSFP} If FEAT_RASv2 is implemented, then all Error records accessible through System registers implement RAS System Architecture version 2.

S_{VBBNY} To access an Error record, software:

1. Sets the error selection register, ERRSELR_EL1.SEL or ERRSELR.SEL, to the index of the record being accessed.
2. Accesses the Error record using the ERX*_EL1 or ERX* System registers, as described in I_{BJNDF}.

I_{WKXSB} The Error records accessed through the System registers might be accessible only to the PE associated with those System registers, or they might be shared and therefore accessible to other PEs through either System registers or as a memory-mapped component.

I_{JMVVD} Direct reads of the System registers, including Error record System registers, can occur speculatively and out-of-order relative to other instructions executed on the same PE.

R_{WFPWF} Direct reads and writes of the Error records through the ERX*_EL1 AArch64 System registers, as described in I_{BJNDF}, are indirect reads of ERRSELR_EL1.

R_{FZBLM} Direct reads and writes of the Error records through the ERX* AArch32 System registers, as described in I_{BJNDF}, are indirect reads of ERRSELR.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IYMGGY Explicit synchronization is required after reading an ERXGSR_EL1 AArch64 System register and before reading ERXSTATUS_EL1.

Example D20-16 Direct reads of ERXGSR_EL1 cause indirect reads of ERRSELR_EL1

1. An instruction A writes the value <n> to ERRSELR_EL1.SEL. <n> is the index of an implemented System register error record.
2. Software executes a first Context synchronization event B in program order after A.
3. An instruction C in program order after B reads ERXGSR_EL1, and observes bit [n MOD 64] == `0b1`.
4. Software executes a second Context synchronization event D in program order after C.
5. An instruction E in program order after D reads ERXSTATUS_EL1.

If there is no other direct or external write to ERR<n>STATUS that clears ERR<n>STATUS.V between C and E, then instruction E observes ERR<n>STATUS.V == `0b1`.

D20.7.1.1 Syndrome registers

IRGMHN ESR_ELx, HSR, and DFSR are exception syndrome registers. The PE records syndrome information in an exception syndrome register on taking a physical SError exception or synchronous External abort exception. ESR_ELx, HSR, and DFSR are also used by other exceptions.

DISR_EL1 and DISR are the deferred error syndrome registers. The PE records syndrome information in a deferred error syndrome register on deferring a physical SError exception.

The PE also records a virtual syndrome value in ESR_EL1, DFSR, DISR_EL1, or DISR on taking or deferring a virtual SError exception. The virtual syndrome value is provided by software in a corresponding virtual error syndrome register, VSESR_EL2, VDFSR, VDISR_EL2, or VDISR respectively.

The PE also records a delegated syndrome value in ESR_EL2, ESR_EL1, VDISR_EL2, or DISR_EL1 on taking or deferring a delegated SError exception. The delegated syndrome value is provided by software in a corresponding delegated error syndrome register, VSESR_EL3 or VDISR_EL3 respectively.

RSLNMV For a given implementation:

- If `ESB` never synchronizes any errors, then DISR_EL1.A and DISR.A might be RES0.
- The deferred, virtual, and delegated syndrome registers are capable of storing any syndrome value that might be recorded by the PE in an exception syndrome register on taking a physical SError exception or synchronous External abort exception.
- If any of ESR_ELx[24:0], HSR[11:9], and DFSR[15:14,12] is not used and always set to zero by the PE on taking a physical SError exception or synchronous External abort exception, then that bit can be RES0 in that exception syndrome register.
- A bit that is not used and always set to zero or always set to one in ESR_ELx or DISR_EL1 by the PE on taking a physical SError exception is permitted to be RES0 or RES1 respectively in the corresponding deferred, virtual, and delegated error syndrome registers. See Table D20-4.

In Table D20-4, the deferred virtual, or delegated error syndrome register bit described in the left-hand column is permitted to be RES0 or RES1 only if the corresponding bit is always set to zero or always set to one (respectively) on taking a physical SError exception in all of the implemented exception syndrome registers listed in the other columns marked *Yes* on that row. Otherwise, the bit is read/write.

Table D20-4 Permitted relaxations for bits in deferred, virtual, and delegated error syndrome registers

Bit is permitted to be res0 or res1	ESR_ELx[*n*] *n* ∈ [24:0]	HSR[*n*] *n* ∈ [11:9]	DFSR[*n*] *n* ∈ [15:14,12]
VSESR_EL3[*n*]	Yes	-	-
VDISR_EL3[*n*]	Yes	-	-
VSESR_EL2[*n*]	Yes	-	Yes
VDISR_EL2[*n*]	Yes	-	Yes
DISR_EL1[*n*]	Yes	-	-

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit is permitted to be res0 or res1	ESR_ELx[*n*] *n* ∈ [24:0]	HSR[*n*] *n* ∈ [11:9]	DFSR[*n*] *n* ∈ [15:14,12]
VDFSR[*n*]	-	-	Yes
VDISR[*n*]	-	-	Yes
DISR[*n*]	-	Yes	Yes

I_{FWGLF} R_{SLNMV} means that VSESR_EL3, VSESR_EL2 and VDFSR can be implemented as RAZ/WI when ESR_ELx[24:0], HSR[11:9], and DFSR[15:14,12] are always set to zero by the PE on taking a physical SError exception or synchronous External abort exception. When this is the case, the PE error state is always reported as Uncategorized error when a physical SError exception is taken to AArch64 state.

I_{GQQCK}, in Error synchronization barriers in a minimal implementation then further allows `ESB` to be executed as a NOP, meaning DISR_EL1, DISR, VDISR_EL2, VDISR_EL3, and VDISR can also be implemented as RAZ/WI.

This allows for a very low-cost implementation of the RAS Extension.

Chapter D21
MPAM PE Architecture

This chapter describes the MPAM Extension PE Architecture. It contains the following sections:

- About MPAM
- PARTID spaces
- Partition Identifiers (PARTIDs)
- Performance Monitoring Groups (PMGs)
- Effect of the MPAM3_EL3.{SDEFLT, FORCE_NS} controls on PE Secure state execution
- Effect of access type on MPAM information
- Virtualization support
- PE-side Maximum bandwidth limit injection control
- MPAM errors
- Synchronization of MPAM System register changes

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.1 About MPAM

D21.1.1 Introduction

IYYSRL In many systems, multiple software execution environments such as applications and virtual machines (VMs) run concurrently, sharing memory system resources such as memory controllers, caches, and interconnects. With no controls on the sharing of resources, software execution environments might cause interference for each other as they try to access resources. This might result in increased latency or reduced bandwidth, or both, for memory accesses for workloads that are performance sensitive.

Memory system resource Partitioning and Monitoring (MPAM) provides software with control mechanisms to apportion the memory system resources between software execution environments. This is done by:

- Memory system resource partitioning.
- Memory system resource usage monitoring, one of the uses of which is to inform adjustment of the partitioning.

IRKDKZ MPAM provides all of:

- An extension to the A-profile PE architecture:
  - A mechanism for privileged software executing in a PE to attach a Partition Identifier (PARTID) label, and a monitoring property called a Performance Monitoring Group (PMG), to a software execution environment in that PE.
  - If FEAT_MPAM_PE_BW_CTRL is implemented, then the PE implements a mechanism for software to impose a maximum limit on the bandwidth that requests from the PE itself can use. See MPAM PE-side Maximum bandwidth limit injection control.
- For the system:
  - A description of the propagation of PARTIDs, PMGs, and PARTID spaces, through the system.
  - A framework for implementing *MPAM resource controls* in Memory System Components (MSCs). These are the controls that partition the resources of MSCs.
  - An extension to that framework, for implementing *MPAM resource monitors* in MSCs.
  - An extension to that framework, for MPAM MSCs to have performance monitoring that is sensitive to a combination of PARTID and PMG.
  - Some implementation-independent, memory-mapped interfaces to memory system component controls for performance resource controls most likely to be deployed in systems.
  - Some implementation-independent, memory-mapped interfaces to memory system component resource monitoring that might be required to monitor the partitioning of memory system resources.

IPKXWQ When designing an SoC, the designer makes several or all the following SoC components *MPAM-compliant*, meaning that they implement one of the FEAT_MPAM versions:

- Requester component types, for example PEs, DSPs, and DMA controllers.
- Components that provide shared memory system resources that it is possible to partition, for example shared caches, shared interconnects and buffers, Memory Management Units (MMUs), and memory channel controllers.

There is no requirement to make all components in an SoC MPAM-compliant.

INJBFK In this chapter:

- An *MPAM Requester* is any type of MPAM-compliant Requester component. This chapter categorizes MPAM Requesters into:
  - *MPAM PE Requesters*, also called *MPAM PEs*.
  - *MPAM Non-PE Requesters*.
- An *MPAM Memory System Component (MPAM MSC)* is an MPAM-compliant component that provides shared memory system resources.

This chapter describes MPAM PE Requesters, and *Arm® Memory System Resource Partitioning and Monitoring (MPAM) System Component Specification* describes MPAM MSCs. The architecture does not describe MPAM Non-PE Requesters.

IHRMSG The architecture permits an MPAM MSC to be implemented as part of another system component. For example, an MPAM PE can contain caches that are MPAM MSCs.

RSMNGB If an MPAM PE contains MPAM MSCs, it must have memory-mapped registers to identify and configure those MPAM MSCs.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.1.2 MPAM information bundles

R_{BDJXQ} MPAM Requesters label every request to the memory system with an *MPAM information bundle*, comprising:

- Two items that together identify a single partition:
  - A number called the Partition Identifier (PARTID).
  - The PARTID space, for example Secure or Non-secure physical PARTID space.

  Each PARTID space defines a set of PARTIDs.
  Each PARTID corresponds to one partition.
- A Performance Monitoring Group (PMG).

D21.1.3 Memory system resource partitioning

R_{DDGSM} Each MPAM MSC implements zero or more *MPAM resource controls*.

I_{GPWRB} Each MPAM resource control has settings for each PARTID.

I_{DTCTY} When an MPAM Requester sends a request, the PARTID space and PARTID in the MPAM information bundle are used as an index into a table in the MPAM MSC, to select the entry that holds the settings for that partition. Those settings configure how the shared partitionable resource is apportioned to that partition.

I_{MHDHR} See also:

- MPAM PE-side Maximum bandwidth limit injection control for MPAM PE-side bandwidth regulation controls.
- For more detail, *Arm® Memory System Resource Partitioning and Monitoring (MPAM) System Component Specification*.

D21.1.4 Memory system resource usage monitoring

R_{RBCMK} Each MPAM MSC implements zero or more *MPAM resource monitors*.

I_{LDRSM} An MPAM resource monitor is associated with a shared partitionable resource in an MPAM MSC, and is able to measure how much a software execution environment is using that resource, by either:

- For a *memory-bandwidth usage* monitor, counting payload bytes that are passing where the monitor is placed.
- For a *cache-storage usage* monitor, counting bytes of the cache storage used.

I_{HQBLT} An MPAM resource monitor must be configured and enabled before it can be queried for usage of the MPAM MSC resource. Each monitor has a configurable filter register that the monitor uses to filter which bytes are counted. Fields in the filter register are writes, reads, PARTID, PMG, and other criteria. For example, a monitor can be configured to be sensitive to a PARTID, a PMG, or both.

I_{LWKZR} The architecture permits a resource monitor to be implemented as part of an MPAM PE.

R_{BGTCC} If an MPAM PE contains MPAM resource monitors, it must have memory-mapped registers to identify and configure those monitors.

I_{BGGWJ} See also:

- For more detail, *Arm® Memory System Resource Partitioning and Monitoring (MPAM) System Component Specification*.

D21.1.5 MPAMn_ELx register naming convention

I_{FFCGH} In an MPAM PE, MPAMn_ELx registers contain the PARTIDs and PMGs that the MPAM PE sends as part of MPAM information bundles. The naming convention of these registers is:

- The n in MPAMn_ELx is the Exception level the register holds PARTIDs and PMGs for. That is, the register supplies PARTIDs and PMGs for execution at ELn.
- The x means that ELx and higher can access the register.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

R_{CSQBF} The following table shows which MPAMn_ELx register supplies PARTIDs and PMGs for which Exception level:

MPAMn_ELx register	Supplies PARTID and PMG when executing at
MPAM0_EL1	EL0 when MPAMHCR_EL2.GSTAPP_PLK is 0.
MPAM1_EL1	EL1, and EL0 when MPAMHCR_EL2.GSTAPP_PLK is 1. See Single PARTID for an EL1 guest OS and all its EL0 applications.
MPAM2_EL2	EL2
MPAM3_EL3	EL3

D21.1.6 The MPAM enable control

R_{XBYGC} The MPAMn_ELx.MPAMEN field at the highest implemented Exception level is the writable *MPAM enable control*. At all lower Exception levels, all other instances of MPAMn_ELx.MPAMEN are read-only copies. For example:

- If EL3 is the highest implemented Exception level, MPAM3_EL3.MPAMEN is the writable MPAM enable control, and MPAM2_EL2.MPAMEN and MPAM1_EL1.MPAMEN are read-only copies.

MPAM0_EL1 does not contain an MPAMEN field.

I_{KRBMV} See the following for the behavior when MPAM is disabled:

- The Default PARTID.
- The Default PMG.
- Interaction of MPAM3_EL3.SDEFLT and the MPAM enable control.

D21.1.7 AArch32 interoperability

I_{RSTCB} MPAM System registers are not accessible from AArch32 state. Therefore, a higher Exception level must set the PARTIDs and PMGs for any Exception level that uses AArch32 state.

D21.1.8 FEAT_MPAM versions

R_{YSNTG} An MPAM PE implements one of these MPAM versions:

Version	Major version reported by ID_AA64PFR0_EL1.MPAM	Minor version reported by ID_AA64PFR1_EL1.MPAM_frac
v0p1	`0b0000`	`0b0001`
v1p0	`0b0001`	`0b0000`
v1p1	`0b0001`	`0b0001`

I_{TGCKZ} v1p0 is the base version. v0p1 and v1p1 include features beyond the base version and are the same except that v0p1 implements the *Force Secure PARTIDs to Non-secure* feature.

R_{KTQFR} The MPAM PE features by MPAM version are:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D21-3 MPAM PE features by MPAM version

MPAM PE feature	MPAMIDR_EL1 ID field	v0p1	v1p0	v1p1	MPAM for RME
PARTID virtualization[a]	HAS_HCR	Optional	Optional	Optional	Optional
Force Secure PARTID to Non-secure[b]	HAS_FORCE_NS	Required	Prohibited	Prohibited	Prohibited
Secure Default PARTID[b]	HAS_SDEFLT	Optional	Prohibited	Optional	Optional
TIDR in MPAM2_EL2	HAS_TIDR	Required	Prohibited	Required	Required
Four PARTID spaces	SP4	Prohibited	Prohibited	Prohibited	Required
Alternative PARTID spaces[c]	HAS_ALTSP	Prohibited	Prohibited	Prohibited	Required
FEAT_MPAM_PE_BW_CTRL[d]	HAS_BW_CTRL	Optional	Prohibited	Optional	Optional

a. See PARTID virtualization.
b. See Effect of the MPAM3_EL3.{SDEFLT, FORCE_NS} controls on PE Secure state execution.
c. See In an MPAM PE with FEAT_RME, selection of primary or alternative PARTID space.
d. See MPAM PE-side Maximum bandwidth limit injection control.

R_{MQDXN} The system features by MPAM version are:

Table D21-4 MPAM system features by MPAM version

MPAM system feature	v0p1	v1p0	v1p1	MPAM for RME
MPAM_NS signal[a]	Required	Required	Required	Prohibited
MPAM_SP signal[a]	Prohibited	Prohibited	Prohibited	Required

a. See Encoding PARTID spaces onto PARTID space signals.

I_{VQQHN} MPAM for RME supports the Realm Management Extension (RME) in systems, MPAM PEs, and *MPAM Memory System Components* (MPAM MSCs).

R_{ZDLYQ} MPAM for RME is required in a PE that implements both RME and MPAM.

D21.1.8.1 Interoperation of SoC components implementing different MPAM versions

I_{JVGNT} There is no requirement for all MPAM PEs in an SoC to implement the same MPAM version. However, each MPAM PE having a different MPAM version might cause software issues.

I_{JCHFV} There is no required relationship between the MPAM version of an MPAM PE and the MPAM version of an MPAM MSC accessed by that MPAM PE.

I_{KGCTV} For more information, see:

- *Arm® Memory System Resource Partitioning and Monitoring (MPAM) System Component Specification*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.2 PARTID spaces

R_{FMXKY} The following physical PARTID spaces are supported:

- Non-secure PARTID space.
- If Secure state is implemented, Secure PARTID space.
- If RME is implemented, both of:
  - Realm PARTID space.
  - Root PARTID space.

I_{DTHSD} In an MPAM PE, MPAMIDR_EL1.SP4 reports whether the MPAM PE supports two or four PARTID spaces.

R_{DJRPQ} In an MPAM PE without FEAT_RME, the physical PARTID space sent as part of an MPAM information bundle depends on the Security state and Exception level of the execution producing the request. If the MPAM version implemented is v0p1, the physical PARTID space also depends on the state of the *Force Non-secure PARTID space* control, MPAM3_EL3.FORCE_NS:

Table D21-5 PARTID space sent by an MPAM PE without FEAT_RME

Security state	PARTID space sent for a request produced by execution at:			In MPAM version v0p1, PARTID space sent when MPAM3_EL3.FORCE_NS is 1:
	EL3	EL2	EL1 and EL0	
Non-secure state	-	Non-secure physical PARTID space	Non-secure physical PARTID space	No change to the behavior[a]
Secure state	Secure physical PARTID space	Secure physical PARTID space	Secure physical PARTID space	Non-secure physical PARTID space

a. The MPAM3_EL3.FORCE_NS control does not affect Non-secure state execution.

R_{NTMXM} In an MPAM PE with FEAT_RME, the physical PARTID space sent as part of an MPAM information bundle depends on the Security state and Exception level of the execution producing the request, and the state of the alternative PARTID space controls, that select whether a *primary* or *alternative* PARTID space is sent:

Table D21-6 PARTID space sent by an MPAM PE with FEAT_RME

Security state	If primary selected, the primary PARTID space sent for a request produced by execution at:			If alternative selected, the alternative sent:
	EL3	EL2	EL1 and EL0	
Non-secure state	-	Non-secure physical PARTID space	Non-secure physical PARTID space	No change to the behavior[a]
Secure state	-	Secure physical PARTID space	Secure physical PARTID space	Non-secure physical PARTID space
Realm state	-	Realm physical PARTID space	Realm physical PARTID space	Non-secure physical PARTID space
Root state	Root physical PARTID space	-	-	Selectable Secure or Non-secure physical PARTID space[a]

a. The alternative PARTID space controls do not affect Non-secure state execution.
b. For detail of how Secure or Non-secure is selected, see In a PE with FEAT_RME, selection of primary or alternative PARTID space.

R_{FFRDD} The Secure physical PARTID space is not used in systems, or system components, that do not implement Secure state.

I_{VNRRQ} See also:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For detail on how an MPAM PE Requester sends a PARTID space, Encoding PARTID spaces onto PARTID space signals.
- For detail on the alternate PARTID space controls, In an MPAM PE with FEAT_RME, selection of primary or alternative PARTID space.

D21.2.1 PARTID space virtualization

I_{CCVLY} In an MPAM PE, if EL2 is implemented and enabled in the current Security state, and MPAMIDR_EL1.HAS_HCR indicates that the MPAM virtualization option is implemented, execution at EL0 and EL1 might produce a *virtual PARTID space*, that is translated to a *physical PARTID space*. For details, see PARTID virtualization.

D21.2.2 In an MPAM PE with FEAT_RME, selection of primary or alternative PARTID space

R_{SWNPB} For EL3 Root state execution:

- MPAM3_EL3.ALTSP_EL3 selects whether EL3 produces the *primary* or *alternative* PARTID space.
- MPAM3_EL3.RT_ALTSP_NS selects whether the alternative PARTID space is Secure or Non-secure:

Table D21-7 PARTID space that EL3 produces, in an MPAM PE with FEAT_RME

ALTSP_EL3	RT_ALTSP_NS	PARTID space that EL3 produces
0	X	Primary PARTID space. Root physical PARTID space.
1	0	Alternative PARTID space. Secure physical PARTID space.
1	1	Alternative PARTID space. Non-secure physical PARTID space.

R_{DFMYN} For execution below EL3, EL3 is either:

- Forcing primary or alternative PARTID spaces for execution at EL2, EL1, and EL0.
- Permitting EL2 to control its own PARTID space, and the PARTID space for EL1 and EL0.

Forcing primary or alternative PARTID spaces for execution at EL2, EL1, and EL0, is by:

1. MPAM3_EL3.ALTSP_HEN=0 disabling the EL2 *alternative PARTID space controls*.
2. MPAM3_EL3.ALTSP_HFC selecting the primary or alternative PARTID space for execution at EL2, EL1, and EL0.

Permitting EL2 to control its own PARTID space, and the PARTID space for EL1 and EL0, is by:

- MPAM3_EL3.ALTSP_HEN=1 enabling the EL2 alternative PARTID space controls, which means that:
  - EL2 can configure MPAM2_EL2.ALTSP_EL2 to select the primary or alternative PARTID space for EL2.
  - EL2 can configure MPAM2_EL2.ALTSP_HFC to select the primary or alternative PARTID space for EL1 and EL0.

See the following tables for execution at EL2, and at EL1 and EL0, respectively:

Table D21-8 PARTID space that EL2 produces, when EL2 is enabled in the Security state, in an MPAM PE with FEAT_RME

MPAM3_EL3.ALTSP_HEN	MPAM3_EL3.ALTSP_HFC	MPAM2_EL2.ALTSP_EL2	PARTID space that EL2 produces
0	0	X	Primary.
0	1	X	Alternative. Non-secure physical PARTID space.
1	X	0	Primary.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MPAM3_EL3.ALTSP_HEN	MPAM3_EL3.ALTSP_HFC	MPAM2_EL2.ALTSP_EL2	PARTID space that EL2 produces
1	X	1	Alternative. Non-secure physical PARTID space.

Table D21-9 PARTID space that EL1 and EL0 produce, in an MPAM PE with FEAT_RME

MPAM3_EL3.ALTSP_HEN	MPAM3_EL3.ALTSP_HFC	MPAM2_EL2.ALTSP_HFC	PARTID space that EL1 and EL0 produce
0	0	X	Primary.
0	1	X	Alternative. Non-secure physical PARTID space.
1	X	0	Primary.
1	X	1	Alternative. Non-secure physical PARTID space.

R_{KXKGR} When EL2 is disabled in the current Security state, EL1 and EL0 produce the alternative PARTID space when MPAM3_EL3.{ALTSP_HEN, ALTSP_HFC} are {0, 1}, and produce the primary PARTID space otherwise.

R_{BTVYC} When MPAM3_EL3.MPAMEN is 0, so that MPAM is disabled from EL3, MPAM2_EL2.{ALTSP_HFC, ALTSP_EL2} are treated as {0, 0}, and MPAM3_EL3.{ALTSP_HEN, ALTSP_HFC, ALTSP_EL3, RT_ALTSP_NS} are effective.

I_{HDJCV} MPAMn_ELx.ALTSP_FRCD reports whether execution at ELn is being forced to produce the alternative PARTID space:

- MPAM2_EL2.ALTSP_FRCD reports, in all implemented Security states, whether EL3 is forcing the alternative PARTID space for execution at EL2.
- MPAM1_EL1.ALTSP_FRCD reports, in all implemented Security states, whether EL3 or EL2 is forcing the alternative PARTID space for execution at EL1 and EL0.

There is no ALTSP_FRCD field in MPAM0_EL1. There is no mechanism for EL0 to discover whether it is producing the primary or alternative PARTID space. However, EL0 is always producing the same PARTID space as either:

- EL2, when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.
- EL1 otherwise.

D21.2.3 Encoding PARTID spaces onto PARTID space signals

R_{VKVCD} The physical PARTID space that an MPAM PE Requester sends as part of an MPAM information bundle is sent by encoding it onto:

- An **MPAM_NS** signal if the MPAM PE does not implement RME.
- An **MPAM_SP** signal if the MPAM PE implements RME.

Table D21-10 Encoding of the physical PARTID space sent if the MPAM PE does not implement FEAT_RME

PARTID space the MPAM PE Requester is sending	Encoding on MPAM_NS signal
Secure physical PARTID space	`0b0`
Non-secure physical PARTID space	`0b1`

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Table D21-11 Encoding of the physical PARTID space sent if the MPAM PE implements FEAT_RME

PARTID space the MPAM PE Requester is sending	Encoding on MPAM_SP signal
Secure physical PARTID space	`0b00`
Non-secure physical PARTID space	`0b01`
Root physical PARTID space	`0b10`
Realm physical PARTID space	`0b11`

In MPAM PEs without Secure state, **MPAM_NS** encoding `0b0` or **MPAM_SP** encoding `0b00` is reserved.

I_{MRBXT} SoCs can be constructed comprising Requester components that all support MPAM_NS, that all support MPAM_SP, or some that support MPAM_NS and some that support MPAM_SP.

I_{TWGKV} In MPAMv0p1, if MPAM3_EL3.FORCE_NS is implemented as:

- RAO/WI, Secure PARTIDs are not implemented, and the MPAM PE Requester always sends MPAM_NS as 1 for both the Secure physical PARTID space and Non-secure physical PARTID space.
- RW, then setting MPAM3_EL3.FORCE_NS to 1 causes the MPAM PE Requester to always send MPAM_NS as 1 for both the Secure physical PARTID space and Non-secure physical PARTID space.

See Effect of the MPAM3_EL3.{SDEFLT, FORCE_NS} controls on MPAM PE Secure state execution.

I_{NZPRL} See also:

- PARTID spaces, for detail on how an MPAM PE Requester determines which physical PARTID space to send.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.3 Partition Identifiers (PARTIDs)

I_{NHJZF} A *Partition Identifier* (PARTID) is a number that has no inherent meaning and does not imply any ordering. The number solely references a particular partition in a PARTID space.

R_{CZHSY} Each PARTID can exist once in each PARTID space.

R_{RBWRS} The scope of a PARTID is bound by its PARTID space. If a PARTID is used in multiple PARTID spaces, then a reference to that PARTID in one PARTID space does not also reference that PARTID in the other PARTID spaces.

I_{NFCZF} Each *MPAM-compliant* component in an SoC is permitted to implement a maximum PARTID width that is less than or equal to the architecturally defined maximum width of 16-bits.

I_{NPBWK} In an MPAM PE, MPAMIDR_EL1.PARTID_MAX reports the maximum PARTID implemented.

R_{PJTCQ} In an MPAM PE, MPAMn_ELx.{PARTID_D, PARTID_I} are permitted to hold PARTIDs in the range 0 to MPAMIDR_EL1.PARTID_MAX, inclusive.

R_{NYXVG} The PARTID that an MPAM PE Requester sends as part of an MPAM information bundle is one of:

- If any of the conditions for the Default PARTID are met, the Default physical PARTID.
- If the PARTID held is *treated as virtual* and a valid mapping exists, the mapped physical PARTID. Also see both:
  - Behavior when a valid mapping does not exist for a PARTID that is treated as virtual.
  - Behavior when a PARTID is out-of-range.
- If the PARTID held is not treated as virtual, it is determined as follows:
  - For an instruction fetch, MPAMn_ELx.PARTID_I is used.
  - For a data access, MPAMn_ELx.PARTID_D is used. However, if a data access is due to the execution of an SME load or store instruction, or of a Streaming SVE mode load or store instruction, MPAMSM_EL1.PARTID_D is used instead.

  Also see Behavior when a PARTID is out-of-range.

I_{QKRPD} Software can set MPAMn_ELx.{PARTID_D, PARTID_I} to the same or different PARTID values.

I_{QDFWX} Arm recommends that all MPAM-compliant components in an SoC implement the same maximum PARTID, though this is not required.

I_{TLVJP} See also:

- About MPAM, for the definitions of *MPAM-compliant* and *PE Requester*.
- PARTID virtualization, for the definition of *treated as virtual*.

D21.3.1 PARTID virtualization

R_{DNZFT} The behaviors in this section apply if all the following are true:

- EL2 is implemented and enabled in the current Security state.
- Any FEAT_MPAM version is implemented.
- MPAMIDR_EL1.HAS_HCR is 1, meaning that the MPAM virtualization option is implemented.
- If a version other than v1p0 is implemented and execution is in Secure state, then in addition:
  - MPAM3_EL3.SDEFLT is 0, preventing generation of the Default physical PARTID in Secure state. See Effect of the MPAM3_EL3.{SDEFLT, FORCE_NS} controls on MPAM PE Secure state execution.

I_{PKKWM} EL2 hypervisor software continuously updates *MPAM virtual PARTID mapping registers*, MPAMVPM0_EL2 to MPAMVPM7_EL2, that map virtual PARTIDs to physical PARTIDs.

I_{TSKGT} Each MPAMVPMn_EL2 register contains four *mapping fields*, and the maximum implemented MPAMVPMn_EL2 is MPAMIDR_EL1.VPMR_MAX. Therefore, the maximum implemented mapping field is (4 x VPMR_MAX) + 3, and virtualized guests are limited to mapping fields in the range 0 to (4 x VPMR_MAX) + 3.

I_{TXFDH}

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Example D21-1

If MPAMIDR_EL1.VPMR_MAX reports:

- `0b000`, the maximum implemented register is MPAMVPM0_EL2, and the maximum implemented mapping field is (4 x 0) + 3 = 3. There are therefore four virtual PARTIDs available for virtualized guests, numbered 0 to 3, that can be mapped to physical PARTIDs.
- `0b111`, the maximum implemented register is MPAMVPM7_EL2, and the maximum implemented mapping field is (4 x 7) + 3 = 31. There are therefore 32 virtual PARTIDs available for virtualized guests, numbered 0 to 31, that can be mapped to physical PARTIDs.

R_{QMSMK}

When:

- MPAMHCR_EL2.EL0_VPMEN is 1, the PARTIDs in MPAM0_EL1.{PARTID_D, PARTID_I} are *treated as virtual*, and EL0 produces requests with virtual PARTID spaces.
- MPAMHCR_EL2.EL1_VPMEN is 1, the PARTIDs in MPAM1_EL1.{PARTID_D, PARTID_I} are treated as virtual, and EL1 produces requests with virtual PARTID spaces.

When a PARTID is treated as virtual, the MPAM PE attempts to map the PARTID to a physical PARTID using a MPAM virtual PARTID mapping register MPAMVPMn_EL2. The PARTID that is treated as virtual is used as an index into both:

- The vector of physical PARTIDs that the mapping registers hold.
- The array of valid flags that MPAMVPMV_EL2 holds.

I_{XGFNP}

Example D21-2 Example of an MPAM PE mapping a virtual PARTID to a physical PARTID

Assume all the following are true:

- EL2 is implemented and enabled in the current Security state.
- Version v1p1 of FEAT_MPAM is implemented, MPAMIDR_EL1.HAS_HCR is 1, meaning that the MPAM virtualization option is implemented, and MPAMIDR_EL1.HAS_SDEFLT is 0, meaning that MPAM3_EL3.SDEFLT is not implemented.
- MPAMHCR_EL2.EL1_VPMEN is 1, meaning that PARTIDs in MPAM1_EL1.{PARTID_D, PARTID_I} are treated as virtual.
- MPAMIDR_EL1.VPMR_MAX is `0b010`, meaning that the maximum implemented mapping field is (4 x 2) + 3 = 11.
- The value of MPAM1_EL1.PARTID_D is 6.

In this example, 6 is treated as virtual and is the index into the array of valid flags and vector of physical PARTIDs. Behavior is:

1. Valid flag MPAMVPMV_EL2.VPM_V<6> is checked:
   1. A result of 1 means a valid mapping exists for virtual PARTID 6. MPAMVPM1_EL2.PhysPARTID6 contains the physical PARTID that the MPAM PE Requester sends.
   2. A result of 0 means *invalid*.
2. If the result is invalid, the mapping for the Default virtual PARTID, 0, is used. If a valid mapping does not exist for virtual PARTID 0, the MPAM PE Requester sends the Default physical PARTID.

R_{XSJVY}

The virtual PARTID spaces are:

- If Secure state is implemented, Secure virtual PARTID space. This translates to the Secure physical PARTID space.
- Non-secure virtual PARTID space. This translates to the Non-secure physical PARTID space.
- If FEAT_RME is implemented, Realm virtual PARTID space. This translates to the Realm physical PARTID space.

I_{BSWTR}

If a virtual PARTID is greater than (4 x MPAMIDR_EL1.VPMR_MAX) + 3, it is an *out-of-range virtual PARTID*.

R_{QTSFN}

When a PARTID is an out-of-range virtual PARTID, the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- The out-of-range virtual PARTID is replaced by any in-range virtual PARTID in the same PARTID space.
- The out-of-range virtual PARTID is replaced by the Default physical PARTID in the same PARTID space.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

I_{HWFQY} In each MPAMVPMn_EL2.PhyPARTID<n> mapping field, the architecture requires implementation of sufficient low-order bits to represent MPAMIDR_EL1.PARTID_MAX. It is permitted to implement the bits that are higher-order than MPAMIDR_EL1.PARTID_MAX as RAZ/WI.

D21.3.2 The Default PARTID

R_{QKQCF} The *Default PARTID* number, in each PARTID space, is 0.

R_{CQXMC} In the following scenario, the MPAM PE attempts to map the *Default virtual PARTID*:

- When no valid mapping exists for a PARTID that is *treated as virtual*.
  See PARTID virtualization.

In each of the following scenarios, the MPAM PE Requester sends the *Default physical PARTID* as part of the MPAM information bundle:

- When the MPAM enable control is 0, meaning MPAM is disabled.
- When the MPAM version implemented is any other than v1p0, the request is from Secure state, and MPAM3_EL3.SDEFLT is implemented and is set to 1. See Effect of the MPAM3_EL3.{SDEFLT, FORCE_NS} controls on MPAM PE Secure state execution.
- When a PARTID is an *out-of-range virtual PARTID* and the choice of CONSTRAINED UNPREDICTABLE behavior is to replace it with the Default physical PARTID. See Behavior when a PARTID is out-of-range.
- When no valid mapping exists for the Default virtual PARTID. See Behavior when a valid mapping does not exist for a PARTID that is treated as virtual.

Note

I_{XCZMJ} The MPAM architecture permits SoC designers to make non-MPAM Requesters label every request to the memory system with the Default physical PARTID.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.4 Performance Monitoring Groups (PMGs)

I_{NQQHK} An MPAM resource monitor measures how much of a shared partitionable resource a software execution environment is using. See Memory system resource usage monitoring. A *Performance Monitoring Group (PMG)* is an identifier used in the filter register of a monitor, MSMON_CFG_MBWU_FLT or MSMON_CFG_CSU_FLT.

Filtering by PMG provides a way to group measurements, and a way to subdivide measurements. For example:

- Multiple monitors, each measuring usage of a different shared resource, can be made sensitive to a single PMG and no PARTIDs, so that they create a group of measurements for usage of the different shared resources by one PMG value.
- Monitors can be made sensitive to both a PARTID and a PMG, so that the PMG provides a subdivision of what is measured for the PARTID.

R_{BVQFD} The PMG that an MPAM PE Requester sends as part of an MPAM information bundle is one of:

- If any of the conditions for the the Default PMG are met, the Default PMG.
- Otherwise, the PMG is determined as follows:
  - For an instruction fetch, MPAMn_ELx.PMG_I is used.
  - For a data access, MPAMn_ELx.PMG_D is used. However, if a data access is due to the execution of an SME load or store instruction, or of a Streaming SVE mode load or store instruction, MPAMSM_EL1.PMG_D is used instead.

  Also see Behavior when a PMG is out-of-range.

I_{JYNXW} Software can set MPAMn_ELx.{PMG_D, PMG_I} to the same or different PMG values.

D21.4.1 PMG virtualization

I_{JNHSB} Performance Monitoring Group (PMG) values are not virtualized. PMGs modify PARTIDs and do not require any further virtualization support.

D21.4.2 The Default PMG

R_{CZSZX} The *Default PMG* number is 0.

R_{PQSLB} In each of the following scenarios, the MPAM PE Requester sends the Default PMG as part of the MPAM information bundle:

- When the MPAM enable control is 0, meaning that MPAM is disabled.
- When a PMG is an *out-of-range* PMG and the choice of CONSTRAINED UNPREDICTABLE behavior is to replace it with the Default PMG. See Behavior when a PMG is out-of-range.
- When a Default PARTID is generated due to a PARTID generation error, and the choice of CONSTRAINED UNPREDICTABLE behavior is to send the Default PMG. See PMG value when a Default PARTID is generated due to an MPAM error.

Note

I_{TJBXP} The MPAM architecture permits SoC designers to make non-MPAM Requesters label every request to the memory system with the Default PMG.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.5 Effect of the MPAM3_EL3.{SDEFLT, FORCE_NS} controls on PE Secure state execution

R_{RFBMQ} The MPAM3_EL3.{SDEFLT, FORCE_NS} controls only affect Secure state execution.

R_{SHYXR} In MPAMv0p1 and from MPAMv1p1, if the *Secure Default* control MPAM3_EL3.SDEFLT is implemented, the PARTID and PMG that Secure state execution produces depends on the value of that control:

MPAM3_EL3.SDEFLT	PARTID and PMG that Secure state execution produces
0b0	MPAMn_ELx.{PARTID_D, PMG_D} or {PARTID_I, PMG_I}. This is compatible with MPAMv1p0.
0b1	The Default PARTID and Default PMG.

R_{XFCWV} In MPAMv0p1, the *Force Non-secure PARTID space* control MPAM3_EL3.FORCE_NS is implemented. If MPAM3_EL3.SDEFLT is also implemented, the PARTID space, PARTID, and PMG that Secure state execution produces are as follows:

MPAM3_EL3 control		PARTID space, PARTID, and PMG that Secure state execution produces
SDEFLT	FORCE_NS	
0b0	0b0	• Secure physical PARTID space. • MPAMn_ELx.{PARTID_D, PMG_D} or {PARTID_I, PMG_I}. This is compatible with MPAMv1p0.
	0b1	• Non-secure physical PARTID space. • MPAMn_ELx.{PARTID_D, PMG_D} or {PARTID_I, PMG_I}.
0b1	0b0	• Secure physical PARTID space. • Default PARTID and Default PMG.
	0b1	• Non-secure physical PARTID space. • Default PARTID and Default PMG.

R_{MSGKT} In MPAMv0p1, it is IMPLEMENTATION DEFINED whether MPAM3_EL3.FORCE_NS is implemented as:

- RAO/WI, and Secure PARTIDs are not implemented.
- RW.

I_{QJPCV} In MPAMv0p1, software can discover whether MPAM3_EL3.FORCE_NS is implemented as RAO/WI or RW by testing whether it is writable to zero.

R_{TRNQL} In MPAM for RME, implementation of MPAM3_EL3.FORCE_NS is not permitted and implementation of the alternative PARTID space controls, that select whether a primary or alternative PARTID space is produced, is required. The effect of MPAM3_EL3.SDEFLT if it is implemented is:

Alternative PARTID space selected?	MPAM3_EL3.SDEFLT	PARTID space, PARTID, and PMG that Secure state execution produces
No	0b0	• Secure physical PARTID space. • MPAMn_ELx.{PARTID_D, PMG_D} or {PARTID_I, PMG_I}. This is compatible with MPAMv1p0.
	0b1	• Secure physical PARTID space. • Default PARTID and Default PMG.
Yes	0b0	• Non-secure physical PARTID space. • MPAMn_ELx.{PARTID_D, PMG_D} or {PARTID_I, PMG_I}.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Alternative PARTID space selected?	MPAM3_EL3.SDEFLT	PARTID space, PARTID, and PMG that Secure state execution produces
	`0b1`	• Non-secure physical PARTID space. • Default PARTID and Default PMG.

D21.5.1 Interaction of MPAM3_EL3.SDEFLT and the MPAM enable control

R_{CBRSV} In MPAMv0p1 and from MPAMv1p1, if the *Secure Default* control MPAM3_EL3.SDEFLT is implemented:

- When the MPAM enable control, MPAMEN, is 0, the MPAM PE Requester sends the Default physical PARTID and the Default PMG with all requests to the memory system.
- When MPAMEN is 1 and SDEFLT is 0, all requests from all Security states produce the PARTID and PMG from the MPAMn_ELx registers.
- When MPAMEN is 1 and SDEFLT is 1:
  - All requests from Secure state produce the Default PARTID and the Default PMG.
  - All requests from all other Security states produce the PARTID and PMG from the MPAMn_ELx registers.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.6 Effect of access type on MPAM information

I_{BZNRF} See the following subsections:

- Translation table accesses.
- Granule Protection Table (GPT) accesses.
- Accesses by enhanced support for nested virtualization.
- AT* instructions.
- Unprivileged memory access instructions.
- Accesses by Statistical Profiling Extension.

D21.6.1 Translation table accesses

R_{FYLGZ} Translation table walk accesses, including hardware updates of translation tables, for:

- Instruction fetches, use the same PARTID_I field as their instruction fetch.
- Data accesses, use the same PARTID_D field as their data access.

D21.6.2 Granule Protection Table (GPT) accesses

R_{MFSPP} In MPAM for RME, Granule Protection Table (GPT) accesses for:

- Instruction fetches, use the same PARTID space, PARTID_I, field, and PMG_I field as their instruction fetch.
- Data accesses, use the same PARTID space, PARTID_D field, and PMG_D field as their data access.
- A translation table walk, use the same PARTID space, PARTID, and PMG as the translation table access.

D21.6.3 Accesses by enhanced support for nested virtualization

R_{NFJPN} In an MPAM PE with FEAT_NV2, when the Effective value of HCR_EL2.{NV, NV2} is {1, 1}, `MRS` and `MSR` accesses to certain registers from EL1 are transformed to memory accesses. Those accesses, and translation table walks generated for those accesses, use MPAM2_EL2.{PARTID_D, PMG_D}. See Support for nested virtualization.

D21.6.4 AT* instructions

R_{RSNZD} Accesses to translation tables by `AT*` instructions are given the MPAM information specified for translation table accesses by a data load instruction that is issued from an IMPLEMENTATION DEFINED choice of:

- The Exception level that the `AT*` instruction was executed from.
- The Exception level that configures the translation regime targeted by the `AT*` instruction.

D21.6.5 Unprivileged memory access instructions

R_{GPVVG} For unprivileged memory access instructions executed at ELx, the resulting memory system requests use the same MPAM labels that are used for regular loads and stores at ELx.

D21.6.6 Accesses by Statistical Profiling Extension

R_{CRJBB} An MPAM PE with FEAT_SPE can be configured to record statistically sampled events into a Profiling Buffer in memory. The buffer is accessed through the owning translation regime. MPAM PARTID, PMG, and PARTID space for SPE writes to the Profiling Buffer must use the SPE owning Exception level MPAM data access values. For example, if the owning Exception level is EL2, the Profiling Buffer writes must be performed with MPAM2_EL2.PARTID_D, MPAM2_EL2.PMG_D, with **MPAM_NS** or **MPAM_SP** reflecting the owning Security state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.6.7 Accesses by Trace Buffer Extension

I_{MNMXW} A PE with FEAT_TRBE can be configured to record trace data into a trace buffer in memory. The MPAM information used for these accesses depends on the operating mode of the Trace Buffer Unit. For more information, see:

- Accesses by Trace Buffer Extension.
- External mode and MPAM.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.7 Virtualization support

I_{HRVFB} See the following subsections:

- Single PARTID for an EL1 guest OS and all its EL0 applications.
- Trap controls to virtualize MPAMIDR_EL1.
- Trap controls to trap accesses to MPAM System registers.
- Trap controls priorities.
- Virtualization of PARTIDs.
- Interaction with FEAT_VHE.
- Support for nested virtualization.

D21.7.1 Single PARTID for an EL1 guest OS and all its EL0 applications

R_{FNKGZ} Setting MPAMHCR_EL2.GSTAPP_PLK to 1 causes MPAM1_EL1 to supply PARTIDs and PMGs for both EL1 and EL0, and causes MPAM0_EL1 to be unused, meaning that an EL1 guest OS and all its EL0 applications are in the same partition.

R_{JNWLV} When MPAMHCR_EL2.{GSTAPP_PLK, EL1_VPMEN} is {1, 1}, the PARTID that results from the mapping process is the PARTID that the MPAM PE Requester sends for requests originating from EL0, as well as for those originating from EL1. See PARTID virtualization.

Note

I_{RMPJJ} EL1 software cannot determine the state of MPAMHCR_EL2.GSTAPP_PLK. MPAMHCR_EL2.GSTAPP_PLK==1 does not affect EL1 accesses to MPAM0_EL1.

D21.7.2 Trap controls to virtualize MPAMIDR_EL1

I_{LDNNY} An EL2 hypervisor is able to provide a virtual view of MPAMIDR_EL1 to an EL1 guest OS by using MPAMHCR_EL2.TRAP_MPAMIDR_EL1, or MPAM2_EL2.TIDR if MPAMIDR_EL1.HAS_TIDR is 1, to trap EL1 accesses to MPAMIDR_EL1. The virtual view shows MPAMIDR_EL1.PARTID_MAX as the largest *virtual PARTID* that the EL2 hypervisor is providing for the EL1 guest OS to use.

See also:

- Partition identifiers (PARTIDs).
- PARTID virtualization.

D21.7.3 Trap controls to trap accesses to MPAM System registers

I_{TKRWM} The MPAM architecture provides trap controls for all the following:

- EL1 accesses to MPAM0_EL1, MPAM1_EL1, and MPAMSM_EL1, to trap these to EL2. See the trap controls MPAM2_EL2.{TRAPMPAM0EL1, TRAPMPAM1EL1, EnMPAMSM} respectively.
- EL1 accesses to MPAMBW0_EL1, MPAMBW1_EL1, and MPAMBWSM_EL1, to trap these to EL2. See the trap controls MPAMBW2_EL2.{nTRAP_MPAMBW0_EL1, nTRAP_MPAMBW1_EL1, nTRAP_MPAMBWSM_EL1} respectively.
- EL2 and EL1 accesses to MPAM System registers, to trap these to EL3. See MPAM3_EL3.TRAPLOWER and MPAMBW3_EL3.nTRAPLOWER.

I_{SQQYN} Accesses to all the following are not subject to any traps:

- MPAM1_EL12.
- MPAM1_EL1 when the Effective value of HCR_EL2.E2H is 1.

See Interaction with FEAT_VHE.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.7.4 Trap controls priorities

R_{CFZGR} MPAM3_EL3.TRAPLOWER and MPAMBW3_EL3.nTRAPLOWER traps have priority over all traps controlled by MPAM registers with names ending in _EL2.

D21.7.5 Virtualization of PARTIDs

I_{JNSFB} See PARTID virtualization.

D21.7.6 Interaction with FEAT_VHE

I_{QQPKC} When the Effective value of HCR_EL2.E2H is 1, the following are alias registers for accesses from EL2:

- MPAM1_EL12 is an alias for MPAM1_EL1. See R_{PHHPL} in System and Special-purpose register aliasing.
- MPAM1_EL1 is an alias for MPAM2_EL2. See R_{JGGMV} in System and Special-purpose register redirection.
- MPAMBW1_EL12 is an alias for MPAMBW1_EL1. See R_{PHHPL} in System and Special-purpose register aliasing.
- MPAMBW1_EL1 is an alias for MPAMBW2_EL2. See R_{JGGMV} in System and Special-purpose register redirection.

I_{LVGCR} If the Effective value of HCR_EL2.E2H is 1, software executing at EL2 can use all of:

- MPAM1_EL12, to control PARTIDs and PMGs for execution at EL1.
- MPAM1_EL1, to configure the MPAM controls that apply to execution at EL2.
- MPAMBW1_EL12, to configure a maximum limit on the bandwidth that EL1 requests use.
- MPAMBW1_EL1, to configure a maximum limit on the bandwidth that EL2 requests use.

I_{FCMPY} The Effective value of HCR_EL2.E2H does not affect:

- Use of the following registers by EL2 software:
  - MPAM0_EL1, to control PARTIDs and PMGs used by applications running at EL0, or MPAMBW0_EL1, to configure a maximum limit on the bandwidth that EL0 requests use. When running applications at EL0, EL2 software also sets HCR_EL2.TGE to 1 to route exceptions from EL0 to EL2.
  - MPAMHCR_EL2.
  - MPAMVPMV_EL2.
  - MPAMVPMn_ELx.
  - MPAMBWCAP_EL2.
- Use of the following registers by EL1 software:
  - MPAM0_EL1, to control PARTIDs and PMGs used by applications running at EL0, and MPAM1_EL1, to control PARTIDs and PMGs used by EL1 software.
  - MPAMBW0_EL1 and MPAMBW1_EL1, to configure maximum limits on the bandwidth that EL0 requests and EL1 requests use, respectively.

R_{XCQTJ} When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the alternative PARTID space in EL0 is selected only if the alternative PARTID space is selected in EL2. When the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, the alternative PARTID space in EL0 is selected only if the alternative PARTID space is selected in EL1.

D21.7.7 Support for nested virtualization

R_{WDPPT} In an MPAM PE with FEAT_NV, when the Effective value of HCR_EL2.{NV, NV2} is {1, 0}, EL1 accesses to the following System registers are trapped to a higher Exception level:

- MPAM1_EL12.
- MPAM2_EL2.
- MPAMHCR_EL2.
- MPAMVPMV_EL2.
- The *MPAM virtual PARTID mapping registers*, MPAMVPM0_EL2 to MPAMVPM7_EL2.
- The *MPAM bandwidth control registers* MPAMBW2_EL2, MPAMBWCAP_EL2, and MPAMBW1_EL12.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For the MPAM bandwidth control registers MPAMBW2_EL2, MPAMBWCAP_EL2, and MPAMBW1_EL12, the controls that determine which Exception level EL1 accesses are trapped to are MPAM3_EL3.TRAPLOWER and MPAMBW3_EL3.nTRAPLOWER:

Table D21-15 MPAM Bandwidth control register traps

MPAM3_EL3.TRAPLOWER	MPAMBW3_EL3.nTRAPLOWER	Behavior when HCR_EL2.{NV, NV2} is {1, 0}
0	0	EL1 access trapped to EL3
0	1	EL1 access trapped to EL2
1	0	EL1 access trapped to EL3
1	1	EL1 access trapped to EL3

Otherwise, for the other registers, the value of MPAM3_EL3.TRAPLOWER determines which higher Exception level EL1 accesses are trapped to:

- When 0, the EL1 accesses are trapped to EL2.
- When 1, the EL1 accesses are trapped to EL3.

I_{XXYXW} In an MPAM PE with FEAT_NV2, Loads and stores generated by transforming register accesses describes the behavior when the Effective value of HCR_EL2.{NV, NV1, NV2} is {1, 0, 1} and {1, 1, 1}, and Table D8-120 includes the MPAM System registers for which that behavior applies.

R_{JPQVQ} In an MPAM PE with FEAT_NV2, when the Effective value of HCR_EL2.{NV, NV2} is {1, 1}, setting MPAM3_EL3.TRAPLOWER to 1 does not cause EL1 accesses to the MPAM System registers in Table D8-120 to be trapped to EL3.

I_{RXGXW} When the Effective value of HCR_EL2.{NV, NV2} is {1, 1}, EL1 accesses to the MPAM System registers are transformed to memory accesses. See Loads and stores generated by transforming register accesses.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D21.8 PE-side Maximum bandwidth limit injection control

I_{CBQCG} If FEAT_MPAM_PE_BW_CTRL is implemented, software can use MPAMBWn_ELx registers to impose a maximum limit on the bandwidth that requests from the MPAM PE use.

R_{VQNTY} When MPAMBWn_ELx.ENABLED is 1 and either of the following is true, MPAM PE requests to the memory system are stalled until the bandwidth the MPAM PE is using drops below the limit configured in MPAMBWn_ELx.MAX:

- MPAMBWIDR_EL1.MAX_LIM is `0b00` or `0b10` and MPAMBWn_ELx.HARDLIM is set.
- MPAMBWIDR_EL1.MAX_LIM is `0b00` or `0b01`, MPAMBWn_ELx.HARDLIM is not set, and an IMPLEMENTATION DEFINED mechanism has determined the MPAM PE downstream resources to be saturated.

Otherwise, MPAM PE requests to the memory system are sent unregulated.

R_{RGLDT} MPAMBWSM_EL1.MAX is used instead of MPAMBWn_ELx.MAX when:

- The MPAM PE is in streaming mode, and:
  - Accessing from SVE load/store/prefetch.
  - Accessing from SIMD&FP load/store.
- Accessing from SME load/store.

I_{DPMDJ} If MPAMIDR_EL1.HAS_HCR is 1, meaning that the MPAM virtualization option is implemented, and FEAT_MPAM_PE_BW_CTRL is implemented, EL2 software can use MPAMBWCAP_EL2 to cap a maximum bandwidth limit assigned by EL1&0 software.

R_{CMMQR} When MPAMBWCAP_EL2.ENABLED is 1, EL1&0 requests to the memory system are regulated based on the limit calculated as MIN(MPAMBWCAP_EL2.CAP, MPAMx_BW_CTRL_EL.MAX) and MIN(MPAMBWCAP_EL2.CAP, MPAMBWSM_EL1.MAX).

I_{VVYKT} If {MPAMBWn_ELx, MPAMBWSM_EL1, MPAMBWCAP_EL2}.HW_SCALE_ENABLE is 1, then hardware is permitted to scale down the maximum limit configured in {MPAMBWn_ELx, MPAMBWSM_EL1}.MAX or MPAMBWCAP_EL2.CAP according to the number of PEs in a group that are all issuing the same specific PARTID_D or PARTID_I at the corresponding exception level.

R_{CRGFM} It is IMPLEMENTATION DEFINED how hardware determines the number of PEs that are all issuing the same specific PARTID_D or PARTID_I at any point in time.

I_{FYXGY} Memory bandwidth regulation relies on tracking bandwidth use by PARTIDs. Bandwidth measurements have a dependence on time, and that dependence is referred to as the *accounting window*. The accounting window tracks bandwidth use over a period of time.

R_{FZMPQ} The PE-side maximum bandwidth limit accounting window scheme and its software-discoverability are IMPLEMENTATION DEFINED.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

D21.9 MPAM errors

R_{DHSBM} An MPAM error is detected when a memory read, memory write, instruction fetch, or translation table walk results in one of:

- The PARTID is *out-of-range*. Either:
  - The PARTID is a physical PARTID and it exceeds MPAMIDR_EL1.PARTID_MAX.
  - The PARTID is *treated as virtual* and it exceeds (4 x MPAMIDR_EL1.VPMR_MAX) + 3.
- The PARTID is treated as virtual and the corresponding MPAMVPMV_EL2.VPM_V<m> valid flag indicates that a valid mapping does not exist.
- The PMG is out-of-range. The PMG exceeds MPAMIDR_EL1.PMG_MAX.

I_{DWCRN} In some implementations, some MPAM errors might never occur. For example, an implementation with only w bits of PARTID and MPAMIDR_EL1.PARTID_MAX as (2^w - 1), and that truncates PARTID values with nonzero bits higher than w - 1, can never have a physical PARTID out-of-range error.

See also:

- PARTID virtualization, for the definitions of *out-of-range* and *treated as virtual*.

D21.9.1 Behavior when a PARTID is out-of-range

R_{YGRQN} When a physical or virtual PARTID from an MPAMn_ELx.PARTID_D or MPAMn_ELx.PARTID_I field is *out-of-range*, the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- The out-of-range PARTID is replaced by any in-range PARTID.
- The out-of-range PARTID is replaced by the Default physical PARTID.

For the replacement PARTID space of a replacement PARTID, see PARTID space on error.

I_{DYBVB} See also:

- PARTID virtualization, for the definition of *out-of-range*.

D21.9.2 Behavior when a valid mapping does not exist for a PARTID that is treated as virtual

R_{NHSJC} If a PARTID from an MPAMn_ELx.PARTID_D or MPAMn_ELx.PARTID_I field, or its replacement if that PARTID was *out-of-range*, is *treated as virtual*, and the corresponding MPAMVPMV_EL2.VPM_V<m> valid flag indicates that a valid mapping does not exist, the mapping for the Default virtual PARTID is used. If a valid mapping does not exist for the Default virtual PARTID, the Default physical PARTID is sent.

I_{FYYSQ} See also:

- PARTID virtualization, for the definitions of *out-of-range* and *treated as virtual*.

D21.9.3 Behavior when a PMG is out-of-range

R_{VPZPD} When a PMG from an MPAMn_ELx.PMG_D or MPAMn_ELx.PMG_I field is *out-of-range*, the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- The out-of-range PMG is replaced by any in-range PMG.
- The out-of-range PMG is replaced by the Default PMG.

D21.9.4 PMG value when a Default PARTID is generated due to an MPAM error

R_{YBYMK} When the Default PARTID is generated due to an MPAM error, the PMG value is a CONSTRAINED UNPREDICTABLE choice of:

- MPAMn_ELx.PMG_D or MPAMn_ELx.PMG_I.
- The Default PMG.

D21.9.5 PARTID space on error

R_{VYHDZ} An MPAM error does not change the PARTID space.

Chapter D22
The Scalable Matrix Extension

This chapter describes the Scalable Matrix Extension. It contains the following sections:

- Overview
- SME traps and exceptions
- Validity of SME and SVE state
- Streaming execution priority
- Floating-point behaviors in Streaming SVE mode
- Floating-point behaviors for instructions that target the SME ZA array
- Security and power considerations

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D22.1 Overview

IYVCPK The *Scalable Matrix Extension* (SME) defines:

- Architectural state capable of holding two-dimensional matrix tiles.
- A *Streaming SVE processing mode*, which supports execution of SVE2 instructions with a vector length that matches the tile width.
- Instructions that accumulate the outer product of vectors into a tile.
- Load, store, and move instructions that transfer a vector to or from a tile row or column.

The extension also defines System registers and fields that identify the presence and capabilities of SME, and enable and control its behavior at each Exception level.

IPYQMB The *Scalable Matrix Extension version 2* (SME2) extends the SME architecture to increase the number of applications that can benefit from the computational efficiency of SME resources, beyond their initial focus on outer products and matrix-matrix multiplication.

SME2 adds data processing instructions with multi-vector operands and a multi-vector predication mechanism.

These include:

- Multi-vector multiply-accumulate instructions, that read SVE Z vectors and accumulate into the SME *ZA array vectors* to permit reuse of the SME outer product hardware for vector operations, including widening multiplies that accumulate into more vectors than they read.
- Multi-vector instructions that read and write multiple SVE Z vectors to preprocess inputs and post-process outputs of the multi-vector multiply-accumulate and outer product instructions.
- An alternative predication mechanism to the SVE predication mechanism, to control operations performed on multiple vector registers.

SME2 also adds:

- Compressed neural network capability using dedicated lookup table instructions and outer product instructions that support binary neural networks.
- A 512-bit architectural register, ZT0, to support the lookup table feature.

DFZHSK Unless stated otherwise, the acronym *SME* applies to all implemented versions of the Scalable Matrix Extension.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D22.2 SME traps and exceptions

I_{QZNRN} This section provides additional details for SME-related exceptions. For a list of exception priorities, see R_{ZFGJP}.

R_{JZTCQ} If FEAT_SME is not implemented, then SME and SME2 instructions are UNDEFINED.

R_{GTKQD} If FEAT_SME2 is not implemented, then SME2 instructions are UNDEFINED.

R_{PLYVH} If any of the following is true, an SVE instruction is UNDEFINED:

- FEAT_SME is not implemented and FEAT_SVE is not implemented.
- FEAT_SVE is not implemented and the instruction is illegal when the PE is in *Streaming SVE mode.*

D_{DMBHW} The *SME-related instructions* are:

- SME data-processing instructions.
- `SMSTART` and `SMSTOP` instructions.
- AArch64 `MRS` and `MSR` instructions which directly access any of the SVCR, SMCR_EL1, SMCR_EL2, or SMCR_EL3 registers.

I_{BLTMB} The CPACR_EL1.SMEN, CPTR_EL2.{SMEN, TSM}, CPTR_EL3.ESM trap and enable controls apply to all SME-related instructions.

I_{RGBVJ} The SMCR_ELx.EZT0 enable controls apply to the following SME2 instructions that access the ZT0 register:

- `LDR (table)`.
- `LUTI2`, `LUTI4`.
- `MOVT`.
- `STR (table)`.
- `ZERO (table)`.

I_{XKMKY} FEAT_SME adds an SME exception syndrome in ESR_ELx to identify instructions that are trapped because of any of:

- The SME trap controls in CPACR_EL1, CPTR_EL2, and CPTR_EL3.
- The SME2 trap controls SMCR_ELx.EZT0.
- The PSTATE.SM and PSTATE.ZA modes.

I_{NWNQZ} When the PE is in *Streaming SVE mode* or when FEAT_SVE is not implemented, the CPACR_EL1.SMEN, CPTR_EL2.{SMEN, TSM}, CPTR_EL3.ESM controls configure SVE instructions to trap, and the CPACR_EL1.ZEN, CPTR_EL2.{ZEN, TZ}, CPTR_EL3.EZ controls do not cause any SVE instructions to be trapped.

I_{PKGPR} When the PE is not in *Streaming SVE mode* and FEAT_SVE is implemented, the CPACR_EL1.ZEN, CPTR_EL2.{ZEN, TZ}, CPTR_EL3.EZ controls configure SVE instructions to trap, and the CPACR_EL1.SMEN, CPTR_EL2.{SMEN, TSM}, CPTR_EL3.ESM controls do not cause any SVE instructions to be trapped.

R_{GGLFV} When an SVE `MOVPRFX` instruction predictably prefixes an SVE instruction that is *illegal* due to the current value of PSTATE.SM or PSTATE.ZA, then the execution of either of the instructions generates an exception due to SME functionality, consistent with the behaviors defined by R_{RWVTR}.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D22.3 Validity of SME and SVE state

I_{VBJBR} The Effective value of PSTATE.SM and the value of PSTATE.ZA configure whether SME architectural state is valid and accessible.

I_{WFHKZ} CPACR_EL1.SMEN, CPTR_EL2.{TSM, SMEN}, and CPTR_EL3.ESM configure whether SME-related instructions can be executed or are trapped.

I_{KKFXN} SMCR_ELx.EZT0 configures whether SME2 instructions that access the ZT0 register can be executed or are trapped.

R_{XCCXW} The controls for trapping SME-related instructions and the controls for the validity of SME architectural state are independent.

I_{JGRTR} Because the trap and architectural state validity are controlled independently, the following scenarios are all permissible:

- Instructions trap, state invalid.
  - For example, an OS traps the first usage of SME-related instructions by a process.
- Instructions trap, state valid.
  - For example, a process was running with valid SME architectural state and an OS configures traps to detect when the next usage of SME architectural state occurs.
  - Enabling the trap does not affect or corrupt the SME architectural state.
- Instructions permitted, state invalid.
  - For example, a process is permitted to execute SME-related instructions but is currently not running in *Streaming SVE mode*. SME data-processing instructions which access SVE vector or predicate registers are *illegal* and are trapped, but SVE instructions operate on the Non-streaming SVE register state. The process can execute an `SMSTART` instruction to enter *Streaming SVE mode*.
  - For example, a process is running in *Streaming SVE mode*, but has not enabled access to the ZA storage. SME instructions that access ZA are *illegal* and are trapped, but the process can execute an `SMSTART` instruction to enable access to the ZA storage.
- Instructions permitted, state valid.
  - For example, a process is running in *Streaming SVE mode*, and has enabled access to ZA storage.

Non-Confidential

D22.4 Streaming execution priority

D_{DXMSW} Streaming execution refers to the execution of instructions by a PE when that PE is in *Streaming SVE mode*.

I_{CMRVS} Arm expects a variety of implementation styles for SME, including styles where more than one PE shares SME and Streaming SVE compute resources.

I_{PQNJS} Shared SME and Streaming SVE compute resources are called a *Streaming Mode Compute Unit* (SMCU).

I_{MZXWD} For implementations that share an SMCU, this architecture provides per-PE mechanisms that software can use to dynamically prioritize performance characteristics experienced by each PE.

D22.4.1 Streaming execution priority for shared implementations

I_{YYRZQ} Execution of certain instructions by a PE in *Streaming SVE mode* might experience a performance dependency on other PEs in the system that are also executing instructions in *Streaming SVE mode*. For example, this might occur when an SMCU is shared between PEs.

I_{WPQVV} The architecture provides a mechanism to control the streaming execution priority of a PE, in SMPRI_EL1. The streaming execution priority of a PE is relative to the streaming execution priority of other PEs, when a performance dependency exists between PEs executing in *Streaming SVE mode*.

I_{KTYTD} An implementation that does not share SMCUs or has no performance dependency between PEs might not need to limit or prioritize execution of one PE relative to another.

I_{HQXBH} The streaming execution priority mechanism is optional.

D_{DGRTS} All PEs that share a given SMCU form a *Priority domain*.

D_{YQFWM} Different *Priority domains* represent unrelated SMCUs.

R_{WPVQK} All PEs in a *Priority domain* have the same value of SMIDR_EL1.Affinity and SMIDR_EL1.Affinity2.

R_{CVLSF} PEs in different *Priority domains* have different values of SMIDR_EL1.Affinity or SMIDR_EL1.Affinity2.

R_{GGDRC} The streaming execution priority in SMPRI_EL1 affects execution of a PE relative to all other PEs in the same *Priority domain.*

R_{SBCRG} All SMCUs in the system have a consistent interpretation of the streaming execution priority values.

R_{RQXFC} The streaming execution priority mechanism affects the execution of instructions by a shared SMCU when the PE is in *Streaming SVE mode* and does not directly control the execution of other types of instruction.

I_{BLMYK} If system software does not support differentiation of streaming execution priority of threads, it is safe to use a value of 0 for all threads.

I_{YBQNW} The architecture considers *Priority domain* to be non-overlapping sets, meaning that in a shared-SMCU system, a PE is associated with at most one SMCU.

D22.4.1.1 Streaming execution context management

I_{PRNMJ} Arm expects that the SVE and SME instructions used by save, restore, and clear routines for the *Streaming SVE mode* SVE registers, the ZA storage, and the ZT0 register when FEAT_SME2 is implemented, are limited to using the following SME and SVE instructions:

- SME `LDR (array vector)` and `STR (array vector)` instructions.
- SME2 `LDR (table)` and `STR (table)` instructions.
- SVE `LDR (vector)` and `STR (vector)` instructions.
- SVE `LDR (predicate)` and `STR (predicate)` instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- SME `ZERO (tiles)` instruction.
- SME2 `ZERO (table)` instruction.
- SVE `DUP (immediate)` instruction with zero immediate.
- SVE `PFALSE` instruction.

For implementations with a shared SMCU, PEs are expected to execute these instructions in a way that experiences a reduced effect of contention for the SMCU from other PEs, compared to other SME and SVE instructions executed in *Streaming SVE mode*.

D22.4.1.2 Streaming execution priority control

I_{RMDCP} The streaming execution priority is controlled by a 4-bit priority value. When the streaming execution priority mechanism is not supported, the priority value is ignored.

I_{FJQRG} A higher priority value corresponds to a higher streaming execution priority. Priority value `15` is the highest priority.

I_{QHKWP} The behavior of any given priority value relative to that of another PE is IMPLEMENTATION DEFINED.

D22.4.1.3 Streaming execution priority virtualization

I_{SQBCZ} The Effective streaming execution priority is either the value configured in SMPRI_EL1 or, if EL2 is implemented and enabled in the current Security state, the value of SMPRI_EL1 mapped into a new value by indexing the fields in SMPRIMAP_EL2. This choice is affected by the current Exception level, and the HCRX_EL2.SMPME configuration.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D22.5 Floating-point behaviors in Streaming SVE mode

D_{DMPBW} Unless stated otherwise, the behaviors in this section apply when the PE is in Streaming SVE mode, to floating-point instructions that place their results in SIMD&FP registers or SVE scalable vector registers, except for:

- SVE BFloat16 instructions `BFDOT` and `BFMMLA`, for which, see BFloat16 behaviors for instructions that calculate sum-of-products.
- FP8 instructions, for which, see Summary of FP8 instruction behaviors.

The instructions:

R_{PHDZL}
- Honor FPCR.{DN, FZ, RMode, FZ16, AH, FIZ}, unless specified otherwise in Flushing denormalized numbers to zero or Alternate BFloat16 behaviors.

R_{GTYSK}
- Produce the expected IEEE 754 default result and update the FPSR cumulative exception flag bits, unless specified otherwise in Alternate BFloat16 behaviors.

R_{FBFNT}
- Disable trapped floating-point exceptions as if FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are all 0, and treat the NEP element preserve control as if it is 0, if FEAT_SME_FA64 is not implemented or not enabled at the current Exception level.

See also:

- Streaming SVE mode.

D22.6 Floating-point behaviors for instructions that target the SME ZA array

D_{HTZVK} Unless stated otherwise, the behaviors in this section apply to SME and SME2 floating-point instructions that place their results in the ZA array, except the SME BFloat16 instructions `BFMOPA` (widening), `BFMOPS` (widening), `BFDOT`, and `BFVDOT`, for which, see BFloat16 behaviors for instructions that calculate sum-of-products.

The instructions:

R_{WLPHB}
- Honor FPCR.{FZ, RMode, FZ16, AH, FIZ}, unless specified otherwise in Flushing denormalized numbers to zero or Alternate BFloat16 behaviors.

R_{RKHHZ}
- Generate the default NaN, as if FPCR.DN is 1.

R_{TGSKG}
- Produce the expected IEEE 754 default result but do not update the FPSR cumulative exception flag bits.

R_{FSWYW}
- Disable trapped floating-point exceptions, as if FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} are all 0.

R_{BWKKQ} The SME instructions that accumulate dot products of pairs of adjacent half-precision elements in the source vectors into single-precision elements in the ZA array:
- Perform a fused sum-of-products without rounding of the intermediate products, but rounding the single-precision sum before addition to the accumulator tile or multi-vector operand element.
- Generate the default NaN as intermediate sum-of-products when any of the following are true:
  - Any multiplier input is a NaN.
  - Any product is infinity $\times$ 0.0.
  - Both products are infinity of differing signs.
- Generate an intermediate sum-of-products of the same infinity when there are products that are infinity all with the same sign.

R_{RPSLK} If FEAT_AFP is implemented, the instructions honor FPCR.{AH, FIZ}, in which case:
- When FPCR.AH is 1, the sign bit of a generated default NaN result is set to 1 instead of 0.
- When FPCR.AH is 1 and FPCR.FZ is 1, a denormal result, detected after rounding with an unbounded exponent has been applied, is flushed to zero.
- When FPCR.AH is 1, the FPCR.FZ control does not cause denormalized inputs to be flushed to zero.
- When FPCR.FIZ is 1, all denormalized inputs are flushed to zero.

R_{TCLRM}
- Honor FPCR.RMode, supporting all four IEEE 754 rounding modes.

R_{VVVNR}
- Honor FPCR.FZ.

R_{TXKVK}
- Honor FPCR.FZ16.

R_{JRRMJ} Those instructions that multiply single elements from each source vector and accumulate their product into the ZA array perform a fused multiply-add to each accumulator tile or multi-vector operand element without rounding of the intermediate products.

D22.7 Security and power considerations

D22.7.1 Security considerations

I_{DXRGG} All SME load and store instructions adhere to the memory access permissions model in The AArch64 Virtual Memory System Architecture.

I_{MGLWR} SME architectural state can be access-controlled, meaning that higher levels of privilege can trap access to the state from the same or lower levels of privilege.

I_{CYPJJ} System software has controls available to save and restore state between unrelated pieces of software, and must ensure that steps are taken to preserve isolation and privacy.

I_{TDPHC} Operations performed in *Streaming SVE mode* respect the requirements of PSTATE.DIT. FEAT_DIT requires data-independent timing when enabled.

D22.7.2 Power considerations

I_{VGWQW} An implementation might use the activity of PSTATE.{SM, ZA} to influence the choice of power-saving states for both functional units and retention of architected state. A PE might consume less power when PSTATE.{SM, ZA} are {0, 0}.

Chapter D23
AArch64 System Register Encoding

This chapter describes the AArch64 System register encoding space. It contains the following sections:

- The System register encoding space
- Moves to and from debug and trace System registers
- Moves to and from non-debug System registers, Special-purpose registers

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D23.1 The System register encoding space

The A64 instruction set includes instructions that access the System register encoding space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to Special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the `CLREX` instruction.
- Architectural hint instructions.

This section describes the parts of the System register encoding space that provides access to the System registers described in AArch64 System Register Descriptions.

Note

- See Fixed values in AArch64 instruction and System register descriptions for information about abbreviations used in the System instruction descriptions.
- In AArch32 state, much of this functionality is provided through the System register interface described in The AArch32 System register interface. In AArch64 state, the parameters used to characterize the System register encoding space are {`op0`, `op1`, `CRn`, `CRm`, `op2`}. These are based on the parameters that characterize the AArch32 System register encoding space, which reflect the original implementation of these registers, as described in Background to the System register interface. There is no particular significance to the naming of these parameters, and no functional distinction between the `opn` parameters and the `CRx` parameters.

Principles of the System instruction class encoding describes some general properties of these encodings. System instruction class encoding overview then describes the top-level encoding of these instructions, identifying that:

- Entries in the encoding space are characterized by the parameter set {`op0`, `op1`, `CRn`, `CRm`, `op2`}.
- `op0` is the most significant parameter for determining allocations in this space.

Much of this encoding space is used for System instructions, as described in The A64 System Instruction Class. This chapter describes only the part of the encoding space that is used for System registers, in the following sections:

- Moves to and from debug and trace System registers.
- Moves to and from non-debug System registers, Special-purpose registers.

D23.2 Moves to and from debug and trace System registers

The instructions that move data to and from the debug, execution environment, and trace System registers are encoded with `op0`== `0b10`. This means the encoding of these instructions is:

31 30 29 28	27 26 25 24	23 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0 1	0 1 0 1	0 0	L	1 0	op1	CRn	CRm	op2	Rt
				op0					

Note

- The section describes the use of all of the `op0`==`0b10` region of the System register encoding space.
- These encodings access the registers that are equivalent to the AArch32 System registers in the (`coproc` == `0b1110`) encoding space.

The value of `op1` provides the next level of decode of these instructions, as follows:

`op1` == {`0b000`, `0b011`, `0b100`, `0b101`, `0b110`, `0b111`}

Debug, PMU, and System PMU registers.

Note

The standard encoding of debug System registers is `op0` == `0b10`, `op1` == {0, 3, 4}. The registers in the `op0` == `0b11` encoding space that are classified as debug System registers are DLR_EL0, DSPSR_EL0, MDCR_EL2, MDCR_EL3, and SDER32_EL3. See Instructions for accessing non-debug System registers for the encodings of these registers.

`op1` == {`0b001`} Trace and BRBE registers.

D23.2.1 Instructions for accessing debug System registers

The instructions for accessing debug System registers are:

```
MSR <System_register>, Xt     ; Write to System register
MRS Xt, <System_register>     ; Read from System register
```

Where `<System_register>` is the register name, for example MDCCSR_EL0.

This section includes only the System register access encodings for which both:

- `op0` is `0b10`.
- The value of `op1` is one of {`0b000`, `0b001`, `0b011`, `0b100`, `0b101`, `0b110`, `0b111`}.

Note

These encodings access the registers that are equivalent to the AArch32 System registers in the (`coproc` == `0b1110`) encoding space. For more information, see Mapping of the System registers between the Execution states.

Table D23-1 shows the mapping of the System register encodings for debug System register access.

Table D23-1 Instruction encodings for debug System register access in the (op0==0b10) encoding space

D23.3 Moves to and from non-debug System registers, Special-purpose registers

The instructions that move data to and from non-debug System registers are encoded with `op0== 0b11`, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:

31 30 29 28	27 26 25 24	23 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0 1	0 1 0 1	0 0	L	1 1	op1	CRn	CRm	op2	Rt
				op0					

The value of `CRn` provides the next level of decode of these instructions, as follows:

`CRn` == {`0b0000`, `0b0001`, `0b0010`, `0b0011`, `0b0101`, `0b0110`, `0b0111`, `0b1001`, `0b1010`, `0b1100`, `0b1101`, `0b1110`}

See Instructions for accessing non-debug System registers.

`CRn` == {`0b0100`}

See Instructions for accessing Special-purpose registers.

`CRn`=={`0b1011`, `0b1111`}

See Reserved encodings for IMPLEMENTATION DEFINED registers.

D23.3.1 Instructions for accessing non-debug System registers

The A64 instructions for accessing System registers are:

```
MSR <System_register>, Xt     ; Write to 64-bit System register
MSRR <System_register>, Xt    ; Write to 128-bit System register
MRS Xt, <System_register>     ; Read from 64-bit System register
MRRS Xt, <System_register>    ; Read from 128-bit System register
```

Where `<System_register>` is the register name, for example MIDR_EL1.

This section includes only the System register access encodings for which both:

- `op0` is `0b11`.
- The value of `CRn` is one of {`0b0000`, `0b0001`, `0b0010`, `0b0011`, `0b0100`, `0b0101`, `0b0110`, `0b0111`, `0b1001`, `0b1010`, `0b1100`, `0b1101`, `0b1110`}.

Note

- These encodings access the registers that are equivalent to the AArch32 System registers in the (`coproc` == `0b1111`) encoding space. For more information, see Mapping of the System registers between the Execution states.
- While this group is described as accessing the non-debug System registers, its correct characterization is by the {`op0`, `CRn`} values given in this subsection, and the group includes the debug System registers DLR_EL0, DSPSR_EL0, MDCR_EL2, MDCR_EL3, and SDER32_EL3, which are described in Debug System registers. These registers are exceptions to the standard encoding of debug System registers, which has `op0` == `0b10`. See Instructions for accessing debug System registers for more information.

Direct accesses to some regions of the System register encoding space have a defined behavior even if no register is currently allocated or implemented for the encodings in those regions. The Feature ID space is the System register space in AArch64 with `op0==3, op1={0, 1, 3}, CRn==0, CRm={0-7}, op2={0-7}`. The properties for this space are that:

- For unused encodings in the part of the space that has `op1` == `0` and `CRm` == `{2-7}`, the following apply:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - If FEAT_FGT is not implemented, it is IMPLEMENTATION DEFINED whether direct reads can be trapped by HCR_EL2.TID3.
  - If FEAT_FGT is implemented, direct reads can be trapped by HCR_EL2.TID3.
  - If FEAT_IDTE3 is implemented, direct reads can be trapped by SCR_EL3.TID3.
  - If FEAT_IDST is not implemented, direct reads from EL0 are UNDEFINED.
  - If FEAT_IDST is implemented, direct reads from EL0 are trapped to EL1 if HCR_EL2.TGE is 0, or to EL2 if HCR_EL2.TGE is 1.
  - Direct reads from EL1 or above that are not trapped behave as Reserved, RES0 to ensure correct behavior if the encodings are used for ID registers in the future.
- For unused encodings in the part of the space that has either `op1 == 0` and `CRm == 0`, or `op1 == {1, 3}`, the following apply:
  - If FEAT_IDST is not implemented, direct reads are UNDEFINED and therefore generate exceptions reported with EC syndrome value `0x00`.
  - If FEAT_IDST is implemented, direct reads generate exceptions reported with EC syndrome value `0x18`.
  - The behavior for direct reads is consistent with the pseudocode function `UnimplementedIDRegister()`.

The instruction encoding for these accesses is:

31 30 29 28	27 26 25 24	23 22	21	20 19	18 16	15 12	11 8	7 5	4 0
1 1 0 1	0 1 0 1	0 0	L	1 1	op1	CRn	CRm	op2	Rt
				op0					

See text for permitted values of CRn

Table D23-2 shows the encodings of the register access instructions.

See the register descriptions for information about the control that determines whether these accesses are permitted.

D23.3.1.1 About the GIC System registers

From version 3 of the GIC architecture, the specification defines three groups of System registers, identified by the prefix of the register name:

ICC_ GIC physical CPU interface System registers.

ICH_ GIC virtual interface control System registers.

ICV_ GIC Virtual CPU interface System registers.

Note

These registers are in addition to the GIC memory-mapped register groups GICC_, GICD_, GICH_, GICR_, GICV_, and GITS_.

When implemented, the GIC System registers form part of an Arm processor implementation, and therefore these registers are included in the register summaries. However, the registers are defined only in the GIC Architecture Specification.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

As Table D23-2 shows, the ICV_* registers have the same {op0, op1, CRn, CRm, op2} encodings as the corresponding ICC_* registers. For these encodings, GIC register configuration fields determine which register is accessed.

For more information, see the *Arm® Generic Interrupt Controller Architecture Specification, GIC architecture version 3 and version 4* (ARM IHI 0069).

D23.3.2 Reserved encodings for IMPLEMENTATION DEFINED registers

The System register encoding space with op0 == 0b11 reserves the following encodings for IMPLEMENTATION DEFINED registers:

31	30	29	28	27	26	25	24	23	22	21	20	19	18 … 16	15	14	13	12	11 … 8	7 … 5	4 … 0
1	1	0	1	0	1	0	1	0	0	L	op0		op1	1	x	1	1	CRm	op2	Rt
														CRn						

The value of L defines the access type and the use of Rt as follows:

0 Write the value in Rt to the IMPLEMENTATION DEFINED register.

1 Read the value of the IMPLEMENTATION DEFINED register to Rt.

For more information about these encodings, see S3_<op1>_<Cn>_<Cm>_<op2>, IMPLEMENTATION DEFINED Registers.

As that section describes, any IMPLEMENTATION DEFINED registers are accessed in a similar way to architecturally-defined System registers, using MRS, MRRS, MSR, and MSRR instructions, see:

- MRS.
- MRRS.
- MSR (immediate).
- MSR (register).
- MSRR.

Accesses to these registers that are not trapped are permitted to be UNDEFINED. Arm recommends that IMPLEMENTATION DEFINED registers that are not UNDEFINED follow the principles in Principles of the System instruction class encoding.

The Arm architecture guarantees not to define any register name prefixed with *IMP_* as part of the standard Arm architecture.

Note

Arm strongly recommends that any register names created in the IMPLEMENTATION DEFINED register spaces be prefixed with *IMP_* and postfixed with *_ELx*, where appropriate.

Chapter D24
AArch64 System Register Descriptions

This chapter defines the AArch64 System registers. It contains the following sections:

- About the AArch64 System registers
- General system control registers
- Debug System registers
- Trace registers
- Performance Monitors registers
- Activity Monitors registers
- Statistical Profiling Extension registers
- Branch Record Buffer Extension registers
- RAS registers
- Generic Timer registers
- Guarded Control Stack registers
- MPAM registers

Non-Confidential

D24.1 About the AArch64 System registers

The following sections describe common features of the AArch64 registers:

- Reading the System register descriptions.
- General behavior of accesses to the AArch64 System registers.
- Principles of the ID scheme for fields in ID registers.

D24.1.1 Reading the System register descriptions

D24.1.1.1 Registers and register names

The title of each section in AArch64 System Register Descriptions refers to a register.

An AArch64 register is accessed using one of the functions `MRS`, `MSR (register)`, `MSR (immediate)`, `MRRS`, or `MSRR`, using an encoding value.

The encoding value is associated with a mnemonic register name, which may not be the same as the name of the register. Tables listing all encodings, mnemonics and the register they access are found in Table D23-1 and Table D23-2.

Some registers can be accessed using multiple encodings.

For example:

- When virtualization is implemented, see System and Special-purpose register redirection.
- When there is an alias mnemonic, see System and Special-purpose register aliasing.
- When a mnemonic accesses a register in an array of registers, for example PMXEVCNTR_EL0.

D24.1.1.2 Register arrays and names

Arrays of registers are indicated by an `<n>` or `<m>` in the title of the register. These are a shortcut for referencing a number of registers with identical field layout. The index letter is considered to be replaced by a number for each individual register in the array.

There are several different ways for a register in an array to be associated with an encoding:

- The same number of encodings as there are registers in the array. The mnemonic will include an index letter, which may not be the same as the register array index letter, and the encodings will be represented in terms of that index letter. For example, see PMEVCNTR<n>.
- One encoding for all registers in the array. Another register is used to select the register in the array to be accessed. For example, see PMXEVCNTR_EL0.
- A group of encodings, used to access a subset of the register array, with another register used to select which bank of registers is accessed. For example, see SPMEVCNTR<n>_EL0.

D24.1.1.3 Multiple conditions in register fields, resets or accessors

Throughout the register descriptions, conditions are used to represent changes of behavior. If multiple conditions apply to the same item, they are not necessarily mutually exclusive. The conditions are ordered so that the first true condition applies, and no further conditions are considered.

D24.1.1.4 Direct register access

In the pseudocode representing access to a particular encoding, direct access to a register is represented by a function using the same name as the register.

On a direct read, the architecturally visible value includes any field-level access controls or conditional read constraints on the value read from the register using the function.

On a direct write, any field-level access controls and constraints are applied to the value before it is written to the register using the function.

The accessibility pseudocode in the register description represents the traps and redirections for read and write accesses, and in most cases, the function to read or write the register is simple. In a few cases, there are more complex behaviors that would not be possible to represent on the register page, and these are documented in A-profile Architecture Pseudocode.

D24.1.1.5 Fixed values and reserved values in the System registers

Some fields or bit ranges in registers are described as reserved, or have a fixed value.

For information on the glossary terms RAZ, RES0, RAO, and RES1, see Fixed values in AArch64 instruction and System register descriptions.

For information on the behavior of reserved values, see Reserved values in System and memory-mapped registers and translation table entries.

D24.1.2 General behavior of accesses to the AArch64 System registers

The following subsections give general information about the behavior of accesses to the System registers:

- Reset behavior of AArch64 System registers.
- Synchronization requirements for AArch64 System registers.

D24.1.2.1 Reset behavior of AArch64 System registers

Reset values apply only to RW registers and fields, however:

- Some RO registers or fields, including feature ID registers and some status registers or register fields, always return a known value.
- Some RW and RO registers or register fields return status information about the PE. Unless the register description indicates that the value is UNKNOWN on reset, a read of the register immediately after a reset returns valid information.
- Some RW and RO registers and fields are aliases of other registers or fields. In these cases, the reset behavior of the aliased register or field determines the value returned by a read of the register immediately after a reset.
- WO registers that only have an effect on writes do not have meaningful reset values. However, an access to a WO register might affect underlying state, and that state might have a defined reset value.
- IMPLEMENTATION DEFINED registers have IMPLEMENTATION DEFINED reset behavior.

After a reset, only a limited subset of the PE state is guaranteed to be set to defined values. Also, for debug and trace System registers, reset requirements must take account of different levels of reset. For more information about the reset behavior of System registers when the PE resets into an Exception level that is using AArch64, see:

- Reset behavior.
- The appropriate Trace architecture specification, for the Trace System registers.

For a PE reset into an Exception level that is using AArch64, the architecture defines which AArch64 System registers have a defined reset value, and when that defined reset value applies. The register descriptions include this information, and Reset behavior summarizes these architectural requirements. Otherwise, RW registers that have a meaningful reset value reset to an architecturally UNKNOWN value.

Note

When the PE resets into an Exception level that is using AArch32, no PE state that relates to execution in AArch64 state is accessible until another reset causes the Execution state to change to AArch64. Therefore, on a reset into AArch32 state, PE state that relates only to execution in AArch64 state cannot have a meaningful reset value.

D24.1.2.1.1 Pseudocode description of resetting System registers

The `AArch64_ResetSystemRegisters()` pseudocode function resets all System registers, and register fields, that have defined reset values, as described in this section and Reset behavior.

Note

For debug and trace System registers, this function resets registers as defined for the appropriate level of reset.

D24.1.2.2 Synchronization requirements for AArch64 System registers

Reads of the System registers can occur out of order with respect to earlier instructions executed on the same PE, provided that both:

- Any data dependencies between the instructions, including read-after-read dependencies, are respected.
- The reads to the register do not occur earlier than the most recent Context Synchronization event to its architectural position in the instruction stream.

Note

In particular, the values read from System registers that hold self-incrementing counts, such as the Performance Monitors counters or the Generic Timer counter or timers, could be accessed from any time after the previous Context Synchronization event. For example, where a memory access is used to communicate a read of such a counter, an `ISB` must be inserted between the read of the memory location that is known to have returned its data, either as a result of a condition on that data or of the read having completed, and the read of the counter, if it is necessary that the counter returns a count value after the memory communication.

Unless otherwise stated in its System register definition, a direct write to a System register requires synchronization before software can rely on the effects of that write to affect instructions appearing in program order after the write. This does not apply to Special-purpose registers. For more information, see Instructions for accessing Special-purpose registers. Direct writes to System registers are not allowed to affect any instructions appearing in program order before the direct write. The only exceptions are:

- All direct writes to the same register, that use the same encoding for that register, are guaranteed to occur in program order relative to each other.
- All direct writes to a register occur in program order with respect to all direct reads to the same register using the same encoding.
- Any System register access that an Arm *Architecture Specification* or equivalent specification defines as not requiring synchronization.
- When FEAT_BRBE is implemented, execution of `BRB INJ` does not require explicit synchronization to use the result of direct writes to the Branch record injection data registers in program order before `BRB INJ`.

Explicit synchronization occurs as a result of a Context Synchronization event, which is one of the following events:

- Execution of an `ISB` instruction.
- Exception entry, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and defines that exception entries to this Exception level are Context Synchronization events.
- Exception return, if FEAT_ExS is not implemented, or if FEAT_ExS is implemented and defines that exception returns from this Exception level are Context Synchronization events.
- Execution of a `DCPS` instruction in Debug state.
- Execution of a `DRPS` instruction in Debug state.
- Exit from Debug state.

Note

The `ISB` and exception entry events are applicable both in Debug state and in Non-debug state.

The pseudocode for each of these events defines the point at which the explicit synchronization takes effect, as a result of a call to the `SynchronizeContext()` function or `InstructionSynchronizationBarrier()` function. The principle behind the position of the call to `SynchronizeContext()` or `InstructionSynchronizationBarrier()` is that it occurs before indirect reads of System registers that are used in the construction of the target context, but is permitted to occur after indirect reads of System registers that apply to the context in which the instruction is executed or from which the event is taken.

Note

For some instructions, this means that some System registers are indirectly read before the explicit synchronization, and therefore changes to those System registers might need an explicit Context synchronization event before the instruction. For example, changes to some fields of HCR_EL2 at EL2 need an explicit ISB in program order before an ERET instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In addition, any system instructions that cause a write to a System register must be synchronized before the result is guaranteed to be visible to subsequent direct reads of that System register.

Direct reads to any one of the following registers, using the same encoding, occur in program order relative to each other:

- ISR_EL1.
- The Generic Timer registers, that is, CNTPCT_EL0 and CNTVCT_EL0, and the Counter registers CNTP_TVAL_EL0, CNTV_TVAL_EL0, CNTHP_TVAL_EL2, and CNTPS_TVAL_EL1.
- DBGCLAIMCLR_EL1.
- The PMU Counters, that is, PMCCNTR_EL0, PMEVCNTR<n>_EL0, PMXEVCNTR_EL0, PMOVSCLR_EL0, and PMOVSSET_EL0.
- The System PMU Counters, that is, SPMEVCNTR<n>_EL0, SPMOVSCLR_EL0, and SPMOVSSET_EL0.
- The Debug Communications Channel System registers, that is, DBGDTRRX_EL0, DBGDTR_EL0, and MDCCSR_EL0.

All other direct reads of System registers can occur in any order if synchronization has not been performed.

Table D24-1 describes the synchronization requirements between two successive read or write accesses to the same register, where the ordering of the read or write accesses is:

1. Program order, in the event that both the reads or writes are caused by an instruction executed on this PE, other than one caused by a memory access by this PE.
2. The order of arrival of asynchronous reads and writes at the PE relative to the execution of instructions that cause reads or writes.
3. The order of arrival of asynchronous reads and writes at the PE relative to each other.

Table D24-1 Synchronization requirements

First read/write	Second read/write	Synchronization requirement
Direct read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None, see Notes
Direct write	Direct read	None
	Direct write	None
	Indirect read	Required
	Indirect write	None, see Notes
Indirect read	Direct read	None
	Direct write	None
	Indirect read	None
	Indirect write	None
Indirect write	Direct read	Required, see Notes
	Direct write	None, see Notes
	Indirect read	Required, see Notes
	Indirect write	None, see Notes

D24.1.2.2.1 Notes

The terms Direct read, Direct write, Indirect read, and Indirect write, as used in Table D24-1, are defined as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Direct read Where software uses an MRS or MRRS System register access instruction to read that register into a general purpose register.

Where a direct read of a register has a side-effect that changes the contents of a register, the effect of a direct read on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to have occurred, and be visible to subsequent direct or indirect reads or writes, if synchronization is performed after the direct read.

Direct write Where software uses an MSR (register) or MSRR access instruction to write to that register from a general purpose register.

Where a direct write to a register has an effect on the register that means that the value in the register is not always the last value that is written (as is the case with set and clear registers), the effect of a direct write on that register is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Indirect read Where an instruction uses a System register to establish operating conditions for the instruction, for example, the TTBR_ELx address or whether memory accesses are forced to be Non-cacheable. This includes situations where the contents of one System register selects what value is read or written using a different register. Indirect reads also include reads of the System register by external agents such as debuggers. Instruction execution from MDSTEPOP_EL1 is an indirect read of MDSTEPOP_EL1. Where an indirect read of a register has a side-effect that changes the contents of that register, that is defined to be an indirect write.

Indirect write Where a System register is written as the consequence of some other instruction, exception, operation, or by the asynchronous operation of an external agent, including the passage of time as seen in counters, timers, or performance counters, the assertion of interrupts, or writes from an external debugger.

Note

Registers such as the Exception Syndrome registers that are indirectly written as part of exception entry do not require additional synchronization. This behavior is independent of the value of SCTLR_ELx.EIS, and the list of affected registers is described in the definition of that field.

The value of a System register does not change unless one of the following occurs:

- As the result of a direct write to the register, that is not specified as being trapped, UNDEFINED or IGNORED.
- As the result of one of the specified indirect writes to the register.
- A reset, if the register has a specified reset behavior for that reset.
- The register holds an UNKNOWN value as the result of one of the above.

Where a direct read or write to a register is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two accesses.

Where an indirect write caused by a direct write is followed by an indirect write caused by an external agent, autonomous asynchronous event, or as a result of memory mapped write, synchronization is required to guarantee the order of those two indirect accesses.

Where a direct read to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated, the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct read and before the subsequent direct or indirect reads or writes.

Where a direct write to one register causes a bit or field in a different register (or the same register using a different encoding) to be updated as a side-effect of that direct write (as opposed to simply being a direct write to the different encoding), the change to the different register (or same register using a different encoding) is defined to be an indirect write. In this case, the indirect write is only guaranteed to be visible to subsequent direct or indirect reads or writes if synchronization is performed after the direct write and before the subsequent direct or indirect reads or writes.

Where indirect writes are caused by the actions of external agents such as debuggers, or by memory-mapped reads or writes by the PE, then an indirect write by that agent and mechanism to a register, followed by an indirect read by that agent and mechanism to the same register using the same address, does not require synchronization.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Where an indirect write occurs as a side-effect of an access, this happens atomically with the access, meaning no other accesses are allowed between the register access and its side-effect.

Note

Even though the 64-bit and 128-bit form of a System register share the same values of `{op0, op1, CRn, CRm, op2}`, they are considered to be distinct encodings. Therefore, explicit synchronization is required to guarantee ordering in all of the following cases:

- MSRR followed by an MRS from the same register.
- MSR (register) followed by an MRRS from the same register.

Where indirect writes to GCSPR_ELx are made by the following instructions, explicit synchronization is not required to be visible to direct reads, indirect reads, and indirect writes in program order after the initial indirect write:

- All Branch with Link instructions.
- All procedure return instructions.
- `GCSPOPM` and `GCSPUSHM`.
- `GCSPOPX`, `GCSPOPCX`, and `GCSPUSHX`.
- `GCSSS1` and `GCSSS2`.

Indirect writes caused by external agents, autonomous asynchronous events, or as a result of memory-mapped writes, to the registers shown in Table D24-2, are required to be observable to:

- Direct reads in finite time without explicit synchronization.
- Subsequent indirect reads without explicit synchronization.

Without explicit synchronization to guarantee the order of the accesses, where the same register is accessed by two or more of a System register access instruction, and external agent, and autonomous asynchronous event, or as a result of a memory-mapped access, the behavior must be as if the accesses occurred atomically and in any order. This applies even if the accesses occur simultaneously.

Table D24-2 Registers with a guarantee of observability, VMSAv8-64

Registers	Notes
ISR_EL1	Interrupt Status Register
DBGCLAIMCLR_EL1, DBGCLAIMSET_EL1	Debug CLAIM registers
CNTPCT_EL0, CNTVCT_EL0, CNTP_TVAL_EL0, CNTV_TVAL_EL0, CNTHP_TVAL_EL2, CNTPS_TVAL_EL1	Generic Timer registers
PMCCNTR_EL0, PMEVCNTR<n>_EL0, PMXEVCNTR_EL0, PMOVSCLR_EL0, PMOVSSET_EL0	PMU Counters
SPMEVCNTR<n>_EL0, SPMOVSCLR_EL0, SPMOVSSET_EL0	System PMU Counters
DBGDTRTX_EL0, DBGDTRRX_EL0, DBGDTR_EL0, and the DCC flags in MDCCSR_EL0 and EDSCR	Debug Communication Channel registers
EDSCR.PipeAdv	External Debug Status and Control Register

In addition to the requirements shown in Table D24-2:

- Indirect writes to the following registers as a result of memory-mapped writes, including accesses by external agents, are required to be observable to the indirect read made in determining the response to a subsequent memory-mapped access without explicit synchronization:
  - OSLAR_EL1. OSLAR_EL1 is indirectly read to determine whether the subsequent access is permitted.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

— EDLAR, if implemented. EDLAR is indirectly read to determine whether a subsequent write or side-effect of an access is ignored.

Note

This requirement is stricter than the general requirement for the observability of indirect writes.

- The requirement that an indirect write to the registers in Table D24-2 is observable to direct reads in finite time does not imply that all observers will observe the indirect write at the same time.

  For example, an increment of the system counter is an autonomous asynchronous event that performs an indirect write to the counter. This asynchronous event might generate a timer interrupt request, resulting in a Context Synchronization event. When a GIC is used, the timer interrupt might arrive at the GIC after the PE has taken an interrupt request from another source, but before software reads the current interrupt ID from the GIC. This means that the GIC might identify the timer interrupt as the current interrupt. Software must not assume that a subsequent direct read of the counter register is guaranteed to observe the updated value of that register.

  Although this example uses the counter-timer registers, it applies equally to other registers that might be linked to interrupt requests, including the PMU and Statistical Profiling status registers.
- When the PE is in Debug state, there are synchronization requirements for the Debug Communication Channel and Instruction Transfer registers. See DCC and ITR access in Debug state.

Note

- The provision of explicit synchronization requirements to System registers is provided to allow the direct access to these registers to be implemented in a small number of cycles, and that updates to multiple registers can be performed quickly with the synchronization penalty being paid only when the updates have occurred.
- Since toolkits might use registers such as the thread-local storage registers within compiled code, it is recommended that access to these registers is implemented to take a small number of cycles.
- While no synchronization is required between a direct write and a direct read, or between a direct read and an indirect write, this does not imply that a direct read causes synchronization of a previous direct write. That is, the sequence direct write → direct read → indirect read, with no intervening context synchronization, does not guarantee that the indirect read observes the result of the direct write.
- If FEAT_MTE_ASYNC is implemented, one of the following is required between an indirect write to TFSRE0_EL1, or any TFSR_ELx accessible at ELy, and a direct read or direct write of that register:

  — A `DSB` instruction with the LD qualifier, or neither the LD nor ST qualifier.
  — An exception entry to ELy with SCTLR_ELy.ITFSB set to 1.

D24.1.3 Principles of the ID scheme for fields in ID registers

The Arm architecture specifies a number of *ID registers* that are characterized as comprising a set of 4-bit *ID fields,* Each ID field identifies the presence, and possibly the level of support for, a particular feature in an implementation of the architecture. These fields follow an architectural model that aids their use by software and provides future compatibility. This section describes that model. ID registers to which this scheme applies identifies the set of ID registers.

A small number of ID fields do not follow the scheme described in this section. In these cases, the field description states that it does not follow this scheme.

Note

- The ID fields described here are unlike the ones that enumerate the number of resources, such as the number of breakpoints, watchpoints, or performance monitors.
- ID fields that do not follow this scheme include the ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, see Alternative ID scheme used for the Performance Monitors Extension version.
- The presence of an ID field for a feature does not imply that the feature is optional.

To provide forward compatibility, software can rely on the features of these fields that are described in this section.

The ID fields, which are either signed or unsigned, use increasing numerical values to indicate increases in functionality. Therefore, for an unsigned ID field, if the value `0x1` indicates the presence of some instructions, then the value `0x2` will

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

indicate the presence of those instructions plus some additional instructions or functionality. This means software can be written in the form:

```
if (value >= number) {
    // do something that relies on the value of the feature
}
```

For ID fields where the value `0x0` defines that a feature is not present, the field holds an unsigned value. This covers the vast majority of such fields.

In a few cases, the architecture has been changed to permit implementations to exclude a feature that has previously been required and for which no ID field has been defined. In these cases, a new ID field is defined and:

- The field holds a signed value.
- The field value `0x0` indicates that the feature is implemented.
- The field value `0xF` indicates that the feature is not implemented.
- Increasingly negative values indicate additional aspects of the architecture that are not implemented as a result of the feature not being implemented.
- Software that depends on the feature can use the test:

```
if value >= 0 {
    // Software features that depend on the presence of the hardware feature
}
```

In some cases, it has been decided retrospectively that the increase in functionality between two consecutive numerical values is too great, and it is desirable to permit an intermediate degree of functionality, and the means to discover this. This is done by the introduction of a *fractional* field that both:

- Is referred to in the definition of the original field.
- Applies only when the original field is at the lower value of the step.

In principle, a fractional field can be used for two different fractional steps, with different meanings associated with each of these steps. For this reason, a fractional field must be interpreted in the context of the field to which it relates and the value of that field. Example D24-1 shows the use of such a field.

Example D24-1 Example of the use of a fractional field

For a field describing some class of functionality:

- The value `0x1` was defined as indicating that item A is present.
- The value `0x2` was defined as indicating that items B and C are present, in addition to item A.

Subsequently, it might be necessary to introduce a second ID field to indicate that A and B only are present. This new field is a fractional field, and might be defined as having the value `0x1` when A and B only are present. This fractional field is valid only when the original ID field has the value `0x1`.

This approach means that:

- Software that depends on the test if `(value >= 0x2)` can rely on features A, B, and C being present,
- Software that depends on the test `if (value >= 0x1)` can rely on feature A being present.
- If new software needs to check only that features A and B are present, then it can test:

```
if (value >= 0x2 || (value == 0x1 && fractional_value >= 0x1)) {
    // Software features that depend on A and B only
}
```

A fractional field uses the same approach of increasing numerical values indicating increasing functionality, and the fractional approach can also be applied recursively to fractional fields.

Non-Confidential

Unused ID fields, and fractional fields that are not applicable, are RES0 to allow their future use when features, or fractional implementation options, are added.

D24.1.3.1 ID registers to which this scheme applies

This scheme applies to the following registers:

AArch64 System registers

- The AArch64 views of the AArch32 feature ID registers given by:
  - The AArch32 Auxiliary Feature register ID_AFR0_EL1.
  - The AArch32 Processor Feature registers ID_PFR0_EL1, ID_PFR1_EL1, and ID_PFR2_EL1.
  - The AArch32 Debug Feature register ID_DFR0_EL1 and ID_DFR1_EL1.
  - The AArch32 Memory Model Feature registers ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, ID_MMFR4_EL1, and ID_MMFR5_EL1.
  - The AArch32 Instruction Set Attribute registers ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, and ID_ISAR6_EL1.
  - The AArch32 Media and VFP Feature registers MVFR0_EL1, MVFR1_EL1, and MVFR2_EL1.
- The AArch64 Auxiliary Feature registers ID_AA64AFR0_EL1 and ID_AA64AFR1_EL1.
- The AArch64 Processor Feature registers ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, and ID_AA64PFR2_EL1.
- The AArch64 Debug Feature registers ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, and ID_AA64DFR2_EL1.
- The AArch64 Memory Model Feature registers ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64MMFR2_EL1, ID_AA64MMFR3_EL1, and ID_AA64MMFR4_EL1.
- The AArch64 Instruction Set Attribute registers ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64ISAR2_EL1, and ID_AA64ISAR3_EL1.
- The AArch64 SVE Feature ID register ID_AA64ZFR0_EL1.

AArch32 System registers

- The AArch32 Auxiliary Feature register ID_AFR0.
- The AArch32 Processor Feature registers ID_PFR0, ID_PFR1, and ID_PFR2.
- The AArch32 Debug Feature register ID_DFR0 and ID_DFR1.
- The AArch32 Memory Model Feature registers ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_MMFR4, and ID_MMFR5.
- The AArch32 Instruction Set Attribute registers ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, ID_ISAR5, and ID_ISAR6.
- The AArch32 Media and FP Feature registers MVFR0, MVFR1, and MVFR2.

Memory-mapped registers

- The External Debug Processor Feature register EDPFR.
- The External Debug Feature register EDDFR, EDDFR1, and EDDFR2.
- The External Debug Auxiliary Processor Feature register EDAA32PFR.

D24.1.3.2 Alternative ID scheme used for the Performance Monitors Extension version

The ID_AA64DFR0_EL1.PMUVer, ID_DFR0_EL1.PerfMon, ID_DFR0.PerfMon and EDDFR.PMUVer fields, that identify the version of the Performance Monitors Extension, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value `0xF` indicates that the Arm-architected Performance Monitors Extension is not implemented.
- If the field value is not `0xF`, the field is treated as an unsigned value, as described for the standard ID scheme.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This means that software that depends on the implementation of a particular version of the Arm Performance Monitors Extension must be written in the form:

```
if (value != 0xF and value >= number) {
    // do something that relies on version 'number' of the feature
}
```

For these fields, Arm deprecates use of the value `0xF` in new implementations.

D24.1.3.3 Alternative ID scheme used for ID_AA64MMFR0_EL1 stage 2 granule sizes

The ID_AA64MMFR0_EL1.{TGran4_2, TGran64_2, TGran16_2} fields that identify the memory translation stage 2 granule size, do not follow the standard ID scheme. Software must treat these fields as follows:

- The value `0x0` indicates that support is identified by another field.
- If the field value is not `0x0`, the value indicates the level of support provided.

This means that software should use a test of the form:

```
if (field !=0 and field > value) {
    // do something that relies on the value of the feature
}
```

D24.1.3.4 Alternative ID scheme used for ID_AA64SMFR0_EL1 and ID_AA64FPFR0_EL1

Apart from the ID_AA64SMFR0_EL1.SMEver field, which is a 4-bit unsigned integer conforming to the standard scheme, software must treat the other fields in these registers as follows:

- A 1-bit field value where the bit is `0b0` indicates that the specified feature or instructions described by this field are not implemented.
- A 1-bit field value where the bit is `0b1` indicates that the specified feature or instructions described by this field are implemented.
- In ID_AA64SMFR0_EL1, a 4-bit field indicates whether a group of related SME instructions is implemented, with permitted values defined in the field description. Bits within such a field which only permit the value `0b0000` might be used to identify new instructions in a future version of SME, without changing the meaning of those bits that permit the value `0b0001`.

D24.2 General system control registers

This section lists the System registers in AArch64 that are not part of one of the other listed groups.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D24.2.1 ACCDATA_EL1, Accelerator Data

The ACCDATA_EL1 characteristics are:

Purpose

Holds the lower 32 bits of the data that is stored by an ST64BV0, Single-copy atomic 64-byte EL0 store instruction.

Configuration

This register is present only when FEAT_LS64_ACCDATA is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to ACCDATA_EL1 are UNDEFINED.

Attributes

ACCDATA_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

ACCDATA, bits [31:0]

Accelerator Data field. Holds bits[31:0] of the data that is stored by an ST64BV0 instruction.

Accessing ACCDATA_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ACCDATA_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b1101	0b0000	0b101

D24.2.2 ACTLR_EL1, Auxiliary Control Register (EL1)

The ACTLR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for execution at EL1 and EL0.

Note

Arm recommends the contents of this register have no effect on the PE when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, and instead the configuration and control fields are provided by the ACTLR_EL2 register. This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

Configuration

AArch64 System register ACTLR_EL1 bits [31:0] are architecturally mapped to AArch32 System register ACTLR[31:0].

AArch64 System register ACTLR_EL1 bits [63:32] are architecturally mapped to AArch32 System register ACTLR2[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ACTLR_EL1 are UNDEFINED.

Attributes

ACTLR_EL1 is a 64-bit register.

Field descriptions

63 … 32	31 … 0
IMPLEMENTATION DEFINED	IMPLEMENTATION DEFINED

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL1

If the IMPLEMENTATION DEFINED ACTLR_EL12 accessor is implemented, the following behaviors are also implemented:

- MRS/MSR to ACTLR_EL1 from EL2 when the Effective value of HCR_EL2.E2H is 1 accesses ACTLR_EL2.
- MRS/MSR to ACTLR_EL1 from EL1 when the Effective value of HCR_EL2.{NV2, NV1, NV} is {1,0,1} accesses ACTLR_EL1 directly and is not transformed to a memory access.
- MRS/MSR to ACTLRALIAS_EL1 behaves in the same way as ACTLR_EL1.

If FEAT_SRMASK is implemented, MSR to ACTLR_EL1 at EL1 are masked by ACTLRMASK_EL1.

Accesses to this register use the following encodings in the System register encoding space:

D24.2.3 ACTLR_EL2, Auxiliary Control Register (EL2)

The ACTLR_EL2 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED configuration and control options for EL2.

Note

Arm recommends the contents of this register are updated to apply to EL0 when the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, gaining configuration and control fields from the ACTLR_EL1. This avoids the need for software to manage the contents of these register when switching between a Guest OS and a Host OS.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

AArch64 System register ACTLR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HACTLR[31:0].

AArch64 System register ACTLR_EL2 bits [63:32] are architecturally mapped to AArch32 System register HACTLR2[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ACTLR_EL2 are UNDEFINED.

Attributes

ACTLR_EL2 is a 64-bit register.

Field descriptions

63 … 32	31 … 0
IMPLEMENTATION DEFINED	IMPLEMENTATION DEFINED

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing ACTLR_EL2

If FEAT_SRMASK is implemented, MSR to ACTLR_EL2 at EL2 are masked by ACTLRMASK_EL2.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ACTLR_EL2

D24.2.7 AFSR0_EL1, Auxiliary Fault Status Register 0 (EL1)

The AFSR0_EL1 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL1.

Configuration

AArch64 System register AFSR0_EL1 bits [31:0] are architecturally mapped to AArch32 System register ADFSR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to AFSR0_EL1 are UNDEFINED.

Attributes

AFSR0_EL1 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AFSR0_EL1

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL3 using the accessor name `AFSR0_EL1` or `AFSR0_EL12` are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, AFSR0_EL1
```

D24.2.11 AFSR1_EL2, Auxiliary Fault Status Register 1 (EL2)

The AFSR1_EL2 characteristics are:

Purpose

Provides additional IMPLEMENTATION DEFINED fault status information for exceptions taken to EL2.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

AArch64 System register AFSR1_EL2 bits [31:0] are architecturally mapped to AArch32 System register HAIFSR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to AFSR1_EL2 are UNDEFINED.

Attributes

AFSR1_EL2 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AFSR1_EL2

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL2 using the accessor name `AFSR1_EL2` or `AFSR1_EL1` are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, AFSR1_EL2
```

D24.2.17 AMAIR_EL1, Auxiliary Memory Attribute Indirection Register (EL1)

The AMAIR_EL1 characteristics are:

Purpose

Provides IMPLEMENTATION DEFINED memory attributes for the memory regions specified by MAIR_EL1.

Configuration

AArch64 System register AMAIR_EL1 bits [31:0] are architecturally mapped to AArch32 System register AMAIR0[31:0].

AArch64 System register AMAIR_EL1 bits [63:32] are architecturally mapped to AArch32 System register AMAIR1[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to AMAIR_EL1 are UNDEFINED.

Attributes

AMAIR_EL1 is a 64-bit register.

Field descriptions

AMAIR_EL1 is permitted to be cached in a TLB.

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing AMAIR_EL1

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL3 using the accessor name `AMAIR_EL1` or `AMAIR_EL12` are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

D24.2.21 APDAKeyLo_EL1, Pointer Authentication Key A for Data (bits[63:0])

The APDAKeyLo_EL1 characteristics are:

Purpose

Holds bits[63:0] of key A used for authentication of data pointer values.

Note

The term APDAKey_EL1 is used to describe the concatenation of APDAKeyHi_EL1: APDAKeyLo_EL1.

Configuration

This register is present only when FEAT_PAuth is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to APDAKeyLo_EL1 are UNDEFINED.

Attributes

APDAKeyLo_EL1 is a 64-bit register.

Field descriptions

63 … 32	31 … 0
64 bit value, bits[63:0] of the 128 bit pointer authentication key value	64 bit value, bits[63:0] of the 128 bit pointer authentication key value

APDAKeyLo, bits [63:0]

64 bit value, bits[63:0] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APDAKeyLo_EL1

D24.2.24 APGAKeyHi_EL1, Pointer Authentication Key A for Code (bits[127:64])

The APGAKeyHi_EL1 characteristics are:

Purpose

Holds bits[127:64] of key used for generic pointer authentication code.

Note

The term APGAKey_EL1 is used to describe the concatenation of APGAKeyHi_EL1: APGAKeyLo_EL1.

Configuration

This register is present only when FEAT_PAuth is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to APGAKeyHi_EL1 are UNDEFINED.

Attributes

APGAKeyHi_EL1 is a 64-bit register.

Field descriptions

```
63                                                                                                                  32
|                                                                                                                   |
|                 64 bit value, bits[127:64] of the 128 bit pointer authentication key value                        |

31                                                                                                                   0
|                                                                                                                   |
|                 64 bit value, bits[127:64] of the 128 bit pointer authentication key value                        |
```

APGAKeyHi, bits [63:0]

64 bit value, bits[127:64] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APGAKeyHi_EL1

Accesses to this register use the following encodings in the System register encoding space:

```

D24.2.25 APGAKeyLo_EL1, Pointer Authentication Key A for Code (bits[63:0])

The APGAKeyLo_EL1 characteristics are:

Purpose

Holds bits[63:0] of key used for generic pointer authentication code.

Note

The term APGAKey_EL1 is used to describe the concatenation of APGAKeyHi_EL1: APGAKeyLo_EL1.

Configuration

This register is present only when FEAT_PAuth is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to APGAKeyLo_EL1 are UNDEFINED.

Attributes

APGAKeyLo_EL1 is a 64-bit register.

Field descriptions

63 … 32	31 … 0
64 bit value, bits[63:0] of the 128 bit pointer authentication key value	64 bit value, bits[63:0] of the 128 bit pointer authentication key value

APGAKeyLo, bits [63:0]

64 bit value, bits[63:0] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APGAKeyLo_EL1

D24.2.29 APIBKeyLo_EL1, Pointer Authentication Key B for Instruction (bits[63:0])

The APIBKeyLo_EL1 characteristics are:

Purpose

Holds bits[63:0] of key B used for authentication of instruction pointer values.

Note

The term APIBKey_EL1 is used to describe the concatenation of APIBKeyHi_EL1: APIBKeyLo_EL1.

Configuration

This register is present only when FEAT_PAuth is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to APIBKeyLo_EL1 are UNDEFINED.

Attributes

APIBKeyLo_EL1 is a 64-bit register.

Field descriptions

63 … 32	31 … 0
64 bit value, bits[63:0] of the 128 bit pointer authentication key value	64 bit value, bits[63:0] of the 128 bit pointer authentication key value

APIBKeyLo, bits [63:0]

64 bit value, bits[63:0] of the 128 bit pointer authentication key value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing APIBKeyLo_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, APIBKeyLo_EL1
```

D24.2.30 CCSIDR2_EL1, Current Cache Size ID Register 2

The CCSIDR2_EL1 characteristics are:

Purpose

Provides the information about the architecture of the currently selected cache from bits[63:32] of CCSIDR_EL1.

Configuration

In an implementation which does not support AArch32 at EL1, it is IMPLEMENTATION DEFINED whether reading this register gives an UNKNOWN value or is UNDEFINED.

The implementation includes one CCSIDR2_EL1 for each cache that it can access. CSSELR_EL1 selects which Cache Size ID Register is accessible.

AArch64 System register CCSIDR2_EL1 bits [31:0] are architecturally mapped to AArch32 System register CCSIDR2[31:0].

This register is present only when FEAT_CCIDX is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to CCSIDR2_EL1 are UNDEFINED.

Attributes

CCSIDR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:24]

Reserved, RES0.

NumSets, bits [23:0]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Accessing CCSIDR2_EL1

If CSSELR_EL1.{TnD, Level, InD} is programmed to a cache level that is not implemented, then on a read of the CCSIDR2_EL1 the behavior is CONSTRAINED UNPREDICTABLE, and can be one of the following:

- The CCSIDR2_EL1 read is treated as NOP.
- The CCSIDR2_EL1 read is UNDEFINED. If FEAT_IDST is implemented, this is permitted to be reported with EC syndrome value `0x18`.
- The CCSIDR2_EL1 read returns an UNKNOWN value.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CCSIDR2_EL1
```

D24.2.31 CCSIDR_EL1, Current Cache Size ID Register

The CCSIDR_EL1 characteristics are:

Purpose

Provides information about the architecture of the currently selected cache.

Configuration

The implementation includes one CCSIDR_EL1 for each cache that it can access. CSSELR_EL1 selects which Cache Size ID Register is accessible.

AArch64 System register CCSIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CCSIDR[31:0].

AArch64 System register CCSIDR_EL1 bits [63:32] are architecturally mapped to AArch32 System register CCSIDR2[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to CCSIDR_EL1 are UNDEFINED.

Attributes

CCSIDR_EL1 is a 64-bit register.

Field descriptions

When FEAT_CCIDX is implemented:

Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Bits [63:56]

Reserved, RES0.

NumSets, bits [55:32]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Bits [31:24]

Reserved, RES0.

Associativity, bits [23:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

LineSize, bits [2:0]

(Log_2(Number of bytes in cache line)) - 4. For example:

- For a line length of 16 bytes: $Log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: $Log_2(32) = 5$, LineSize entry = 1.

Note

The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.

When FEAT_MTE2 is implemented, where a cache only holds Allocation tags, this field is RES0.

Otherwise:

Note

The parameters NumSets, Associativity, and LineSize in these registers define the architecturally visible parameters that are required for the cache maintenance by Set/Way instructions. They are not guaranteed to represent the actual microarchitectural features of a design. You cannot make any inference about the actual sizes of caches based on these parameters.

Bits [63:32]

Reserved, RES0.

Bits [31:28]

Reserved, UNKNOWN.

NumSets, bits [27:13]

(Number of sets in cache) - 1, therefore a value of 0 indicates 1 set in the cache. The number of sets does not have to be a power of 2.

Associativity, bits [12:3]

(Associativity of cache) - 1, therefore a value of 0 indicates an associativity of 1. The associativity does not have to be a power of 2.

LineSize, bits [2:0]

(Log_2(Number of bytes in cache line)) - 4. For example:

- For a line length of 16 bytes: $Log_2(16) = 4$, LineSize entry = 0. This is the minimum line length.
- For a line length of 32 bytes: $Log_2(32) = 5$, LineSize entry = 1.

When FEAT_MTE2 is implemented, where a cache only holds Allocation tags, this field is RES0.

Note

The C++ 17 specification has two defined parameters relating to the granularity of memory that does not interfere. For generic software and tools, Arm will set the hardware_destructive_interference_size parameter to 256 bytes and the hardware_constructive_interference_size parameter to 64 bytes.

D24.2.32 CLIDR_EL1, Cache Level ID Register

The CLIDR_EL1 characteristics are:

Purpose

Identifies the type of cache, or caches, that are implemented at each level and can be managed using the architected cache maintenance instructions that operate by set/way, up to a maximum of seven levels. Also identifies the Level of Coherence (LoC) and Level of Unification (LoU) for the cache hierarchy.

Configuration

AArch64 System register CLIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CLIDR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to CLIDR_EL1 are UNDEFINED.

Attributes

CLIDR_EL1 is a 64-bit register.

Field descriptions

Bits [63:47]

Reserved, RES0.

Ttype<n> , bits [2(n-1)+34:2(n-1)+33], for n = 7 to 1

When FEAT_MTE2 is implemented:

Tag cache type. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy.

Ttype<n>	Meaning
0b00	No Tag Cache.
0b01	Separate Allocation Tag Cache.
0b10	Unified Allocation Tag and Data cache, Allocation Tags and Data in unified lines.
0b11	Unified Allocation Tag and Data cache, Allocation Tags and Data in separate lines.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ICB, bits [32:30]

Inner cache boundary. This field indicates the boundary for caching Inner Cacheable memory regions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ICB	Meaning
0b000	Not disclosed by this mechanism.
0b001	L1 cache is the highest Inner Cacheable level.
0b010	L2 cache is the highest Inner Cacheable level.
0b011	L3 cache is the highest Inner Cacheable level.
0b100	L4 cache is the highest Inner Cacheable level.
0b101	L5 cache is the highest Inner Cacheable level.
0b110	L6 cache is the highest Inner Cacheable level.
0b111	L7 cache is the highest Inner Cacheable level.

Access to this field is RO.

LoUU, bits [29:27]

Level of Unification Uniprocessor for the cache hierarchy.

For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

Note

This field does not describe the requirements for instruction cache invalidation. See CTR_EL0.DIC.

Note

When FEAT_S2FWB is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

LoC, bits [26:24]

Level of Coherence for the cache hierarchy.

For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

LoUIS, bits [23:21]

Level of Unification Inner Shareable for the cache hierarchy.

For a description of the values of this field, see Terminology for Clean, Invalidate, and Clean and Invalidate instructions.

Note

This field does not describe the requirements for instruction cache invalidation. See CTR_EL0.DIC.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

When FEAT_S2FWB is implemented, the architecture requires that this field is zero so that no levels of data cache need to be cleaned in order to manage coherency with instruction fetches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Ctype<n> , bits [3(n-1)+2:3(n-1)], for n = 7 to 1

Cache Type fields. Indicate the type of cache that is implemented and can be managed using the architected cache maintenance instructions that operate by set/way at each level, from Level 1 up to a maximum of seven levels of cache hierarchy. Possible values of each field are:

Ctype<n>	Meaning
0b000	No cache.
0b001	Instruction cache only.
0b010	Data cache only.
0b011	Separate instruction and data caches.
0b100	Unified cache.

All other values are reserved.

If software reads the Cache Type fields from Ctype1 upwards, once it has seen a value of 0b000, no caches that can be managed using the architected cache maintenance instructions that operate by set/way exist at further-out levels of the hierarchy. So, for example, if Ctype3 is the first Cache Type field with a value of 0b000, the values of Ctype4 to Ctype7 must be ignored.

Accessing CLIDR_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CLIDR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b001	0b0000	0b0000	0b001

```
if !IsFeatureImplemented(FEAT_AA64) then
    UnimplementedIDRegister();
elsif PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);
    else

D24.2.33 CONTEXTIDR_EL1, Context ID Register (EL1)

The CONTEXTIDR_EL1 characteristics are:

Purpose

Identifies the current Process Identifier.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configuration

AArch64 System register CONTEXTIDR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CONTEXTIDR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to CONTEXTIDR_EL1 are UNDEFINED.

Attributes

CONTEXTIDR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

Note

In AArch32 state, when TTBCR.EAE is set to 0, CONTEXTIDR.ASID holds the ASID.
In AArch64 state, CONTEXTIDR_EL1 is independent of the ASID, and for the EL1&0 translation regime either TTBR0_EL1 or TTBR1_EL1 holds the ASID.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CONTEXTIDR_EL1

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL3 using the accessor name `CONTEXTIDR_EL1` or `CONTEXTIDR_EL12` are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

D24.2.34 CONTEXTIDR_EL2, Context ID Register (EL2)

The CONTEXTIDR_EL2 characteristics are:

Purpose

Identifies the current Process Identifier for EL2.

The value of the whole of this register is called the Context ID and is used by:

- The debug logic, for Linked and Unlinked Context ID matching.
- The trace logic, to identify the current process.

The significance of this register is for debug and trace use only.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

This register is present only when FEAT_Debugv8p1 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to CONTEXTIDR_EL2 are UNDEFINED.

Attributes

CONTEXTIDR_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

PROCID, bits [31:0]

Process Identifier. This field must be programmed with a unique value that identifies the current process.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing CONTEXTIDR_EL2

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL2 using the accessor name `CONTEXTIDR_EL2` or `CONTEXTIDR_EL1` are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

D24.2.35 CPACR_EL1, Architectural Feature Access Control Register

The CPACR_EL1 characteristics are:

Purpose

Controls access to trace, SME, Streaming SVE, SVE, and Advanced SIMD and floating-point functionality.

Configuration

AArch64 System register CPACR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CPACR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to CPACR_EL1 are UNDEFINED.

Attributes

CPACR_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

When FEAT_NV2p1 is implemented:

Reserved for software use in nested virtualization.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL1 is the current Exception level, IsSystemRegisterMaskingEnabled(EL1), and CPACRMASK_EL1.TCPAC == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

TAM, bit [30]

When FEAT_AMUv1 is implemented and FEAT_NV2p1 is implemented:

Reserved for software use in nested virtualization.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL1 is the current Exception level, IsSystemRegisterMaskingEnabled(EL1), and CPACRMASK_EL1.TAM == '1', access to this field is RO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

E0POE, bit [29]

When FEAT_S1POE is implemented:

Enable access to POR_EL0.

Traps EL0 accesses to POR_EL0, from AArch64 state only to EL1, or to EL2 when it is implemented and enabled in the current Security state and HCR_EL2.TGE is 1. The exception is reported using EC syndrome value `0x18`.

E0POE	Meaning
`0b0`	This control causes EL0 access to POR_EL0 to be trapped.
`0b1`	This control does not cause any instructions to be trapped.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, this field has no effect on execution at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL1 is the current Exception level, IsSystemRegisterMaskingEnabled(EL1), and CPACRMASK_EL1.E0POE == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

TTA, bit [28]

When System register access to the trace unit registers is implemented:

Traps EL0 and EL1 System register accesses to all implemented trace System registers from both Execution states to EL1, or to EL2 when it is implemented and enabled in the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to trace System registers are trapped, reported using EC syndrome value `0x18`.
- In AArch32 state, MRC and MCR accesses to trace System registers are trapped, reported using EC syndrome value `0x05`.
- In AArch32 state, MRRC and MCRR accesses to trace System registers are trapped, reported using EC syndrome value `0x0C`.

TTA	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	This control causes EL0 and EL1 System register accesses to all implemented trace System registers to be trapped.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- The ETMv4 architecture and ETE do not permit EL0 to access the trace System registers. If the trace unit implements FEAT_ETMv4 or FEAT_ETE, EL0 accesses to the trace System registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.TTA is 1.
- The Arm architecture does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, this field has no effect on execution at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL1 is the current Exception level, IsSystemRegisterMaskingEnabled(EL1), and CPACRMASK_EL1.TTA == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [27:26]

Reserved, RES0.

SMEN, bits [25:24]

When FEAT_SME is implemented:

Traps execution at EL1 and EL0 of SME instructions, SVE instructions when FEAT_SVE is not implemented or the PE is in Streaming SVE mode, and instructions that directly access the SVCR or SMCR_EL1 System registers to EL1, or to EL2 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1.

When instructions that directly access the SVCR System register are trapped with reference to this control, the `MSR SVCRSM`, `MSR SVCRZA`, and `MSR SVCRSMZA` instructions are also trapped.

The exception is reported using EC syndrome value `0x1D`, with an ISS code of `0x0000000`.

This field does not affect whether Streaming SVE or SME register values are valid.

A trap taken as a result of CPACR_EL1.SMEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

SMEN	Meaning
`0b00`	This control causes execution of these instructions at EL1 and EL0 to be trapped.
`0b01`	This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
`0b10`	This control causes execution of these instructions at EL1 and EL0 to be trapped.
`0b11`	This control does not cause execution of any instructions to be trapped.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, this field has no effect on execution at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SRMASK is implemented, EL1 is the current Exception level, IsSystemRegisterMaskingEnabled(EL1), and CPACRMASK_EL1.SMEN == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [23:22]

Reserved, RES0.

FPEN, bits [21:20]

Traps execution at EL1 and EL0 of instructions that access the Advanced SIMD and floating-point registers from both Execution states to EL1, reported using EC syndrome value `0x07`, or to EL2 reported using EC syndrome value `0x00` when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1, as follows:

- In AArch64 state, accesses to FPMR, FPCR, FPSR, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.
- In AArch32 state, FPSCR, and any of the SIMD and floating-point registers Q0-15, including their views as D0-D31 registers or S0-31 registers.

Traps execution at EL1 and EL0 of SME and SVE instructions to EL1, or to EL2 when EL2 is implemented and enabled for the current Security state and HCR_EL2.TGE is 1. The exception is reported using EC syndrome value `0x07`.

A trap taken as a result of CPACR_EL1.SMEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

A trap taken as a result of CPACR_EL1.ZEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

FPEN	Meaning
`0b00`	This control causes execution of these instructions at EL1 and EL0 to be trapped.
`0b01`	This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
`0b10`	This control causes execution of these instructions at EL1 and EL0 to be trapped.
`0b11`	This control does not cause execution of any instructions to be trapped.

Writes to MVFR0, MVFR1, and MVFR2 from EL1 or higher are CONSTRAINED UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONSTRAINED UNPREDICTABLE behavior.

Note

- Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to FPSID, MVFR0, MVFR1, MVFR2, and FPEXC are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPACR_EL1.FPEN is not `0b11`.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, this field has no effect on execution at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL1 is the current Exception level, IsSystemRegisterMaskingEnabled(EL1), and CPACRMASK_EL1.FPEN == '1', access to this field is RO.

Bits [19:18]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ZEN, bits [17:16]

When FEAT_SVE is implemented:

Traps execution at EL1 and EL0 of SVE instructions when the PE is not in Streaming SVE mode, and instructions that directly access the ZCR_EL1 System register to EL1, or to EL2 when EL2 is implemented and enabled in the current Security state and HCR_EL2.TGE is 1.

The exception is reported using EC syndrome value `0x19`.

A trap taken as a result of CPACR_EL1.ZEN has precedence over a trap taken as a result of CPACR_EL1.FPEN.

ZEN	Meaning
`0b00`	This control causes execution of these instructions at EL1 and EL0 to be trapped.
`0b01`	This control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL1 to be trapped.
`0b10`	This control causes execution of these instructions at EL1 and EL0 to be trapped.
`0b11`	This control does not cause execution of any instructions to be trapped.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, this field has no effect on execution at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL1 is the current Exception level, IsSystemRegisterMaskingEnabled(EL1), and CPACRMASK_EL1.ZEN == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [15:0]

Reserved, RES0.

Accessing CPACR_EL1

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL3 using the accessor name `CPACR_EL1` or `CPACR_EL12` are not guaranteed to be ordered with respect to accesses using the other accessor name.

If FEAT_SRMASK is implemented, accesses to CPACR_EL1 are masked by CPACRMASK_EL1.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CPACR_EL1
```

op0	op1	CRn	CRm	op2

D24.2.36 CPACRMASK_EL1, Architectural Feature Access Control Masking Register

The CPACRMASK_EL1 characteristics are:

Purpose

Mask register to prevent updates of fields in CPACR_EL1 on writes to CPACR_EL1 or CPACRALIAS_EL1.

Configuration

This register is present only when FEAT_SRMASK is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to CPACRMASK_EL1 are UNDEFINED.

Attributes

CPACRMASK_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

When FEAT_NV2p1 is implemented:

Mask bit for TCPAC.

TCPAC	Meaning
0b0	CPACR_EL1.TCPAC is writable.
0b1	CPACR_EL1.TCPAC is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TAM, bit [30]

When FEAT_AMUv1 is implemented and FEAT_NV2p1 is implemented:

Mask bit for TAM.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TAM	Meaning
0b0	CPACR_EL1.TAM is writable.
0b1	CPACR_EL1.TAM is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E0POE, bit [29]

When FEAT_S1POE is implemented:

Mask bit for E0POE.

E0POE	Meaning
0b0	CPACR_EL1.E0POE is writable.
0b1	CPACR_EL1.E0POE is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TTA, bit [28]

When System register access to the trace unit registers is implemented:

Mask bit for TTA.

TTA	Meaning
0b0	CPACR_EL1.TTA is writable.
0b1	CPACR_EL1.TTA is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bits [27:25]

Reserved, RES0.

SMEN, bit [24]

When FEAT_SME is implemented:

Mask bit for SMEN.

SMEN	Meaning
0b0	CPACR_EL1.SMEN is writable.
0b1	CPACR_EL1.SMEN is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [23:21]

Reserved, RES0.

FPEN, bit [20]

Mask bit for FPEN.

FPEN	Meaning
0b0	CPACR_EL1.FPEN is writable.
0b1	CPACR_EL1.FPEN is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bits [19:17]

Reserved, RES0.

ZEN, bit [16]

When FEAT_SVE is implemented:

Mask bit for ZEN.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ZEN	Meaning
0b0	CPACR_EL1.ZEN is writable.
0b1	CPACR_EL1.ZEN is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL1, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [15:0]

Reserved, RES0.

Accessing CPACRMASK_EL1

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL3 using the accessor name CPACRMASK_EL1 or CPACRMASK_EL12 are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CPACRMASK_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0001	0b0100	0b010

D24.2.37 CPTR_EL2, Architectural Feature Trap Register (EL2)

The CPTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of accesses to CPACR, CPACR_EL1, trace, Activity Monitor, SME, Streaming SVE, SVE, and Advanced SIMD and floating-point functionality.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

AArch64 System register CPTR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HCPTR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to CPTR_EL2 are UNDEFINED.

Attributes

CPTR_EL2 is a 64-bit register.

Field descriptions

When EffectiveHCR_EL2_E2H() == '1':

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

In AArch64 state, traps accesses to CPACR_EL1 from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x18`.

In AArch32 state, traps accesses to CPACR from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x03`.

TCPAC	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	EL1 accesses to CPACR_EL1 and CPACR are trapped to EL2, when EL2 is enabled in the current Security state.

When the Effective value of HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

CPACR_EL1 and CPACR are not accessible at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL2 is the current Exception level, IsSystemRegisterMaskingEnabled(EL2), and CPTRMASK_EL2.TCPAC == '1', access to this field is RO.

TAM, bit [30]

When FEAT_AMUv1 is implemented:

Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitors System registers to EL2, as follows:

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x18`:
  - AMUSERENR_EL0, AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCNTR0<n>_EL0, AMEVCNTR1<n>_EL0, AMEVTYPER0<n>_EL0, and AMEVTYPER1<n>_EL0.
- In AArch32 state, MRC or MCR accesses to the following registers are trapped to EL2 and reported using EC syndrome value `0x03`:
  - AMUSERENR, AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPER0<n>, and AMEVTYPER1<n>.
- In AArch32 state, MRRC or MCRR accesses to AMEVCNTR0<n> and AMEVCNTR1<n>, are trapped to EL2, reported using EC syndrome value `0x04`.

TAM	Meaning
`0b0`	Accesses from EL1 and EL0 to Activity Monitors System registers are not trapped.
`0b1`	Accesses from EL1 and EL0 to Activity Monitors System registers are trapped to EL2, when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL2 is the current Exception level, IsSystemRegisterMaskingEnabled(EL2), and CPTRMASK_EL2.TAM == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

E0POE, bit [29]

When FEAT_S1POE is implemented:

Enable access to POR_EL0.

Traps EL0 accesses to POR_EL0 to EL2, from AArch64 state only. The exception is reported using EC syndrome value `0x18`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

E0POE	Meaning
0b0	This control causes EL0 access to POR_EL0 to be trapped.
0b1	This control does not cause any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL2 is the current Exception level, IsSystemRegisterMaskingEnabled(EL2), and CPTRMASK_EL2.E0POE == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

TTA, bit [28]

When System register access to the trace unit registers is implemented:

Traps System register accesses to all implemented trace System registers from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to trace System registers with op0=2, op1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x18.
- In AArch32 state, MRC or MCR accesses to trace System registers with cpnum=14, opc1=1, and CRn<0b1000 are trapped to EL2, reported using EC syndrome value 0x05.

TTA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Any attempt at EL0, EL1 or EL2, to execute a System register access to an implemented trace System register is trapped to EL2, when EL2 is enabled in the current Security state, unless HCR_EL2.TGE is 0 and it is trapped by CPACR.NSTRCDIS or CPACR_EL1.TTA. When HCR_EL2.TGE is 1, any attempt at EL0 or EL2 to execute a System register access to an implemented trace System register is trapped to EL2, when EL2 is enabled in the current Security state.

Note

The ETMv4 architecture and ETE do not permit EL0 to access the trace System registers. If the trace unit implements FEAT_ETMv4 or ETE, EL0 accesses to the trace System registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.
EL2 does not provide traps on trace register accesses through the optional Memory-mapped interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL2 is the current Exception level, IsSystemRegisterMaskingEnabled(EL2), and CPTRMASK_EL2.TTA == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [27:26]

Reserved, RES0.

SMEN, bits [25:24]

When FEAT_SME is implemented:

Traps execution at EL2, EL1, and EL0 of SME instructions, SVE instructions when FEAT_SVE is not implemented or the PE is in Streaming SVE mode, and instructions that directly access the SVCR, SMCR_EL1, or SMCR_EL2 System registers to EL2, when EL2 is enabled in the current Security state.

When instructions that directly access the SVCR System register are trapped with reference to this control, the `MSR SVCRSM`, `MSR SVCRZA`, and `MSR SVCRSMZA` instructions are also trapped.

The exception is reported using EC syndrome value `0x1D`, with an ISS code of `0x0000000`.

This field does not affect whether Streaming SVE or SME register values are valid.

A trap taken as a result of CPTR_EL2.SMEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

SMEN	Meaning
`0b00`	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
`0b01`	When HCR_EL2.TGE is 0, this control does not cause execution of any instructions to be trapped. When HCR_EL2.TGE is 1, this control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL2 to be trapped.
`0b10`	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
`0b11`	This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL2 is the current Exception level, IsSystemRegisterMaskingEnabled(EL2), and CPTRMASK_EL2.SMEN == ‘1’, access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [23:22]

Reserved, RES0.

FPEN, bits [21:20]

Traps execution at EL2, EL1, and EL0 of instructions that access the Advanced SIMD and floating-point registers from both Execution states to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x07`.

Traps execution at EL2, EL1, and EL0 of SME and SVE instructions to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x07`.

When FEAT_FPMR is implemented, traps execution at EL2, EL1, and EL0 of instructions that access FPMR to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x07`

A trap taken as a result of CPTR_EL2.SMEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

A trap taken as a result of CPTR_EL2.ZEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FPEN	Meaning
0b00	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
0b01	When HCR_EL2.TGE is 0, this control does not cause execution of any instructions to be trapped. When HCR_EL2.TGE is 1, this control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL2 to be trapped.
0b10	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
0b11	This control does not cause execution of any instructions to be trapped.

Writes to MVFR0, MVFR1, and MVFR2 from EL1 or higher are CONSTRAINED UNPREDICTABLE and whether these accesses can be trapped by this control depends on implemented CONSTRAINED UNPREDICTABLE behavior.

Note

- Attempts to write to the FPSID count as use of the registers for accesses from EL1 or higher.
- Accesses from EL0 to FPSID, MVFR0, MVFR1, MVFR2, and FPEXC are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.FPEN is not 0b11.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL2 is the current Exception level, IsSystemRegisterMaskingEnabled(EL2), and CPTRMASK_EL2.FPEN == '1', access to this field is RO.

Bits [19:18]

Reserved, RES0.

ZEN, bits [17:16]

When FEAT_SVE is implemented:

Traps execution at EL2, EL1, and EL0 of SVE instructions when the PE is not in Streaming SVE mode, and instructions that directly access the ZCR_EL1 or ZCR_EL2 System registers to EL2, when EL2 is enabled in the current Security state.

The exception is reported using EC syndrome value 0x19.

A trap taken as a result of CPTR_EL2.ZEN has precedence over a trap taken as a result of CPTR_EL2.FPEN.

ZEN	Meaning
0b00	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
0b01	When HCR_EL2.TGE is 0, this control does not cause execution of any instructions to be trapped. When HCR_EL2.TGE is 1, this control causes execution of these instructions at EL0 to be trapped, but does not cause execution of any instructions at EL2 to be trapped.
0b10	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.
0b11	This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_SRMASK is implemented, EL2 is the current Exception level, IsSystemRegisterMaskingEnabled(EL2), and CPTRMASK_EL2.ZEN == '1', access to this field is RO.

Otherwise:

Reserved, RES0.

Bits [15:0]

Reserved, RES0.

Otherwise:

This format applies in all Armv8.0 implementations.

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

In AArch64 state, traps accesses to CPACR_EL1 from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x18`.

In AArch32 state, traps accesses to CPACR from EL1 to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x03`.

TCPAC	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	EL1 accesses to the following registers are trapped to EL2, when EL2 is enabled in the current Security state: • CPACR_EL1. • CPACR.

When HCR_EL2.TGE is 1, this control does not cause any instructions to be trapped.

Note

CPACR_EL1 and CPACR are not accessible at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TAM, bit [30]

When FEAT_AMUv1 is implemented:

Trap Activity Monitor access. Traps EL1 and EL0 accesses to all Activity Monitors System registers to EL2, as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x18`:
  - AMUSERENR_EL0, AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCNTR0<n>_EL0, AMEVCNTR1<n>_EL0, AMEVTYPER0<n>_EL0, and AMEVTYPER1<n>_EL0.
- In AArch32 state, MCR or MRC accesses to the following registers are trapped to EL2 and reported using EC syndrome value `0x03`:
  - AMUSERENR, AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPER0<n>, and AMEVTYPER1<n>.
- In AArch32 state, MCRR or MRRC accesses to AMEVCNTR0<n> and AMEVCNTR1<n>, are trapped to EL2, reported using EC syndrome value `0x04`.

TAM	Meaning
`0b0`	Accesses from EL1 and EL0 to Activity Monitors System registers are not trapped.
`0b1`	Accesses from EL1 and EL0 to Activity Monitors System registers are trapped to EL2, when EL2 is enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:21]

Reserved, RES0.

TTA, bit [20]

When System register access to the trace unit registers is implemented:

Traps System register accesses to all implemented trace System registers from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

- In AArch64 state, accesses to trace System registers with op0=2, op1=1, and CRn<`0b1000` are trapped to EL2, reported using EC syndrome value `0x18`.
- In AArch32 state, MRC or MCR accesses to trace System registers with cpnum=14, opc1=1, and CRn<`0b1000` are trapped to EL2, reported using EC syndrome value `0x05`.

TTA	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	Any attempt at EL0, EL1, or EL2, to execute a System register access to an implemented trace System register is trapped to EL2, when EL2 is enabled in the current Security state, unless it is trapped by one of the following controls: • CPACR_EL1.TTA. • CPACR.TRCDIS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

- FEAT_ETMv4 and FEAT_ETE do not permit EL0 to access the trace System registers. EL0 accesses to the trace System registers are UNDEFINED, and any resulting exception is higher priority than an exception that would be generated because the value of CPTR_EL2.TTA is 1.
- EL2 does not provide traps on trace register accesses through the optional memory-mapped interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, any side-effects that are normally associated with the access do not occur before the exception is taken.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [19:14]

Reserved, RES0.

Bit [13]

Reserved, RES1.

TSM, bit [12]

When FEAT_SME is implemented:

Traps execution at EL2, EL1, and EL0 of SME instructions, SVE instructions when FEAT_SVE is not implemented or the PE is in Streaming SVE mode, and instructions that directly access the SVCR, SMCR_EL1, or SMCR_EL2 System registers to EL2, when EL2 is enabled in the current Security state.

When instructions that directly access the SVCR System register are trapped with reference to this control, the `MSR SVCRSM`, `MSR SVCRZA`, and `MSR SVCRSMZA` instructions are also trapped.

The exception is reported using EC syndrome value `0x1D`, with an ISS code of `0x0000000`.

This field does not affect whether Streaming SVE or SME register values are valid.

A trap taken as a result of CPTR_EL2.TSM has precedence over a trap taken as a result of CPTR_EL2.TFP.

TSM	Meaning
`0b0`	This control does not cause execution of any instructions to be trapped.
`0b1`	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES1.

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps execution of instructions which access the Advanced SIMD and floating-point functionality, from both Execution states to EL2, when EL2 is enabled in the current Security state, as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In AArch64 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x07`:
  - FPCR, FPSR, FPEXC32_EL2, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-31 registers.
  - If FEAT_FPMR is implemented, FPMR.
- In AArch32 state, accesses to the following registers are trapped to EL2, reported using EC syndrome value `0x07`:
  - MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-15, including their views as D0-D31 registers or S0-31 registers. For the purposes of this trap, the architecture defines a VMSR access to FPSID from EL1 or higher as an access to a SIMD and floating-point register. Otherwise, permitted VMSR accesses to FPSID are ignored.

Traps execution at the same Exception levels of SME and SVE instructions to EL2, when EL2 is enabled in the current Security state. The exception is reported using EC syndrome value `0x07`.

A trap taken as a result of CPTR_EL2.TSM has precedence over a trap taken as a result of CPTR_EL2.TFP.

A trap taken as a result of CPTR_EL2.TZ has precedence over a trap taken as a result of CPTR_EL2.TFP.

TFP	Meaning
`0b0`	This control does not cause execution of any instructions to be trapped.
`0b1`	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

Note

FPEXC32_EL2 is not accessible from EL0 using AArch64.
FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [9]

Reserved, RES1.

TZ, bit [8]

When FEAT_SVE is implemented:

Traps execution at EL2, EL1, and EL0 of SVE instructions when the PE is not in Streaming SVE mode, and instructions that directly access the ZCR_EL2 or ZCR_EL1 System registers to EL2, when EL2 is enabled in the current Security state.

The exception is reported using EC syndrome value `0x19`.

A trap taken as a result of CPTR_EL2.TZ has precedence over a trap taken as a result of CPTR_EL2.TFP.

TZ	Meaning
`0b0`	This control does not cause execution of any instructions to be trapped.
`0b1`	This control causes execution of these instructions at EL2, EL1, and EL0 to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES1.

Bits [7:0]

Reserved, RES1.

Accessing CPTR_EL2

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL2 using the accessor name `CPTR_EL2` or `CPACR_EL1` are not guaranteed to be ordered with respect to accesses using the other accessor name.

If FEAT_SRMASK is implemented, accesses to CPTR_EL2 are masked by CPTRMASK_EL2.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CPTR_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b010

```

D24.2.38 CPTR_EL3, Architectural Feature Trap Register (EL3)

The CPTR_EL3 characteristics are:

Purpose

Controls trapping to EL3 of accesses to CPACR, CPACR_EL1, HCPTR, CPTR_EL2, trace, Activity Monitor, SME, Streaming SVE, SVE, and Advanced SIMD and floating-point functionality.

Configuration

This register is present only when EL3 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to CPTR_EL3 are UNDEFINED.

Attributes

CPTR_EL3 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

Traps all of the following to EL3, from both Execution states and any Security state.

- EL2 accesses to CPTR_EL2, reported using EC syndrome value `0x18`, or HCPTR, reported using EC syndrome value `0x03`.
- EL2 and EL1 accesses to CPACR_EL1 reported using EC syndrome value `0x18`, or CPACR reported using EC syndrome value `0x03`.

When CPTR_EL3.TCPAC is:

TCPAC	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	EL2 accesses to the CPTR_EL2 or HCPTR, and EL2 and EL1 accesses to the CPACR_EL1 or CPACR, are trapped to EL3, unless they are trapped by CPTR_EL2.TCPAC.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TAM, bit [30]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_AMUv1 is implemented:

Trap Activity Monitor access. Traps EL2, EL1, and EL0 accesses to all Activity Monitors System registers to EL3.

Accesses to the Activity Monitors System registers are trapped as follows:

- In AArch64 state, the following registers are trapped to EL3 and reported using EC syndrome value `0x18`:
  - AMUSERENR_EL0, AMCFGR_EL0, AMCGCR_EL0, AMCNTENCLR0_EL0, AMCNTENCLR1_EL0, AMCNTENSET0_EL0, AMCNTENSET1_EL0, AMCR_EL0, AMEVCNTR0<n>_EL0, AMEVCNTR1<n>_EL0, AMEVTYPER0<n>_EL0, and AMEVTYPER1<n>_EL0.
- In AArch32 state, accesses with MRC or MCR to the following registers reported using EC syndrome value `0x03`:
  - AMUSERENR, AMCFGR, AMCGCR, AMCNTENCLR0, AMCNTENCLR1, AMCNTENSET0, AMCNTENSET1, AMCR, AMEVTYPER0<n>, and AMEVTYPER1<n>.
- In AArch32 state, accesses with MRRC or MCRR to the following registers, reported using EC syndrome value `0x04`:
  - AMEVCNTR0<n>, AMEVCNTR1<n>.

TAM	Meaning
`0b0`	Accesses from EL2, EL1, and EL0 to Activity Monitors System registers are not trapped.
`0b1`	Accesses from EL2, EL1, and EL0 to Activity Monitors System registers are trapped to EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [29:21]

Reserved, RES0.

TTA, bit [20]

When System register access to the trace unit registers is implemented:

Traps System register accesses. Accesses to the trace System registers, from all Exception levels, any Security state, and both Execution states are trapped to EL3 as follows:

- In AArch64 state, trace System registers with op0=2, op1=1, and CRn<`0b1000` are trapped to EL3 and reported using EC syndrome value `0x18`.
- In AArch32 state, accesses using MCR or MRC to the trace System registers with cpnum=14, opc1=1, and CRn<`0b1000` are reported using EC syndrome value `0x05`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTA	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Any System register access to the trace System registers is trapped to EL3, unless it is trapped by CPACR.TRCDIS, CPACR_EL1.TTA, or CPTR_EL2.TTA.

Note

The ETMv4 architecture and ETE do not permit EL0 to access the trace System registers. If the trace unit implements FEAT_ETMv4 or FEAT_ETE, EL0 accesses to the trace System registers are UNDEFINED, and any resulting exception is higher priority than this trap exception.
EL3 does not provide traps on trace System register accesses through the Memory-mapped interface.

System register accesses to the trace System registers can have side-effects. When a System register access is trapped, no side-effects occur before the exception is taken, see 'Configurable instruction controls'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [19:13]

Reserved, RES0.

ESM, bit [12]

When FEAT_SME is implemented:

Traps execution of SME instructions, SVE instructions when FEAT_SVE is not implemented or the PE is in Streaming SVE mode, and instructions that directly access the SMCR_EL1, SMCR_EL2, SMCR_EL3, SMPRI_EL1, SMPRIMAP_EL2, or SVCR System registers, from all Exception levels and any Security state, to EL3.

When instructions that directly access the SVCR System register are trapped with reference to this control, the `MSR SVCRSM`, `MSR SVCRZA`, and `MSR SVCRSMZA` instructions are also trapped.

When direct accesses to SMPRI_EL1 and SMPRIMAP_EL2 are trapped, the exception is reported using EC syndrome value `0x18`. Otherwise, the exception is reported using EC syndrome value `0x1D`, with an ISS code of `0x0000000`.

This field does not affect whether Streaming SVE or SME register values are valid.

A trap taken as a result of CPTR_EL3.ESM has precedence over a trap taken as a result of CPTR_EL3.TFP.

ESM	Meaning
0b0	This control causes execution of these instructions at all Exception levels to be trapped.
0b1	This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [11]

Reserved, RES0.

TFP, bit [10]

Traps execution of instructions which access the Advanced SIMD and floating-point functionality, from all Exception levels, any Security state, and both Execution states, to EL3.

This includes the following registers, all reported using EC syndrome value `0x07`:

- FPCR, FPSR, FPEXC32_EL2, and any of the SIMD and floating-point registers V0-V31, including their views as D0-D31 registers or S0-S31 registers.
- If FEAT_FPMR is implemented, FPMR.
- MVFR0, MVFR1, MVFR2, FPSCR, FPEXC, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers.
- VMSR accesses to FPSID.

Permitted VMSR accesses to FPSID are ignored, but for the purposes of this trap the architecture defines a VMSR access to the FPSID from EL1 or higher as an access to a SIMD and floating-point register.

Traps execution at all Exception levels of SME and SVE instructions to EL3 from any Security state. The exception is reported using EC syndrome value `0x07`.

A trap taken as a result of CPTR_EL3.ESM has precedence over a trap taken as a result of CPTR_EL3.TFP.

A trap taken as a result of CPTR_EL3.EZ has precedence over a trap taken as a result of CPTR_EL3.TFP.

TFP	Meaning
`0b0`	This control does not cause execution of any instructions to be trapped.
`0b1`	This control causes execution of these instructions at all Exception levels to be trapped.

Note

FPEXC32_EL2 is not accessible from EL0 using AArch64.
FPSID, MVFR0, MVFR1, and FPEXC are not accessible from EL0 using AArch32.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [9]

Reserved, RES0.

EZ, bit [8]

When FEAT_SVE is implemented:

Traps execution of SVE instructions when the PE is not in Streaming SVE mode, and instructions that directly access the ZCR_EL3, ZCR_EL2, or ZCR_EL1 System registers, from all Exception levels and any Security state, to EL3.

The exception is reported using EC syndrome value `0x19`.

A trap taken as a result of CPTR_EL3.EZ has precedence over a trap taken as a result of CPTR_EL3.TFP.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EZ	Meaning
0b0	This control causes execution of these instructions at all Exception levels to be trapped.
0b1	This control does not cause execution of any instructions to be trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [7:0]

Reserved, RES0.

Accessing CPTR_EL3

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CPTR_EL3
```

op0	op1	CRn	CRm	op2
0b11	0b110	0b0001	0b0001	0b010

```
if !(HaveEL(EL3) && IsFeatureImplemented(FEAT_AA64)) then

D24.2.39 CPTRMASK_EL2, Architectural Feature Trap Masking Register

The CPTRMASK_EL2 characteristics are:

Purpose

Mask register to prevent updates of fields in CPTR_EL2 on writes.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

This register is present only when FEAT_SRMASK is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to CPTRMASK_EL2 are UNDEFINED.

Attributes

CPTRMASK_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

TCPAC, bit [31]

Mask bit for TCPAC.

TCPAC	Meaning
0b0	CPTR_EL2.TCPAC is writable.
0b1	CPTR_EL2.TCPAC is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TAM, bit [30]

When FEAT_AMUv1 is implemented:

Mask bit for TAM.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TAM	Meaning
0b0	CPTR_EL2.TAM is writable.
0b1	CPTR_EL2.TAM is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E0POE, bit [29]

When FEAT_S1POE is implemented:

Mask bit for E0POE.

E0POE	Meaning
0b0	CPTR_EL2.E0POE is writable.
0b1	CPTR_EL2.E0POE is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TTA, bit [28]

When System register access to the trace unit registers is implemented:

Mask bit for TTA.

TTA	Meaning
0b0	CPTR_EL2.TTA is writable.
0b1	CPTR_EL2.TTA is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [27:25]

Reserved, RES0.

SMEN, bit [24]

When FEAT_SME is implemented:

Mask bit for SMEN.

SMEN	Meaning
0b0	CPTR_EL2.SMEN is writable.
0b1	CPTR_EL2.SMEN is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [23:21]

Reserved, RES0.

FPEN, bit [20]

Mask bit for FPEN.

FPEN	Meaning
0b0	CPTR_EL2.FPEN is writable.
0b1	CPTR_EL2.FPEN is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bits [19:17]

Reserved, RES0.

ZEN, bit [16]

When FEAT_SVE is implemented:

Mask bit for ZEN.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ZEN	Meaning
0b0	CPTR_EL2.ZEN is writable.
0b1	CPTR_EL2.ZEN is not writable.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [15:0]

Reserved, RES0.

Accessing CPTRMASK_EL2

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL2 using the accessor name CPTRMASK_EL2 or CPACRMASK_EL1 are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, CPTRMASK_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0100	0b010

```

D24.2.40 CSSELR_EL1, Cache Size Selection Register

The CSSELR_EL1 characteristics are:

Purpose

Selects the current Cache Size ID Register, CCSIDR_EL1, by specifying the required cache level and the cache type (either instruction or data cache).

Configuration

AArch64 System register CSSELR_EL1 bits [31:0] are architecturally mapped to AArch32 System register CSSELR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to CSSELR_EL1 are UNDEFINED.

Attributes

CSSELR_EL1 is a 64-bit register.

Field descriptions

Bits [63:5]

Reserved, RES0.

TnD, bit [4]

When FEAT_MTE2 is implemented:

Allocation Tag not Data bit.

TnD	Meaning
0b0	Data, Instruction or Unified cache.
0b1	Separate Allocation Tag cache.

When CSSELR_EL1.InD == 1, this bit is RES0.

If CSSELR_EL1.{TnD, Level, InD} is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR_EL1 is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Level, bits [3:1]

Cache level of required cache.

Level	Meaning
0b000	Level 1 cache.
0b001	Level 2 cache.
0b010	Level 3 cache.
0b011	Level 4 cache.
0b100	Level 5 cache.
0b101	Level 6 cache.
0b110	Level 7 cache.

All other values are reserved.

If CSSELR_EL1.{TnD, Level, InD} is programmed to a cache level that is not implemented, then the value for this field on a read of CSSELR_EL1 is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

InD, bit [0]

Instruction not Data bit.

InD	Meaning
0b0	Data or unified cache.
0b1	Instruction cache.

If CSSELR_EL1.{TnD, Level, InD} is programmed to a cache level that is not implemented, then a read of CSSELR_EL1 is CONSTRAINED UNPREDICTABLE, and returns UNKNOWN values for CSSELR_EL1.{Level, InD}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D24.2.41 CTR_EL0, Cache Type Register

The CTR_EL0 characteristics are:

Purpose

Provides information about the architecture of the caches.

Configuration

AArch64 System register CTR_EL0 bits [31:0] are architecturally mapped to AArch32 System register CTR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to CTR_EL0 are UNDEFINED.

Attributes

CTR_EL0 is a 64-bit register.

Field descriptions

Bits [63:38]

Reserved, RES0.

TminLine, bits [37:32]

When FEAT_MTE2 is implemented:

Tag minimum Line. Log_2 of the number of words covered by Allocation Tags in the smallest cache line of all caches which can contain Allocation tags that are controlled by the PE.

Note

- For an implementation with cache lines containing 64 bytes of data and 4 Allocation Tags, this will be $log_2(64/4) = 4$.
- For an implementation with Allocations Tags in separate cache lines of 128 Allocation Tags per line, this will be $log_2(128*16/4) = 9$.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Bit [31]

Reserved, RES1.

Bit [30]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DIC, bit [29]

Instruction cache invalidation requirements for data to instruction coherence.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DIC	Meaning
0b0	Instruction cache invalidation to the Point of Unification is required for data to instruction coherence.
0b1	Instruction cache invalidation to the Point of Unification is not required for data to instruction coherence.

All PEs in the same Inner Shareable shareability domain must have a common value of this field.

Note

If CTR_EL0.DIC is 1, instruction cache maintenance is not required after overwriting instructions, including for different VA aliases of the affected Locations, regardless of the value of CTR_EL0.L1Ip.

Access to this field is RO.

IDC, bit [28]

Data cache clean requirements for instruction to data coherence. The meaning of this bit is:

The value of this field is an IMPLEMENTATION DEFINED choice of:

IDC	Meaning
0b0	Data cache clean to the Point of Unification is required for instruction to data coherence, unless CLIDR_EL1.LoC == 0b000 or (CLIDR_EL1.LoUIS == 0b000 and CLIDR_EL1.LoUU == 0b000).
0b1	Data cache clean to the Point of Unification is not required for instruction to data coherence.

If CTR_EL0.DIC is 1 then the value reported in this field must also be 1.

The Effective value of IDC is 1 if any of the following are true:

- CTR_EL0.IDC == 1.
- CLIDR_EL1.LoC == 0b000.
- CLIDR_EL1.LoUIS == 0b000 and CLIDR_EL1.LoUU == 0b000.

All PEs in the same Inner Shareable shareability domain must have a common Effective value of IDC.

Access to this field is RO.

CWG, bits [27:24]

Cache writeback granule. Log_2 of the number of words of the maximum size of memory that can be overwritten as a result of the eviction of a cache entry that has had a memory location in it modified.

A value of 0b0000 indicates that this register does not provide Cache writeback granule information and either:

- The architectural maximum of 512 words (2KB) must be assumed.
- The Cache writeback granule can be determined from maximum cache line size encoded in the Cache Size ID Registers.

Values greater than 0b1001 are reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Arm recommends that an implementation that does not support cache write-back implements this field as `0b0001`. This applies, for example, to an implementation that supports only write-through caches.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

ERG, bits [23:20]

Exclusives reservation granule. Log_2 of the number of words of the maximum size of the reservation granule that has been implemented for the Load-Exclusive and Store-Exclusive instructions.

The use of the value `0b0000` is deprecated.

The value `0b0001` and values greater than `0b1001` are reserved.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

DminLine, bits [19:16]

Log_2 of the number of words in the smallest cache line of all the data caches and unified caches that are controlled by the PE.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

L1Ip, bits [15:14]

Level 1 instruction cache policy. Indicates the indexing and tagging policy for the L1 instruction cache.

The value of this field is an IMPLEMENTATION DEFINED choice of:

L1Ip	Meaning
`0b00`	Reserved.
`0b01`	ASID-tagged Virtual Index, Virtual Tag (AIVIVT).
`0b10`	Virtual Index, Physical Tag (VIPT).
`0b11`	Physical Index, Physical Tag (PIPT).

From Armv8.0, the value `0b01` is reserved.

Access to this field is RO.

Bits [13:4]

Reserved, RES0.

IminLine, bits [3:0]

Log_2 of the number of words in the smallest cache line of all the instruction caches that are controlled by the PE.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

D24.2.42 DACR32_EL2, Domain Access Control Register

The DACR32_EL2 characteristics are:

Purpose

Allows access to the AArch32 DACR register from AArch64 state only. Its value has no effect on execution in AArch64 state.

Configuration

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

AArch64 System register DACR32_EL2 bits [31:0] are architecturally mapped to AArch32 System register DACR[31:0].

This register is present only when FEAT_AA32EL1 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to DACR32_EL2 are UNDEFINED.

Attributes

DACR32_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

D<n> , bits [2n+1:2n], for n = 15 to 0

Domain n access permission, where n = 0 to 15. Permitted values are:

D<n>	Meaning
0b00	No access. Any access to the domain generates a Domain fault.
0b01	Client. Accesses are checked against the permission bits in the translation tables.
0b11	Manager. Accesses are not checked against the permission bits in the translation tables.

The value 0b10 is reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D24.2.43 DCZID_EL0, Data Cache Zero ID Register

The DCZID_EL0 characteristics are:

Purpose

Indicates the block size that is written with byte values of 0 by the DC ZVA (Data Cache Zero by Address) System instruction.

If FEAT_MTE is implemented, this register indicates the granularity at which the DC GVA and DC GZVA instructions write.

Configuration

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to DCZID_EL0 are UNDEFINED.

Attributes

DCZID_EL0 is a 64-bit register.

Field descriptions

Bits [63:5]

Reserved, RES0.

DZP, bit [4]

Data Zero Prohibited. This field indicates whether use of DC ZVA instructions is permitted or prohibited.

If FEAT_MTE is implemented, this field indicates whether use of the DC GVA and DC GZVA instructions are permitted or prohibited.

DZP	Meaning
0b0	Instructions are permitted.
0b1	Instructions are prohibited.

The value read from this field is governed by the current Exception level and the values of the following fields:

- The Effective value of HCR_EL2.TDZ.
- When the Effective value of HCR_EL2.{E2H, TGE} != ‘11’, SCTLR_EL1.DZE.
- When the Effective value of HCR_EL2.{E2H, TGE} == ‘11’, SCTLR_EL2.DZE.

BS, bits [3:0]

Log_2 of the block size in words written by a DC ZVA instruction. The maximum size supported is 2KB, indicated by value 0b1001.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_MTE2 is implemented, then this field determines the block size written by a DC GVA or DC GZVA instruction and the minimum size supported is 16 bytes, indicated by value `0b0010`.

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing DCZID_EL0

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, DCZID_EL0
```

op0	op1	CRn	CRm	op2
0b11	0b011	0b0000	0b0000	0b111

```
if !IsFeatureImplemented(FEAT_AA64) then

D24.2.44 ESR_EL1, Exception Syndrome Register (EL1)

The ESR_EL1 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL1.

Configuration

AArch64 System register ESR_EL1 bits [31:0] are architecturally mapped to AArch32 System register DFSR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ESR_EL1 are UNDEFINED.

Attributes

ESR_EL1 is a 64-bit register.

Field descriptions

ESR_EL1 is made UNKNOWN as a result of an exception return from EL1.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL1, the value of ESR_EL1 is UNKNOWN. The value written to ESR_EL1 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Bits [63:56]

Reserved, RES0.

ISS2, bits [55:32]

ISS2 encoding for an exception, the bit assignments are:

ISS2 encoding for an exception from a Data Abort

Bits [23:12]

Reserved, RES0.

HDBSSF, bit [11]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_HDBSS is implemented, FEAT_NV is implemented, IsSecondStage(Fault), and GetESR_ELx_DFSC(EL1) IN {'0011xx', '01001x', '0101xx', '10001x', '1001xx'}:

Indicates that the fault was caused by the HDBSS.

When DFSC indicates a stage 2 Permission fault, this field indicates whether that fault was caused because HDBSS cannot have data appended, because the HDBSS is either full or in an error state.

When DFSC indicates a synchronous External abort on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

When DFSC indicates a Granule Protection Fault on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

HDBSSF	Meaning
`0b0`	Fault was not caused by HDBSS.
`0b1`	Fault was caused by HDBSS.

This field only applies for stage 2 Permission faults.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TnD, bit [10]

When FEAT_MTE_CANONICAL_TAGS is implemented:

Tag not Data.

If a memory access generates a Data Abort for a stage 1 Permission fault, this field indicates whether the fault is due to an Allocation Tag access.

TnD	Meaning
`0b0`	Permission fault is not due to a write of an Allocation Tag to Canonically Tagged memory.
`0b1`	Permission fault is due to a write of an Allocation Tag to Canonically Tagged memory.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TagAccess, bit [9]

When FEAT_MTE_PERM is implemented and FEAT_NV is implemented:

NoTagAccess fault.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If a memory access generates a Data Abort for a Permission fault, this field indicates whether the fault is due to the NoTagAccess memory attribute.

TagAccess	Meaning
0b0	Permission fault is not due to the NoTagAccess memory attribute, and not due to an access using a Tag VA.
0b1	Permission fault is due to the NoTagAccess memory attribute.

For all other Data Aborts this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

GCS, bit [8]

When FEAT_GCS is implemented:

Guarded Control Stack data access.

If a memory access generates a Data Abort, this field indicates whether the fault is due to a Guarded Control Stack data access.

GCS	Meaning
0b0	The Data Abort is not due to a Guarded control stack data access.
0b1	The Data Abort is due to a Guarded control stack data access. The ISV field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AssuredOnly, bit [7]

When FEAT_THE is implemented and FEAT_NV is implemented:

AssuredOnly flag.

If EL2 provides information regarding a stage 2 Data Abort to EL1, then this field holds information about the fault.

If this field is 1 and ESR_EL1.GCS is also 1, then the AssuredOnly check might have been the result of VTCR_EL2.GCSH configuration.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AssuredOnly	Meaning
0b0	The Data Abort is not due to AssuredOnly.
0b1	The Data Abort is due to AssuredOnly.

For all other Data Aborts this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Overlay, bit [6]

When FEAT_S1POE is implemented:

Overlay flag.

If a memory access generates a Data Abort for a Permission fault, then this field holds information about the fault.

Overlay	Meaning
0b0	Data Abort is not due to Overlay Permissions.
0b1	Data Abort is due to Overlay Permissions.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DirtyBit, bit [5]

When FEAT_S1PIE is implemented:

DirtyBit flag.

If a write access to memory generates a Data Abort for a Permission fault using Indirect Permission, then this field holds information about the fault.

DirtyBit	Meaning
0b0	Permission Fault is not due to dirty state.
0b1	Permission Fault is due to dirty state.

For any other fault or Access, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Xs, bits [4:0]

When FEAT_LS64 is implemented:

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort exception reported with ISV=1, then this field holds register specifier, Xs.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort exception reported with ISV=1, then this field holds register specifier, Xs.

Otherwise, this field is RES0.

Otherwise:

Reserved, RES0.

ISS2 encoding for an exception from an Instruction Abort

Bits [23:12]

Reserved, RES0.

HDBSSF, bit [11]

When FEAT_HDBSS is implemented and FEAT_NV is implemented:

Indicates that the fault was caused by the HDBSS.

When IFSC indicates a stage 2 Permission fault, this field indicates whether that fault was caused because HDBSS cannot have data appended, because the HDBSS is either full or in an error state.

When IFSC indicates a synchronous External abort on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

When IFSC indicates a Granule Protection Fault on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

HDBSSF	Meaning
0b0	Fault was not caused by HDBSS.
0b1	Fault was caused by HDBSS.

This field only applies for stage 2 Permission faults.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bits [10:8]

Reserved, RES0.

AssuredOnly, bit [7]

When FEAT_THE is implemented and FEAT_NV is implemented:

AssuredOnly flag.

If EL2 provides information regarding a stage 2 Instruction Abort to EL1, then this field holds information about the fault.

AssuredOnly	Meaning
`0b0`	The Instruction Abort is not due to AssuredOnly.
`0b1`	The Instruction Abort is due to AssuredOnly.

For all other Instruction Aborts this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Overlay, bit [6]

When FEAT_S1POE is implemented:

Overlay flag.

If a memory access generates a Instruction Abort for a Permission fault, then this field holds information about the fault.

Overlay	Meaning
`0b0`	Instruction Abort is not due to Overlay Permissions.
`0b1`	Instruction Abort is due to Overlay Permissions.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS2 encoding for an exception from a Watchpoint exception

23 … 9	8	7 … 0
RES0	GCS	RES0

Bits [23:9]

Reserved, RES0.

GCS, bit [8]

When FEAT_GCS is implemented:

Guarded control stack data access.

Indicates that the Watchpoint exception is due to a Guarded control stack data access.

GCS	Meaning
0b0	The Watchpoint exception is not due to a Guarded control stack data access.
0b1	The Watchpoint exception is due to a Guarded control stack data access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS2 encoding for all other exceptions

23 … 0
RES0

Bits [23:0]

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b000000	Unknown reason.	ISS encoding for exceptions with an unknown reason	ISS2 encoding for all other exceptions	
0b000001	Trapped WF* instruction execution. Conditional WF* instructions that fail their condition code check do not cause an exception.	ISS encoding for an exception from a WF* instruction	ISS2 encoding for all other exceptions	
0b000011	Trapped MCR or MRC access with (coproc==0b1111) that is not reported using EC value 0b000000.	ISS encoding for an exception from an MCR or MRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b000100	Trapped MCRR or MRRC access with (coproc==0b1111) that is not reported using EC value 0b000000.	ISS encoding for an exception from an MCRR or MRRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b000101	Trapped MCR or MRC access with (coproc==0b1110).	ISS encoding for an exception from an MCR or MRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b000110	Trapped LDC or STC access. The only architected uses of these instruction are: • An STC to write data to memory from DBGDTRRXint. • An LDC to read data from memory to DBGDTRTXint.	ISS encoding for an exception from an LDC or STC instruction	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b000111	Access to SME, SVE, Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control. Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.	ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps	ISS2 encoding for all other exceptions	
0b001001	Trapped use of a Pointer authentication instruction.	ISS encoding for an exception from a trapped Pointer Authentication instruction	ISS2 encoding for all other exceptions	FEAT_PAuth is implemented
0b001010	Trapped execution of any instruction not covered by other EC values.	ISS encoding for an exception from any other instruction	ISS2 encoding for all other exceptions	FEAT_LS64 is implemented
0b001100	Trapped MRRC access with (coproc==0b1110).	ISS encoding for an exception from an MCRR or MRRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b001101	Branch Target Exception.	ISS encoding for a Branch Target Exception	ISS2 encoding for all other exceptions	FEAT_BTI is implemented
0b001110	Illegal Execution state.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b010001	SVC instruction execution in AArch32 state.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b010100	Trapped MSRR, MRRS or System instruction execution in AArch64 state, that is not reported using EC value 0b000000.	ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	FEAT_SYSREG128 is implemented or FEAT_SYSINSTR128 is implemented
0b010101	SVC instruction execution in AArch64 state.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b011000	Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC values 0b000000, 0b000001, or 0b000111. This includes all instructions that cause exceptions that are part of the encoding space defined in 'System instruction class encoding overview', except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.	ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b011001	Access to SVE functionality trapped as a result of CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC value 0b000000.	ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ	ISS2 encoding for all other exceptions	FEAT_SVE is implemented
0b011010	Trapped ERET, ERETAA, or ERETAB instruction execution.	ISS encoding for an exception from an ERET, ERETAA, or ERETAB instruction	ISS2 encoding for all other exceptions	FEAT_FGT is implemented or FEAT_NV is implemented
0b011100	Exception from a PAC Fail	ISS encoding for a PAC Fail exception	ISS2 encoding for all other exceptions	FEAT_FPAC is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b011101	Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, CPTR_EL3.ESM, or an attempted execution of an instruction that is illegal because of the value of PSTATE.SM or PSTATE.ZA, that is not reported using EC value 0b000000.	ISS encoding for an exception due to SME functionality	ISS2 encoding for all other exceptions	FEAT_SME is implemented
0b100000	Instruction Abort from a lower Exception level. Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100001	Instruction Abort taken without a change in Exception level. Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100010	PC alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b100100	Data Abort exception from a lower Exception level. Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100101	Data Abort exception taken without a change in Exception level. Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100110	SP alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b100111	Memory Operation Exception.	ISS encoding for an exception from the Memory Copy and Memory Set instructions	ISS2 encoding for all other exceptions	FEAT_MOPS is implemented
0b101000	Trapped floating-point exception taken from AArch32 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b101100	Trapped floating-point exception taken from AArch64 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b101101	GCS exception.	ISS encoding for a GCS exception	ISS2 encoding for all other exceptions	FEAT_GCS is implemented
0b101111	SError exception.	ISS encoding for an SError exception	ISS2 encoding for all other exceptions	
0b110000	Breakpoint exception from a lower Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110001	Breakpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110010	Software Step exception from a lower Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110011	Software Step exception taken without a change in Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110100	Watchpoint exception from a lower Exception level.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b110101	Watchpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b111000	BKPT instruction execution in AArch32 state.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b111100	BRK instruction execution in AArch64 state.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b111101	Profiling exception	ISS encoding for a Profiling exception	ISS2 encoding for all other exceptions	FEAT_EBEP is implemented, or FEAT_SPE_EXC is implemented, or FEAT_TRBE_EXC is implemented

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

IL	Meaning
0b0	16-bit instruction trapped.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IL	Meaning

`0b1`	32-bit instruction trapped. This value is also used when the exception is one of the following:
	• An SError exception.
	• An Instruction Abort exception.
	• A PC alignment fault exception.
	• An SP alignment fault exception.
	• A Data Abort exception for which the value of the ISV bit is 0.
	• An Illegal Execution state exception.
	• Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
	  • ‘0’: 16-bit T32 BKPT instruction.
	  • ‘1’: 32-bit A32 BKPT instruction or A64 BRK instruction.
	• An exception reported using EC value `0b000000`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

For an exception taken from AArch32 state, see ‘Mapping of the general-purpose registers between the Execution states’.

If the AArch32 register descriptor is `0b1111`, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value `0b11111`.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  - The value `0b11111`.

ISS encoding for exceptions with an unknown reason

24 … 0
RES0

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for exceptions with an unknown reason

When an exception is reported using this EC value, the IL field is set to 1.

This EC value is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
  - Instruction encodings that are unallocated.
  - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR_EL3.SMD.
  - An HLT instruction when disabled by EDSCR.HDE.
- Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.
- Attempted execution of an MSR or MRS instruction using a _EL12 register name when the Effective value of HCR_EL2.E2H is not 1.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction when the value of HCR_EL2.TGE is 1 and EL2 is disabled or not implemented in the current Security state.
  - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon.
- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, and EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to SPSR_mon, SP_mon, or LR_mon.
- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1. If the value of HCR_EL2.TGE is 0, this exception is reported using an ESR_EL1.EC value of `0b000111`.
- If FEAT_UINJ is implemented, an Undefined exception caused by attempting to execute any instruction when PSTATE.UINJ is 1.

ISS encoding for an exception from a WF* instruction

24	23 – 20	19 – 10	9 – 5	4 – 3	2	1 – 0
CV	COND	RES0	RN	RES0	RV	TI

CV, bit [24]

Condition code valid.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:10]

Reserved, RES0.

RN, bits [9:5]

When FEAT_WFxT is implemented:

Register Number. Indicates the register number supplied for a WFET or WFIT instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:3]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

RV, bit [2]

When FEAT_WFxT is implemented:

Register field Valid.

If TI[1] == 1, then this field indicates whether RN holds a valid register number for the register argument to the trapped `WFET` or `WFIT` instruction.

RV	Meaning
`0b0`	Register field invalid.
`0b1`	Register field valid.

If TI[1] == 0, then this field is RES0.

This field is set to 1 on a trap on `WFET` or `WFIT`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

TI	Meaning	Applies when
`0b00`	WFI trapped.	
`0b01`	WFE trapped.	
`0b10`	WFIT trapped.	FEAT_WFxT is implemented
`0b11`	WFET trapped.	FEAT_WFxT is implemented

When FEAT_WFxT is implemented, this is a two bit field as shown. Otherwise, bit[1] is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a WF* instruction

The following fields describe configuration settings for generating this exception:

- HCR.{TWE, TWI}.
- SCTLR_EL1.{nTWE, nTWI}.
- SCTLR_EL2.{nTWE, nTWI}.
- HCR_EL2.{TWE, TWI}.
- SCR_EL3.{TWE, TWI}.

ISS encoding for an exception from an MCR or MRC access

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

24	23 20	19 17	16 14	13 10	9 5	4 1	0
CV	COND	Opc2	Opc1	CRn	Rt	CRm	Direction

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value `0b000`.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value `0b111`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

If the Rt value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See ‘Mapping of the general-purpose registers between the Execution states’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value `0b0000`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write to System register space. MCR instruction.
`0b1`	Read from System register space. MRC or VMRS instruction.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an MCR or MRC access

The following fields describe configuration settings for generating exceptions from an MCR or MRC access using coproc `0b1111`, that are reported using EC value `0b000011`:

- If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, trapped to EL1.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- PMUSERENR_EL0.{ER, CR, SW, EN}, for accesses to Performance Monitor System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- HCR.{TRVM, TVM} and HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, trapped to EL2.
- HCR.TTLB and HCR_EL2.TTLB, for execution of TLB maintenance instructions at EL1 using AArch32 state, trapped to EL2.
- HCR.{TSW, TPC, TPU} and HCR_EL2.{TSW, TPC, TPU} for execution of cache maintenance instructions at EL0 and EL1 using AArch32 state, trapped to EL2.
- HCR.TAC and HCR_EL2.TACR, for accesses to the Auxiliary Control Register at EL1 using AArch32 state, trapped to EL2.
- HCR.TIDCP and HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations at EL0 and EL1 using AArch32 state, trapped to EL2.
- If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, trapped to EL2.
- HCR.{TID1, TID2, TID3} and HCR_EL2.{TID1, TID2, TID3}, for accesses to ID registers at EL0 and EL1 using AArch32 state, trapped to EL2.
- HCR2.TERR, for Non-secure accesses to error record registers at EL1 using AArch32 state, trapped to EL2.
- HCPTR.TCPAC and CPTR_EL2.TCPAC, for accesses to CPACR_EL1 or CPACR using AArch32 state, trapped to EL2.
- HSTR.T<n> and HSTR_EL2.T<n>, for accesses to System registers using AArch32 state, trapped to EL2.
- CNTHCTL.PL1PCEN and CNTHCTL_EL2.EL1PCEN, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HDCR.TTRF, for Non-secure accesses to trace filter control registers from System registers using AArch32 state, trapped to EL2.
- HDCR.{TPM, TPMCR} and MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HCPTR.TAM and CPTR_EL2.TAM, for accesses to Activity Monitors System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- CPTR_EL3.TCPAC, for accesses to CPACR from EL1 and EL2, and accesses to HCPTR from EL2 using AArch32 state, trapped to EL3.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- CPTR_EL3.TAM, for accesses to Activity Monitors System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, access to some registers at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions from an MCR or MRC access using coproc `0b1110`, that are reported using EC value `0b000101`:

- CPACR_EL1.TTA for accesses to trace System registers, trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers at EL0 and EL1 using AArch32 state, trapped to EL1 or EL2.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC System registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC System registers at EL0, EL1, and EL2 trapped to EL3.
- HCR.TID0 and HCR_EL2.TID0, for accesses to the JIDR register in the ID group 0 at EL0 and EL1 using AArch32, trapped to EL2.
- HCPTR.TTA and CPTR_EL2.TTA, for accesses to trace System registers using AArch32, trapped to EL2.
- HDCR.TDRA and MDCR_EL2.TDRA, for accesses to Debug ROM registers DBGDRAR and

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DBGDSAR using AArch32, trapped to EL2.
- HDCR.TDOSA and MDCR_EL2.TDOSA, for accesses to powerdown debug System registers, using AArch32 state, trapped to EL2.
- HDCR.TDA and MDCR_EL2.TDA, for accesses to other debug System registers, using AArch32 state, trapped to EL2.
- CPTR_EL3.TTA, for accesses to trace System registers using AArch32, trapped to EL3.
- MDCR_EL3.TDOSA, for accesses to powerdown debug System registers using AArch32, trapped to EL3.
- MDCR_EL3.TDA, for accesses to other debug System registers, using AArch32, trapped to EL3.

The following fields describe configuration settings for generating exceptions from a VMSR or VMRS access, that are reported using EC value `0b001000`:

- HCR.TID0 and HCR_EL2.TID0, for accesses to the FPSID register in ID group 0 at EL1 using AArch32 state, VMRS access trapped to EL2.
- HCR.TID3 and HCR_EL2.TID3, for accesses to registers in ID group 3 including MVFR0, MVFR1 and MVFR2, VMRS access trapped to EL2.
- HCPTR.{TCP10, TCP11}, for Non-secure accesses to FPSCR, FPSID, FPEXC, MVFR0, MVFR1, and MVFR2, trapped to EL2.

ISS encoding for an exception from any other instruction

ISS, bits [24:0]

ISS	Meaning	Applies when
`0b0000000000000000000000000`	`ST64BV` instruction trapped.	FEAT_LS64_V is implemented
`0b0000000000000000000000001`	`ST64BV0` instruction trapped.	FEAT_LS64_ACCDATA is implemented
`0b0000000000000000000000010`	`LD64B` or `ST64B` instruction trapped.	FEAT_LS64 is implemented

All other values are reserved.

ISS encoding for an exception from an MCRR or MRRC access

CV, bit [24]

Condition code valid.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

If the Rt2 value is not 0b1111, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt2 value is 0b1111:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value 0b11111.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See 'Mapping of the general-purpose registers between the Execution states'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer.

If the Rt value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See 'Mapping of the general-purpose registers between the Execution states'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write to System register space. MCRR instruction.
`0b1`	Read from System register space. MRRC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an MCRR or MRRC access

The following fields describe configuration settings for generating exceptions from an MCRR or MRRC access using coproc `0b1111`, that are reported using EC value `0b000100`:

- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, trapped to EL1 or EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- PMUSERENR_EL0.{CR, EN}, for accesses to Performance Monitor System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- AMUSERENR_EL0.{EN}, for accesses to Activity Monitors System registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 using AArch32 state, trapped to EL1 or EL2.
- HCR.{TRVM, TVM} and HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, trapped to EL2.
- HCR2.TERR, for Non-secure accesses to error record registers at EL1 using AArch32 state, trapped to EL2.
- HSTR.T<n> and HSTR_EL2.T<n>, for accesses to System registers using AArch32 state, trapped to EL2.
- CNTHCTL.{PL1PCEN, PL1PCTEN} and CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HDCR.TPM and MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HCPTR.TAM and CPTR_EL2.TAM, for accesses to Activity Monitors System registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 and EL1 using AArch32 state, trapped to EL2.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- CPTR_EL3.TAM, for accesses to Activity Monitors System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, HDFGRTR_EL2.PMCCNTR_EL0 for MRRC access and HDFGWTR_EL2.PMCCNTR_EL0 for MCRR access to PMCCNTR at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions from an MCRR or MRRC access using coproc `0b1110`, that are reported using EC value `0b001100`:

- MDSCR_EL1.TDCC, for accesses to the Debug ROM registers DBGDSAR and DBGDRAR at EL0 using AArch32 state, trapped to EL1 or EL2.
- HDCR.TDRA and MDCR_EL2.TDRA, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, trapped to EL2.
- MDCR_EL3.TDA, for accesses to debug System registers, using AArch32, trapped to EL3.
- CPACR_EL1.TTA for accesses to trace System registers using AArch32, trapped to EL1 or EL2.
- HCPTR.TTA and CPTR_EL2.TTA, for accesses to trace System registers using AArch32, trapped to EL2.
- CPTR_EL3.TTA, for accesses to trace System registers using AArch32, trapped to EL3.

Note

If FEAT_ETMv4 or FEAT_ETE are implemented, MCRR and MRRC accesses to trace System registers are UNDEFINED and the resulting exception is higher priority than an exception due to these traps.

ISS encoding for an exception from an LDC or STC instruction

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]

The immediate value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

Rn, bits [9:5]

The Rn value from the issued instruction, the general-purpose register used for the transfer.

If the Rn value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rn value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

See ‘Mapping of the general-purpose registers between the Execution states’.

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

Offset	Meaning
`0b0`	Subtract offset.
`0b1`	Add offset.

This bit corresponds to the U bit in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

AM	Meaning
`0b000`	Immediate unindexed.
`0b001`	Immediate post-indexed.
`0b010`	Immediate offset.
`0b011`	Immediate pre-indexed.
`0b100`	For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
`0b110`	For a trapped STC instruction, this encoding is reserved.

The values `0b101` and `0b111` are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in ‘Reserved values in System and memory-mapped registers and translation table entries’.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Direction	Meaning
0b0	Write to memory. STC instruction.
0b1	Read from memory. LDC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an LDC or STC instruction

The following fields describe the configuration settings from an LDC or STC access for the traps that are reported using EC value 0b000110:

- MDSCR_EL1.TDCC, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL1 or EL2.
- HDCR.TDA and MDCR_EL2.TDA, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL2.
- MDCR_EL3.TDA, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC System registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC System registers at EL0, EL1, and EL2 trapped to EL3.

ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

24	23 20	19 0
CV	COND	RES0

The accesses covered by this trap include:

- Execution of Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.
- Execution of SVE instructions.
- Execution of SME instructions.

For an implementation that does not include either SVE or support for Advanced SIMD and floating-point, the exception is reported using the EC value 0b000000.

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

The following fields describe the configuration settings for the traps that are reported using EC value `0b000111`:

- HCPTR.{TCP10, TCP11}, for Non-secure accesses to Advanced SIMD and floating-point registers and instructions, trapped to EL2.
- HCPTR.TASE, for Non-secure accesses to Advanced SIMD functionality, trapped to EL2.
- CPACR_EL1.FPEN, for accesses to SIMD and floating-point registers trapped to EL1.
- CPTR_EL2.FPEN and CPTR_EL2.TFP, for accesses to SIMD and floating-point registers trapped to EL2.
- CPTR_EL3.TFP, for accesses to SIMD and floating-point registers trapped to EL3.

ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

24 … 0
RES0

The accesses covered by this trap include:

- Execution of SVE instructions when the PE is not in Streaming SVE mode.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Accesses to the SVE System registers, ZCR_ELx.

For an implementation that does not include SVE, the exception is reported using the EC value `0b000000`.

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

The following fields describe the configuration settings for the traps that are reported using EC value `0b011001`:

- CPACR_EL1.ZEN, for execution of SVE instructions and accesses to SVE registers at EL1 or EL0, trapped to EL1.
- CPTR_EL2.ZEN and CPTR_EL2.TZ, for execution of SVE instructions and accesses to SVE registers at EL0, EL1, or EL2, trapped to EL2.
- CPTR_EL3.EZ, for execution of SVE instructions and accesses to SVE registers from all Exception levels, trapped to EL3.

ISS encoding for a Profiling exception

Bits [24:6]

Reserved, RES0.

FSC, bits [5:1]

Indicates why the Profiling exception was generated.

FSC	Meaning	Applies when
`0b00000`	PMU Profiling exception. The exception was generated because at least one PMU counter overflow status flag was 1.	FEAT_EBEP is implemented
`0b00001`	Profiling Buffer management event. The exception was generated because PMBSR_EL1.S was 1.	FEAT_SPE_EXC is implemented
`0b00010`	Trace buffer management event. The exception was generated because TRBSR_EL1.IRQ was 1.	FEAT_TRBE_EXC is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see 'PC alignment checking'.

'SP alignment checking' describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from the Memory Copy and Memory Set instructions

MemInst, bit [24]

Indicates the memory instruction class causing the exception.

MemInst	Meaning
0b0	CPYFE*, CPYFM*, CPYE*, and CPYM* instructions.
0b1	The instruction that caused the exception is in one of the following instruction classes: • SETE*, SETM*. • SETGE*, SETGM*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

isSETG, bit [23]

Indicates whether the instruction belongs to one of the following instruction classes:

- SETGE*, SETGM*.

isSETG	Meaning
0b0	The instruction that caused the exception is not in one of the specified classes.
0b1	The instruction that caused the exception is in one of the specified classes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Options, bits [22:19]

Options : the Options field of the instruction.

For Memory Copy instructions, bits[22:19] forms the Options field, which holds the bits[15:12] of the instruction.

For Memory Set instructions:

- Bits[22:21] are RES0.
- Bits[20:19] form the Options field, which holds the bits[13:12] of the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FromEpilogue, bit [18]

Indicates whether the instruction belongs to one of the following epilogue classes of Memory Copy or Memory Set instructions:

- CPYE*, CPYFE*.
- SETE*, SETGE*.

FromEpilogue	Meaning
`0b0`	The instruction that caused the exception is not in one of the specified classes.
`0b1`	The instruction that caused the exception is in one of the specified classes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FormatOption, bits [17:16]

Reports the Option used to encode the initial Xs, Xd, and Xn register values provided to the instruction that generated the exception.

FormatOption	Meaning
`0b00`	Option B.
`0b01`	Option A.
`0b10`	Option A.
`0b11`	Option B.

For more information, see Memory Copy and Memory Set exceptions.

Note

This field was previously presented as two separate bits, WrongOption, bit[17] and OptionA, bit [16], which were already expected to be used together and not individually.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

destreg, bits [14:10]

The destination register value from the issued instruction, containing the destination address.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

srcreg, bits [9:5]

The source register value from the issued instruction, containing either the source address or the source data.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

sizereg, bits [4:0]

The size register value from the issued instruction, containing the number of bytes to be transferred or set.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from HVC or SVC instruction execution

24 … 16	15 … 0
RES0	imm16

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from HVC or SVC instruction execution

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see ‘SVC’ and ‘HVC’.

For A64 instructions, see ‘SVC’ and ‘HVC’.

Non-Confidential

If FEAT_FGT is implemented, HFGITR_EL2.{SVC_EL1, SVC_EL0} control fine-grained traps on SVC execution.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

For system instructions which require that the opcode Rt field is set to `0b11111`, but where the trapped instruction has a different value of Rt, an implementation is permitted to return the value `0b11111`, instead of the value of Rt from the trapped instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write access, including MSR instructions.
0b1	Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

For exceptions caused by System instructions, see 'System instructions' subsection of 'Branches, exception generating and System instructions' for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL1.
- SCTLR_EL1.UCI, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UCT, for accesses to CTR_EL0 using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- SCTLR_EL1.DZE, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- CPACR_EL1.TTA, for accesses to the trace System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- PMUSERENR_EL0, for accesses to the Performance Monitor System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TDZ, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TTLB, for execution of TLB maintenance instructions using AArch64 state, execution is trapped to EL2.
- If FEAT_EVT is implemented, the following registers control traps for EL1 and EL0 registers and instructions that use this EC value:
  - HCR_EL2.{TICAB, TOCU, TID4}.
  - HCR2.{TICAB, TOCU, TID4}.
- If FEAT_EVT2 is implemented, the following registers control traps for EL1 and EL0 instructions that use this EC value:
  - HCR_EL2.{TTLBOS, TTLBIS}.
- If FEAT_EVT2 is implemented, HCR2.TTLBIS controls traps for EL1 and EL0 instructions using AArch32 state that use this EC value.
- HCR_EL2.{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- HCR_EL2.TACR, for accesses to the Auxiliary Control Register, ACTLR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- If FEAT_MTE2 is implemented, HCR_EL2.TID5, for accesses to GMID_EL1, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.
- If FEAT_IDTE3 is implemented, SCR_EL3.TID3, for accesses to ID group 3 registers using AArch64 state, at EL1 and EL2, trapped to EL3.
- CPTR_EL2.TCPAC, for accesses to CPACR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TTA, for accesses to the trace System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TTRF, for accesses to the trace filter control register, TRFCR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDOSA, for accesses to powerdown debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDA, for accesses to debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TAM, for accesses to Activity Monitors System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{NV, NV1}, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
- HCR_EL2.AT, for execution of AT S1E* instructions, using AArch64 state, execution is trapped to EL2.
- HCR_EL2.{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.
- SCR_EL3.APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL3.
- SCR_EL3.ST, for accesses to the Counter-timer Physical Secure timer registers, using AArch64 state, MSR or MRS access trapped to EL3.
- SCR_EL3.{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access trapped to EL3.
- CPTR_EL3.TCPAC, for accesses to CPTR_EL2 and CPACR_EL1 using AArch64 state, MSR or MRS access trapped to EL3.
- CPTR_EL3.TTA, for accesses to the trace System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TTRF, for accesses to the trace filter control registers, TRFCR_EL1 and TRFCR_EL2, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TDA, for accesses to debug System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TDOSA, for accesses to powerdown debug System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- If FEAT_SPE is implemented:
  - MDCR_EL3.NSPB for accesses to Statistical Profiling and Profiling Buffer control registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
  - MDCR_EL2.TPMS for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 trapped to EL2.
- CPTR_EL3.TAM, for accesses to Activity Monitors System registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If FEAT_FGT is implemented:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - SCR_EL3.FGTEn, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
  - HFGRTR_EL2 for reads and HFGWTR_EL2 for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 trapped to EL2.
  - HFGITR_EL2 for execution of system instructions trapped to EL2.
  - HDFGRTR_EL2 for reads and HDFGWTR_EL2 for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 state trapped to EL2.
  - HAFGRTR_EL2 for reads of Activity Monitor counters, using AArch64 state, MRS access at EL0 and EL1 trapped to EL2.
- If FEAT_RNG_TRAP is implemented, SCR_EL3.TRNDR for reads of RNDR and RNDRRS using AArch64 state, MRS access trapped to EL3.
- If FEAT_SME is implemented:
  - CPTR_EL3.ESM, for MSR or MRS accesses to SMPRI_EL1 at EL1, EL2, and EL3, trapped to EL3.
  - CPTR_EL3.ESM, for MSR or MRS accesses to SMPRIMAP_EL2 at EL2 and EL3, trapped to EL3.
  - SCTLR_EL1.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL1 or EL2.
  - SCTLR_EL2.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL2.
  - SCR_EL3.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, EL1, and EL2, trapped to EL3.
- If FEAT_FPMR is implemented:
  - SCTLR_EL1.EnFPM, for accesses to FPMR at EL0, trapped to EL1 or EL2.
  - SCTLR_EL2.EnFPM, for accesses to FPMR at EL0, trapped to EL2.
  - HCRX_EL2.EnFPM, for accesses to FPMR at EL0 and EL1, trapped to EL2.
  - SCR_EL3.EnFPM, for accesses to FPMR at EL0, EL1, and EL2, trapped to EL3.
- If FEAT_NMI is implemented, HCRX_EL2.TALLINT, for MSR writes of ALLINT at EL1, trapped to EL2.
- If FEAT_FGT2 is implemented:
  - SCR_EL3.FGTEn2, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
  - HFGRTR2_EL2 for reads and HFGWTR2_EL2 for writes of registers, using AArch64 state, using MSR or MRS access at EL1 trapped to EL2.
  - HDFGRTR2_EL2 for reads and HDFGWTR2_EL2 for writes of registers, using AArch64 state, using MSR or MRS access at EL0 and EL1 trapped to EL2.
  - HFGITR2_EL2 for execution of system instructions trapped to EL2.
- If FEAT_ITE is implemented, MDCR_EL3.EnITE, for accesses to Instrumentation trace System registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If FEAT_MEC is implemented, SCR_EL3.MECEn, for accesses to MECID registers at EL2, trapped to EL3.
- If FEAT_SPE_FDS is implemented, MDCR_EL3.EnPMS3 for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
- If FEAT_SPE_nVM is implemented, MDCR_EL3.EnPMS4 for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
- If FEAT_RASv2 is implemented, SCR_EL3.TWERR, for accesses to Error Record registers, MSR access at EL1 and EL2 trapped to EL3.
- If FEAT_Debugv8p9 is implemented, MDCR_EL3.EBWE for accesses of MDSELR_EL1, using AArch64 state, MRS or MSR access at EL2 and EL1 trapped to EL3.
- If FEAT_PMUv3p9, FEAT_SPMU, FEAT_EBEP, or FEAT_PMUv3_SS is implemented, MDCR_EL3.EnPM2, for accesses to PMU System registers, using AArch64 state, MSR or MRS access at EL2, EL1, and EL0, trapped to EL3.
- If FEAT_PMUv3_SS is implemented, MDCR_EL3.EnPMSS, for accesses to PMU Snapshot registers, using AArch64 state, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_THE is implemented, SCR_EL3.RCWMASKEn for accesses to RCWMASK_EL1 and RCWSMASK_EL1, using AArch64 state, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_AIE is implemented, SCR_EL3.AIEn for accesses to Extended Memory Attribute registers, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_S1PIE, FEAT_S2PIE, FEAT_S1POE, or FEAT_S2POE is implemented, SCR_EL3.PIEn for accesses to Permission Indirection, Overlay registers, MSR or MRS access at EL2, EL1 and EL0 trapped to EL3.
- If FEAT_MPAM_PE_BW_CTRL is implemented, MPAMBW2_EL2.{nTRAP_MPAMBWIDR_EL1, nTRAP_MPAMBW0_EL1, nTRAP_MPAMBW1_EL1} for accesses to MPAMBWn_EL1 registers, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_MPAM_PE_BW_CTRL and FEAT_SME are implemented, MPAMBW2_EL2.nTRAP_MPAMBWSM_EL1, for accesses to MPAMBWSM_EL1, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.
- If FEAT_MPAM_PE_BW_CTRL is implemented, MPAMBW3_EL3.nTRAPLOWER, for accesses to MPAMBW2_EL2 and MPAMBWn_EL1 registers, using AArch64 state, MRS or MSR access at EL1, trapped to EL3.
- If FEAT_HACDBS is implemented, SCR_EL3.HACDBSEn, for accesses to HACDBSBR_EL2 and HACDBSCONS_EL2, using AArch64 state, MRS or MSR access at EL2, trapped to EL3.
- If FEAT_HDBSS is implemented, SCR_EL3.HDBSSEn, for accesses to HDBSSBR_EL2 and HDBSSPROD_EL2, using AArch64 state, MRS or MSR access at EL2, trapped to EL3.
- If FEAT_SRMASK is implemented, SCR_EL3.SRMASKEn, for MSR or MRS accesses at EL1 or EL2 to the MASK registers using AArch64 state, trapped to EL3.

ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:6]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

Note

This value represents register pair of X[Rt:0], X[Rt:1].

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write access, MSRR instructions.
`0b1`	Read access, MRRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

The following fields describe configuration settings for generating exceptions from an MSRR or MRRS access that are reported using EC value `0b010100`:

- If FEAT_FGT is implemented:
  - HFGRTR_EL2 for reads and HFGWTR_EL2 for writes of registers, using AArch64 state, accesses at EL1 trapped to EL2.
- If FEAT_FGT2 is implemented:
  - HFGRTR2_EL2.nRCWSMASK_EL1 for reads and HFGWTR2_EL2.nRCWSMASK_EL1 for writes of RCWSMASK_EL1, using AArch64 state, accesses at EL1 trapped to EL2.
- If FEAT_SYSREG128 is implemented:
  - SCTLR2_EL1.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL0 trapped to EL1.
  - SCTLR2_EL2.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL0 trapped to EL2.
  - HCRX_EL2.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL1 and EL0 trapped to EL2.
  - SCR_EL3.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL2, EL1, and EL0 trapped to EL3.
- If FEAT_D128 is implemented:
  - HCR_EL2.{TRVM, TVM} for accesses to TTBR0_EL1 and TTBR1_EL1, accesses at EL1 and EL0 trapped to EL2.
  - HCRX_EL2.D128En for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL1 trapped to EL2.
  - HFGITR_EL2 for execution of TLBIP system instructions trapped to EL2.
  - HCR_EL2.{TTLB, TTLBOS, TTLBIS}, for execution of TLBIP instructions using AArch64 state, execution is trapped to EL2.
  - SCR_EL3.D128En for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL2 and EL1 trapped to EL3.
- If FEAT_THE is implemented, SCR_EL3.RCWMASKEn for accesses to RCWMASK_EL1 and RCWSMASK_EL1, using AArch64 state, accesses at EL2 and EL1 trapped to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS encoding for an exception from an Instruction Abort

The ISS2 encoding for an exception from an Instruction Abort includes further information about the exception if any of the following are true:

- FEAT_S1POE is implemented and a memory access generates a Instruction Abort due to a Permission fault.
- FEAT_HDBSS is implemented.
- FEAT_THE is implemented.

Bits [24:15]

Reserved, RES0.

PFV, bit [14]

When FEAT_PFAR is implemented and GetESR_ELx_IFSC(EL1) IN {'010000', '01001x', '0101xx'}:

PFAR Valid. Describes whether the PFAR_EL1 register is valid.

PFV	Meaning
0b0	PFAR_EL1 is UNKNOWN.
0b1	PFAR_EL1 is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [13]

Reserved, RES0.

SET, bits [12:11]

When FEAT_RAS is implemented and GetESR_ELx_IFSC(EL1) IN {'010000', '01001x', '0101xx'}:

Synchronous Error Type. Describes the PE error state after taking the Instruction Abort exception.

SET	Meaning	Applies when
0b00	Recoverable state (UER).	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SET	Meaning	Applies when
0b10	Uncontainable (UC).	FEAT_RASv2 is not implemented
0b11	Restartable state (UEO).	

All other values are reserved.

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001000	Access flag fault, level 0.	FEAT_LPA2 is implemented
0b001100	Permission fault, level 0.	FEAT_LPA2 is implemented
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010010	Synchronous External abort on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented
0b010011	Synchronous External abort on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning	Applies when
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011011	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented and FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100010	Granule Protection Fault on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented and FEAT_RME is implemented
0b100011	Granule Protection Fault on translation table walk or hardware update of translation table, level -1.	FEAT_RME is implemented and FEAT_LPA2 is implemented
0b100100	Granule Protection Fault on translation table walk or hardware update of translation table, level 0.	FEAT_RME is implemented
0b100101	Granule Protection Fault on translation table walk or hardware update of translation table, level 1.	FEAT_RME is implemented
0b100110	Granule Protection Fault on translation table walk or hardware update of translation table, level 2.	FEAT_RME is implemented
0b100111	Granule Protection Fault on translation table walk or hardware update of translation table, level 3.	FEAT_RME is implemented
0b101000	Granule Protection Fault, not on translation table walk or hardware update of translation table.	FEAT_RME is implemented
0b101001	Address size fault, level -1.	FEAT_LPA2 is implemented
0b101010	Translation fault, level -2.	FEAT_D128 is implemented
0b101011	Translation fault, level -1.	FEAT_LPA2 is implemented
0b101100	Address Size fault, level -2.	FEAT_D128 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning	Applies when
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented

All other values are reserved.

For more information about the lookup level associated with a fault, see 'The lookup level associated with MMU faults'.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception due to SME functionality

24 … 3	2 … 0
RES0	SMTC

The accesses covered by this trap include:

- Execution of SME instructions.
- Execution of SVE and Advanced SIMD instructions, when the PE is in Streaming SVE mode.
- Direct accesses of SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3.

Bits [24:3]

Reserved, RES0.

SMTC, bits [2:0]

SME Trap Code. Identifies the reason for instruction trapping.

SMTC	Meaning	Applies when
0b000	Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, or CPTR_EL3.ESM, that is not reported using EC value 0b000000.	
0b001	Advanced SIMD, SVE, or SVE2 instruction trapped because PSTATE.SM is 1.	
0b010	SME instruction trapped because PSTATE.SM is 0.	
0b011	SME instruction trapped because PSTATE.ZA is 0.	
0b100	Access to the SME2 ZT0 register trapped as a result of SMCR_EL1.EZT0, SMCR_EL2.EZT0, or SMCR_EL3.EZT0.	FEAT_SME2 is implemented

All other values are reserved.

Additional Information for ISS encoding for an exception due to SME functionality

The following fields describe the configuration settings for the traps that are reported using the EC value 0b011101:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- CPACR_EL1.SMEN, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR and SMCR_EL1 System registers at EL1 and EL0, trapped to EL1 or EL2.
- CPTR_EL2.SMEN and CPTR_EL2.TSM, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2 at EL2, EL1, and EL0, trapped to EL2.
- CPTR_EL3.ESM, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3 from all Exception levels and any Security state, trapped to EL3.
- If FEAT_SME2 is implemented:
  - SMCR_EL1.EZT0, for accesses to ZT0 at EL1 and EL0, trapped to EL1 or EL2.
  - SMCR_EL2.EZT0, for accesses to ZT0 at EL2, EL1, and EL0, trapped to EL2.
  - SMCR_EL3.EZT0, for accesses to ZT0 at any Exception level, trapped to EL3.

ISS encoding for an exception from a Data Abort

The ISS2 encoding for an exception from a Data Abort includes further information about the exception when any of the following features are implemented:

- FEAT_LS64_V.
- FEAT_LS64_ACCDATA.
- FEAT_S1POE or FEAT_S2POE.
- FEAT_S1PIE or FEAT_S2PIE.
- FEAT_GCS.
- FEAT_MTE_CANONICAL_TAGS.
- FEAT_HDBSS.
- FEAT_MTE_PERM.

ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] represents the instruction syndrome fields {SAS, SSE, SRT, SF, AR}.

ISV	Meaning
0b0	No valid instruction syndrome. ISS[23:14] do not represent an instruction syndrome.
0b1	ISS[23:14] hold a valid instruction syndrome.

The ISV field is only relevant for the following instructions:

- An AArch64 load or store of a single general-purpose register (including the register specified with 0b11111, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- An AArch32 instruction LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT, where both of the following apply:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - It is not performing register writeback.
  - It is not using R15 as a source or destination register.
- If FEAT_LS64 is implemented, an LD64B or ST64B instruction.
- If FEAT_LS64_V is implemented, an ST64BV instruction.
- If FEAT_LS64_ACCDATA is implemented, an ST64BV0 instruction.

The ISV field is 1 if all of the following apply:

- The fault was not a stage 2 fault on a stage 1 translation table walk.
- If FEAT_RAS is implemented, the fault was not any kind of synchronous External abort.
- Any of the following apply:
  - The fault was generated by one of the described AArch64 load or store instructions that transfer a single general-purpose register, and any of the following apply:
    - The fault was a stage 2 fault.
  - The fault was generated by one of the described AArch32 instructions and any of the following apply:
    - The fault was a stage 2 fault.
  - The fault was generated by one of the FEAT_LS64, FEAT_LS64_V or FEAT_LS64_ACCDATA instructions and the fault was a Translation fault, Access flag fault or Permission fault.
- One of the following applies:
  - The address reported in FAR_EL1 is the lowest address accessed by the instruction.
  - The address reported in FAR_EL1 is not the lowest address accessed by the instruction, and the implementation reports ISV as 1 in this case. Arm recommends against this behavior.

The value of this field is UNKNOWN when the following occurs:

- Stage 2 faults when the exception was generated in Debug state, in memory access mode.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

Otherwise the value of this field is 0.

Note

The value of this field is 0 if any of the following apply:

- FEAT_MOPS is implemented and the fault was for a memory access generated by a Memory Copy and Memory Set instruction.
- FEAT_MTE is implemented and the fault was for a direct access to Allocation Tags.
- FEAT_GCS is implemented and the fault was for a Guarded control stack data access.
- FEAT_NV2 is implemented and the fault was for a System register access that was transformed to a load or store relative to VNCR_EL2.
- FEAT_LSE is implemented and the fault was for an atomic instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == '1':

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

SAS	Meaning
0b00	Byte
0b01	Halfword
0b10	Word
0b11	Doubleword

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == '1':

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

SSE	Meaning
`0b0`	Sign-extension not required.
`0b1`	Data item must be sign-extended.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [20:16]

When ISV == '1':

SRT, bits [20:16]

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

If the exception was taken from an Exception level that is using AArch32, then this is the AArch64 view of the register. See ‘Mapping of the general-purpose registers between the Execution states’.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When ISV == '0', FEAT_RASv2 is implemented, and GetESR_ELx_DFSC(EL1) IN {'010000', '01001x', '0101xx'}:

WU, bits [1:0] of bits [20:16]

Write Update. Describes whether a store instruction that generated an External abort updated the location.

WU	Meaning
0b00	Not a store instruction or translation table update, or the location might have been updated.
0b10	Store instruction or translation table update that did not update the location.
0b11	Store instruction or translation table update that updated the location.

In the description of this field, a store instruction is any memory-writing instruction that explicitly performs a store. This includes instructions that both read and write memory.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [15]

When ISV == '1':

SF, bit [15]

Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

SF	Meaning
0b0	Instruction loads/stores a 32-bit general-purpose register.
0b1	Instruction loads/stores a 64-bit general-purpose register.

Note

This field specifies the register width identified by the instruction, not the Execution state.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

FnP, bit [15]

FAR not Precise.

FnP	Meaning	Applies when
0b0	The FAR holds the faulting virtual address that generated the Data Abort.	
0b1	The FAR holds any virtual address within the naturally-aligned granule that contains the faulting virtual address that generated a Data Abort due to an SVE contiguous vector load/store instruction, or an SME load/store instruction. For more information about the naturally-aligned fault granule, see FAR_ELx (for example, FAR_EL1).	FEAT_SME is implemented or FEAT_SVE is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [14]

When ISV == '1':

AR, bit [14]

Acquire/Release.

AR	Meaning
0b0	Instruction did not have acquire/release semantics.
0b1	Instruction did have acquire/release semantics.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_PFAR is implemented and GetESR_ELx_DFSC(EL1) IN {'010000', '01001x', '0101xx'}:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PFV, bit [14]

PFAR Valid. Describes whether the PFAR_EL1 register is valid.

PFV	Meaning
0b0	PFAR_EL1 is UNKNOWN.
0b1	PFAR_EL1 is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [13]

Reserved, RES0.

Bits [12:11]

When GetESR_ELx_DFSC(EL1) IN {'00xxxx', '10101x'} and !(GetESR_ELx_DFSC(EL1) IN {'0000xx'}):

LST, bits [12:11]

Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort reported with ISV=1.

LST	Meaning	Applies when
0b00	The instruction that generated the Data Abort is not specified by this field.	
0b01	An ST64BV instruction generated the Data Abort.	FEAT_LS64_V is implemented
0b10	An LD64B or ST64B instruction generated the Data Abort.	FEAT_LS64 is implemented
0b11	An ST64BV0 instruction generated the Data Abort.	FEAT_LS64_ACCDATA is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL1) == '010000':

SET, bits [12:11]

Synchronous Error Type. Used when a synchronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SET	Meaning	Applies when
0b00	Recoverable state (UER).	
0b10	Uncontainable (UC).	FEAT_RASv2 is not implemented
0b11	Restartable state (UEO).	

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

CM	Meaning
0b0	The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CM	Meaning
0b1	The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Abort caused by an instruction reading from a memory location.
0b1	Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- If FEAT_RASv2 is implemented, an External abort on an Atomic access, reported with ESR_EL1.WU set to 0b00.
- A fault reported using a DFSC value of 0b110101, indicating an unsupported Exclusive or atomic access.
- A fault reported using a DFSC value of 0b110001, indicating an unsupported atomic hardware update fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001000	Access flag fault, level 0.	FEAT_LPA2 is implemented
0b001100	Permission fault, level 0.	FEAT_LPA2 is implemented
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010001	Synchronous Tag Check Fault.	FEAT_MTE2 is implemented
0b010010	Synchronous External abort on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented
0b010011	Synchronous External abort on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011011	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented and FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC	Meaning	Applies when
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100001	Alignment fault.	
0b100010	Granule Protection Fault on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented and FEAT_RME is implemented
0b100011	Granule Protection Fault on translation table walk or hardware update of translation table, level -1.	FEAT_RME is implemented and FEAT_LPA2 is implemented
0b100100	Granule Protection Fault on translation table walk or hardware update of translation table, level 0.	FEAT_RME is implemented
0b100101	Granule Protection Fault on translation table walk or hardware update of translation table, level 1.	FEAT_RME is implemented
0b100110	Granule Protection Fault on translation table walk or hardware update of translation table, level 2.	FEAT_RME is implemented
0b100111	Granule Protection Fault on translation table walk or hardware update of translation table, level 3.	FEAT_RME is implemented
0b101000	Granule Protection Fault, not on translation table walk or hardware update of translation table.	FEAT_RME is implemented
0b101001	Address size fault, level -1.	FEAT_LPA2 is implemented
0b101010	Translation fault, level -2.	FEAT_D128 is implemented
0b101011	Translation fault, level -1.	FEAT_LPA2 is implemented
0b101100	Address Size fault, level -2.	FEAT_D128 is implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).	
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).	

All other values are reserved.

For more information about the lookup level associated with a fault, see ‘The lookup level associated with MMU faults’.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

24	23	22 … 11	10 … 8	7	6 … 5	4	3	2	1	0
RES0	TFV	RES0	VECITR	IDF	RES0	IXF	UFF	OFF	DZF	IOF

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

TFV	Meaning
0b0	The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
0b1	One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see 'Floating-point exceptions and exception traps'.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IDF	Meaning
0b0	Input denormal floating-point exception has not occurred.
0b1	Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IXF	Meaning
0b0	Inexact floating-point exception has not occurred.
0b1	Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

UFF	Meaning
0b0	Underflow floating-point exception has not occurred.
0b1	Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

OFF	Meaning
0b0	Overflow floating-point exception has not occurred.
0b1	Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

DZF	Meaning
0b0	Divide by Zero floating-point exception has not occurred.
0b1	Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IOF	Meaning
0b0	Invalid Operation floating-point exception has not occurred.
0b1	Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a trapped floating-point exception

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for a GCS exception

Bit [24]

Reserved, RES0.

ExType, bits [23:20]

The first level classification of GCS exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ExType	Meaning
0b0000	The exception reported is a Guarded Control Stack Data Check Exception.
0b0001	The exception reported is an EXLOCK Exception.
0b0010	The exception reported is a trap exception on GCSSTR or GCSSTTR instruction execution.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:15]

Reserved, RES0.

Raddr, bits [14:10]

When GetESR_ELx_ExType(EL1) == '0010':

Indicates the data address register number supplied in the instruction that has been trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [9:5]

When GetESR_ELx_ExType(EL1) == '0000':

Rn, bits [9:5]

Indicates a register number used by the instruction that caused the Guarded Control Stack Data Check Exception.

For a procedure return instruction reported with ESR_EL1.ISS.IT as 0b00000, contains the register number for the register which contains the target address of the branch.

For a GCSPOPM instruction reported with ESR_EL1.ISS.IT as 0b00001, contains the register number for the register which is the destination register of the instruction.

For a procedure return instruction reported with ESR_EL1.ISS.IT as 0b00010 or 0b00011, contains the value 0b11110, indicating X30.

For a GCSSS1 instruction reported with ESR_EL1.ISS.IT as 0b00100, contains the register number for the register which is the input register of the instruction.

If ESR_EL1.ISS.IT is reported as 0b00101 or 0b01000, this field is UNKNOWN

If ESR_EL1.ISS.IT is reported as 0b01001, this field is 0b11111

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When GetESR_ELx_ExType(EL1) == '0010':

Rvalue, bits [9:5]

Indicates the data value register number supplied in the instruction that has been trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

IT, bits [4:0]

When GetESR_ELx_ExType(EL1) == '0000':

Type of the instruction that caused the Guarded Control Stack Data Check Exception.

IT	Meaning
`0b00000`	Guarded Control Stack Data Check Exception is from a procedure return instruction without Pointer authentication.
`0b00001`	Guarded Control Stack Data Check Exception is from a GCSPOPM instruction.
`0b00010`	Guarded Control Stack Data Check Exception is from a procedure return instruction with Pointer authentication that uses key A.
`0b00011`	Guarded Control Stack Data Check Exception is from a procedure return instruction with Pointer authentication that uses key B.
`0b00100`	Guarded Control Stack Data Check Exception is from a GCSSS1 instruction.
`0b00101`	Guarded Control Stack Data Check Exception is from a GCSSS2 instruction.
`0b01000`	Guarded Control Stack Data Check Exception is from a GCSPOPCX instruction.
`0b01001`	Guarded Control Stack Data Check Exception is from a GCSPOPX instruction.

All other values are reserved

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Additional Information for ISS encoding for a GCS exception

The following fields describe the configuration settings for the traps that are reported using EC value `0b101101` and ExType value `0b0010`:

- GCSCRE0_EL1.STREn
- GCSCR_EL1.STREn.
- GCSCR_EL2.STREn.
- GCSCR_EL3.STREn.
- HFGITR_EL2.nGCSSTR_EL1.

ISS encoding for an SError exception

Note

In earlier versions of the architecture, an SError exception is referred to as an SError interrupt or an asynchronous External abort exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

IDS	Meaning
0b0	Bits [23:0] of the ISS field holds the fields described in this encoding. **Note** If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.
0b1	Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError exception.

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:19]

Reserved, RES0.

ELS, bit [18]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL1) == '010001':

Meaning of ELR_ELx.

ELS	Meaning
0b0	Asynchronous. Does not indicate the trigger for the exception.
0b1	Synchronous. The exception was triggered by the instruction at ELR_ELx.

SError exceptions that report this field is 1 are not required to be precise.

The ESR_EL1.AET field describes whether the exception is precise or imprecise.

Corrected, Recoverable or Restartable exceptions are precise. Unrecoverable or Uncontainable exceptions are imprecise.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WU, bits [17:16]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL1) == '010001':

Write Update. Describes whether a store instruction that generated an External abort updated the location.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

WU	Meaning
0b00	Not a store instruction or translation table update, or the location might have been updated.
0b10	Store instruction or translation table update that did not update the location.
0b11	Store instruction or translation table update that updated the location.

In the description of this field, a store instruction is any memory-writing instruction that explicitly performs a store. This includes instructions that both read and write memory.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VFV, bit [15]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL1) == '010001':

FAR Valid. Indicates the FAR_EL1 register contains a valid virtual address.

VFV	Meaning
0b0	FAR_EL1 is not valid, and holds an UNKNOWN value.
0b1	FAR_EL1 contains a valid virtual address associated with the error.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PFV, bit [14]

When FEAT_PFAR is implemented and GetESR_ELx_DFSC(EL1) == '010001':

PFAR Valid. Describes whether the PFAR_EL1 register is valid.

PFV	Meaning
0b0	PFAR_EL1 is UNKNOWN.
0b1	PFAR_EL1 is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IESB, bit [13]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_IESB is implemented and GetESR_ELx_DFSC(EL1) == '010001':

Implicit error synchronization event.

IESB	Meaning
0b0	One of the following applies: • The SError exception was not synchronized by the implicit error synchronization event. • The SError exception was not taken immediately following an implicit error synchronization event. • The SError exception was either not synchronized by the implicit error synchronization event or not taken immediately. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 0.
0b1	The SError exception was synchronized by the implicit error synchronization event, taken immediately, and one of the following applies: • The implicit error synchronization event was on an exception entry. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception entry, and the exception is taken immediately after exception entry, this field is set to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception return, and the exception is taken immediately before the exception return, this field is set to an IMPLEMENTATION SPECIFIC choice of 0 or 1.

For all other SError exceptions, this field is set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL1) == '010001':

Asynchronous Error Type.

Describes the PE error state after taking the SError exception.

AET	Meaning
0b000	Uncontainable (UC).
0b001	Unrecoverable state (UEU).
0b010	Restartable state (UEO).
0b011	Recoverable state (UER).
0b110	Corrected (CE).

All other values are reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If multiple errors are taken as a single SError exception, the overall PE error state is reported.

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL1) == '010001':

External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [8]

Reserved, RES0.

WnRV, bit [7]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL1) == '010001':

ESR_EL1.WnR valid.

WnRV	Meaning
`0b0`	ESR_EL1.WnR is not valid and has been set to 0.
`0b1`	ESR_EL1.WnR is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WnR, bit [6]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL1) == '010001':

Write-not-Read. When the WnRV field is 1, indicates whether an exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

WnR	Meaning
0b0	Exception was caused by an instruction reading from a memory location.
0b1	Exception was caused by an instruction writing to a memory location.

Accessing this bit has the following behavior:

- This bit is RES0 if ESR_EL1.WnRV is 0.
- This bit is not valid and reads UNKNOWN if an External abort on a Atomic access, reported with ESR_EL1.WU == 0b00.
- Otherwise RW.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

Data Fault Status Code.

DFSC	Meaning
0b000000	Uncategorized error.
0b010001	Asynchronous SError exception.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

24 … 6	5 … 0
RES0	IFSC

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

For more information about generating these exceptions:

- For exceptions from AArch64, see 'Breakpoint exceptions'.
- For exceptions from AArch32, see 'Breakpoint exceptions' and 'Vector Catch exceptions'.

ISS encoding for an exception from a Software Step exception

24	23 … 7	6	5 … 0
ISV	RES0	EX	IFSC

ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

ISV	Meaning
0b0	EX bit is RES0.
0b1	EX bit is valid.

Arm deprecates software use of this field.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

EX	Meaning
0b0	An instruction other than a Load-Exclusive instruction was stepped.
0b1	A Load-Exclusive instruction was stepped.

Arm deprecates software use of this field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Software Step exception

For more information about generating these exceptions, see 'Software Step exceptions'.

ISS encoding for an exception from a Watchpoint exception

Bit [24]

Reserved, RES0.

WPT, bits [23:18]

When FEAT_Debugv8p2 is implemented:

Watchpoint number.

All other values are reserved.

Otherwise:

Reserved, RES0.

WPTV, bit [17]

When FEAT_Debugv8p2 is implemented:

Watchpoint number Valid.

WPTV	Meaning
0b0	The WPT field is invalid, and holds an UNKNOWN value.
0b1	The WPT field is valid, and holds the number of a watchpoint that triggered a Watchpoint exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_Debugv8p9 is implemented, value 0 is not permitted.

When a Watchpoint exception is triggered by a watchpoint match:

- If FEAT_Debugv8p9 is implemented or the PE sets any of FnV, FnP, or WPF to 1, then the PE sets WPTV to 1.
- Otherwise, the PE sets WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

Otherwise:

Reserved, RES0.

WPF, bit [16]

Watchpoint might be false-positive.

WPF	Meaning	Applies when
0b0	The watchpoint matched an address or address range that was accessed by the instruction.	
0b1	The watchpoint matched an address or address range that might not have been accessed by the instruction.	FEAT_SVE is implemented or FEAT_SME is implemented

Arm strongly recommends that this bit is set to 0, other than when one of the following instructions might generate a watchpoint match for an address or address range that the instruction does not access:

- An SVE contiguous vector load/store instruction, when the PE is in Streaming SVE mode.
- An SME load/store instruction.

FnP, bit [15]

FAR not Precise.

This field only has meaning if the FAR is valid; that is, when the FnV field is 0. If the FnV field is 1, the FnP field is 0.

FnP	Meaning	Applies when
0b0	If the FnV field is 0, the FAR holds the virtual address of an access or set of contiguous accesses that triggered a Watchpoint exception.	
0b1	The FAR holds any address within the smallest implemented translation granule that contains the virtual address of an access or set of contiguous accesses that triggered a Watchpoint exception.	FEAT_SVE is implemented or FEAT_SME is implemented

Bits [14:11]

Reserved, RES0.

FnV, bit [10]

FAR not Valid.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FnV	Meaning	Applies when
0b0	The FAR is valid, and its value is as described by the FnP field.	
0b1	The FAR is invalid, and holds an UNKNOWN value.	FEAT_SVE is implemented or FEAT_SME is implemented

Bit [9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance instruction:

CM	Meaning
0b0	The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Watchpoint exception was generated by the execution of a cache maintenance instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as a cache maintenance instructions, and therefore their execution does not cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Watchpoint exception caused by an instruction reading from a memory location.
0b1	Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Watchpoint exception

For more information about generating these exceptions, see 'Watchpoint exceptions'.

ISS encoding for an exception from execution of a Breakpoint instruction

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

For the AArch32 BKPT instructions, the comment field is described as the immediate field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from execution of a Breakpoint instruction

For more information about generating these exceptions, see 'Breakpoint instruction exceptions'.

ISS encoding for an exception from an ERET, ERETAA, or ERETAB instruction

This EC value applies when:

- FEAT_FGT is implemented.
- The Effective value of HCR_EL2.NV is 1.

Bits [24:2]

Reserved, RES0.

ERET, bit [1]

Indicates whether an ERET or ERETA* instruction was trapped to EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ERET	Meaning
0b0	ERET instruction trapped to EL1.
0b1	ERETAA or ERETAB instruction trapped to EL1.

If this bit is 0, the ERETA field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ERETA, bit [0]

Indicates whether an ERETAA or ERETAB instruction was trapped to EL1.

ERETA	Meaning
0b0	ERETAA instruction trapped to EL1.
0b1	ERETAB instruction trapped to EL1.

When the ERET field is 0, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an ERET, ERETAA, or ERETAB instruction

For more information about generating these exceptions, see HCR_EL2.NV.

If FEAT_FGT is implemented, HFGITR_EL2.ERET controls fine-grained trap exceptions from ERET, ERETAA, and ERETAB execution.

ISS encoding for a Branch Target Exception

24 … 2	1 0
RES0	BTYPE

Bits [24:2]

Reserved, RES0.

BTYPE, bits [1:0]

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

Additional Information for ISS encoding for a Branch Target Exception

For more information about generating these exceptions, see 'The AArch64 application level programmers model'.

ISS encoding for an exception from a trapped Pointer Authentication instruction

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

24 … 0
RES0

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from a trapped Pointer Authentication instruction

For more information about generating these exceptions, see:

- HCR_EL2.API, for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.
- SCR_EL3.API, for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL3.

ISS encoding for a PAC Fail exception

24 … 2	1	0
RES0	DnI	BnA

Bits [24:2]

Reserved, RES0.

DnI, bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

DnI	Meaning
0b0	Instruction Key.
0b1	Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BnA, bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

BnA	Meaning
0b0	A key.
0b1	B key.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for a PAC Fail exception

The following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTDA, AUTDZA.
- AUTDB, AUTDZB.
- AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA.
- AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB.
- AUTIASPPC, AUTIASPPCR, AUTIA171615.
- AUTIBSPPC, AUTIBSPPCR, AUTIB171615.

If FEAT_FPACCOMBINE is implemented, the following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- RETAA, RETAB.
- RETAASPPC, RETABSPPC.
- RETAASPPCR, RETABSPPCR.
- BLRAA, BLRAAZ, BLRAB, BLRABZ.
- BRAA, BRAB, BRAAZ, BRABZ.
- ERETAA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL1

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL3 using the accessor name ESR_EL1 or ESR_EL12 are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ESR_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0101	0b0010	0b000

```
if !IsFeatureImplemented(FEAT_AA64) then
    Undefined();
elsif PSTATE.EL == EL0 then

D24.2.45 ESR_EL2, Exception Syndrome Register (EL2)

The ESR_EL2 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL2.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

AArch64 System register ESR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HSR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ESR_EL2 are UNDEFINED.

Attributes

ESR_EL2 is a 64-bit register.

Field descriptions

ESR_EL2 is made UNKNOWN as a result of an exception return from EL2.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL2, the value of ESR_EL2 is UNKNOWN. The value written to ESR_EL2 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Bits [63:56]

Reserved, RES0.

ISS2, bits [55:32]

ISS2 encoding for an exception, the bit assignments are:

ISS2 encoding for an exception from a Data Abort

Bits [23:12]

Reserved, RES0.

HDBSSF, bit [11]

When FEAT_HDBSS is implemented, IsSecondStage(Fault), and GetESR_ELx_DFSC(EL2) IN {'0011xx', '01001x', '0101xx', '10001x', '1001xx'}:

When DFSC indicates a stage 2 Permission fault, this field indicates whether that fault was caused because HDBSS cannot have data appended, because the HDBSS is either full or in an error state.

When DFSC indicates a synchronous External abort on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

When DFSC indicates a Granule Protection Fault on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

HDBSSF	Meaning
`0b0`	Fault was not caused by HDBSS.
`0b1`	Fault was caused by HDBSS.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TnD, bit [10]

When FEAT_MTE_CANONICAL_TAGS is implemented:

Tag not Data.

If a memory access generates a Data Abort for a stage 1 Permission fault, this field indicates whether the fault is due to an Allocation Tag access.

TnD	Meaning
`0b0`	Permission fault is not due to a write of an Allocation Tag to Canonically Tagged memory.
`0b1`	Permission fault is due to a write of an Allocation Tag to Canonically Tagged memory.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TagAccess, bit [9]

When FEAT_MTE_PERM is implemented:

NoTagAccess fault.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If a memory access generates a Data Abort for a Permission fault, this field indicates whether the fault is due to the NoTagAccess memory attribute.

TagAccess	Meaning
0b0	Permission fault is not due to the NoTagAccess memory attribute, and not due to an access using a Tag VA.
0b1	Permission fault is due to the NoTagAccess memory attribute.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

GCS, bit [8]

When FEAT_GCS is implemented:

Guarded Control Stack data access.

If a memory access generates a Data Abort, this field indicates whether the fault is due to a Guarded Control Stack data access.

GCS	Meaning
0b0	The Data Abort is not due to a Guarded control stack data access.
0b1	The Data Abort is due to a Guarded control stack data access. The ISV field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AssuredOnly, bit [7]

When FEAT_THE is implemented:

AssuredOnly flag.

If a memory access generates a Data Abort for a stage 2 Permission fault, this field holds information about the fault.

If this field is 1 and ESR_EL2.GCS is 1, then the AssuredOnly check might have been the result of VTCR_EL2.GCSH configuration.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AssuredOnly	Meaning
0b0	The Data Abort is not due to AssuredOnly.
0b1	The Data Abort is due to AssuredOnly.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Overlay, bit [6]

When FEAT_S1POE is implemented or FEAT_S2POE is implemented:

Overlay flag.

If a memory access generates a Data Abort for a Permission fault, this field holds information about the fault.

Overlay	Meaning
0b0	The Data Abort is not due to Overlay Permissions.
0b1	The Data Abort is due to Overlay Permissions.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DirtyBit, bit [5]

When FEAT_S1PIE is implemented or FEAT_S2PIE is implemented:

DirtyBit flag.

If a write access to memory generates a Data Abort for a Permission fault using Indirect Permission, this field holds information about the fault.

DirtyBit	Meaning
0b0	Permission Fault is not due to dirty state.
0b1	Permission Fault is due to dirty state.

For any other fault or Access, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Xs, bits [4:0]

When FEAT_LS64 is implemented:

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort exception reported with ISV=1, then this field holds register specifier, Xs.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort exception reported with ISV=1, then this field holds register specifier, Xs.

Otherwise, this field is RES0.

Otherwise:

Reserved, RES0.

ISS2 encoding for an exception from an Instruction Abort

Bits [23:12]

Reserved, RES0.

HDBSSF, bit [11]

When FEAT_HDBSS is implemented:

Indicates that the fault was caused by the HDBSS.

When IFSC indicates a stage 2 Permission fault, this field indicates whether that fault was caused because HDBSS cannot have data appended, because the HDBSS is either full or in an error state.

When IFSC indicates a synchronous External abort on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

When IFSC indicates a Granule Protection Fault on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

HDBSSF	Meaning
0b0	Fault was not caused by HDBSS.
0b1	Fault was caused by HDBSS.

This field only applies for stage 2 Permission faults.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bits [10:8]

Reserved, RES0.

AssuredOnly, bit [7]

When FEAT_THE is implemented:

AssuredOnly flag.

If a memory access generates a Instruction Abort for a Permission fault, then this field holds information about the fault.

AssuredOnly	Meaning
0b0	Instruction Abort is not due to AssuredOnly.
0b1	Instruction Abort is due to stage 2 AssuredOnly attribute.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Overlay, bit [6]

When FEAT_S1POE is implemented or FEAT_S2POE is implemented:

Overlay flag.

If a memory access generates a Instruction Abort for a Permission fault, then this field holds information about the fault.

Overlay	Meaning
0b0	Instruction Abort is not due to Overlay Permissions.
0b1	Instruction Abort is due to Overlay Permissions.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DirtyBit, bit [5]

When FEAT_S2PIE is implemented:

DirtyBit flag.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If a write access to memory generates an Instruction Abort for a Permission fault using Indirect Permission, this field holds information about the fault.

DirtyBit	Meaning
0b0	Permission Fault is not due to dirty state.
0b1	Permission Fault is due to dirty state.

For any other fault or Access, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:0]

Reserved, RES0.

ISS2 encoding for an exception from a Watchpoint exception

Bits [23:9]

Reserved, RES0.

GCS, bit [8]

When FEAT_GCS is implemented:

Guarded control stack data access.

Indicates that the Watchpoint exception is due to a Guarded control stack data access.

GCS	Meaning
0b0	The Watchpoint exception is not due to a Guarded control stack data access.
0b1	The Watchpoint exception is due to a Guarded control stack data access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [7:0]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS2 encoding for all other exceptions

23	0
RES0	

Bits [23:0]

Reserved, RES0.

EC, bits [31:26]

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC	Meaning	ISS	ISS2	Applies when
`0b000000`	Unknown reason.	ISS encoding for exceptions with an unknown reason	ISS2 encoding for all other exceptions	
`0b000001`	Trapped WF* instruction execution. Conditional WF* instructions that fail their condition code check do not cause an exception.	ISS encoding for an exception from a WF* instruction	ISS2 encoding for all other exceptions	
`0b000011`	Trapped MCR or MRC access with (coproc==`0b1111`) that is not reported using EC value `0b000000`.	ISS encoding for an exception from an MCR or MRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
`0b000100`	Trapped MCRR or MRRC access with (coproc==`0b1111`) that is not reported using EC value `0b000000`.	ISS encoding for an exception from an MCRR or MRRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
`0b000101`	Trapped MCR or MRC access with (coproc==`0b1110`).	ISS encoding for an exception from an MCR or MRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
`0b000110`	Trapped LDC or STC access. The only architected uses of these instruction are: • An STC to write data to memory from DBGDTRRXint. • An LDC to read data from memory to DBGDTRTXint.	ISS encoding for an exception from an LDC or STC instruction	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b000111	Access to SME, SVE, Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control. Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value 0b000000.	ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps	ISS2 encoding for all other exceptions	
0b001000	Trapped VMRS access, from ID group trap, that is not reported using EC value 0b000111.	ISS encoding for an exception from an MCR or MRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b001001	Trapped use of a Pointer authentication instruction.	ISS encoding for an exception from a trapped Pointer Authentication instruction	ISS2 encoding for all other exceptions	FEAT_PAuth is implemented
0b001010	Trapped execution of any instruction not covered by other EC values.	ISS encoding for an exception from any other instruction	ISS2 encoding for all other exceptions	FEAT_LS64 is implemented, or FEAT_SPEv1p5 is implemented, or FEAT_TRBEv1p1 is implemented
0b001100	Trapped MRRC access with (coproc==0b1110).	ISS encoding for an exception from an MCRR or MRRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b001101	Branch Target Exception.	ISS encoding for a Branch Target Exception	ISS2 encoding for all other exceptions	FEAT_BTI is implemented
0b001110	Illegal Execution state.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b010001	SVC instruction execution in AArch32 state. This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TGE is 1.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b010010	HVC instruction execution in AArch32 state, when HVC is not disabled.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b010011	SMC instruction execution in AArch32 state, when SMC is not disabled. This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.	ISS encoding for an exception from SMC instruction execution in AArch32 state	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b010100	Trapped MSRR, MRRS or System instruction execution in AArch64 state, that is not reported using EC value 0b000000.	ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	FEAT_SYSREG128 is implemented or FEAT_SYSINSTR128 is implemented
0b010101	SVC instruction execution in AArch64 state.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b010110	HVC instruction execution in AArch64 state, when HVC is not disabled.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b010111	SMC instruction execution in AArch64 state, when SMC is not disabled. This is reported in ESR_EL2 only when the exception is generated because the value of HCR_EL2.TSC is 1.	ISS encoding for an exception from SMC instruction execution in AArch64 state	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b011000	Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC values 0b000000, 0b000001 or 0b000111. This includes all instructions that cause exceptions that are part of the encoding space defined in 'System instruction class encoding overview', except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.	ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b011001	Access to SVE functionality trapped as a result of CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC value 0b000000.	ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ	ISS2 encoding for all other exceptions	FEAT_SVE is implemented
0b011010	Trapped ERET, ERETAA, or ERETAB instruction execution.	ISS encoding for an exception from an ERET, ERETAA, or ERETAB instruction	ISS2 encoding for all other exceptions	FEAT_FGT is implemented or FEAT_NV is implemented
0b011100	Exception from a PAC Fail	ISS encoding for a PAC Fail exception	ISS2 encoding for all other exceptions	FEAT_FPAC is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b011101	Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, CPTR_EL3.ESM, or an attempted execution of an instruction that is illegal because of the value of PSTATE.SM or PSTATE.ZA, that is not reported using EC value 0b000000.	ISS encoding for an exception due to SME functionality	ISS2 encoding for all other exceptions	FEAT_SME is implemented
0b100000	Instruction Abort from a lower Exception level. Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100001	Instruction Abort taken without a change in Exception level. Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	
0b100010	PC alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b100100	Data Abort exception from a lower Exception level, excluding Data Abort exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. These Data Abort exceptions might be generated from Exception levels in any Execution state. Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b100101	Data Abort exception without a change in Exception level, or Data Abort exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100110	SP alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b100111	Memory Operation Exception.	ISS encoding for an exception from the Memory Copy and Memory Set instructions	ISS2 encoding for all other exceptions	FEAT_MOPS is implemented
0b101000	Trapped floating-point exception taken from AArch32 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b101100	Trapped floating-point exception taken from AArch64 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b101101	GCS exception.	ISS encoding for a GCS exception	ISS2 encoding for all other exceptions	FEAT_GCS is implemented
0b101111	SError exception.	ISS encoding for an SError exception	ISS2 encoding for all other exceptions	
0b110000	Breakpoint exception from a lower Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b110001	Breakpoint exception taken without a change in Exception level.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	
0b110010	Software Step exception from a lower Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110011	Software Step exception taken without a change in Exception level.	ISS encoding for an exception from a Software Step exception	ISS2 encoding for all other exceptions	
0b110100	Watchpoint from a lower Exception level, excluding Watchpoint Exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support. These Watchpoint Exceptions might be generated from Exception levels using any Execution state.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b110101	Watchpoint exceptions without a change in Exception level, or Watchpoint exceptions taken to EL2 as a result of accesses generated associated with VNCR_EL2 as part of nested virtualization support.	ISS encoding for an exception from a Watchpoint exception	ISS2 encoding for an exception from a Watchpoint exception	
0b111000	BKPT instruction execution in AArch32 state.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b111010	Vector Catch exception from AArch32 state. The only case where a Vector Catch exception is taken to an Exception level that is using AArch64 is when the exception is routed to EL2 and EL2 is using AArch64.	ISS encoding for an exception from a Breakpoint or Vector Catch debug exception	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b111100	BRK instruction execution in AArch64 state.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b111101	Profiling exception	ISS encoding for a Profiling exception	ISS2 encoding for all other exceptions	FEAT_EBEP is implemented, or FEAT_SPE_EXC is implemented, or FEAT_TRBE_EXC is implemented

Non-Confidential

All other EC values are reserved by Arm, and:

- Unused values in the range `0b000000` - `0b101100` (`0x00` - `0x2C`) are reserved for future use for synchronous exceptions.
- Unused values in the range `0b101101` - `0b111111` (`0x2D` - `0x3F`) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

IL	Meaning
`0b0`	16-bit instruction trapped.

`0b1`	32-bit instruction trapped. This value is also used when the exception is one of the following:
	• An SError exception.
	• An Instruction Abort exception.
	• A PC alignment fault exception.
	• An SP alignment fault exception.
	• A Data Abort exception for which the value of the ISV bit is 0.
	• An Illegal Execution state exception.
	• Any debug exception except for Breakpoint instruction exceptions. For Breakpoint instruction exceptions, this bit has its standard meaning:
	  • ‘0’: 16-bit T32 BKPT instruction.
	  • ‘1’: 32-bit A32 BKPT instruction or A64 BRK instruction.
	• An exception reported using EC value `0b000000`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

For an exception taken from AArch32 state, see ‘Mapping of the general-purpose registers between the Execution states’.

If the AArch32 register descriptor is `0b1111`, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value `0b11111`.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The value `0b11111`.

ISS encoding for exceptions with an unknown reason

24 … 0
RES0

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for exceptions with an unknown reason

When an exception is reported using this EC value, the IL field is set to 1.

This EC value is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
  - Instruction encodings that are unallocated.
  - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR_EL3.SMD.
  - An HLT instruction when disabled by EDSCR.HDE.
- Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.
- Attempted execution of an MSR or MRS instruction using a _EL12 register name when the Effective value of HCR_EL2.E2H is not 1.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction when the value of HCR_EL2.TGE is 1 and EL2 is disabled or not implemented in the current Security state.
  - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon.
- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, and EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to SPSR_mon, SP_mon, or LR_mon.
- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1. If the value of HCR_EL2.TGE is 0, this exception is reported using an ESR_EL2.EC value of `0b000111`.

Non-Confidential

- If FEAT_UINJ is implemented, an Undefined exception caused by attempting to execute any instruction when PSTATE.UINJ is 1.

ISS encoding for an exception from a WF* instruction

24	23 20	19 10	9 5	4 3	2	1 0
CV	COND	RES0	RN	RES0	RV	TI

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [19:10]

Reserved, RES0.

RN, bits [9:5]

When FEAT_WFxT is implemented:

Register Number. Indicates the register number supplied for a `WFET` or `WFIT` instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:3]

Reserved, RES0.

RV, bit [2]

When FEAT_WFxT is implemented:

Register field Valid.

If TI[1] == 1, then this field indicates whether RN holds a valid register number for the register argument to the trapped `WFET` or `WFIT` instruction.

RV	Meaning
`0b0`	Register field invalid.
`0b1`	Register field valid.

If TI[1] == 0, then this field is RES0.

This field is set to 1 on a trap on `WFET` or `WFIT`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

TI	Meaning	Applies when
`0b00`	WFI trapped.	
`0b01`	WFE trapped.	
`0b10`	WFIT trapped.	FEAT_WFxT is implemented
`0b11`	WFET trapped.	FEAT_WFxT is implemented

When FEAT_WFxT is implemented, this is a two bit field as shown. Otherwise, bit[1] is RES0.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a WF* instruction

The following fields describe configuration settings for generating this exception:

- HCR.{TWE, TWI}.
- SCTLR_EL1.{nTWE, nTWI}.
- SCTLR_EL2.{nTWE, nTWI}.
- HCR_EL2.{TWE, TWI}.
- SCR_EL3.{TWE, TWI}.

ISS encoding for an exception from an MCR or MRC access

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value `0b000`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value `0b111`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

If the Rt value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See 'Mapping of the general-purpose registers between the Execution states'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value `0b0000`.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write to System register space. MCR instruction.
`0b1`	Read from System register space. MRC or VMRS instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an MCR or MRC access

The following fields describe configuration settings for generating exceptions from an MCR or MRC access using coproc `0b1111`, that are reported using EC value `0b000011`:

- If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, trapped to EL1.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- PMUSERENR_EL0.{ER, CR, SW, EN}, for accesses to Performance Monitor System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- HCR.{TRVM, TVM} and HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, trapped to EL2.
- HCR.TTLB and HCR_EL2.TTLB, for execution of TLB maintenance instructions at EL1 using AArch32 state, trapped to EL2.
- HCR.{TSW, TPC, TPU} and HCR_EL2.{TSW, TPC, TPU} for execution of cache maintenance instructions at EL0 and EL1 using AArch32 state, trapped to EL2.
- HCR.TAC and HCR_EL2.TACR, for accesses to the Auxiliary Control Register at EL1 using AArch32 state, trapped to EL2.
- HCR.TIDCP and HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations at EL0 and EL1 using AArch32 state, trapped to EL2.
- If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, trapped to EL2.
- HCR.{TID1, TID2, TID3} and HCR_EL2.{TID1, TID2, TID3}, for accesses to ID registers at EL0 and EL1 using AArch32 state, trapped to EL2.
- HCR2.TERR, for Non-secure accesses to error record registers at EL1 using AArch32 state, trapped to EL2.
- HCPTR.TCPAC and CPTR_EL2.TCPAC, for accesses to CPACR_EL1 or CPACR using AArch32 state, trapped to EL2.
- HSTR.T<n> and HSTR_EL2.T<n>, for accesses to System registers using AArch32 state, trapped to EL2.
- CNTHCTL.PL1PCEN and CNTHCTL_EL2.EL1PCEN, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HDCR.TTRF, for Non-secure accesses to trace filter control registers from System registers using AArch32 state, trapped to EL2.
- HDCR.{TPM, TPMCR} and MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HCPTR.TAM and CPTR_EL2.TAM, for accesses to Activity Monitors System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- CPTR_EL3.TCPAC, for accesses to CPACR from EL1 and EL2, and accesses to HCPTR from EL2 using AArch32 state, trapped to EL3.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- CPTR_EL3.TAM, for accesses to Activity Monitors System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, access to some registers at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions from an MCR or MRC access using coproc `0b1110`, that are reported using EC value `0b000101`:

- CPACR_EL1.TTA for accesses to trace System registers, trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers at EL0 and EL1 using AArch32 state, trapped to EL1 or EL2.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC System registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC System registers at EL0, EL1, and EL2 trapped to EL3.
- HCR.TID0 and HCR_EL2.TID0, for accesses to the JIDR register in the ID group 0 at EL0 and EL1 using AArch32, trapped to EL2.
- HCPTR.TTA and CPTR_EL2.TTA, for accesses to trace System registers using AArch32, trapped to EL2.
- HDCR.TDRA and MDCR_EL2.TDRA, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, trapped to EL2.
- HDCR.TDOSA and MDCR_EL2.TDOSA, for accesses to powerdown debug System registers, using AArch32 state, trapped to EL2.
- HDCR.TDA and MDCR_EL2.TDA, for accesses to other debug System registers, using AArch32 state, trapped to EL2.
- CPTR_EL3.TTA, for accesses to trace System registers using AArch32, trapped to EL3.
- MDCR_EL3.TDOSA, for accesses to powerdown debug System registers using AArch32, trapped to EL3.
- MDCR_EL3.TDA, for accesses to other debug System registers, using AArch32, trapped to EL3.

The following fields describe configuration settings for generating exceptions from a VMSR or VMRS access, that are reported using EC value `0b001000`:

- HCR.TID0 and HCR_EL2.TID0, for accesses to the FPSID register in ID group 0 at EL1 using AArch32 state, VMRS access trapped to EL2.
- HCR.TID3 and HCR_EL2.TID3, for accesses to registers in ID group 3 including MVFR0, MVFR1 and MVFR2, VMRS access trapped to EL2.
- HCPTR.{TCP10, TCP11}, for Non-secure accesses to FPSCR, FPSID, FPEXC, MVFR0, MVFR1, and MVFR2, trapped to EL2.

ISS encoding for an exception from any other instruction

24 … 0
ISS

ISS, bits [24:0]

ISS	Meaning	Applies when
`0b0000000000000000000000000`	`ST64BV` instruction trapped.	FEAT_LS64_V is implemented
`0b0000000000000000000000001`	`ST64BV0` instruction trapped.	FEAT_LS64_ACCDATA is implemented
`0b0000000000000000000000010`	`LD64B` or `ST64B` instruction trapped.	FEAT_LS64 is implemented
`0b0000000000000000000000011`	`PSB CSYNC` instruction trapped.	FEAT_SPEv1p5 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS	Meaning	Applies when
0b00000000000000000000000100	TSB CSYNC instruction trapped.	FEAT_TRBEv1p1 is implemented

All other values are reserved.

ISS encoding for an exception from an MCRR or MRRC access

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

If the Rt2 value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt2 value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See ‘Mapping of the general-purpose registers between the Execution states’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer.

If the Rt value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See ‘Mapping of the general-purpose registers between the Execution states’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write to System register space. MCRR instruction.
0b1	Read from System register space. MRRC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an MCRR or MRRC access

The following fields describe configuration settings for generating exceptions from an MCRR or MRRC access using coproc 0b1111, that are reported using EC value 0b000100:

- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- PMUSERENR_EL0.{CR, EN}, for accesses to Performance Monitor System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- AMUSERENR_EL0.{EN}, for accesses to Activity Monitors System registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 using AArch32 state, trapped to EL1 or EL2.
- HCR.{TRVM, TVM} and HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, trapped to EL2.
- HCR2.TERR, for Non-secure accesses to error record registers at EL1 using AArch32 state, trapped to EL2.
- HSTR.T<n> and HSTR_EL2.T<n>, for accesses to System registers using AArch32 state, trapped to EL2.
- CNTHCTL.{PL1PCEN, PL1PCTEN} and CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HDCR.TPM and MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HCPTR.TAM and CPTR_EL2.TAM, for accesses to Activity Monitors System registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 and EL1 using AArch32 state, trapped to EL2.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- CPTR_EL3.TAM, for accesses to Activity Monitors System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, HDFGRTR_EL2.PMCCNTR_EL0 for MRRC access and HDFGWTR_EL2.PMCCNTR_EL0 for MCRR access to PMCCNTR at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions from an MCRR or MRRC access using coproc 0b1110, that are reported using EC value 0b001100:

- MDSCR_EL1.TDCC, for accesses to the Debug ROM registers DBGDSAR and DBGDRAR at EL0 using AArch32 state, trapped to EL1 or EL2.
- HDCR.TDRA and MDCR_EL2.TDRA, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, trapped to EL2.
- MDCR_EL3.TDA, for accesses to debug System registers, using AArch32, trapped to EL3.
- CPACR_EL1.TTA for accesses to trace System registers using AArch32, trapped to EL1 or EL2.
- HCPTR.TTA and CPTR_EL2.TTA, for accesses to trace System registers using AArch32, trapped to EL2.
- CPTR_EL3.TTA, for accesses to trace System registers using AArch32, trapped to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

If FEAT_ETMv4 or FEAT_ETE are implemented, MCRR and MRRC accesses to trace System registers are UNDEFINED and the resulting exception is higher priority than an exception due to these traps.

ISS encoding for an exception from an LDC or STC instruction

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]

The immediate value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

Rn, bits [9:5]

The Rn value from the issued instruction, the general-purpose register used for the transfer.

If the Rn value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rn value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See 'Mapping of the general-purpose registers between the Execution states'.

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

Offset	Meaning
`0b0`	Subtract offset.
`0b1`	Add offset.

This bit corresponds to the U bit in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AM	Meaning
0b000	Immediate unindexed.
0b001	Immediate post-indexed.
0b010	Immediate offset.
0b011	Immediate pre-indexed.
0b100	For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
0b110	For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in 'Reserved values in System and memory-mapped registers and translation table entries'.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write to memory. STC instruction.
0b1	Read from memory. LDC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an LDC or STC instruction

The following fields describe the configuration settings from an LDC or STC access for the traps that are reported using EC value 0b000110:

- MDSCR_EL1.TDCC, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL1 or EL2.
- HDCR.TDA and MDCR_EL2.TDA, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL2.
- MDCR_EL3.TDA, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC System registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC System registers at EL0, EL1, and EL2 trapped to EL3.

ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The accesses covered by this trap include:

- Execution of Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.
- Execution of SVE instructions.
- Execution of SME instructions.

For an implementation that does not include either SVE or support for Advanced SIMD and floating-point, the exception is reported using the EC value `0b000000`.

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Additional Information for ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

The following fields describe the configuration settings for the traps that are reported using EC value `0b000111`:

- HCPTR.{TCP10, TCP11}, for Non-secure accesses to Advanced SIMD and floating-point registers and instructions, trapped to EL2.
- HCPTR.TASE, for Non-secure accesses to Advanced SIMD functionality, trapped to EL2.
- CPACR_EL1.FPEN, for accesses to SIMD and floating-point registers trapped to EL1.
- CPTR_EL2.FPEN and CPTR_EL2.TFP, for accesses to SIMD and floating-point registers trapped to EL2.
- CPTR_EL3.TFP, for accesses to SIMD and floating-point registers trapped to EL3.

ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

24 … 0
RES0

The accesses covered by this trap include:

- Execution of SVE instructions when the PE is not in Streaming SVE mode.
- Accesses to the SVE System registers, ZCR_ELx.

For an implementation that does not include SVE, the exception is reported using the EC value `0b000000`.

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

The following fields describe the configuration settings for the traps that are reported using EC value `0b011001`:

- CPACR_EL1.ZEN, for execution of SVE instructions and accesses to SVE registers at EL1 or EL0, trapped to EL1.
- CPTR_EL2.ZEN and CPTR_EL2.TZ, for execution of SVE instructions and accesses to SVE registers at EL0, EL1, or EL2, trapped to EL2.
- CPTR_EL3.EZ, for execution of SVE instructions and accesses to SVE registers from all Exception levels, trapped to EL3.

ISS encoding for a Profiling exception

24 … 6	5 … 1	0
RES0	FSC	RES0

Bits [24:6]

Reserved, RES0.

FSC, bits [5:1]

Indicates why the Profiling exception was generated.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FSC	Meaning	Applies when
0b00000	PMU Profiling exception. The exception was generated because at least one PMU counter overflow status flag was 1.	FEAT_EBEP is implemented
0b00001	Profiling Buffer management event. The exception was generated because PMBSR_EL2.S was 1.	FEAT_SPE_EXC is implemented
0b00010	Trace buffer management event. The exception was generated because TRBSR_EL2.IRQ was 1.	FEAT_TRBE_EXC is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see 'PC alignment checking'.

'SP alignment checking' describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from the Memory Copy and Memory Set instructions

MemInst, bit [24]

Indicates the memory instruction class causing the exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MemInst	Meaning
0b0	CPYFE*, CPYFM*, CPYE*, and CPYM* instructions.
0b1	The instruction that caused the exception is in one of the following instruction classes: • SETE*, SETM*. • SETGE*, SETGM*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

isSETG, bit [23]

Indicates whether the instruction belongs to one of the following instruction classes:

- SETGE*, SETGM*.

isSETG	Meaning
0b0	The instruction that caused the exception is not in one of the specified classes.
0b1	The instruction that caused the exception is in one of the specified classes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Options, bits [22:19]

Options : the Options field of the instruction.

For Memory Copy instructions, bits[22:19] forms the Options field, which holds the bits[15:12] of the instruction.

For Memory Set instructions:

- Bits[22:21] are RES0.
- Bits[20:19] form the Options field, which holds the bits[13:12] of the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FromEpilogue, bit [18]

Indicates whether the instruction belongs to one of the following epilogue classes of Memory Copy or Memory Set instructions:

- CPYE*, CPYFE*.
- SETE*, SETGE*.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FromEpilogue	Meaning
0b0	The instruction that caused the exception is not in one of the specified classes.
0b1	The instruction that caused the exception is in one of the specified classes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FormatOption, bits [17:16]

Reports the Option used to encode the initial Xs, Xd, and Xn register values provided to the instruction that generated the exception.

FormatOption	Meaning
0b00	Option B.
0b01	Option A.
0b10	Option A.
0b11	Option B.

For more information, see Memory Copy and Memory Set exceptions.

Note

This field was previously presented as two separate bits, WrongOption, bit[17] and OptionA, bit [16], which were already expected to be used together and not individually.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

destreg, bits [14:10]

The destination register value from the issued instruction, containing the destination address.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

srcreg, bits [9:5]

The source register value from the issued instruction, containing either the source address or the source data.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

sizereg, bits [4:0]

The size register value from the issued instruction, containing the number of bytes to be transferred or set.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS encoding for an exception from HVC or SVC instruction execution

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from HVC or SVC instruction execution

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see 'SVC' and 'HVC'.

For A64 instructions, see 'SVC' and 'HVC'.

If FEAT_FGT is implemented, HFGITR_EL2.{SVC_EL1, SVC_EL0} control fine-grained traps on SVC execution.

ISS encoding for an exception from SMC instruction execution in AArch32 state

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from EL1 because HCR_EL2.TSC is 1, the ISS encoding is as shown in the diagram.

CV, bit [24]

Condition code valid.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to 0b1110.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to 0b1110.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to 0b1110, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to 0b1110, or to the value of any condition that applied to the instruction.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

CCKNOWNPASS	Meaning
0b0	The instruction was unconditional, or was conditional and passed its condition code check.
0b1	The instruction was conditional, and might have failed its condition code check.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

In an implementation in which an SMC instruction that fails it code check is not trapped, this field can always return the value 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [18:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from SMC instruction execution in AArch32 state

HCR.TSC describes the configuration settings for trapping SMC instructions to EL2.

HCR_EL2.TSC describes the configuration settings for trapping SMC instructions to EL2.

ISS encoding for an exception from SMC instruction execution in AArch64 state

24 … 16	15 … 0
RES0	imm16

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from SMC instruction execution in AArch64 state

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

HCR_EL2.TSC describes the configuration settings for trapping SMC from EL1 modes.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

24 … 22	21 20	19 … 17	16 … 14	13 … 10	9 … 5	4 … 1	0
RES0	Op0	Op2	Op1	CRn	Rt	CRm	Direction

Bits [24:22]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

For system instructions which require that the opcode Rt field is set to `0b11111`, but where the trapped instruction has a different value of Rt, an implementation is permitted to return the value `0b11111`, instead of the value of Rt from the trapped instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write access, including MSR instructions.
`0b1`	Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For exceptions caused by System instructions, see 'System instructions' subsection of 'Branches, exception generating and System instructions' for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value `0b011000`:

- If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL1.
- SCTLR_EL1.UCI, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UCT, for accesses to CTR_EL0 using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- SCTLR_EL1.DZE, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- CPACR_EL1.TTA, for accesses to the trace System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- PMUSERENR_EL0, for accesses to the Performance Monitor System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TDZ, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TTLB, for execution of TLB maintenance instructions using AArch64 state, execution is trapped to EL2.
- If FEAT_EVT is implemented, the following registers control traps for EL1 and EL0 registers and instructions that use this EC value:
  - HCR_EL2.{TICAB, TOCU, TID4}.
  - HCR2.{TICAB, TOCU, TID4}.
- If FEAT_EVT2 is implemented, the following registers control traps for EL1 and EL0 instructions that use this EC value:
  - HCR_EL2.{TTLBOS, TTLBIS}.
- If FEAT_EVT2 is implemented, HCR2.TTLBIS controls traps for EL1 and EL0 instructions using AArch32 state that use this EC value.
- HCR_EL2.{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TACR, for accesses to the Auxiliary Control Register, ACTLR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.
- If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- If FEAT_MTE2 is implemented, HCR_EL2.TID5, for accesses to GMID_EL1, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.
- If FEAT_IDTE3 is implemented, SCR_EL3.TID3, for accesses to ID group 3 registers using AArch64 state, at EL1 and EL2, trapped to EL3.
- CPTR_EL2.TCPAC, for accesses to CPACR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TTA, for accesses to the trace System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TTRF, for accesses to the trace filter control register, TRFCR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.

- MDCR_EL2.TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDOSA, for accesses to powerdown debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDA, for accesses to debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TAM, for accesses to Activity Monitors System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{NV, NV1}, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
- HCR_EL2.AT, for execution of AT S1E* instructions, using AArch64 state, execution is trapped to EL2.
- HCR_EL2.{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.
- SCR_EL3.APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL3.
- SCR_EL3.ST, for accesses to the Counter-timer Physical Secure timer registers, using AArch64 state, MSR or MRS access trapped to EL3.
- SCR_EL3.{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access trapped to EL3.
- CPTR_EL3.TCPAC, for accesses to CPTR_EL2 and CPACR_EL1 using AArch64 state, MSR or MRS access trapped to EL3.
- CPTR_EL3.TTA, for accesses to the trace System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TTRF, for accesses to the trace filter control registers, TRFCR_EL1 and TRFCR_EL2, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TDA, for accesses to debug System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TDOSA, for accesses to powerdown debug System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- If FEAT_SPE is implemented:
  - MDCR_EL3.NSPB for accesses to Statistical Profiling and Profiling Buffer control registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
  - MDCR_EL2.TPMS for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 trapped to EL2.
- CPTR_EL3.TAM, for accesses to Activity Monitors System registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If FEAT_FGT is implemented:
  - SCR_EL3.FGTEn, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
  - HFGRTR_EL2 for reads and HFGWTR_EL2 for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 trapped to EL2.
  - HFGITR_EL2 for execution of system instructions trapped to EL2.
  - HDFGRTR_EL2 for reads and HDFGWTR_EL2 for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 state trapped to EL2.
  - HAFGRTR_EL2 for reads of Activity Monitor counters, using AArch64 state, MRS access at EL0 and EL1 trapped to EL2.
- If FEAT_RNG_TRAP is implemented, SCR_EL3.TRNDR for reads of RNDR and RNDRRS using AArch64 state, MRS access trapped to EL3.
- If FEAT_SME is implemented:
  - CPTR_EL3.ESM, for MSR or MRS accesses to SMPRI_EL1 at EL1, EL2, and EL3, trapped to EL3.
  - CPTR_EL3.ESM, for MSR or MRS accesses to SMPRIMAP_EL2 at EL2 and EL3, trapped to EL3.
  - SCTLR_EL1.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL1 or EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - SCTLR_EL2.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL2.
  - SCR_EL3.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, EL1, and EL2, trapped to EL3.
- If FEAT_FPMR is implemented:
  - SCTLR_EL1.EnFPM, for accesses to FPMR at EL0, trapped to EL1 or EL2.
  - SCTLR_EL2.EnFPM, for accesses to FPMR at EL0, trapped to EL2.
  - HCRX_EL2.EnFPM, for accesses to FPMR at EL0 and EL1, trapped to EL2.
  - SCR_EL3.EnFPM, for accesses to FPMR at EL0, EL1, and EL2, trapped to EL3.
- If FEAT_NMI is implemented, HCRX_EL2.TALLINT, for MSR writes of ALLINT at EL1, trapped to EL2.
- If FEAT_FGT2 is implemented:
  - SCR_EL3.FGTEn2, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
  - HFGRTR2_EL2 for reads and HFGWTR2_EL2 for writes of registers, using AArch64 state, using MSR or MRS access at EL1 trapped to EL2.
  - HDFGRTR2_EL2 for reads and HDFGWTR2_EL2 for writes of registers, using AArch64 state, using MSR or MRS access at EL0 and EL1 trapped to EL2.
  - HFGITR2_EL2 for execution of system instructions trapped to EL2.
- If FEAT_ITE is implemented, MDCR_EL3.EnITE, for accesses to Instrumentation trace System registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If FEAT_MEC is implemented, SCR_EL3.MECEn, for accesses to MECID registers at EL2, trapped to EL3.
- If FEAT_SPE_FDS is implemented, MDCR_EL3.EnPMS3 for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
- If FEAT_SPE_nVM is implemented, MDCR_EL3.EnPMS4 for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
- If FEAT_RASv2 is implemented, SCR_EL3.TWERR, for accesses to Error Record registers, MSR access at EL1 and EL2 trapped to EL3.
- If FEAT_Debugv8p9 is implemented, MDCR_EL3.EBWE for accesses of MDSELR_EL1, using AArch64 state, MRS or MSR access at EL2 and EL1 trapped to EL3.
- If FEAT_PMUv3p9, FEAT_SPMU, FEAT_EBEP, or FEAT_PMUv3_SS is implemented, MDCR_EL3.EnPM2, for accesses to PMU System registers, using AArch64 state, MSR or MRS access at EL2, EL1, and EL0, trapped to EL3.
- If FEAT_PMUv3_SS is implemented, MDCR_EL3.EnPMSS, for accesses to PMU Snapshot registers, using AArch64 state, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_THE is implemented, SCR_EL3.RCWMASKEn for accesses to RCWMASK_EL1 and RCWSMASK_EL1, using AArch64 state, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_AIE is implemented, SCR_EL3.AIEn for accesses to Extended Memory Attribute registers, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_S1PIE, FEAT_S2PIE, FEAT_S1POE, or FEAT_S2POE is implemented, SCR_EL3.PIEn for accesses to Permission Indirection, Overlay registers, MSR or MRS access at EL2, EL1 and EL0 trapped to EL3.
- If FEAT_MPAM_PE_BW_CTRL is implemented, MPAMBW2_EL2.{nTRAP_MPAMBWIDR_EL1, nTRAP_MPAMBW0_EL1, nTRAP_MPAMBW1_EL1} for accesses to MPAMBWn_EL1 registers, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.
- If FEAT_MPAM_PE_BW_CTRL and FEAT_SME are implemented, MPAMBW2_EL2.nTRAP_MPAMBWSM_EL1, for accesses to MPAMBWSM_EL1, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.
- If FEAT_MPAM_PE_BW_CTRL is implemented, MPAMBW3_EL3.nTRAPLOWER, for accesses to MPAMBW2_EL2 and MPAMBWn_EL1 registers, using AArch64 state, MRS or MSR access at EL1, trapped to EL3.
- If FEAT_HACDBS is implemented, SCR_EL3.HACDBSEn, for accesses to HACDBSBR_EL2 and HACDBSCONS_EL2, using AArch64 state, MRS or MSR access at EL2, trapped to EL3.
- If FEAT_HDBSS is implemented, SCR_EL3.HDBSSEn, for accesses to HDBSSBR_EL2 and HDBSSPROD_EL2, using AArch64 state, MRS or MSR access at EL2, trapped to EL3.
- If FEAT_SRMASK is implemented, SCR_EL3.SRMASKEn, for MSR or MRS accesses at EL1 or EL2 to the MASK registers using AArch64 state, trapped to EL3.

ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:6]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

Note

This value represents register pair of X[Rt:0], X[Rt:1].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [5]

Reserved, RES0.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write access, MSRR instructions.
`0b1`	Read access, MRRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

The following fields describe configuration settings for generating exceptions from an MSRR or MRRS access that are reported using EC value `0b010100`:

- If FEAT_FGT is implemented:
  - HFGRTR_EL2 for reads and HFGWTR_EL2 for writes of registers, using AArch64 state, accesses at EL1 trapped to EL2.
- If FEAT_FGT2 is implemented:
  - HFGRTR2_EL2.nRCWSMASK_EL1 for reads and HFGWTR2_EL2.nRCWSMASK_EL1 for writes of RCWSMASK_EL1, using AArch64 state, accesses at EL1 trapped to EL2.
- If FEAT_SYSREG128 is implemented:
  - SCTLR2_EL1.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL0 trapped to EL1.
  - SCTLR2_EL2.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL0 trapped to EL2.
  - HCRX_EL2.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL1 and EL0 trapped to EL2.
  - SCR_EL3.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL2, EL1, and EL0 trapped to EL3.
- If FEAT_D128 is implemented:
  - HCR_EL2.{TRVM, TVM} for accesses to TTBR0_EL1 and TTBR1_EL1, accesses at EL1 and EL0 trapped to EL2.
  - HCRX_EL2.D128En for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL1 trapped to EL2.
  - HFGITR_EL2 for execution of TLBIP system instructions trapped to EL2.
  - HCR_EL2.{TTLB, TTLBOS, TTLBIS}, for execution of TLBIP instructions using AArch64 state, execution is trapped to EL2.
  - SCR_EL3.D128En for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL2 and EL1 trapped to EL3.
- If FEAT_THE is implemented, SCR_EL3.RCWMASKEn for accesses to RCWMASK_EL1 and RCWSMASK_EL1, using AArch64 state, accesses at EL2 and EL1 trapped to EL3.

ISS encoding for an exception from an Instruction Abort

The ISS2 encoding for an exception from an Instruction Abort includes further information about the exception if any of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- FEAT_THE is implemented and memory access generates an Instruction Abort for AssuredOnly.
- FEAT_S1POE or FEAT_S2POE is implemented and a memory access generates an Instruction Abort due to a Permission fault.
- FEAT_HDBSS.
- FEAT_S2PIE.

Bits [24:22]

Reserved, RES0.

TopLevel, bit [21]

When FEAT_THE is implemented:

Indicates if the fault was due to TopLevel.

TopLevel	Meaning
`0b0`	Fault is not due to TopLevel.
`0b1`	Fault is due to TopLevel.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [20:15]

Reserved, RES0.

PFV, bit [14]

When FEAT_PFAR is implemented:

PFAR Valid. Describes whether the PFAR_EL2 register is valid.

PFV	Meaning
`0b0`	PFAR_EL2 is UNKNOWN.
`0b1`	PFAR_EL2 is valid.

This field is valid only if the IFSC code is `0b10000`, `0b01001x`, or `0b0101xx`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [13]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SET, bits [12:11]

When FEAT_RAS is implemented and GetESR_ELx_IFSC(EL2) == '010000':

Synchronous Error Type. When IFSC is `0b010000`, describes the PE error state after taking the Instruction Abort exception.

SET	Meaning	Applies when
`0b00`	Recoverable state (UER).	
`0b10`	Uncontainable (UC).	FEAT_RASv2 is not implemented
`0b11`	Restartable state (UEO).	

All other values are reserved.

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

When GetESR_ELx_IFSC(EL2) == '010000':

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
`0b0`	FAR is valid.
`0b1`	FAR is not valid, and holds an UNKNOWN value.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [8]

Reserved, RES0.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001000	Access flag fault, level 0.	FEAT_LPA2 is implemented
0b001100	Permission fault, level 0.	FEAT_LPA2 is implemented
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning	Applies when
0b010010	Synchronous External abort on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented
0b010011	Synchronous External abort on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011011	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented and FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100010	Granule Protection Fault on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented and FEAT_RME is implemented
0b100011	Granule Protection Fault on translation table walk or hardware update of translation table, level -1.	FEAT_RME is implemented and FEAT_LPA2 is implemented
0b100100	Granule Protection Fault on translation table walk or hardware update of translation table, level 0.	FEAT_RME is implemented
0b100101	Granule Protection Fault on translation table walk or hardware update of translation table, level 1.	FEAT_RME is implemented
0b100110	Granule Protection Fault on translation table walk or hardware update of translation table, level 2.	FEAT_RME is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning	Applies when
0b100111	Granule Protection Fault on translation table walk or hardware update of translation table, level 3.	FEAT_RME is implemented
0b101000	Granule Protection Fault, not on translation table walk or hardware update of translation table.	FEAT_RME is implemented
0b101001	Address size fault, level -1.	FEAT_LPA2 is implemented
0b101010	Translation fault, level -2.	FEAT_D128 is implemented
0b101011	Translation fault, level -1.	FEAT_LPA2 is implemented
0b101100	Address Size fault, level -2.	FEAT_D128 is implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented

All other values are reserved.

For more information about the lookup level associated with a fault, see 'The lookup level associated with MMU faults'.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception due to SME functionality

The accesses covered by this trap include:

- Execution of SME instructions.
- Execution of SVE and Advanced SIMD instructions, when the PE is in Streaming SVE mode.
- Direct accesses of SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3.

Bits [24:3]

Reserved, RES0.

SMTC, bits [2:0]

SME Trap Code. Identifies the reason for instruction trapping.

SMTC	Meaning	Applies when
0b000	Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, or CPTR_EL3.ESM, that is not reported using EC value 0b000000.	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SMTC	Meaning	Applies when
0b001	Advanced SIMD, SVE, or SVE2 instruction trapped because PSTATE.SM is 1.	
0b010	SME instruction trapped because PSTATE.SM is 0.	
0b011	SME instruction trapped because PSTATE.ZA is 0.	
0b100	Access to the SME2 ZT0 register trapped as a result of SMCR_EL1.EZT0, SMCR_EL2.EZT0, or SMCR_EL3.EZT0.	FEAT_SME2 is implemented

All other values are reserved.

Additional Information for ISS encoding for an exception due to SME functionality

The following fields describe the configuration settings for the traps that are reported using the EC value 0b011101:

- CPACR_EL1.SMEN, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR and SMCR_EL1 System registers at EL1 and EL0, trapped to EL1 or EL2.
- CPTR_EL2.SMEN and CPTR_EL2.TSM, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2 at EL2, EL1, and EL0, trapped to EL2.
- CPTR_EL3.ESM, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3 from all Exception levels and any Security state, trapped to EL3.
- If FEAT_SME2 is implemented:
  - SMCR_EL1.EZT0, for accesses to ZT0 at EL1 and EL0, trapped to EL1 or EL2.
  - SMCR_EL2.EZT0, for accesses to ZT0 at EL2, EL1, and EL0, trapped to EL2.
  - SMCR_EL3.EZT0, for accesses to ZT0 at any Exception level, trapped to EL3.

ISS encoding for an exception from a Data Abort

The ISS2 encoding for an exception from a Data Abort includes further information about the exception when any of the following features are implemented:

- FEAT_LS64_V.
- FEAT_LS64_ACCDATA.
- FEAT_THE.
- FEAT_S1POE or FEAT_S2POE.
- FEAT_S1PIE or FEAT_S2PIE.
- FEAT_GCS.
- FEAT_MTE_CANONICAL_TAGS.
- FEAT_MTE_PERM.
- FEAT_HDBSS.

ISV, bit [24]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] represents the instruction syndrome fields {SAS, SSE, SRT, SF, AR}.

ISV	Meaning
`0b0`	No valid instruction syndrome. ISS[23:14] do not represent an instruction syndrome.
`0b1`	ISS[23:14] hold a valid instruction syndrome.

The ISV field is only relevant for the following instructions:

- An AArch64 load or store of a single general-purpose register (including the register specified with `0b11111`, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- An AArch32 instruction LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT, where both of the following apply:
  - It is not performing register writeback.
  - It is not using R15 as a source or destination register.
- If FEAT_LS64 is implemented, an LD64B or ST64B instruction.
- If FEAT_LS64_V is implemented, an ST64BV instruction.
- If FEAT_LS64_ACCDATA is implemented, an ST64BV0 instruction.

The ISV field is 1 if all of the following apply:

- The fault was not a stage 2 fault on a stage 1 translation table walk.
- If FEAT_RAS is implemented, the fault was not any kind of synchronous External abort.
- Any of the following apply:
  - The fault was generated by one of the described AArch64 load or store instructions that transfer a single general-purpose register, and any of the following apply:
    - The fault was a stage 2 fault.
  - The fault was generated by one of the described AArch32 instructions and any of the following apply:
    - The fault was a stage 2 fault.
  - The fault was generated by one of the FEAT_LS64, FEAT_LS64_V or FEAT_LS64_ACCDATA instructions and the fault was a Translation fault, Access flag fault or Permission fault.
- One of the following applies:
  - The address reported in FAR_EL2 is the lowest address accessed by the instruction.
  - The address reported in FAR_EL2 is not the lowest address accessed by the instruction, and the implementation reports ISV as 1 in this case. Arm recommends against this behavior.

The value of this field is UNKNOWN when the following occurs:

- Stage 2 faults when the exception was generated in Debug state, in memory access mode.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

Otherwise the value of this field is 0.

Note

The value of this field is 0 if any of the following apply:

- FEAT_MOPS is implemented and the fault was for a memory access generated by a Memory Copy and Memory Set instruction.
- FEAT_MTE is implemented and the fault was for a direct access to Allocation Tags.
- FEAT_GCS is implemented and the fault was for a Guarded control stack data access.
- FEAT_NV2 is implemented and the fault was for a System register access that was transformed to a load or store relative to VNCR_EL2.
- FEAT_LSE is implemented and the fault was for an atomic instruction.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == '1':

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

SAS	Meaning
`0b00`	Byte
`0b01`	Halfword
`0b10`	Word
`0b11`	Doubleword

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [21]

When ISV == '1':

SSE, bit [21]

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

SSE	Meaning
`0b0`	Sign-extension not required.
`0b1`	Data item must be sign-extended.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When ISV == '0' and FEAT_THE is implemented:

TopLevel, bit [21]

Indicates if the fault was due to TopLevel.

TopLevel	Meaning
0b0	Fault is not due to TopLevel.
0b1	Fault is due to TopLevel.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [20:16]

When ISV == '1':

SRT, bits [20:16]

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

If the exception was taken from an Exception level that is using AArch32, then this is the AArch64 view of the register. See 'Mapping of the general-purpose registers between the Execution states'.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When ISV == '0', FEAT_RASv2 is implemented, and GetESR_ELx_DFSC(EL2) IN {'010000', '01001x', '0101xx'}:

WU, bits [1:0] of bits [20:16]

Write Update. Describes whether a store instruction that generated an External abort updated the location.

WU	Meaning
0b00	Not a store instruction or translation table update, or the location might have been updated.
0b10	Store instruction or translation table update that did not update the location.
0b11	Store instruction or translation table update that updated the location.

In the description of this field, a store instruction is any memory-writing instruction that explicitly performs a store. This includes instructions that both read and write memory.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [15]

When ISV == '1':

SF, bit [15]

Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

SF	Meaning
0b0	Instruction loads/stores a 32-bit general-purpose register.
0b1	Instruction loads/stores a 64-bit general-purpose register.

Note

This field specifies the register width identified by the instruction, not the Execution state.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

FnP, bit [15]

FAR not Precise.

FnP	Meaning	Applies when
0b0	The FAR holds the faulting virtual address that generated the Data Abort.	
0b1	The FAR holds any virtual address within the naturally-aligned granule that contains the faulting virtual address that generated a Data Abort due to an SVE contiguous vector load/store instruction, or an SME load/store instruction. For more information about the naturally-aligned fault granule, see FAR_ELx (for example, FAR_EL1).	FEAT_SME is implemented or FEAT_SVE is implemented

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [14]

When ISV == '1':

AR, bit [14]

Acquire/Release.

AR	Meaning
0b0	Instruction did not have acquire/release semantics.
0b1	Instruction did have acquire/release semantics.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_PFAR is implemented, ISV == '0', and GetESR_ELx_DFSC(EL2) IN {'010000', '01001x', '0101xx'}:

PFV, bit [14]

PFAR Valid. Describes whether the PFAR_EL2 register is valid.

PFV	Meaning
0b0	PFAR_EL2 is UNKNOWN.
0b1	PFAR_EL2 is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VNCR, bit [13]

Indicates that the fault came from use of VNCR_EL2 register by EL1 code.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

VNCR	Meaning	Applies when
0b0	The fault was not generated by the use of VNCR_EL2 by EL1 code.	
0b1	The fault was generated by the use of VNCR_EL2 by EL1 code.	FEAT_NV2 is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [12:11]

When GetESR_ELx_DFSC(EL2) IN {'00xxxx', '10101x'} and !(GetESR_ELx_DFSC(EL2) IN {'0000xx'}):

LST, bits [12:11]

Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort reported with ISV=1.

LST	Meaning	Applies when
0b00	The instruction that generated the Data Abort is not specified by this field.	
0b01	An ST64BV instruction generated the Data Abort.	FEAT_LS64_V is implemented
0b10	An LD64B or ST64B instruction generated the Data Abort.	FEAT_LS64 is implemented
0b11	An ST64BV0 instruction generated the Data Abort.	FEAT_LS64_ACCDATA is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL2) == '010000':

SET, bits [12:11]

Synchronous Error Type. Used when a synchronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

SET	Meaning	Applies when
0b00	Recoverable state (UER).	
0b10	Uncontainable (UC). If FEAT_RASv2 is implemented, this value is reserved.	FEAT_RASv2 is implemented
0b11	Restartable state (UEO).	

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

CM	Meaning
0b0	The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Abort caused by an instruction reading from a memory location.
0b1	Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- If FEAT_RASv2 is implemented, an External abort on an Atomic access, reported with ESR_EL2.WU set to 0b00.
- A fault reported using a DFSC value of 0b110101, indicating an unsupported Exclusive or atomic access.
- A fault reported using a DFSC value of 0b110001, indicating an unsupported atomic hardware update fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC	Meaning	Applies when
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001000	Access flag fault, level 0.	FEAT_LPA2 is implemented
0b001100	Permission fault, level 0.	FEAT_LPA2 is implemented
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010001	Synchronous Tag Check Fault.	FEAT_MTE2 is implemented
0b010010	Synchronous External abort on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented
0b010011	Synchronous External abort on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011011	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented and FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100001	Alignment fault.	
0b100010	Granule Protection Fault on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented and FEAT_RME is implemented
0b100011	Granule Protection Fault on translation table walk or hardware update of translation table, level -1.	FEAT_RME is implemented and FEAT_LPA2 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC	Meaning	Applies when
0b100100	Granule Protection Fault on translation table walk or hardware update of translation table, level 0.	FEAT_RME is implemented
0b100101	Granule Protection Fault on translation table walk or hardware update of translation table, level 1.	FEAT_RME is implemented
0b100110	Granule Protection Fault on translation table walk or hardware update of translation table, level 2.	FEAT_RME is implemented
0b100111	Granule Protection Fault on translation table walk or hardware update of translation table, level 3.	FEAT_RME is implemented
0b101000	Granule Protection Fault, not on translation table walk or hardware update of translation table.	FEAT_RME is implemented
0b101001	Address size fault, level -1.	FEAT_LPA2 is implemented
0b101010	Translation fault, level -2.	FEAT_D128 is implemented
0b101011	Translation fault, level -1.	FEAT_LPA2 is implemented
0b101100	Address Size fault, level -2.	FEAT_D128 is implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).	
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).	

All other values are reserved.

For more information about the lookup level associated with a fault, see ‘The lookup level associated with MMU faults’.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TFV	Meaning
0b0	The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
0b1	One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see 'Floating-point exceptions and exception traps'.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IDF	Meaning
0b0	Input denormal floating-point exception has not occurred.
0b1	Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IXF	Meaning
0b0	Inexact floating-point exception has not occurred.
0b1	Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

UFF	Meaning
0b0	Underflow floating-point exception has not occurred.
0b1	Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

OFF	Meaning
0b0	Overflow floating-point exception has not occurred.
0b1	Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

DZF	Meaning
0b0	Divide by Zero floating-point exception has not occurred.
0b1	Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IOF	Meaning
0b0	Invalid Operation floating-point exception has not occurred.
0b1	Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a trapped floating-point exception

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for a GCS exception

Bit [24]

Reserved, RES0.

ExType, bits [23:20]

The first level classification of GCS exceptions.

ExType	Meaning
0b0000	The exception reported is a Guarded Control Stack Data Check Exception.
0b0001	The exception reported is an EXLOCK Exception.
0b0010	The exception reported is a trap exception on GCSSTR or GCSSTTR instruction execution.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:15]

Reserved, RES0.

Raddr, bits [14:10]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When GetESR_ELx_ExType(EL2) == '0010':

Indicates the data address register number supplied in the instruction that has been trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [9:5]

When GetESR_ELx_ExType(EL2) == '0000':

Rn, bits [9:5]

Indicates a register number used by the instruction that caused the Guarded Control Stack Data Check Exception.

For a procedure return instruction reported with ESR_EL2.ISS.IT as `0b00000`, contains the register number for the register which contains the target address of the branch.

For a GCSPOPM instruction reported with ESR_EL2.ISS.IT as `0b00001`, contains the register number for the register which is the destination register of the instruction.

For a procedure return instruction reported with ESR_EL2.ISS.IT as `0b00010` or `0b00011`, contains the value `0b11110`, indicating X30.

For a GCSSS1 instruction reported with ESR_EL2.ISS.IT as `0b00100`, contains the register number for the register which is the input register of the instruction.

If ESR_EL2.ISS.IT is reported as `0b00101` or `0b01000`, this field is UNKNOWN

If ESR_EL2.ISS.IT is reported as `0b01001`, this field is `0b11111`

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When GetESR_ELx_ExType(EL2) == '0010':

Rvalue, bits [9:5]

Indicates the data value register number supplied in the instruction that has been trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IT, bits [4:0]

When GetESR_ELx_ExType(EL2) == '0000':

Type of the instruction that caused the Guarded Control Stack Data Check Exception.

IT	Meaning
`0b00000`	Guarded Control Stack Data Check Exception is from a procedure return instruction without Pointer authentication.
`0b00001`	Guarded Control Stack Data Check Exception is from a GCSPOPM instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IT	Meaning
0b00010	Guarded Control Stack Data Check Exception is from a procedure return instruction with Pointer authentication that uses key A.
0b00011	Guarded Control Stack Data Check Exception is from a procedure return instruction with Pointer authentication that uses key B.
0b00100	Guarded Control Stack Data Check Exception is from a GCSSS1 instruction.
0b00101	Guarded Control Stack Data Check Exception is from a GCSSS2 instruction.
0b01000	Guarded Control Stack Data Check Exception is from a GCSPOPCX instruction.
0b01001	Guarded Control Stack Data Check Exception is from a GCSPOPX instruction.

All other values are reserved

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Additional Information for ISS encoding for a GCS exception

The following fields describe the configuration settings for the traps that are reported using EC value 0b101101 and ExType value 0b0010:

- GCSCRE0_EL1.STREn
- GCSCR_EL1.STREn.
- GCSCR_EL2.STREn.
- GCSCR_EL3.STREn.
- HFGITR_EL2.nGCSSTR_EL1.

ISS encoding for an SError exception

Note

In earlier versions of the architecture, an SError exception is referred to as an SError interrupt or an asynchronous External abort exception.

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

IDS	Meaning
0b0	Bits [23:0] of the ISS field holds the fields described in this encoding. **Note** If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IDS	Meaning
0b1	Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError exception.

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:19]

Reserved, RES0.

ELS, bit [18]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL2) == '010001':

Meaning of ELR_ELx.

ELS	Meaning
0b0	Asynchronous. Does not indicate the trigger for the exception.
0b1	Synchronous. The exception was triggered by the instruction at ELR_ELx.

SError exceptions that report this field is 1 are not required to be precise.

The ESR_EL2.AET field describes whether the exception is precise or imprecise.

Corrected, Recoverable or Restartable exceptions are precise. Unrecoverable or Uncontainable exceptions are imprecise.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WU, bits [17:16]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL2) == '010001':

Write Update. Describes whether a store instruction that generated an External abort updated the location.

WU	Meaning
0b00	Not a store instruction or translation table update, or the location might have been updated.
0b10	Store instruction or translation table update that did not update the location.
0b11	Store instruction or translation table update that updated the location.

In the description of this field, a store instruction is any memory-writing instruction that explicitly performs a store. This includes instructions that both read and write memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VFV, bit [15]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL2) == '010001':

FAR Valid. Indicates the FAR_EL2 register contains a valid virtual address.

VFV	Meaning
0b0	FAR_EL2 is not valid, and holds an UNKNOWN value.
0b1	FAR_EL2 contains a valid virtual address associated with the error.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PFV, bit [14]

When FEAT_PFAR is implemented and GetESR_ELx_DFSC(EL2) == '010001':

PFAR Valid. Describes whether the PFAR_EL2 register is valid.

PFV	Meaning
0b0	PFAR_EL2 is UNKNOWN.
0b1	PFAR_EL2 is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented and GetESR_ELx_DFSC(EL2) == '010001':

Implicit error synchronization event.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IESB	Meaning
0b0	One of the following applies: • The SError exception was not synchronized by the implicit error synchronization event. • The SError exception was not taken immediately following an implicit error synchronization event. • The SError exception was either not synchronized by the implicit error synchronization event or not taken immediately. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 0.
0b1	The SError exception was synchronized by the implicit error synchronization event, taken immediately, and one of the following applies: • The implicit error synchronization event was on an exception entry. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception entry, and the exception is taken immediately after exception entry, this field is set to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception return, and the exception is taken immediately before the exception return, this field is set to an IMPLEMENTATION SPECIFIC choice of 0 or 1.

For all other SError exceptions, this field is set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL2) == '010001':

Asynchronous Error Type.

Describes the PE error state after taking the SError exception.

AET	Meaning
0b000	Uncontainable (UC).
0b001	Unrecoverable state (UEU).
0b010	Restartable state (UEO).
0b011	Recoverable state (UER).
0b110	Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError exception, the overall PE error state is reported.

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL2) == '010001':

External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [8]

Reserved, RES0.

WnRV, bit [7]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL2) == '010001':

ESR_EL2.WnR valid.

WnRV	Meaning
`0b0`	ESR_EL2.WnR is not valid and has been set to 0.
`0b1`	ESR_EL2.WnR is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WnR, bit [6]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL2) == '010001':

Write-not-Read. When the WnRV field is 1, indicates whether an exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
`0b0`	Exception was caused by an instruction reading from a memory location.
`0b1`	Exception was caused by an instruction writing to a memory location.

Accessing this bit has the following behavior:

- This bit is RES0 if ESR_EL2.WnRV is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- This bit is not valid and reads UNKNOWN if an External abort on a Atomic access, reported with ESR_EL2.WU == `0b00`.
- Otherwise RW.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

Data Fault Status Code.

DFSC	Meaning
`0b000000`	Uncategorized error.
`0b010001`	Asynchronous SError exception.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

24 … 6	5 … 0
RES0	IFSC

Bits [24:6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning
`0b100010`	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Additional Information for ISS encoding for an exception from a Breakpoint or Vector Catch debug exception

For more information about generating these exceptions:

- For exceptions from AArch64, see 'Breakpoint exceptions'.
- For exceptions from AArch32, see 'Breakpoint exceptions' and 'Vector Catch exceptions'.

ISS encoding for an exception from a Software Step exception

24	23 … 7	6	5 … 0
ISV	RES0	EX	IFSC

ISV, bit [24]

Instruction syndrome valid. Indicates whether the EX bit, ISS[6], is valid, as follows:

ISV	Meaning
0b0	EX bit is RES0.
0b1	EX bit is valid.

Arm deprecates software use of this field.

See the EX bit description for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:7]

Reserved, RES0.

EX, bit [6]

Exclusive operation. If the ISV bit is set to 1, this bit indicates whether a Load-Exclusive instruction was stepped.

EX	Meaning
0b0	An instruction other than a Load-Exclusive instruction was stepped.
0b1	A Load-Exclusive instruction was stepped.

Arm deprecates software use of this field.

If the ISV bit is set to 0, this bit is RES0, indicating no syndrome data is available.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IFSC, bits [5:0]

Instruction Fault Status Code.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Software Step exception

For more information about generating these exceptions, see 'Software Step exceptions'.

ISS encoding for an exception from a Watchpoint exception

Bit [24]

Reserved, RES0.

WPT, bits [23:18]

When FEAT_Debugv8p2 is implemented:

Watchpoint number.

All other values are reserved.

Otherwise:

Reserved, RES0.

WPTV, bit [17]

When FEAT_Debugv8p2 is implemented:

Watchpoint number Valid.

WPTV	Meaning
0b0	The WPT field is invalid, and holds an UNKNOWN value.
0b1	The WPT field is valid, and holds the number of a watchpoint that triggered a Watchpoint exception.

If FEAT_Debugv8p9 is implemented, value 0 is not permitted.

When a Watchpoint exception is triggered by a watchpoint match:

- If FEAT_Debugv8p9 is implemented or the PE sets any of FnV, FnP, or WPF to 1, then the PE sets WPTV to 1.
- Otherwise, the PE sets WPTV to an IMPLEMENTATION DEFINED value, 0 or 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

WPF, bit [16]

Watchpoint might be false-positive.

WPF	Meaning	Applies when
0b0	The watchpoint matched an address or address range that was accessed by the instruction.	
0b1	The watchpoint matched an address or address range that might not have been accessed by the instruction.	FEAT_SVE is implemented or FEAT_SME is implemented

Arm strongly recommends that this bit is set to 0, other than when one of the following instructions might generate a watchpoint match for an address or address range that the instruction does not access:

- An SVE contiguous vector load/store instruction, when the PE is in Streaming SVE mode.
- An SME load/store instruction.

FnP, bit [15]

FAR not Precise.

This field only has meaning if the FAR is valid; that is, when the FnV field is 0. If the FnV field is 1, the FnP field is 0.

FnP	Meaning	Applies when
0b0	If the FnV field is 0, the FAR holds the virtual address of an access or set of contiguous accesses that triggered a Watchpoint exception.	
0b1	The FAR holds any address within the smallest implemented translation granule that contains the virtual address of an access or set of contiguous accesses that triggered a Watchpoint exception.	FEAT_SVE is implemented or FEAT_SME is implemented

Bit [14]

Reserved, RES0.

VNCR, bit [13]

Indicates that the watchpoint came from use of VNCR_EL2 register by EL1 code.

VNCR	Meaning	Applies when
0b0	The watchpoint was not generated by the use of VNCR_EL2 by EL1 code.	
0b1	The watchpoint was generated by the use of VNCR_EL2 by EL1 code.	FEAT_NV2 is implemented

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [12:11]

Reserved, RES0.

FnV, bit [10]

FAR not Valid.

FnV	Meaning	Applies when
0b0	The FAR is valid, and its value is as described by the FnP field.	
0b1	The FAR is invalid, and holds an UNKNOWN value.	FEAT_SVE is implemented or FEAT_SME is implemented

Bit [9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Watchpoint exception came from a cache maintenance instruction:

CM	Meaning
0b0	The Watchpoint exception was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Watchpoint exception was generated by the execution of a cache maintenance instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as a cache maintenance instructions, and therefore their execution does not cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [7]

Reserved, RES0.

WnR, bit [6]

Write not Read. Indicates whether the Watchpoint exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Watchpoint exception caused by an instruction reading from a memory location.
0b1	Watchpoint exception caused by an instruction writing to a memory location.

For Watchpoint exceptions on cache maintenance instructions, this bit always returns a value of 1.

For Watchpoint exceptions from an atomic instruction, this field is set to 0 if a read of the location would have generated the Watchpoint exception, otherwise it is set to 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If multiple watchpoints match on the same access, it is UNPREDICTABLE which watchpoint generates the Watchpoint exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning
0b100010	Debug exception.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a Watchpoint exception

For more information about generating these exceptions, see 'Watchpoint exceptions'.

ISS encoding for an exception from execution of a Breakpoint instruction

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

For the AArch32 BKPT instructions, the comment field is described as the immediate field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from execution of a Breakpoint instruction

For more information about generating these exceptions, see 'Breakpoint instruction exceptions'.

ISS encoding for an exception from an ERET, ERETAA, or ERETAB instruction

This EC value applies when:

- FEAT_FGT is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Effective value of HCR_EL2.NV is 1.

Bits [24:2]

Reserved, RES0.

ERET, bit [1]

Indicates whether an ERET or ERETA* instruction was trapped to EL2.

ERET	Meaning
0b0	ERET instruction trapped to EL2.
0b1	ERETAA or ERETAB instruction trapped to EL2.

If this bit is 0, the ERETA field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ERETA, bit [0]

Indicates whether an ERETAA or ERETAB instruction was trapped to EL2.

ERETA	Meaning
0b0	ERETAA instruction trapped to EL2.
0b1	ERETAB instruction trapped to EL2.

When the ERET field is 0, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an ERET, ERETAA, or ERETAB instruction

For more information about generating these exceptions, see HCR_EL2.NV.

If FEAT_FGT is implemented, HFGITR_EL2.ERET controls fine-grained trap exceptions from ERET, ERETAA, and ERETAB execution.

ISS encoding for a Branch Target Exception

24 … 2	1 0
RES0	BTYPE

Bits [24:2]

Reserved, RES0.

BTYPE, bits [1:0]

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Additional Information for ISS encoding for a Branch Target Exception

For more information about generating these exceptions, see 'The AArch64 application level programmers model'.

ISS encoding for an exception from a trapped Pointer Authentication instruction

24 … 0
RES0

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from a trapped Pointer Authentication instruction

For more information about generating these exceptions, see:

- HCR_EL2.API, for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.
- SCR_EL3.API, for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL3.

ISS encoding for a PAC Fail exception

24 … 2	1	0
RES0	DnI	BnA

Bits [24:2]

Reserved, RES0.

DnI, bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

DnI	Meaning
0b0	Instruction Key.
0b1	Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BnA, bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BnA	Meaning
0b0	A key.
0b1	B key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for a PAC Fail exception

The following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTDA, AUTDZA.
- AUTDB, AUTDZB.
- AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA.
- AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB.
- AUTIASPPC, AUTIASPPCR, AUTIA171615.
- AUTIBSPPC, AUTIBSPPCR, AUTIB171615.

If FEAT_FPACCOMBINE is implemented, the following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- RETAA, RETAB.
- RETAASPPC, RETABSPPC.
- RETAASPPCR, RETABSPPCR.
- BLRAA, BLRAAZ, BLRAB, BLRABZ.
- BRAA, BRAB, BRAAZ, BRABZ.
- ERETAA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

Accessing ESR_EL2

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL2 using the accessor name ESR_EL2 or ESR_EL1 are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ESR_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0101	0b0010	0b000

```
if !IsFeatureImplemented(FEAT_AA64) then
    Undefined();

D24.2.46 ESR_EL3, Exception Syndrome Register (EL3)

The ESR_EL3 characteristics are:

Purpose

Holds syndrome information for an exception taken to EL3.

Configuration

This register is present only when EL3 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to ESR_EL3 are UNDEFINED.

Attributes

ESR_EL3 is a 64-bit register.

Field descriptions

ESR_EL3 is made UNKNOWN as a result of an exception return from EL3.

When an UNPREDICTABLE instruction is treated as UNDEFINED, and the exception is taken to EL3, the value of ESR_EL3 is UNKNOWN. The value written to ESR_EL3 must be consistent with a value that could be created as a result of an exception from the same Exception level that generated the exception as a result of a situation that is not UNPREDICTABLE at that Exception level, in order to avoid the possibility of a privilege violation.

Bits [63:56]

Reserved, RES0.

ISS2, bits [55:32]

ISS2 encoding for an exception, the bit assignments are:

ISS2 encoding for an exception from a Data Abort

Bits [23:12]

Reserved, RES0.

HDBSSF, bit [11]

When FEAT_HDBSS is implemented, IsSecondStage(Fault), and GetESR_ELx_DFSC(EL3) IN {'0011xx', '01001x', '0101xx', '10001x', '1001xx'}:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Indicates that the fault was caused by the HDBSS.

When DFSC indicates a synchronous External abort on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

HDBSSF	Meaning
0b0	Fault was not caused by HDBSS.
0b1	Fault was caused by HDBSS.

This field only applies for stage 2 Permission faults.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TnD, bit [10]

When FEAT_MTE_CANONICAL_TAGS is implemented:

Tag not Data.

If a memory access generates a Data Abort for a stage 1 Permission fault, this field indicates whether the fault is due to an Allocation Tag access.

TnD	Meaning
0b0	Permission fault is not due to a write of an Allocation Tag to Canonically Tagged memory.
0b1	Permission fault is due to a write of an Allocation Tag to Canonically Tagged memory.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [9]

Reserved, RES0.

GCS, bit [8]

When FEAT_GCS is implemented:

Guarded Control Stack data access.

If a memory access generates a Data Abort, this field indicates whether the fault is due to a Guarded Control Stack data access.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GCS	Meaning
0b0	The Data Abort is not due to a Guarded control stack data access.
0b1	The Data Abort is due to a Guarded control stack data access. The ISV field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [7]

Reserved, RES0.

Overlay, bit [6]

When FEAT_S1POE is implemented:

Overlay flag.

If a memory access generates a Data Abort for a Permission fault, then this field holds information about the fault.

Overlay	Meaning
0b0	Data Abort is not due to Overlay Permissions.
0b1	Data Abort is due to Overlay Permissions.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DirtyBit, bit [5]

When FEAT_S1PIE is implemented:

DirtyBit flag.

If a write access to memory generates a Data Abort for a Permission fault using Indirect Permission, then this field holds information about the fault.

DirtyBit	Meaning
0b0	Permission Fault is not due to dirty state.
0b1	Permission Fault is due to dirty state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For any other fault or Access, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Xs, bits [4:0]

When FEAT_LS64 is implemented:

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort exception reported with ISV=1, then this field holds register specifier, Xs.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort exception reported with ISV=1, then this field holds register specifier, Xs.

Otherwise, this field is RES0.

Otherwise:

Reserved, RES0.

ISS2 encoding for an exception from an Instruction Abort

Bits [23:12]

Reserved, RES0.

HDBSSF, bit [11]

When FEAT_HDBSS is implemented:

Indicates that the fault was caused by the HDBSS.

When IFSC indicates a synchronous External abort on translation table walk or hardware update of translation table, this field indicates whether the fault was caused by a write to the HDBSS.

HDBSSF	Meaning
0b0	Fault was not caused by HDBSS.
0b1	Fault was caused by HDBSS.

This field only applies for stage 2 Permission faults.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

Bits [10:7]

Reserved, RES0.

Overlay, bit [6]

When FEAT_S1POE is implemented:

Overlay flag.

If a memory access generates a Instruction Abort for a Permission fault, then this field holds information about the fault.

Overlay	Meaning
`0b0`	Instruction Abort is not due to Overlay Permissions.
`0b1`	Instruction Abort is due to Overlay Permissions.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [5:0]

Reserved, RES0.

ISS2 encoding for a Granule Protection Check exception

Bits [23:12]

Reserved, RES0.

HDBSSF, bit [11]

When FEAT_HDBSS is implemented and IsSecondStage(Fault):

Indicates that the fault was caused by the HDBSS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

HDBSSF	Meaning
0b0	Fault was not caused by HDBSS.
0b1	Fault was caused by HDBSS.

This field only applies for stage 2 Permission faults.

For any other fault, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [10:9]

Reserved, RES0.

GCS, bit [8]

When FEAT_GCS is implemented:

Guarded control stack data access.

Indicates that the Granule Protection Check Exception is due to a Guarded control stack data access.

GCS	Meaning
0b0	The Granule Protection Check Exception is not due to a Guarded control stack data access.
0b1	The Granule Protection Check Exception is due to a Guarded control stack data access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [7:0]

Reserved, RES0.

ISS2 encoding for all other exceptions

23 … 0
RES0

Bits [23:0]

Reserved, RES0.

EC, bits [31:26]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Exception Class. Indicates the reason for the exception that this register holds information about.

For each EC value, the table references a subsection that gives information about:

- The cause of the exception, for example the configuration required to enable the trap.
- The encoding of the associated ISS.

Possible values of the EC field are:

EC	Meaning	ISS	ISS2	Applies when
`0b000000`	Unknown reason.	ISS encoding for exceptions with an unknown reason	ISS2 encoding for all other exceptions	
`0b000001`	Trapped WF* instruction execution. Conditional WF* instructions that fail their condition code check do not cause an exception.	ISS encoding for an exception from a WF* instruction	ISS2 encoding for all other exceptions	
`0b000011`	Trapped MCR or MRC access with (coproc==`0b1111`) that is not reported using EC value `0b000000`.	ISS encoding for an exception from an MCR or MRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
`0b000100`	Trapped MCRR or MRRC access with (coproc==`0b1111`) that is not reported using EC value `0b000000`.	ISS encoding for an exception from an MCRR or MRRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
`0b000101`	Trapped MCR or MRC access with (coproc==`0b1110`).	ISS encoding for an exception from an MCR or MRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
`0b000110`	Trapped LDC or STC access. The only architected uses of these instruction are: • An STC to write data to memory from DBGDTRRXint. • An LDC to read data from memory to DBGDTRTXint.	ISS encoding for an exception from an LDC or STC instruction	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
`0b000111`	Access to SME, SVE, Advanced SIMD or floating-point functionality trapped by CPACR_EL1.FPEN, CPTR_EL2.FPEN, CPTR_EL2.TFP, or CPTR_EL3.TFP control. Excludes exceptions resulting from CPACR_EL1 when the value of HCR_EL2.TGE is 1, or because SVE or Advanced SIMD and floating-point are not implemented. These are reported with EC value `0b000000`.	ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps	ISS2 encoding for all other exceptions	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b001001	Trapped use of a Pointer authentication instruction.	ISS encoding for an exception from a trapped Pointer Authentication instruction	ISS2 encoding for all other exceptions	FEAT_PAuth is implemented
0b001010	Trapped execution of any instruction not covered by other EC values.	ISS encoding for an exception from any other instruction	ISS2 encoding for all other exceptions	FEAT_LS64 is implemented
0b001100	Trapped MRRC access with (coproc==0b1110).	ISS encoding for an exception from an MCRR or MRRC access	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b001101	Branch Target Exception.	ISS encoding for a Branch Target Exception	ISS2 encoding for all other exceptions	FEAT_BTI is implemented
0b001110	Illegal Execution state.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b010011	SMC instruction execution in AArch32 state, when SMC is not disabled.	ISS encoding for an exception from SMC instruction execution in AArch32 state	ISS2 encoding for all other exceptions	FEAT_AA32 is implemented
0b010100	Trapped MSRR, MRRS or System instruction execution in AArch64 state, that is not reported using EC value 0b000000.	ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	FEAT_SYSREG128 is implemented or FEAT_SYSINSTR128 is implemented
0b010101	SVC instruction execution in AArch64 state.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b010110	HVC instruction execution in AArch64 state, when HVC is not disabled.	ISS encoding for an exception from HVC or SVC instruction execution	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b010111	SMC instruction execution in AArch64 state, when SMC is not disabled.	ISS encoding for an exception from SMC instruction execution in AArch64 state	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b011000	Trapped MSR, MRS or System instruction execution in AArch64 state, that is not reported using EC values 0b000000, 0b000001 or 0b000111. This includes all instructions that cause exceptions that are part of the encoding space defined in 'System instruction class encoding overview', except for those exceptions reported using EC values 0b000000, 0b000001, or 0b000111.	ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b011001	Access to SVE functionality trapped as a result of CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ, that is not reported using EC value 0b000000.	ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ	ISS2 encoding for all other exceptions	FEAT_SVE is implemented
0b011100	Exception from a PAC Fail	ISS encoding for a PAC Fail exception	ISS2 encoding for all other exceptions	FEAT_FPAC is implemented
0b011101	Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, CPTR_EL3.ESM, or an attempted execution of an instruction that is illegal because of the value of PSTATE.SM or PSTATE.ZA, that is not reported using EC value 0b000000.	ISS encoding for an exception due to SME functionality	ISS2 encoding for all other exceptions	FEAT_SME is implemented
0b011110	Granule Protection Check exception	ISS encoding for a Granule Protection Check exception	ISS2 encoding for a Granule Protection Check exception	FEAT_RME is implemented
0b011111	IMPLEMENTATION DEFINED exception to EL3.	ISS encoding for an IMPLEMENTATION DEFINED exception to EL3	ISS2 encoding for all other exceptions	
0b100000	Instruction Abort from a lower Exception level. Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for an exception from an Instruction Abort	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b100001	Instruction Abort taken without a change in Exception level. Used for MMU faults generated by instruction accesses and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from an Instruction Abort	ISS2 encoding for all other exceptions	
0b100010	PC alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b100100	Data Abort exception from a lower Exception level. Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100101	Data Abort exception taken without a change in Exception level. Used for MMU faults generated by data accesses, alignment faults other than those caused by Stack Pointer misalignment, and synchronous External aborts, including synchronous parity or ECC errors. Not used for debug-related exceptions.	ISS encoding for an exception from a Data Abort	ISS2 encoding for an exception from a Data Abort	
0b100110	SP alignment fault exception.	ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault	ISS2 encoding for all other exceptions	
0b100111	Memory Operation Exception.	ISS encoding for an exception from the Memory Copy and Memory Set instructions	ISS2 encoding for all other exceptions	FEAT_MOPS is implemented
0b101100	Trapped floating-point exception taken from AArch64 state. This EC value is valid if the implementation supports trapping of floating-point exceptions, otherwise it is reserved. Whether a floating-point implementation supports trapping of floating-point exceptions is IMPLEMENTATION DEFINED.	ISS encoding for an exception from a trapped floating-point exception	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b101101	GCS exception.	ISS encoding for a GCS exception	ISS2 encoding for all other exceptions	FEAT_GCS is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EC	Meaning	ISS	ISS2	Applies when
0b101111	SError exception.	ISS encoding for an SError exception	ISS2 encoding for all other exceptions	
0b111100	BRK instruction execution in AArch64 state. This is reported in ESR_EL3 only if a BRK instruction is executed at EL3. This is the only debug exception that can be taken to EL3 when EL3 is using AArch64.	ISS encoding for an exception from execution of a Breakpoint instruction	ISS2 encoding for all other exceptions	FEAT_AA64 is implemented
0b111101	Profiling exception	ISS encoding for a Profiling exception	ISS2 encoding for all other exceptions	FEAT_EBEP is implemented, or FEAT_SPE_EXC is implemented, or FEAT_TRBE_EXC is implemented

All other EC values are reserved by Arm, and:

- Unused values in the range 0b000000 - 0b101100 (0x00 - 0x2C) are reserved for future use for synchronous exceptions.
- Unused values in the range 0b101101 - 0b111111 (0x2D - 0x3F) are reserved for future use, and might be used for synchronous or asynchronous exceptions.

The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IL, bit [25]

Instruction Length for synchronous exceptions. Possible values of this bit are:

IL	Meaning
0b0	16-bit instruction trapped.
0b1	32-bit instruction trapped. This value is also used when the exception is one of the following: • An SError exception. • An Instruction Abort exception. • A PC alignment fault exception. • An SP alignment fault exception. • A Data Abort exception for which the value of the ISV bit is 0. • An Illegal Execution state exception. • Any debug exception except for Breakpoint instruction exceptions. • An exception reported using EC value 0b000000.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS, bits [24:0]

Instruction Specific Syndrome. Architecturally, this field can be defined independently for each defined Exception class. However, in practice, some ISS encodings are used for more than one Exception class.

Typically, an ISS encoding has a number of subfields. When an ISS subfield holds a register number, the value returned in that field is the AArch64 view of the register number.

For an exception taken from AArch32 state, see 'Mapping of the general-purpose registers between the Execution states'.

If the AArch32 register descriptor is `0b1111`, then:

- If the instruction that generated the exception was not UNPREDICTABLE, the field takes the value `0b11111`.
- If the instruction that generated the exception was UNPREDICTABLE, the field takes an UNKNOWN value that must be either:
  - The AArch64 view of the register number of a register that might have been used at the Exception level from which the exception was taken.
  - The value `0b11111`.

ISS encoding for exceptions with an unknown reason

24 … 0
RES0

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for exceptions with an unknown reason

When an exception is reported using this EC value, the IL field is set to 1.

This EC value is used for all exceptions that are not covered by any other EC value. This includes exceptions that are generated in the following situations:

- The attempted execution of an instruction bit pattern that has no allocated instruction or that is not accessible at the current Exception level and Security state, including:
  - A read access using a System register pattern that is not allocated for reads or that does not permit reads at the current Exception level and Security state.
  - A write access using a System register pattern that is not allocated for writes or that does not permit writes at the current Exception level and Security state.
  - Instruction encodings that are unallocated.
  - Instruction encodings for instructions or System registers that are not implemented in the implementation.
- In Debug state, the attempted execution of an instruction bit pattern that is not accessible in Debug state.
- In Non-debug state, the attempted execution of an instruction bit pattern that is not accessible in Non-debug state.
- In AArch32 state, attempted execution of a short vector floating-point instruction.
- In an implementation that does not include Advanced SIMD and floating-point functionality, an attempted access to Advanced SIMD or floating-point functionality under conditions where that access would be permitted if that functionality was present. This includes the attempted execution of an Advanced SIMD or floating-point instruction, and attempted accesses to Advanced SIMD and floating-point System registers.
- An exception generated because of the value of one of the SCTLR_EL1.{ITD, SED, CP15BEN} control bits.
- Attempted execution of:
  - An HVC instruction when disabled by HCR_EL2.HCD or SCR_EL3.HCE.
  - An SMC instruction when disabled by SCR_EL3.SMD.
  - An HLT instruction when disabled by EDSCR.HDE.
- Attempted execution of an MSR or MRS instruction to access SP_EL0 when the value of SPSel.SP is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Attempted execution of an MSR or MRS instruction using a _EL12 register name when the Effective value of HCR_EL2.E2H is not 1.
- Attempted execution, in Debug state, of:
  - A DCPS1 instruction when the value of HCR_EL2.TGE is 1 and EL2 is disabled or not implemented in the current Security state.
  - A DCPS2 instruction from EL1 or EL0 when EL2 is disabled or not implemented in the current Security state.
  - A DCPS3 instruction when the value of EDSCR.SDD is 1, or when EL3 is not implemented.
- When EL3 is using AArch64, attempted execution from Secure EL1 of an SRS instruction using R13_mon.
- In Debug state when the value of EDSCR.SDD is 1, the attempted execution at EL2, EL1, and EL0 of an instruction that is configured to trap to EL3.
- In AArch32 state, the attempted execution of an MRS (banked register) or an MSR (banked register) instruction to SPSR_mon, SP_mon, or LR_mon.
- An exception that is taken to EL2 because the value of HCR_EL2.TGE is 1. If the value of HCR_EL2.TGE is 0, this exception is reported using an ESR_EL3.EC value of `0b000111`.
- If FEAT_UINJ is implemented, an Undefined exception caused by attempting to execute any instruction when PSTATE.UINJ is 1.

ISS encoding for an exception from a WF* instruction

24	23 20	19 10	9 5	4 3	2	1 0
CV	COND	RES0	RN	RES0	RV	TI

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:10]

Reserved, RES0.

RN, bits [9:5]

When FEAT_WFxT is implemented:

Register Number. Indicates the register number supplied for a `WFET` or `WFIT` instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [4:3]

Reserved, RES0.

RV, bit [2]

When FEAT_WFxT is implemented:

Register field Valid.

If TI[1] == 1, then this field indicates whether RN holds a valid register number for the register argument to the trapped `WFET` or `WFIT` instruction.

RV	Meaning
`0b0`	Register field invalid.
`0b1`	Register field valid.

If TI[1] == 0, then this field is RES0.

This field is set to 1 on a trap on `WFET` or `WFIT`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TI, bits [1:0]

Trapped instruction. Possible values of this bit are:

TI	Meaning	Applies when
0b00	WFI trapped.	
0b01	WFE trapped.	
0b10	WFIT trapped.	FEAT_WFxT is implemented
0b11	WFET trapped.	FEAT_WFxT is implemented

When FEAT_WFxT is implemented, this is a two bit field as shown. Otherwise, bit[1] is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a WF* instruction

The following fields describe configuration settings for generating this exception:

- HCR.{TWE, TWI}.
- SCTLR_EL1.{nTWE, nTWI}.
- SCTLR_EL2.{nTWE, nTWI}.
- HCR_EL2.{TWE, TWI}.
- SCR_EL3.{TWE, TWI}.

ISS encoding for an exception from an MCR or MRC access

CV, bit [24]

Condition code valid.

CV	Meaning
0b0	The COND field is not valid.
0b1	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc2, bits [19:17]

The Opc2 value from the issued instruction.

For a trapped VMRS access, holds the value `0b000`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [16:14]

The Opc1 value from the issued instruction.

For a trapped VMRS access, holds the value `0b111`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

For a trapped VMRS access, holds the reg field from the VMRS instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

If the Rt value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See 'Mapping of the general-purpose registers between the Execution states'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

For a trapped VMRS access, holds the value `0b0000`.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write to System register space. MCR instruction.
`0b1`	Read from System register space. MRC or VMRS instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an MCR or MRC access

The following fields describe configuration settings for generating exceptions from an MCR or MRC access using coproc `0b1111`, that are reported using EC value `0b000011`:

- If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, trapped to EL1.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- PMUSERENR_EL0.{ER, CR, SW, EN}, for accesses to Performance Monitor System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- HCR.{TRVM, TVM} and HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, trapped to EL2.
- HCR.TTLB and HCR_EL2.TTLB, for execution of TLB maintenance instructions at EL1 using AArch32 state, trapped to EL2.
- HCR.{TSW, TPC, TPU} and HCR_EL2.{TSW, TPC, TPU} for execution of cache maintenance instructions at EL0 and EL1 using AArch32 state, trapped to EL2.
- HCR.TAC and HCR_EL2.TACR, for accesses to the Auxiliary Control Register at EL1 using AArch32 state, trapped to EL2.
- HCR.TIDCP and HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations at EL0 and EL1 using AArch32 state, trapped to EL2.
- If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch32 state, trapped to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- HCR.{TID1, TID2, TID3} and HCR_EL2.{TID1, TID2, TID3}, for accesses to ID registers at EL0 and EL1 using AArch32 state, trapped to EL2.
- HCR2.TERR, for Non-secure accesses to error record registers at EL1 using AArch32 state, trapped to EL2.
- HCPTR.TCPAC and CPTR_EL2.TCPAC, for accesses to CPACR_EL1 or CPACR using AArch32 state, trapped to EL2.
- HSTR.T<n> and HSTR_EL2.T<n>, for accesses to System registers using AArch32 state, trapped to EL2.
- CNTHCTL.PL1PCEN and CNTHCTL_EL2.EL1PCEN, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HDCR.TTRF, for Non-secure accesses to trace filter control registers from System registers using AArch32 state, trapped to EL2.
- HDCR.{TPM, TPMCR} and MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HCPTR.TAM and CPTR_EL2.TAM, for accesses to Activity Monitors System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- CPTR_EL3.TCPAC, for accesses to CPACR from EL1 and EL2, and accesses to HCPTR from EL2 using AArch32 state, trapped to EL3.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- CPTR_EL3.TAM, for accesses to Activity Monitors System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, access to some registers at EL0, trapped to EL2.

The following fields describe configuration settings for generating exceptions from an MCR or MRC access using coproc `0b1110`, that are reported using EC value `0b000101`:

- CPACR_EL1.TTA for accesses to trace System registers, trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers at EL0 and EL1 using AArch32 state, trapped to EL1 or EL2.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC System registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC System registers at EL0, EL1, and EL2 trapped to EL3.
- HCR.TID0 and HCR_EL2.TID0, for accesses to the JIDR register in the ID group 0 at EL0 and EL1 using AArch32, trapped to EL2.
- HCPTR.TTA and CPTR_EL2.TTA, for accesses to trace System registers using AArch32, trapped to EL2.
- HDCR.TDRA and MDCR_EL2.TDRA, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, trapped to EL2.
- HDCR.TDOSA and MDCR_EL2.TDOSA, for accesses to powerdown debug System registers, using AArch32 state, trapped to EL2.
- HDCR.TDA and MDCR_EL2.TDA, for accesses to other debug System registers, using AArch32 state, trapped to EL2.
- CPTR_EL3.TTA, for accesses to trace System registers using AArch32, trapped to EL3.
- MDCR_EL3.TDOSA, for accesses to powerdown debug System registers using AArch32, trapped to EL3.
- MDCR_EL3.TDA, for accesses to other debug System registers, using AArch32, trapped to EL3.

The following fields describe configuration settings for generating exceptions from a VMSR or VMRS access, that are reported using EC value `0b001000`:

- HCR.TID0 and HCR_EL2.TID0, for accesses to the FPSID register in ID group 0 at EL1 using AArch32 state, VMRS access trapped to EL2.
- HCR.TID3 and HCR_EL2.TID3, for accesses to registers in ID group 3 including MVFR0, MVFR1 and MVFR2, VMRS access trapped to EL2.
- HCPTR.{TCP10, TCP11}, for Non-secure accesses to FPSCR, FPSID, FPEXC, MVFR0, MVFR1, and MVFR2, trapped to EL2.

ISS encoding for an exception from any other instruction

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS, bits [24:0]

ISS	Meaning	Applies when
`0b0000000000000000000000000`	`ST64BV` instruction trapped.	FEAT_LS64_V is implemented
`0b0000000000000000000000001`	`ST64BV0` instruction trapped.	FEAT_LS64_ACCDATA is implemented
`0b0000000000000000000000010`	`LD64B` or `ST64B` instruction trapped.	FEAT_LS64 is implemented

All other values are reserved.

ISS encoding for an exception from an MCRR or MRRC access

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Opc1, bits [19:16]

The Opc1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

Rt2, bits [14:10]

The Rt2 value from the issued instruction, the second general-purpose register used for the transfer.

If the Rt2 value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt2 value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See ‘Mapping of the general-purpose registers between the Execution states’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the first general-purpose register used for the transfer.

If the Rt value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rt value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See 'Mapping of the general-purpose registers between the Execution states'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write to System register space. MCRR instruction.
`0b1`	Read from System register space. MRRC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an MCRR or MRRC access

The following fields describe configuration settings for generating exceptions from an MCRR or MRRC access using coproc `0b1111`, that are reported using EC value `0b000100`:

- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN}, for accesses to the Generic Timer Registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- PMUSERENR_EL0.{CR, EN}, for accesses to Performance Monitor System registers from EL0 using AArch32 state, trapped to EL1 or EL2.
- AMUSERENR_EL0.{EN}, for accesses to Activity Monitors System registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 using AArch32 state, trapped to EL1 or EL2.
- HCR.{TRVM, TVM} and HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers from EL1 using AArch32 state, trapped to EL2.
- HCR2.TERR, for Non-secure accesses to error record registers at EL1 using AArch32 state, trapped to EL2.
- HSTR.T<n> and HSTR_EL2.T<n>, for accesses to System registers using AArch32 state, trapped to EL2.
- CNTHCTL.{PL1PCEN, PL1PCTEN} and CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HDCR.TPM and MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers from EL0 and EL1 using AArch32 state, trapped to EL2.
- HCPTR.TAM and CPTR_EL2.TAM, for accesses to Activity Monitors System registers AMEVCNTR0<n> and AMEVCNTR1<n> from EL0 and EL1 using AArch32 state, trapped to EL2.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- CPTR_EL3.TAM, for accesses to Activity Monitors System registers from EL0, EL1 and EL2 using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, HDFGRTR_EL2.PMCCNTR_EL0 for MRRC access and HDFGWTR_EL2.PMCCNTR_EL0 for MCRR access to PMCCNTR at EL0, trapped to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The following fields describe configuration settings for generating exceptions from an MCRR or MRRC access using coproc `0b1110`, that are reported using EC value `0b001100`:

- MDSCR_EL1.TDCC, for accesses to the Debug ROM registers DBGDSAR and DBGDRAR at EL0 using AArch32 state, trapped to EL1 or EL2.
- HDCR.TDRA and MDCR_EL2.TDRA, for accesses to Debug ROM registers DBGDRAR and DBGDSAR using AArch32, trapped to EL2.
- MDCR_EL3.TDA, for accesses to debug System registers, using AArch32, trapped to EL3.
- CPACR_EL1.TTA for accesses to trace System registers using AArch32, trapped to EL1 or EL2.
- HCPTR.TTA and CPTR_EL2.TTA, for accesses to trace System registers using AArch32, trapped to EL2.
- CPTR_EL3.TTA, for accesses to trace System registers using AArch32, trapped to EL3.

Note

If FEAT_ETMv4 or FEAT_ETE are implemented, MCRR and MRRC accesses to trace System registers are UNDEFINED and the resulting exception is higher priority than an exception due to these traps.

ISS encoding for an exception from an LDC or STC instruction

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

imm8, bits [19:12]

The immediate value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:10]

Reserved, RES0.

Rn, bits [9:5]

The Rn value from the issued instruction, the general-purpose register used for the transfer.

If the Rn value is not `0b1111`, then the reported value gives the AArch64 view of the register. Otherwise, if the Rn value is `0b1111`:

- If the instruction that generated the exception is not UNPREDICTABLE, then the register specifier takes the value `0b11111`.
- If the instruction that generated the exception is UNPREDICTABLE, then the register specifier takes an UNKNOWN value, which is restricted to either:
  - The AArch64 view of one of the registers that could have been used in AArch32 state at the Exception level that the instruction was executed at.
  - The value `0b11111`.

See 'Mapping of the general-purpose registers between the Execution states'.

This field is valid only when AM[2] is 0, indicating an immediate form of the LDC or STC instruction. When AM[2] is 1, indicating a literal form of the LDC or STC instruction, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Offset, bit [4]

Indicates whether the offset is added or subtracted:

Offset	Meaning
`0b0`	Subtract offset.
`0b1`	Add offset.

This bit corresponds to the U bit in the instruction encoding.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AM, bits [3:1]

Addressing mode. The permitted values of this field are:

AM	Meaning
0b000	Immediate unindexed.
0b001	Immediate post-indexed.
0b010	Immediate offset.
0b011	Immediate pre-indexed.
0b100	For a trapped STC instruction or a trapped T32 LDC instruction this encoding is reserved.
0b110	For a trapped STC instruction, this encoding is reserved.

The values 0b101 and 0b111 are reserved. The effect of programming this field to a reserved value is that behavior is CONSTRAINED UNPREDICTABLE, as described in 'Reserved values in System and memory-mapped registers and translation table entries'.

Bit [2] in this subfield indicates the instruction form, immediate or literal.

Bits [1:0] in this subfield correspond to the bits {P, W} in the instruction encoding.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
0b0	Write to memory. STC instruction.
0b1	Read from memory. LDC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from an LDC or STC instruction

The following fields describe the configuration settings from an LDC or STC access for the traps that are reported using EC value 0b000110:

- MDSCR_EL1.TDCC, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL1 or EL2.
- HDCR.TDA and MDCR_EL2.TDA, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL2.
- MDCR_EL3.TDA, for accesses to DBGDTRTXint and DBGDTRRXint, using AArch32 state, trapped to EL3.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC System registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC System registers at EL0, EL1, and EL2 trapped to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

24	23 20	19 0
CV	COND	RES0

The accesses covered by this trap include:

- Execution of Advanced SIMD and floating-point instructions.
- Accesses to the Advanced SIMD and floating-point System registers.
- Execution of SVE instructions.
- Execution of SME instructions.

For an implementation that does not include either SVE or support for Advanced SIMD and floating-point, the exception is reported using the EC value `0b000000`.

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an access to a register or instruction resulting from the FPEN and TFP traps

The following fields describe the configuration settings for the traps that are reported using EC value `0b000111`:

- HCPTR.{TCP10, TCP11}, for Non-secure accesses to Advanced SIMD and floating-point registers and instructions, trapped to EL2.
- HCPTR.TASE, for Non-secure accesses to Advanced SIMD functionality, trapped to EL2.
- CPACR_EL1.FPEN, for accesses to SIMD and floating-point registers trapped to EL1.
- CPTR_EL2.FPEN and CPTR_EL2.TFP, for accesses to SIMD and floating-point registers trapped to EL2.
- CPTR_EL3.TFP, for accesses to SIMD and floating-point registers trapped to EL3.

ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

24 … 0
RES0

The accesses covered by this trap include:

- Execution of SVE instructions when the PE is not in Streaming SVE mode.
- Accesses to the SVE System registers, ZCR_ELx.

For an implementation that does not include SVE, the exception is reported using the EC value `0b000000`.

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an access to SVE functionality, resulting from CPACR_EL1.ZEN, CPTR_EL2.ZEN, CPTR_EL2.TZ, or CPTR_EL3.EZ

The following fields describe the configuration settings for the traps that are reported using EC value `0b011001`:

- CPACR_EL1.ZEN, for execution of SVE instructions and accesses to SVE registers at EL1 or EL0, trapped to EL1.
- CPTR_EL2.ZEN and CPTR_EL2.TZ, for execution of SVE instructions and accesses to SVE registers at EL0, EL1, or EL2, trapped to EL2.
- CPTR_EL3.EZ, for execution of SVE instructions and accesses to SVE registers from all Exception levels, trapped to EL3.

ISS encoding for a Profiling exception

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [24:6]

Reserved, RES0.

FSC, bits [5:1]

Indicates why the Profiling exception was generated.

FSC	Meaning	Applies when
0b00000	PMU Profiling exception. The exception was generated because at least one PMU counter overflow status flag was 1.	FEAT_EBEP is implemented
0b00001	Profiling Buffer management event. The exception was generated because PMBSR_EL3.S was 1.	FEAT_SPE_EXC is implemented
0b00010	Trace buffer management event. The exception was generated because TRBSR_EL3.IRQ was 1.	FEAT_TRBE_EXC is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [0]

Reserved, RES0.

ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from an Illegal Execution state, or a PC or SP alignment fault

There are no configuration settings for generating Illegal Execution state exceptions and PC alignment fault exceptions. For more information about PC alignment fault exceptions, see 'PC alignment checking'.

'SP alignment checking' describes the configuration settings for generating SP alignment fault exceptions.

ISS encoding for an exception from the Memory Copy and Memory Set instructions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MemInst, bit [24]

Indicates the memory instruction class causing the exception.

MemInst	Meaning
0b0	CPYFE*, CPYFM*, CPYE*, and CPYM* instructions.
0b1	The instruction that caused the exception is in one of the following instruction classes: • SETE*, SETM*. • SETGE*, SETGM*.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

isSETG, bit [23]

Indicates whether the instruction belongs to one of the following instruction classes:

- SETGE*, SETGM*.

isSETG	Meaning
0b0	The instruction that caused the exception is not in one of the specified classes.
0b1	The instruction that caused the exception is in one of the specified classes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Options, bits [22:19]

Options : the Options field of the instruction.

For Memory Copy instructions, bits[22:19] forms the Options field, which holds the bits[15:12] of the instruction.

For Memory Set instructions:

- Bits[22:21] are RES0.
- Bits[20:19] form the Options field, which holds the bits[13:12] of the instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FromEpilogue, bit [18]

Indicates whether the instruction belongs to one of the following epilogue classes of Memory Copy or Memory Set instructions:

- CPYE*, CPYFE*.
- SETE*, SETGE*.

FromEpilogue	Meaning
`0b0`	The instruction that caused the exception is not in one of the specified classes.
`0b1`	The instruction that caused the exception is in one of the specified classes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FormatOption, bits [17:16]

Reports the Option used to encode the initial Xs, Xd, and Xn register values provided to the instruction that generated the exception.

FormatOption	Meaning
`0b00`	Option B.
`0b01`	Option A.
`0b10`	Option A.
`0b11`	Option B.

For more information, see Memory Copy and Memory Set exceptions.

Note

This field was previously presented as two separate bits, WrongOption, bit[17] and OptionA, bit [16], which were already expected to be used together and not individually.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [15]

Reserved, RES0.

destreg, bits [14:10]

The destination register value from the issued instruction, containing the destination address.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

srcreg, bits [9:5]

The source register value from the issued instruction, containing either the source address or the source data.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

sizereg, bits [4:0]

The size register value from the issued instruction, containing the number of bytes to be transferred or set.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from HVC or SVC instruction execution

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the HVC or SVC instruction.

For an HVC instruction, and for an A64 SVC instruction, this is the value of the imm16 field of the issued instruction.

For an A32 or T32 SVC instruction:

- If the instruction is unconditional, then:
  - For the T32 instruction, this field is zero-extended from the imm8 field of the instruction.
  - For the A32 instruction, this field is the bottom 16 bits of the imm24 field of the instruction.
- If the instruction is conditional, this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from HVC or SVC instruction execution

In AArch32 state, the HVC instruction is unconditional, and a conditional SVC instruction generates an exception only if it passes its condition code check. Therefore, the syndrome information for these exceptions does not require conditionality information.

For T32 and A32 instructions, see 'SVC' and 'HVC'.

For A64 instructions, see 'SVC' and 'HVC'.

If FEAT_FGT is implemented, HFGITR_EL2.{SVC_EL1, SVC_EL0} control fine-grained traps on SVC execution.

ISS encoding for an exception from SMC instruction execution in AArch32 state

For an SMC instruction that completes normally and generates an exception that is taken to EL3, the ISS encoding is RES0.

For an SMC instruction that is trapped to EL2 from EL1 because HCR_EL2.TSC is 1, the ISS encoding is as shown in the diagram.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CV, bit [24]

Condition code valid.

CV	Meaning
`0b0`	The COND field is not valid.
`0b1`	The COND field is valid.

For exceptions taken from AArch64, CV is set to 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether CV is set to 1 or set to 0. See the description of the COND field for more information.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

COND, bits [23:20]

For exceptions taken from AArch64, this field is set to `0b1110`.

The condition code for the trapped instruction. This field is valid only for exceptions taken from AArch32, and only when the value of CV is 1.

For exceptions taken from AArch32:

- When an A32 instruction is trapped, CV is set to 1 and:
  - If the instruction is conditional, COND is set to the condition code field value from the instruction.
  - If the instruction is unconditional, COND is set to `0b1110`.
- A conditional A32 instruction that is known to pass its condition code check can be presented either:
  - With COND set to `0b1110`, the value for unconditional.
  - With the COND value held in the instruction.
- When a T32 instruction is trapped, it is IMPLEMENTATION DEFINED whether:
  - CV is set to 0 and COND is set to an UNKNOWN value. Software must examine the SPSR.IT field to determine the condition, if any, of the T32 instruction.
  - CV is set to 1 and COND is set to the condition code for the condition that applied to the instruction.
- For an implementation that, for both T32 and A32 instructions, takes an exception on a trapped conditional instruction only if the instruction passes its condition code check, these definitions mean that when CV is set to 1 it is IMPLEMENTATION DEFINED whether the COND field is set to `0b1110`, or to the value of any condition that applied to the instruction.

This field is valid only if CCKNOWNPASS is 1, otherwise it is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CCKNOWNPASS, bit [19]

Indicates whether the instruction might have failed its condition code check.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CCKNOWNPASS	Meaning
0b0	The instruction was unconditional, or was conditional and passed its condition code check.
0b1	The instruction was conditional, and might have failed its condition code check.

Note

In an implementation in which an SMC instruction that fails it code check is not trapped, this field can always return the value 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [18:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from SMC instruction execution in AArch32 state

HCR.TSC describes the configuration settings for trapping SMC instructions to EL2.

HCR_EL2.TSC describes the configuration settings for trapping SMC instructions to EL2.

ISS encoding for an exception from SMC instruction execution in AArch64 state

24 … 16	15 … 0
RES0	imm16

Bits [24:16]

Reserved, RES0.

imm16, bits [15:0]

The value of the immediate field from the issued SMC instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from SMC instruction execution in AArch64 state

The value of ISS[24:0] described here is used both:

- When an SMC instruction is trapped from EL1 modes.
- When an SMC instruction is not trapped, so completes normally and generates an exception that is taken to EL3.

HCR_EL2.TSC describes the configuration settings for trapping SMC from EL1 modes.

ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

24 22	21 20	19 17	16 14	13 10	9 5	4 1	0
RES0	Op0	Op2	Op1	CRn	Rt	CRm	Direction

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:5]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

For system instructions which require that the opcode Rt field is set to `0b11111`, but where the trapped instruction has a different value of Rt, an implementation is permitted to return the value `0b11111`, instead of the value of Rt from the trapped instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Direction	Meaning
0b0	Write access, including MSR instructions.
0b1	Read access, including MRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSR, MRS, or System instruction execution in AArch64 state

For exceptions caused by System instructions, see 'System instructions' subsection of 'Branches, exception generating and System instructions' for the encoding values returned by an instruction.

The following fields describe configuration settings for generating the exception that is reported using EC value 0b011000:

- If FEAT_TIDCP1 is implemented, SCTLR_EL1.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL1.
- SCTLR_EL1.UCI, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UCT, for accesses to CTR_EL0 using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- SCTLR_EL1.DZE, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL1 or EL2.
- SCTLR_EL1.UMA, for accesses to the PSTATE interrupt masks using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- CPACR_EL1.TTA, for accesses to the trace System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- MDSCR_EL1.TDCC, for accesses to the Debug Communications Channel (DCC) registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- If FEAT_FGT is implemented, MDCR_EL2.TDCC for accesses to the DCC registers at EL0 and EL1 trapped to EL2, and MDCR_EL3.TDCC for accesses to the DCC registers at EL0, EL1, and EL2 trapped to EL3.
- CNTKCTL_EL1.{EL0PTEN, EL0VTEN, EL0PCTEN, EL0VCTEN} accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- PMUSERENR_EL0, for accesses to the Performance Monitor System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- AMUSERENR_EL0.EN, for accesses to Activity Monitors System registers using AArch64 state, MSR or MRS access trapped to EL1 or EL2.
- HCR_EL2.{TRVM, TVM}, for accesses to virtual memory control registers using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TDZ, for execution of DC ZVA instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TTLB, for execution of TLB maintenance instructions using AArch64 state, execution is trapped to EL2.
- If FEAT_EVT is implemented, the following registers control traps for EL1 and EL0 registers and instructions that use this EC value:
  - HCR_EL2.{TICAB, TOCU, TID4}.
  - HCR2.{TICAB, TOCU, TID4}.
- If FEAT_EVT2 is implemented, the following registers control traps for EL1 and EL0 instructions that use this EC value:
  - HCR_EL2.{TTLBOS, TTLBIS}.
- If FEAT_EVT2 is implemented, HCR2.TTLBIS controls traps for EL1 and EL0 instructions using AArch32 state that use this EC value.
- HCR_EL2.{TSW, TPC, TPU}, for execution of cache maintenance instructions using AArch64 state, execution is trapped to EL2.
- HCR_EL2.TACR, for accesses to the Auxiliary Control Register, ACTLR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.TIDCP, for accesses to lockdown, DMA, and TCM operations using AArch64 state, MSR or MRS access trapped to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_TIDCP1 is implemented, SCTLR_EL2.TIDCP, for EL0 accesses to IMPLEMENTATION DEFINED functionality using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{TID1, TID2, TID3}, for accesses to ID group 1, ID group 2 or ID group 3 registers, using AArch64 state, MSR or MRS access trapped to EL2.
- If FEAT_MTE2 is implemented, HCR_EL2.TID5, for accesses to GMID_EL1, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.
- If FEAT_IDTE3 is implemented, SCR_EL3.TID3, for accesses to ID group 3 registers using AArch64 state, at EL1 and EL2, trapped to EL3.
- CPTR_EL2.TCPAC, for accesses to CPACR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TTA, for accesses to the trace System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TTRF, for accesses to the trace filter control register, TRFCR_EL1, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDRA, for accesses to Debug ROM registers, using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDOSA, for accesses to powerdown debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- CNTHCTL_EL2.{EL1PCEN, EL1PCTEN}, for accesses to the Generic Timer registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.TDA, for accesses to debug System registers using AArch64 state, MSR or MRS access trapped to EL2.
- MDCR_EL2.{TPM, TPMCR}, for accesses to Performance Monitor System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- CPTR_EL2.TAM, for accesses to Activity Monitors System registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL2.
- HCR_EL2.{NV, NV1}, for Nested virtualization register access, using AArch64 state, MSR or MRS access, trapped to EL2.
- HCR_EL2.AT, for execution of AT S1E* instructions, using AArch64 state, execution is trapped to EL2.
- HCR_EL2.{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access, trapped to EL2.
- SCR_EL3.APK, for accesses to Pointer authentication key registers, using AArch64 state, MSR or MRS access trapped to EL3.
- SCR_EL3.ST, for accesses to the Counter-timer Physical Secure timer registers, using AArch64 state, MSR or MRS access trapped to EL3.
- SCR_EL3.{TERR, FIEN}, for accesses to RAS registers, using AArch64 state, MSR or MRS access trapped to EL3.
- CPTR_EL3.TCPAC, for accesses to CPTR_EL2 and CPACR_EL1 using AArch64 state, MSR or MRS access trapped to EL3.
- CPTR_EL3.TTA, for accesses to the trace System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TTRF, for accesses to the trace filter control registers, TRFCR_EL1 and TRFCR_EL2, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TDA, for accesses to debug System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TDOSA, for accesses to powerdown debug System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- MDCR_EL3.TPM, for accesses to Performance Monitor System registers, using AArch64 state, MSR or MRS access trapped to EL3.
- If FEAT_SPE is implemented:
  - MDCR_EL3.NSPB for accesses to Statistical Profiling and Profiling Buffer control registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
  - MDCR_EL2.TPMS for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 trapped to EL2.
- CPTR_EL3.TAM, for accesses to Activity Monitors System registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If FEAT_FGT is implemented:
  - SCR_EL3.FGTEn, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
  - HFGRTR_EL2 for reads and HFGWTR_EL2 for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 trapped to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - HFGITR_EL2 for execution of system instructions trapped to EL2.
  - HDFGRTR_EL2 for reads and HDFGWTR_EL2 for writes of registers, using AArch64 state, MSR or MRS access at EL0 and EL1 state trapped to EL2.
  - HAFGRTR_EL2 for reads of Activity Monitor counters, using AArch64 state, MRS access at EL0 and EL1 trapped to EL2.
- If FEAT_RNG_TRAP is implemented, SCR_EL3.TRNDR for reads of RNDR and RNDRRS using AArch64 state, MRS access trapped to EL3.
- If FEAT_SME is implemented:
  - CPTR_EL3.ESM, for MSR or MRS accesses to SMPRI_EL1 at EL1, EL2, and EL3, trapped to EL3.
  - CPTR_EL3.ESM, for MSR or MRS accesses to SMPRIMAP_EL2 at EL2 and EL3, trapped to EL3.
  - SCTLR_EL1.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL1 or EL2.
  - SCTLR_EL2.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, trapped to EL2.
  - SCR_EL3.EnTP2, for MSR or MRS accesses to TPIDR2_EL0 at EL0, EL1, and EL2, trapped to EL3.
- If FEAT_FPMR is implemented:
  - SCTLR_EL1.EnFPM, for accesses to FPMR at EL0, trapped to EL1 or EL2.
  - SCTLR_EL2.EnFPM, for accesses to FPMR at EL0, trapped to EL2.
  - HCRX_EL2.EnFPM, for accesses to FPMR at EL0 and EL1, trapped to EL2.
  - SCR_EL3.EnFPM, for accesses to FPMR at EL0, EL1, and EL2, trapped to EL3.
- If FEAT_NMI is implemented, HCRX_EL2.TALLINT, for MSR writes of ALLINT at EL1, trapped to EL2.
- If FEAT_FGT2 is implemented:
  - SCR_EL3.FGTEn2, for accesses to the fine-grained trap registers, MSR or MRS access at EL2 trapped to EL3.
  - HFGRTR2_EL2 for reads and HFGWTR2_EL2 for writes of registers, using AArch64 state, using MSR or MRS access at EL1 trapped to EL2.
  - HDFGRTR2_EL2 for reads and HDFGWTR2_EL2 for writes of registers, using AArch64 state, using MSR or MRS access at EL0 and EL1 trapped to EL2.
  - HFGITR2_EL2 for execution of system instructions trapped to EL2.
- If FEAT_ITE is implemented, MDCR_EL3.EnITE, for accesses to Instrumentation trace System registers, using AArch64 state, MSR or MRS access, trapped to EL3.
- If FEAT_MEC is implemented, SCR_EL3.MECEn, for accesses to MECID registers at EL2, trapped to EL3.
- If FEAT_SPE_FDS is implemented, MDCR_EL3.EnPMS3 for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
- If FEAT_SPE_nVM is implemented, MDCR_EL3.EnPMS4 for accesses to SPE registers, using AArch64 state, MSR or MRS access at EL1 and EL2 trapped to EL3.
- If FEAT_RASv2 is implemented, SCR_EL3.TWERR, for accesses to Error Record registers, MSR access at EL1 and EL2 trapped to EL3.
- If FEAT_Debugv8p9 is implemented, MDCR_EL3.EBWE for accesses of MDSELR_EL1, using AArch64 state, MRS or MSR access at EL2 and EL1 trapped to EL3.
- If FEAT_PMUv3p9, FEAT_SPMU, FEAT_EBEP, or FEAT_PMUv3_SS is implemented, MDCR_EL3.EnPM2, for accesses to PMU System registers, using AArch64 state, MSR or MRS access at EL2, EL1, and EL0, trapped to EL3.
- If FEAT_PMUv3_SS is implemented, MDCR_EL3.EnPMSS, for accesses to PMU Snapshot registers, using AArch64 state, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_THE is implemented, SCR_EL3.RCWMASKEn for accesses to RCWMASK_EL1 and RCWSMASK_EL1, using AArch64 state, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_AIE is implemented, SCR_EL3.AIEn for accesses to Extended Memory Attribute registers, MSR or MRS access at EL2 and EL1 trapped to EL3.
- If FEAT_S1PIE, FEAT_S2PIE, FEAT_S1POE, or FEAT_S2POE is implemented, SCR_EL3.PIEn for accesses to Permission Indirection, Overlay registers, MSR or MRS access at EL2, EL1 and EL0 trapped to EL3.
- If FEAT_MPAM_PE_BW_CTRL is implemented, MPAMBW2_EL2.{nTRAP_MPAMBWIDR_EL1, nTRAP_MPAMBW0_EL1, nTRAP_MPAMBW1_EL1} for accesses to MPAMBWn_EL1 registers, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.
- If FEAT_MPAM_PE_BW_CTRL and FEAT_SME are implemented, MPAMBW2_EL2.nTRAP_MPAMBWSM_EL1, for accesses to MPAMBWSM_EL1, using AArch64 state, MRS or MSR access at EL1, trapped to EL2.
- If FEAT_MPAM_PE_BW_CTRL is implemented, MPAMBW3_EL3.nTRAPLOWER, for accesses

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

to MPAMBW2_EL2 and MPAMBWn_EL1 registers, using AArch64 state, MRS or MSR access at EL1, trapped to EL3.
- If FEAT_HACDBS is implemented, SCR_EL3.HACDBSEn, for accesses to HACDBSBR_EL2 and HACDBSCONS_EL2, using AArch64 state, MRS or MSR access at EL2, trapped to EL3.
- If FEAT_HDBSS is implemented, SCR_EL3.HDBSSEn, for accesses to HDBSSBR_EL2 and HDBSSPROD_EL2, using AArch64 state, MRS or MSR access at EL2, trapped to EL3.
- If FEAT_SRMASK is implemented, SCR_EL3.SRMASKEn, for MSR or MRS accesses at EL1 or EL2 to the MASK registers using AArch64 state, trapped to EL3.

ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

Bits [24:22]

Reserved, RES0.

Op0, bits [21:20]

The Op0 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op2, bits [19:17]

The Op2 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Op1, bits [16:14]

The Op1 value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CRn, bits [13:10]

The CRn value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Rt, bits [9:6]

The Rt value from the issued instruction, the general-purpose register used for the transfer.

Note

This value represents register pair of X[Rt:0], X[Rt:1].

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [5]

Reserved, RES0.

CRm, bits [4:1]

The CRm value from the issued instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Direction, bit [0]

Indicates the direction of the trapped instruction.

Direction	Meaning
`0b0`	Write access, MSRR instructions.
`0b1`	Read access, MRRS instructions.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from MSRR, MRRS, or 128-bit System instruction execution in AArch64 state

The following fields describe configuration settings for generating exceptions from an MSRR or MRRS access that are reported using EC value `0b010100`:

- If FEAT_FGT is implemented:
  - HFGRTR_EL2 for reads and HFGWTR_EL2 for writes of registers, using AArch64 state, accesses at EL1 trapped to EL2.
- If FEAT_FGT2 is implemented:
  - HFGRTR2_EL2.nRCWSMASK_EL1 for reads and HFGWTR2_EL2.nRCWSMASK_EL1 for writes of RCWSMASK_EL1, using AArch64 state, accesses at EL1 trapped to EL2.
- If FEAT_SYSREG128 is implemented:
  - SCTLR2_EL1.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL0 trapped to EL1.
  - SCTLR2_EL2.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL0 trapped to EL2.
  - HCRX_EL2.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL1 and EL0 trapped to EL2.
  - SCR_EL3.EnIDCP128 for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL2, EL1, and EL0 trapped to EL3.
- If FEAT_D128 is implemented:
  - HCR_EL2.{TRVM, TVM} for accesses to TTBR0_EL1 and TTBR1_EL1, accesses at EL1 and EL0 trapped to EL2.
  - HCRX_EL2.D128En for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL1 trapped to EL2.
  - HFGITR_EL2 for execution of TLBIP system instructions trapped to EL2.
  - HCR_EL2.{TTLB, TTLBOS, TTLBIS}, for execution of TLBIP instructions using AArch64 state, execution is trapped to EL2.
  - SCR_EL3.D128En for accesses to 128-bit IMPLEMENTATION DEFINED System registers, accesses at EL2 and EL1 trapped to EL3.
- If FEAT_THE is implemented, SCR_EL3.RCWMASKEn for accesses to RCWMASK_EL1 and RCWSMASK_EL1, using AArch64 state, accesses at EL2 and EL1 trapped to EL3.

ISS encoding for an IMPLEMENTATION DEFINED exception to EL3

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

24 … 0
IMPLEMENTATION DEFINED

IMPLEMENTATION DEFINED, bits [24:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from an Instruction Abort

The ISS2 encoding for an exception from an Instruction Abort includes further information about the exception if any of the following are true:

- FEAT_S1POE is implemented and a memory access generates a Instruction Abort due to a Permission fault.
- FEAT_HDBSS is implemented.
- FEAT_THE is implemented.

Bits [24:15]

Reserved, RES0.

PFV, bit [14]

When FEAT_PFAR is implemented and GetESR_ELx_IFSC(EL3) IN {'010000', '01001x', '0101xx'}:

PFAR Valid. Describes whether the MFAR_EL3 register is valid.

PFV	Meaning
0b0	MFAR_EL3 is UNKNOWN.
0b1	MFAR_EL3 is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [13]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SET, bits [12:11]

When FEAT_RAS is implemented and GetESR_ELx_IFSC(EL3) IN {'010000', '01001x', '0101xx'}:

Synchronous Error Type. Describes the PE error state after taking the Instruction Abort exception.

SET	Meaning	Applies when
`0b00`	Recoverable state (UER).	
`0b10`	Uncontainable (UC).	FEAT_RASv2 is not implemented
`0b11`	Restartable state (UEO).	

All other values are reserved.

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
`0b0`	FAR is valid.
`0b1`	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the IFSC code is `0b010000`. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [8]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

IFSC, bits [5:0]

Instruction Fault Status Code.

IFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001000	Access flag fault, level 0.	FEAT_LPA2 is implemented
0b001100	Permission fault, level 0.	FEAT_LPA2 is implemented
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010010	Synchronous External abort on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning	Applies when
0b010011	Synchronous External abort on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011011	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented and FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100010	Granule Protection Fault on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented and FEAT_RME is implemented
0b100011	Granule Protection Fault on translation table walk or hardware update of translation table, level -1.	FEAT_RME is implemented and FEAT_LPA2 is implemented
0b100100	Granule Protection Fault on translation table walk or hardware update of translation table, level 0.	FEAT_RME is implemented
0b100101	Granule Protection Fault on translation table walk or hardware update of translation table, level 1.	FEAT_RME is implemented
0b100110	Granule Protection Fault on translation table walk or hardware update of translation table, level 2.	FEAT_RME is implemented
0b100111	Granule Protection Fault on translation table walk or hardware update of translation table, level 3.	FEAT_RME is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IFSC	Meaning	Applies when
0b101000	Granule Protection Fault, not on translation table walk or hardware update of translation table.	FEAT_RME is implemented
0b101001	Address size fault, level -1.	FEAT_LPA2 is implemented
0b101010	Translation fault, level -2.	FEAT_D128 is implemented
0b101011	Translation fault, level -1.	FEAT_LPA2 is implemented
0b101100	Address Size fault, level -2.	FEAT_D128 is implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented

All other values are reserved.

For more information about the lookup level associated with a fault, see 'The lookup level associated with MMU faults'.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception due to SME functionality

24 … 3	2 … 0
RES0	SMTC

The accesses covered by this trap include:

- Execution of SME instructions.
- Execution of SVE and Advanced SIMD instructions, when the PE is in Streaming SVE mode.
- Direct accesses of SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3.

Bits [24:3]

Reserved, RES0.

SMTC, bits [2:0]

SME Trap Code. Identifies the reason for instruction trapping.

SMTC	Meaning	Applies when
0b000	Access to SME functionality trapped as a result of CPACR_EL1.SMEN, CPTR_EL2.SMEN, CPTR_EL2.TSM, or CPTR_EL3.ESM, that is not reported using EC value 0b000000.	
0b001	Advanced SIMD, SVE, or SVE2 instruction trapped because PSTATE.SM is 1.	
0b010	SME instruction trapped because PSTATE.SM is 0.	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SMTC	Meaning	Applies when
0b011	SME instruction trapped because PSTATE.ZA is 0.	
0b100	Access to the SME2 ZT0 register trapped as a result of SMCR_EL1.EZT0, SMCR_EL2.EZT0, or SMCR_EL3.EZT0.	FEAT_SME2 is implemented

All other values are reserved.

Additional Information for ISS encoding for an exception due to SME functionality

The following fields describe the configuration settings for the traps that are reported using the EC value 0b011101:

- CPACR_EL1.SMEN, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR and SMCR_EL1 System registers at EL1 and EL0, trapped to EL1 or EL2.
- CPTR_EL2.SMEN and CPTR_EL2.TSM, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2 at EL2, EL1, and EL0, trapped to EL2.
- CPTR_EL3.ESM, for execution of SME instructions, SVE instructions when the PE is in Streaming SVE mode, and instructions that directly access SVCR, SMCR_EL1, SMCR_EL2, SMCR_EL3 from all Exception levels and any Security state, trapped to EL3.
- If FEAT_SME2 is implemented:
  - SMCR_EL1.EZT0, for accesses to ZT0 at EL1 and EL0, trapped to EL1 or EL2.
  - SMCR_EL2.EZT0, for accesses to ZT0 at EL2, EL1, and EL0, trapped to EL2.
  - SMCR_EL3.EZT0, for accesses to ZT0 at any Exception level, trapped to EL3.

ISS encoding for a Granule Protection Check exception

Bits [24:22]

Reserved, RES0.

S2PTW, bit [21]

Indicates whether the Granule Protection Check exception was on an access made for a stage 2 translation table walk.

S2PTW	Meaning
0b0	Fault not on a stage 2 translation table walk.
0b1	Fault on a stage 2 translation table walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

InD, bit [20]

Indicates whether the Granule Protection Check exception was on an instruction or data access.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

InD	Meaning
0b0	Data access.
0b1	Instruction access.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GPCSC, bits [19:14]

Granule Protection Check Status Code.

GPCSC	Meaning
0b000000	GPT address size fault at level 0.
0b000100	GPT walk fault at level 0.
0b000101	GPT walk fault at level 1.
0b001100	Granule protection fault at level 0.
0b001101	Granule protection fault at level 1.
0b010100	Synchronous External abort on GPT fetch at level 0.
0b010101	Synchronous External abort on GPT fetch at level 1.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VNCR, bit [13]

Indicates that the fault came from use of VNCR_EL2 register by EL1 code.

VNCR	Meaning	Applies when
0b0	The fault was not generated by the use of VNCR_EL2 by EL1 code.	
0b1	The fault was generated by the use of VNCR_EL2 by EL1 code.	FEAT_NV2 is implemented

When InD is 1, this field is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [12:9]

Reserved, RES0.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CM	Meaning
0b0	The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

Indicates whether the Granule Protection Check exception was on an access for stage 2 translation for a stage 1 translation table walk:

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Abort caused by an instruction reading from a memory location.
0b1	Abort caused by an instruction writing to a memory location.

When InD is 1, this field is RES0.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- An External abort on an Atomic access.
- A fault reported using a DFSC value of 0b110101, indicating an unsupported Exclusive or atomic access.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- A fault reported using a DFSC value of `0b110001`, indicating an unsupported atomic hardware update fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

xFSC, bits [5:0]

Instruction or Data Fault Status Code.

xFSC	Meaning	Applies when
`0b100011`	Granule Protection Fault on translation table walk or hardware update of translation table, level -1.	FEAT_RME is implemented and FEAT_LPA2 is implemented
`0b100100`	Granule Protection Fault on translation table walk or hardware update of translation table, level 0.	FEAT_RME is implemented
`0b100101`	Granule Protection Fault on translation table walk or hardware update of translation table, level 1.	FEAT_RME is implemented
`0b100110`	Granule Protection Fault on translation table walk or hardware update of translation table, level 2.	FEAT_RME is implemented
`0b100111`	Granule Protection Fault on translation table walk or hardware update of translation table, level 3.	FEAT_RME is implemented
`0b101000`	Granule Protection Fault, not on translation table walk or hardware update of translation table.	FEAT_RME is implemented

All other values are reserved.

For more information about the lookup level associated with a fault, see 'The lookup level associated with MMU faults'.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a Data Abort

The ISS2 encoding for an exception from a Data Abort includes further information about the exception when any of the following features are implemented:

- FEAT_LS64_V.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- FEAT_LS64_ACCDATA.
- FEAT_S1POE or FEAT_S2POE.
- FEAT_S1PIE or FEAT_S2PIE.
- FEAT_GCS.
- FEAT_MTE_CANONICAL_TAGS.
- FEAT_HDBSS.
- FEAT_MTE_PERM.

ISV, bit [24]

Instruction Syndrome Valid. Indicates whether the syndrome information in ISS[23:14] represents the instruction syndrome fields {SAS, SSE, SRT, SF, AR}.

ISV	Meaning
`0b0`	No valid instruction syndrome. ISS[23:14] do not represent an instruction syndrome.
`0b1`	ISS[23:14] hold a valid instruction syndrome.

The ISV field is only relevant for the following instructions:

- An AArch64 load or store of a single general-purpose register (including the register specified with `0b11111`, including those with Acquire/Release semantics, but excluding Load Exclusive or Store Exclusive and excluding those with writeback).
- An AArch32 instruction LDR, LDA, LDRT, LDRSH, LDRSHT, LDRH, LDAH, LDRHT, LDRSB, LDRSBT, LDRB, LDAB, LDRBT, STR, STL, STRT, STRH, STLH, STRHT, STRB, STLB, or STRBT, where both of the following apply:
  - It is not performing register writeback.
  - It is not using R15 as a source or destination register.
- If FEAT_LS64 is implemented, an LD64B or ST64B instruction.
- If FEAT_LS64_V is implemented, an ST64BV instruction.
- If FEAT_LS64_ACCDATA is implemented, an ST64BV0 instruction.

The ISV field is 1 if all of the following apply:

- The fault was not a stage 2 fault on a stage 1 translation table walk.
- If FEAT_RAS is implemented, the fault was not any kind of synchronous External abort.
- Any of the following apply:
  - The fault was generated by one of the described AArch64 load or store instructions that transfer a single general-purpose register, and any of the following apply:
    - The fault was a stage 2 fault.
  - The fault was generated by one of the described AArch32 instructions and any of the following apply:
    - The fault was a stage 2 fault.
  - The fault was generated by one of the FEAT_LS64, FEAT_LS64_V or FEAT_LS64_ACCDATA instructions and the fault was a Translation fault, Access flag fault or Permission fault.
- One of the following applies:
  - The address reported in FAR_EL3 is the lowest address accessed by the instruction.
  - The address reported in FAR_EL3 is not the lowest address accessed by the instruction, and the implementation reports ISV as 1 in this case. Arm recommends against this behavior.

The value of this field is UNKNOWN when the following occurs:

- Stage 2 faults when the exception was generated in Debug state, in memory access mode.

When FEAT_RAS is not implemented, it is IMPLEMENTATION DEFINED whether ISV is set to 1 or 0 on a synchronous External abort on a stage 2 translation table walk.

Otherwise the value of this field is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The value of this field is 0 if any of the following apply:

- FEAT_MOPS is implemented and the fault was for a memory access generated by a Memory Copy and Memory Set instruction.
- FEAT_MTE is implemented and the fault was for a direct access to Allocation Tags.
- FEAT_GCS is implemented and the fault was for a Guarded control stack data access.
- FEAT_NV2 is implemented and the fault was for a System register access that was transformed to a load or store relative to VNCR_EL2.
- FEAT_LSE is implemented and the fault was for an atomic instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SAS, bits [23:22]

When ISV == '1':

Syndrome Access Size. Indicates the size of the access attempted by the faulting operation.

SAS	Meaning
`0b00`	Byte
`0b01`	Halfword
`0b10`	Word
`0b11`	Doubleword

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is `0b11`.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SSE, bit [21]

When ISV == '1':

Syndrome Sign Extend. For a byte, halfword, or word load operation, indicates whether the data item must be sign extended.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SSE	Meaning
0b0	Sign-extension not required.
0b1	Data item must be sign-extended.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

For all other operations, this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [20:16]

When ISV == '1':

SRT, bits [20:16]

Syndrome Register Transfer. The register number of the Wt/Xt/Rt operand of the faulting instruction.

If the exception was taken from an Exception level that is using AArch32, then this is the AArch64 view of the register. See 'Mapping of the general-purpose registers between the Execution states'.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When ISV == '0', FEAT_RASv2 is implemented, and GetESR_ELx_DFSC(EL3) IN {'010000', '01001x', '0101xx'}:

WU, bits [1:0] of bits [20:16]

Write Update. Describes whether a store instruction that generated an External abort updated the location.

WU	Meaning
0b00	Not a store instruction or translation table update, or the location might have been updated.
0b10	Store instruction or translation table update that did not update the location.
0b11	Store instruction or translation table update that updated the location.

In the description of this field, a store instruction is any memory-writing instruction that explicitly performs a store. This includes instructions that both read and write memory.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [15]

When ISV == '1':

SF, bit [15]

Sixty Four bit general-purpose register transfer. Width of the register accessed by the instruction is 64-bit.

SF	Meaning
0b0	Instruction loads/stores a 32-bit general-purpose register.
0b1	Instruction loads/stores a 64-bit general-purpose register.

Note

This field specifies the register width identified by the instruction, not the Execution state.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 1.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

FnP, bit [15]

FAR not Precise.

FnP	Meaning	Applies when
0b0	The FAR holds the faulting virtual address that generated the Data Abort.	
0b1	The FAR holds any virtual address within the naturally-aligned granule that contains the faulting virtual address that generated a Data Abort due to an SVE contiguous vector load/store instruction, or an SME load/store instruction. For more information about the naturally-aligned fault granule, see FAR_ELx (for example, FAR_EL1).	FEAT_SME is implemented or FEAT_SVE is implemented

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bit [14]

When ISV == '1':

AR, bit [14]

Acquire/Release.

AR	Meaning
0b0	Instruction did not have acquire/release semantics.
0b1	Instruction did have acquire/release semantics.

When FEAT_LS64 is implemented, if a memory access generated by an LD64B or ST64B instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_V is implemented, if a memory access generated by an ST64BV instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

When FEAT_LS64_ACCDATA is implemented, if a memory access generated by an ST64BV0 instruction generates a Data Abort for a Translation fault, Access flag fault, or Permission fault, then this field is 0.

This field is UNKNOWN when the value of ISV is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_PFAR is implemented and GetESR_ELx_DFSC(EL3) IN {'010000', '01001x', '0101xx'}:

PFV, bit [14]

PFAR Valid. Describes whether the MFAR_EL3 register is valid.

PFV	Meaning
0b0	MFAR_EL3 is UNKNOWN.
0b1	MFAR_EL3 is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VNCR, bit [13]

Indicates that the fault came from use of VNCR_EL2 register by EL1 code.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

VNCR	Meaning	Applies when
0b0	The fault was not generated by the use of VNCR_EL2 by EL1 code.	
0b1	The fault was generated by the use of VNCR_EL2 by EL1 code.	FEAT_NV2 is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [12:11]

When GetESR_ELx_DFSC(EL3) IN {'00xxxx', '10101x'} and !(GetESR_ELx_DFSC(EL3) IN {'0000xx'}):

LST, bits [12:11]

Load/Store Type. Used when a Translation fault, Access flag fault, or Permission fault generates a Data Abort reported with ISV=1.

LST	Meaning	Applies when
0b00	The instruction that generated the Data Abort is not specified by this field.	
0b01	An ST64BV instruction generated the Data Abort.	FEAT_LS64_V is implemented
0b10	An LD64B or ST64B instruction generated the Data Abort.	FEAT_LS64 is implemented
0b11	An ST64BV0 instruction generated the Data Abort.	FEAT_LS64_ACCDATA is implemented

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL3) == '010000':

SET, bits [12:11]

Synchronous Error Type. Used when a synchronous External abort, not on a Translation table walk or hardware update of the Translation table, generated the Data Abort. Describes the PE error state after taking the Data Abort exception.

SET	Meaning	Applies when
0b00	Recoverable state (UER).	
0b10	Uncontainable (UC).	FEAT_RASv2 is not implemented
0b11	Restartable state (UEO).	

Note

Software can use this information to determine what recovery might be possible. Taking a synchronous External abort exception might result in a PE state that is not recoverable.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnV, bit [10]

FAR not Valid, for a synchronous External abort other than a synchronous External abort on a translation table walk.

FnV	Meaning
0b0	FAR is valid.
0b1	FAR is not valid, and holds an UNKNOWN value.

This field is valid only if the DFSC code is 0b010000. It is RES0 for all other aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EA, bit [9]

External abort type. This bit can provide an IMPLEMENTATION DEFINED classification of External aborts.

For any abort other than an External abort this bit returns a value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CM, bit [8]

Cache maintenance. Indicates whether the Data Abort came from a cache maintenance or address translation instruction:

CM	Meaning
0b0	The Data Abort was not generated by the execution of one of the System instructions identified in the description of value 1.
0b1	The Data Abort was generated by either the execution of a cache maintenance instruction or by a synchronous fault on the execution of an address translation instruction. The DC ZVA, DC GVA, and DC GZVA instructions are not classified as cache maintenance instructions, and therefore their execution cannot cause this field to be set to 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

S1PTW, bit [7]

For a stage 2 fault, indicates whether the fault was a stage 2 fault on an access made for a stage 1 translation table walk:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

S1PTW	Meaning
0b0	Fault not on a stage 2 translation for a stage 1 translation table walk.
0b1	Fault on the stage 2 translation of an access for a stage 1 translation table walk.

For any abort other than a stage 2 fault this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

WnR, bit [6]

Write not Read. Indicates whether a synchronous abort was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
0b0	Abort caused by an instruction reading from a memory location.
0b1	Abort caused by an instruction writing to a memory location.

For faults on cache maintenance and address translation instructions, this bit always returns a value of 1.

For faults from an atomic instruction that both reads and writes from a memory location, this bit is set to 0 if a read of the address specified by the instruction would have generated the fault which is being reported, otherwise it is set to 1. The architecture permits, but does not require, a relaxation of this requirement such that for all stage 2 aborts on stage 1 translation table walks for atomic instructions, the WnR bit is always 0.

This field is UNKNOWN for:

- If FEAT_RASv2 is implemented, an External abort on an Atomic access, reported with ESR_EL3.WU set to 0b00.
- A fault reported using a DFSC value of 0b110101, indicating an unsupported Exclusive or atomic access.
- A fault reported using a DFSC value of 0b110001, indicating an unsupported atomic hardware update fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DFSC, bits [5:0]

Data Fault Status Code.

DFSC	Meaning	Applies when
0b000000	Address size fault, level 0 of translation or translation table base register.	
0b000001	Address size fault, level 1.	
0b000010	Address size fault, level 2.	
0b000011	Address size fault, level 3.	
0b000100	Translation fault, level 0.	
0b000101	Translation fault, level 1.	

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC	Meaning	Applies when
0b000110	Translation fault, level 2.	
0b000111	Translation fault, level 3.	
0b001001	Access flag fault, level 1.	
0b001010	Access flag fault, level 2.	
0b001011	Access flag fault, level 3.	
0b001000	Access flag fault, level 0.	FEAT_LPA2 is implemented
0b001100	Permission fault, level 0.	FEAT_LPA2 is implemented
0b001101	Permission fault, level 1.	
0b001110	Permission fault, level 2.	
0b001111	Permission fault, level 3.	
0b010000	Synchronous External abort, not on translation table walk or hardware update of translation table.	
0b010001	Synchronous Tag Check Fault.	FEAT_MTE2 is implemented
0b010010	Synchronous External abort on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented
0b010011	Synchronous External abort on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented
0b010100	Synchronous External abort on translation table walk or hardware update of translation table, level 0.	
0b010101	Synchronous External abort on translation table walk or hardware update of translation table, level 1.	
0b010110	Synchronous External abort on translation table walk or hardware update of translation table, level 2.	
0b010111	Synchronous External abort on translation table walk or hardware update of translation table, level 3.	
0b011000	Synchronous parity or ECC error on memory access, not on translation table walk.	FEAT_RAS is not implemented
0b011011	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level -1.	FEAT_LPA2 is implemented and FEAT_RAS is not implemented
0b011100	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 0.	FEAT_RAS is not implemented
0b011101	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 1.	FEAT_RAS is not implemented
0b011110	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 2.	FEAT_RAS is not implemented
0b011111	Synchronous parity or ECC error on memory access on translation table walk or hardware update of translation table, level 3.	FEAT_RAS is not implemented
0b100001	Alignment fault.	
0b100010	Granule Protection Fault on translation table walk or hardware update of translation table, level -2.	FEAT_D128 is implemented and FEAT_RME is implemented
0b100011	Granule Protection Fault on translation table walk or hardware update of translation table, level -1.	FEAT_RME is implemented and FEAT_LPA2 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DFSC	Meaning	Applies when
0b100100	Granule Protection Fault on translation table walk or hardware update of translation table, level 0.	FEAT_RME is implemented
0b100101	Granule Protection Fault on translation table walk or hardware update of translation table, level 1.	FEAT_RME is implemented
0b100110	Granule Protection Fault on translation table walk or hardware update of translation table, level 2.	FEAT_RME is implemented
0b100111	Granule Protection Fault on translation table walk or hardware update of translation table, level 3.	FEAT_RME is implemented
0b101000	Granule Protection Fault, not on translation table walk or hardware update of translation table.	FEAT_RME is implemented
0b101001	Address size fault, level -1.	FEAT_LPA2 is implemented
0b101010	Translation fault, level -2.	FEAT_D128 is implemented
0b101011	Translation fault, level -1.	FEAT_LPA2 is implemented
0b101100	Address Size fault, level -2.	FEAT_D128 is implemented
0b110000	TLB conflict abort.	
0b110001	Unsupported atomic hardware update fault.	FEAT_HAF is implemented
0b110100	IMPLEMENTATION DEFINED fault (Lockdown).	
0b110101	IMPLEMENTATION DEFINED fault (Unsupported Exclusive or Atomic access).	

All other values are reserved.

For more information about the lookup level associated with a fault, see ‘The lookup level associated with MMU faults’.

If the S1PTW bit is set, then the level refers the level of the stage2 translation that is translating a stage 1 translation walk.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

ISS encoding for an exception from a trapped floating-point exception

Bit [24]

Reserved, RES0.

TFV, bit [23]

Trapped Fault Valid bit. Indicates whether the IDF, IXF, UFF, OFF, DZF, and IOF bits hold valid information about trapped floating-point exceptions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TFV	Meaning
0b0	The IDF, IXF, UFF, OFF, DZF, and IOF bits do not hold valid information about trapped floating-point exceptions and are UNKNOWN.
0b1	One or more floating-point exceptions occurred during an operation performed while executing the reported instruction. The IDF, IXF, UFF, OFF, DZF, and IOF bits indicate trapped floating-point exceptions that occurred. For more information, see 'Floating-point exceptions and exception traps'.

It is IMPLEMENTATION DEFINED whether this field is set to 0 on an exception generated by a trapped floating-point exception from an instruction that is performing floating-point operations on more than one lane of a vector.

Note

This is not a requirement. Implementations can set this field to 1 on a trapped floating-point exception from an instruction and return valid information in the {IDF, IXF, UFF, OFF, DZF, IOF} fields.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [22:11]

Reserved, RES0.

VECITR, bits [10:8]

For a trapped floating-point exception from an instruction executed in AArch32 state this field is RES1.

For a trapped floating-point exception from an instruction executed in AArch64 state this field is UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IDF, bit [7]

Input Denormal floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IDF	Meaning
0b0	Input denormal floating-point exception has not occurred.
0b1	Input denormal floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IXF	Meaning
0b0	Inexact floating-point exception has not occurred.
0b1	Inexact floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

UFF, bit [3]

Underflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

UFF	Meaning
0b0	Underflow floating-point exception has not occurred.
0b1	Underflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

OFF, bit [2]

Overflow floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

OFF	Meaning
0b0	Overflow floating-point exception has not occurred.
0b1	Overflow floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DZF, bit [1]

Divide by Zero floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

DZF	Meaning
0b0	Divide by Zero floating-point exception has not occurred.
0b1	Divide by Zero floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IOF, bit [0]

Invalid Operation floating-point exception trapped bit. If the TFV field is 0, this bit is UNKNOWN. Otherwise, the possible values of this bit are:

IOF	Meaning
0b0	Invalid Operation floating-point exception has not occurred.
0b1	Invalid Operation floating-point exception occurred during execution of the reported instruction.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from a trapped floating-point exception

In an implementation that supports the trapping of floating-point exceptions:

- From an Exception level using AArch64, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.
- From an Exception level using AArch32, the FPSCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits enable each of the floating-point exception traps.

ISS encoding for a GCS exception

Bit [24]

Reserved, RES0.

ExType, bits [23:20]

The first level classification of GCS exceptions.

ExType	Meaning
0b0000	The exception reported is a Guarded Control Stack Data Check Exception.
0b0001	The exception reported is an EXLOCK Exception.
0b0010	The exception reported is a trap exception on GCSSTR or GCSSTTR instruction execution.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [19:15]

Reserved, RES0.

Raddr, bits [14:10]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When GetESR_ELx_ExType(EL3) == '0010':

Indicates the data address register number supplied in the instruction that has been trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [9:5]

When GetESR_ELx_ExType(EL3) == '0000':

Rn, bits [9:5]

Indicates a register number used by the instruction that caused the Guarded Control Stack Data Check Exception.

For a procedure return instruction reported with ESR_EL3.ISS.IT as `0b00000`, contains the register number for the register which contains the target address of the branch.

For a GCSPOPM instruction reported with ESR_EL3.ISS.IT as `0b00001`, contains the register number for the register which is the destination register of the instruction.

For a procedure return instruction reported with ESR_EL3.ISS.IT as `0b00010` or `0b00011`, contains the value `0b11110`, indicating X30.

For a GCSSS1 instruction reported with ESR_EL3.ISS.IT as `0b00100`, contains the register number for the register which is the input register of the instruction.

If ESR_EL3.ISS.IT is reported as `0b00101` or `0b01000`, this field is UNKNOWN

If ESR_EL3.ISS.IT is reported as `0b01001`, this field is `0b11111`

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When GetESR_ELx_ExType(EL3) == '0010':

Rvalue, bits [9:5]

Indicates the data value register number supplied in the instruction that has been trapped.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IT, bits [4:0]

When GetESR_ELx_ExType(EL3) == '0000':

Type of the instruction that caused the Guarded Control Stack Data Check Exception.

IT	Meaning
`0b00000`	Guarded Control Stack Data Check Exception is from a procedure return instruction without Pointer authentication.
`0b00001`	Guarded Control Stack Data Check Exception is from a GCSPOPM instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IT	Meaning
0b00010	Guarded Control Stack Data Check Exception is from a procedure return instruction with Pointer authentication that uses key A.
0b00011	Guarded Control Stack Data Check Exception is from a procedure return instruction with Pointer authentication that uses key B.
0b00100	Guarded Control Stack Data Check Exception is from a GCSSS1 instruction.
0b00101	Guarded Control Stack Data Check Exception is from a GCSSS2 instruction.
0b01000	Guarded Control Stack Data Check Exception is from a GCSPOPCX instruction.
0b01001	Guarded Control Stack Data Check Exception is from a GCSPOPX instruction.

All other values are reserved

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Additional Information for ISS encoding for a GCS exception

The following fields describe the configuration settings for the traps that are reported using EC value 0b101101 and ExType value 0b0010:

- GCSCRE0_EL1.STREn
- GCSCR_EL1.STREn.
- GCSCR_EL2.STREn.
- GCSCR_EL3.STREn.
- HFGITR_EL2.nGCSSTR_EL1.

ISS encoding for an SError exception

Note

In earlier versions of the architecture, an SError exception is referred to as an SError interrupt or an asynchronous External abort exception.

IDS, bit [24]

IMPLEMENTATION DEFINED syndrome.

IDS	Meaning
0b0	Bits [23:0] of the ISS field holds the fields described in this encoding. **Note** If FEAT_RAS is not implemented, bits [23:0] of the ISS field are RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IDS	Meaning
0b1	Bits [23:0] of the ISS field holds IMPLEMENTATION DEFINED syndrome information that can be used to provide additional information about the SError exception.

Note

This field was previously called ISV.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [23:19]

Reserved, RES0.

ELS, bit [18]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL3) == '010001':

Meaning of ELR_ELx.

ELS	Meaning
0b0	Asynchronous. Does not indicate the trigger for the exception.
0b1	Synchronous. The exception was triggered by the instruction at ELR_ELx.

SError exceptions that report this field is 1 are not required to be precise.

The ESR_EL3.AET field describes whether the exception is precise or imprecise.

Corrected, Recoverable or Restartable exceptions are precise. Unrecoverable or Uncontainable exceptions are imprecise.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WU, bits [17:16]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL3) == '010001':

Write Update. Describes whether a store instruction that generated an External abort updated the location.

WU	Meaning
0b00	Not a store instruction or translation table update, or the location might have been updated.
0b10	Store instruction or translation table update that did not update the location.
0b11	Store instruction or translation table update that updated the location.

In the description of this field, a store instruction is any memory-writing instruction that explicitly performs a store. This includes instructions that both read and write memory.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VFV, bit [15]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL3) == '010001':

FAR Valid. Indicates the FAR_EL3 register contains a valid virtual address.

VFV	Meaning
0b0	FAR_EL3 is not valid, and holds an UNKNOWN value.
0b1	FAR_EL3 contains a valid virtual address associated with the error.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PFV, bit [14]

When FEAT_PFAR is implemented and GetESR_ELx_DFSC(EL3) == '010001':

PFAR Valid. Describes whether the MFAR_EL3 register is valid.

PFV	Meaning
0b0	MFAR_EL3 is UNKNOWN.
0b1	MFAR_EL3 is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

IESB, bit [13]

When FEAT_IESB is implemented and GetESR_ELx_DFSC(EL3) == '010001':

Implicit error synchronization event.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IESB	Meaning
0b0	One of the following applies: • The SError exception was not synchronized by the implicit error synchronization event. • The SError exception was not taken immediately following an implicit error synchronization event. • The SError exception was either not synchronized by the implicit error synchronization event or not taken immediately. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 0.
0b1	The SError exception was synchronized by the implicit error synchronization event, taken immediately, and one of the following applies: • The implicit error synchronization event was on an exception entry. • The implicit error synchronization event was on an exception return, and implementation chose to set this field to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception entry, and the exception is taken immediately after exception entry, this field is set to 1.

When an SError exception is synchronized by an implicit error synchronization event on exception return, and the exception is taken immediately before the exception return, this field is set to an IMPLEMENTATION SPECIFIC choice of 0 or 1.

For all other SError exceptions, this field is set to 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AET, bits [12:10]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL3) == '010001':

Asynchronous Error Type.

Describes the PE error state after taking the SError exception.

AET	Meaning
0b000	Uncontainable (UC).
0b001	Unrecoverable state (UEU).
0b010	Restartable state (UEO).
0b011	Recoverable state (UER).
0b110	Corrected (CE).

All other values are reserved.

If multiple errors are taken as a single SError exception, the overall PE error state is reported.

Note

Software can use this information to determine what recovery might be possible. The recovery software must also examine any implemented fault records to determine the location and extent of the error.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EA, bit [9]

When FEAT_RAS is implemented and GetESR_ELx_DFSC(EL3) == '010001':

External abort type. Provides an IMPLEMENTATION DEFINED classification of External aborts.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [8]

Reserved, RES0.

WnRV, bit [7]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL3) == '010001':

ESR_EL3.WnR valid.

WnRV	Meaning
`0b0`	ESR_EL3.WnR is not valid and has been set to 0.
`0b1`	ESR_EL3.WnR is valid.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

WnR, bit [6]

When FEAT_RASv2 is implemented and GetESR_ELx_DFSC(EL3) == '010001':

Write-not-Read. When the WnRV field is 1, indicates whether an exception was caused by an instruction writing to a memory location, or by an instruction reading from a memory location.

WnR	Meaning
`0b0`	Exception was caused by an instruction reading from a memory location.
`0b1`	Exception was caused by an instruction writing to a memory location.

Accessing this bit has the following behavior:

- This bit is RES0 if ESR_EL3.WnRV is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- This bit is not valid and reads UNKNOWN if an External abort on a Atomic access, reported with ESR_EL3.WU == `0b00`.
- Otherwise RW.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DFSC, bits [5:0]

When FEAT_RAS is implemented:

Data Fault Status Code.

DFSC	Meaning
`0b000000`	Uncategorized error.
`0b010001`	Asynchronous SError exception.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISS encoding for an exception from execution of a Breakpoint instruction

24 … 16	15 … 0
RES0	Comment

Bits [24:16]

Reserved, RES0.

Comment, bits [15:0]

Set to the instruction comment field value, zero extended as necessary.

For the AArch32 BKPT instructions, the comment field is described as the immediate field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for an exception from execution of a Breakpoint instruction

For more information about generating these exceptions, see ‘Breakpoint instruction exceptions’.

ISS encoding for a Branch Target Exception

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

24 … 2	1 … 0
RES0	BTYPE

Bits [24:2]

Reserved, RES0.

BTYPE, bits [1:0]

This field is set to the PSTATE.BTYPE value that generated the Branch Target Exception.

Additional Information for ISS encoding for a Branch Target Exception

For more information about generating these exceptions, see 'The AArch64 application level programmers model'.

ISS encoding for an exception from a trapped Pointer Authentication instruction

24 … 0
RES0

Bits [24:0]

Reserved, RES0.

Additional Information for ISS encoding for an exception from a trapped Pointer Authentication instruction

For more information about generating these exceptions, see:

- HCR_EL2.API, for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL2.
- SCR_EL3.API, for exceptions from Pointer authentication instructions, using AArch64 state, trapped to EL3.

ISS encoding for a PAC Fail exception

24 … 2	1	0
RES0	DnI	BnA

Bits [24:2]

Reserved, RES0.

DnI, bit [1]

This field indicates whether the exception is as a result of an Instruction key or a Data key.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DnI	Meaning
0b0	Instruction Key.
0b1	Data Key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BnA, bit [0]

This field indicates whether the exception is as a result of an A key or a B key.

BnA	Meaning
0b0	A key.
0b1	B key.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Additional Information for ISS encoding for a PAC Fail exception

The following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- AUTDA, AUTDZA.
- AUTDB, AUTDZB.
- AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA.
- AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB.
- AUTIASPPC, AUTIASPPCR, AUTIA171615.
- AUTIBSPPC, AUTIBSPPCR, AUTIB171615.

If FEAT_FPACCOMBINE is implemented, the following instructions generate a PAC Fail exception when the Pointer Authentication Code (PAC) is incorrect:

- RETAA, RETAB.
- RETAASPPC, RETABSPPC.
- RETAASPPCR, RETABSPPCR.
- BLRAA, BLRAAZ, BLRAB, BLRABZ.
- BRAA, BRAB, BRAAZ, BRABZ.
- ERETAA, ERETAB.
- LDRAA, LDRAB, whether the authenticated address is written back to the base register or not.

D24.2.47 FAR_EL1, Fault Address Register (EL1)

The FAR_EL1 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction Abort exceptions, Data Abort exceptions, PC alignment fault exceptions and Watchpoint exceptions that are taken to EL1.

Configuration

AArch64 System register FAR_EL1 bits [31:0] are architecturally mapped to AArch32 System register DFAR[31:0].

AArch64 System register FAR_EL1 bits [63:32] are architecturally mapped to AArch32 System register IFAR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to FAR_EL1 are UNDEFINED.

Attributes

FAR_EL1 is a 64-bit register.

Field descriptions

```
63                                                                                                  32
|                   Faulting Virtual Address for synchronous exceptions taken to EL1                |

31                                                                                                   0
|                   Faulting Virtual Address for synchronous exceptions taken to EL1                |
```

VA, bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL1. Exceptions that set the FAR_EL1 are Instruction Aborts (EC `0x20` or `0x21`), Data Aborts (EC `0x24` or `0x25`), PC alignment faults (EC `0x22`), and Watchpoints (EC `0x34` or `0x35`). ESR_EL1.EC holds the EC syndrome value for the exception.

For a synchronous External abort:

- If the VA that generated the abort was from an address range for which Address tagging is enabled for the translation regime in use when the abort was generated, then bits[63:56] of FAR_EL1 are UNKNOWN.
- If the VA that generated the abort was from an address range for which Address tagging is disabled and Logical Address Tagging is enabled for the translation regime in use when the abort was generated, then bits[59:56] of FAR_EL1 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if ESR_EL1.FnV is 0, and FAR_EL1 is UNKNOWN if ESR_EL1.FnV is 1.

On an exception due to a Tag Check Fault caused by a data cache maintenance or other DC instruction, the address held in FAR_EL1 is IMPLEMENTATION DEFINED as one of the following:

- The lowest address that gave rise to the fault.
- The address specified in the register argument of the instruction as generated by MMU faults caused by DC ZVA.

If a memory fault that sets FAR_EL1 is generated from an STZGM instruction, the address held in FAR_EL1 is IMPLEMENTATION DEFINED as one of the following:

- The lowest address that gave rise to the fault.
- The address specified in the register argument.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If a memory fault that sets FAR_EL1, other than a Tag Check Fault, is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR_EL1 is taken from an Exception level using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_ELx are `0x00000001`:

- The faulting address was generated by a load or store instruction that sequentially incremented from address `0xFFFFFFFF`. Such a load or store instruction is CONSTRAINED UNPREDICTABLE.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

When the PE sets ESR_EL1.{ISV,FnP} to {0,1} on taking a Data Abort exception, the PE sets FAR_EL1 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Data Abort exception.

When the PE sets ESR_EL1.{FnV,FnP} to {0,1} on taking a Watchpoint exception, the PE sets FAR_EL1 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Watchpoint exception.

The naturally-aligned fault granule is one of:

- When ESR_EL1.DFSC is `0b010001`, indicating a Synchronous Tag Check fault, it is a 16-byte tag granule.
- When ESR_EL1.DFSC is `0b11010x`, indicating an IMPLEMENTATION DEFINED fault, it is an IMPLEMENTATION DEFINED granule.
- Otherwise, it is the smallest implemented translation granule.

When FEAT_MOPS is implemented, the value in FAR_EL1 on a synchronous exception from any of the Memory Copy and Memory Set instructions is determined as follows:

- For an MMU fault reported as a Data Abort, the value is within the address range of the relevant translation granule, aligned to the size of the relevant translation granule of the address that generated the Data Abort. Bits[(n-1):0] of the value are UNKNOWN, where 2^n is the relevant translation granule size in bytes. For the purpose of calculating the relevant translation granule, if the MMU is disabled for a stage of translation, then the current translation granule size is equal to 2^{64} for stage 1, and the PARange for stage 2. The relevant translation granule is:
  - For MMU faults generated at stage 1, the current stage 1 translation granule.
  - For MMU faults generated at stage 2, the smaller of the current stage 1 translation granule and the current stage 2 translation granule.
  - If FEAT_RME is implemented, for a synchronous Data Abort generated as the result of a GPF, the smallest of the current stage 1 translation granule, the current stage 2 translation granule and the configured granule size in GPCCR_EL3.PGS.
- For a Data Abort generated by a Tag Check Fault, the value is any address that caused a Tag Check Fault within the block size of the load or store.
- For a Watchpoint exception, the value is an address range of the size defined by the DCZID_EL0.BS field. This address does not need to be the element with a watchpoint, but can be some earlier element.
- Otherwise, the value is the lowest address in the block size of the load or store.

For a Data Abort exception or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see ‘Address tagging’.

For a synchronous Tag Check Fault:

- If FEAT_MTE_TAGGED_FAR is implemented or Address tagging is disabled for the translation regime in use when the abort was generated, all bits of FAR_EL1 are not UNKNOWN.
- If FEAT_MTE_TAGGED_FAR is not implemented and Address tagging is enabled for the translation regime in use when the abort was generated, bits[63:60] of FAR_EL1 are UNKNOWN.

Execution at EL0 makes FAR_EL1 become UNKNOWN.

Note

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or Data Abort. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For all other exceptions taken to EL1, FAR_EL1 is UNKNOWN.

FAR_EL1 is made UNKNOWN on an exception return from EL1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL1

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL3 using the accessor name `FAR_EL1` or `FAR_EL12` are not guaranteed to be ordered with respect to accesses using the other accessor name.

Accesses to this register use the following encodings in the System register encoding space:

```

D24.2.48 FAR_EL2, Fault Address Register (EL2)

The FAR_EL2 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction Abort exceptions, Data Abort exceptions, PC alignment fault exceptions and Watchpoint exceptions that are taken to EL2.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

AArch64 System register FAR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HDFAR[31:0].

AArch64 System register FAR_EL2 bits [63:32] are architecturally mapped to AArch32 System register HIFAR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to FAR_EL2 are UNDEFINED.

Attributes

FAR_EL2 is a 64-bit register.

Field descriptions

VA, bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL2. Exceptions that set the FAR_EL2 are Instruction Aborts (EC `0x20` or `0x21`), Data Aborts (EC `0x24` or `0x25`), PC alignment faults (EC `0x22`), and Watchpoints (EC `0x34` or `0x35`). ESR_EL2.EC holds the EC syndrome value for the exception.

For a synchronous External abort:

- If the VA that generated the abort was from an address range for which Address tagging is enabled for the translation regime in use when the abort was generated, then bits[63:56] of FAR_EL2 are UNKNOWN.
- If the VA that generated the abort was from an address range for which Address tagging is disabled and Logical Address Tagging is enabled for the translation regime in use when the abort was generated, then bits[59:56] of FAR_EL2 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if ESR_EL2.FnV is 0, and FAR_EL2 is UNKNOWN if ESR_EL2.FnV is 1.

On an exception due to a Tag Check Fault caused by a data cache maintenance or other DC instruction, the address held in FAR_EL2 is IMPLEMENTATION DEFINED as one of the following:

- The lowest address that gave rise to the fault.
- The address specified in the register argument of the instruction as generated by MMU faults caused by DC ZVA.

If a memory fault that sets FAR_EL2 is generated from an STZGM instruction, the address held in FAR_EL2 is IMPLEMENTATION DEFINED as one of the following:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The lowest address that gave rise to the fault.
- The address specified in the register argument.

If a memory fault that sets FAR_EL2, other than a Tag Check Fault, is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR_EL2 is taken from an Exception level using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_ELx are `0x00000001`:

- The faulting address was generated by a load or store instruction that sequentially incremented from address `0xFFFFFFFF`. Such a load or store instruction is CONSTRAINED UNPREDICTABLE.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

When the PE sets ESR_EL2.{ISV,FnP} to {0,1} on taking a Data Abort exception, the PE sets FAR_EL2 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Data Abort exception.

When the PE sets ESR_EL2.{FnV,FnP} to {0,1} on taking a Watchpoint exception, the PE sets FAR_EL2 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Watchpoint exception.

The naturally-aligned fault granule is one of:

- When ESR_EL2.DFSC is `0b010001`, indicating a Synchronous Tag Check fault, it is a 16-byte tag granule.
- When ESR_EL2.DFSC is `0b11010x`, indicating an IMPLEMENTATION DEFINED fault, it is an IMPLEMENTATION DEFINED granule.
- Otherwise, it is the smallest implemented translation granule.

When FEAT_MOPS is implemented, the value in FAR_EL2 on a synchronous exception from any of the Memory Copy and Memory Set instructions is determined as follows:

- For an MMU fault reported as a Data Abort, the value is within the address range of the relevant translation granule, aligned to the size of the relevant translation granule of the address that generated the Data Abort. Bits[(n-1):0] of the value are UNKNOWN, where 2^n is the relevant translation granule size in bytes. For the purpose of calculating the relevant translation granule, if the MMU is disabled for a stage of translation, then the current translation granule size is equal to 2^{64} for stage 1, and the PARange for stage 2. The relevant translation granule is:
  - For MMU faults generated at stage 1, the current stage 1 translation granule.
  - For MMU faults generated at stage 2, the smaller of the current stage 1 translation granule and the current stage 2 translation granule.
  - If FEAT_RME is implemented, for a synchronous Data Abort generated as the result of a GPF, the smallest of the current stage 1 translation granule, the current stage 2 translation granule and the configured granule size in GPCCR_EL3.PGS.
- For a Data Abort generated by a Tag Check Fault, the value is any address that caused a Tag Check Fault within the block size of the load or store.
- For a Watchpoint exception, the value is an address range of the size defined by the DCZID_EL0.BS field. This address does not need to be the element with a watchpoint, but can be some earlier element.
- Otherwise, the value is the lowest address in the block size of the load or store.

For a Data Abort exception or Watchpoint exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see 'Address tagging'.

For a synchronous Tag Check Fault:

- If FEAT_MTE_TAGGED_FAR is implemented or Address tagging is disabled for the translation regime in use when the abort was generated, all bits of FAR_EL2 are not UNKNOWN.
- If FEAT_MTE_TAGGED_FAR is not implemented and Address tagging is enabled for the translation regime in use when the abort was generated, bits[63:60] of FAR_EL2 are UNKNOWN.

Execution at EL1 or EL0 makes FAR_EL2 become UNKNOWN.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Note

The address held in this field is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or Data Abort. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

For all other exceptions taken to EL2, FAR_EL2 is UNKNOWN.

FAR_EL2 is made UNKNOWN on an exception return from EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL2

When the Effective value of HCR_EL2.E2H is 1, without explicit synchronization, accesses from EL2 using the accessor name `FAR_EL2` or `FAR_EL1` are not guaranteed to be ordered with respect to accesses using the other accessor name.

D24.2.49 FAR_EL3, Fault Address Register (EL3)

The FAR_EL3 characteristics are:

Purpose

Holds the faulting Virtual Address for all synchronous Instruction Abort exceptions, Data Abort exceptions and PC alignment fault exceptions that are taken to EL3.

Configuration

This register is present only when EL3 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to FAR_EL3 are UNDEFINED.

Attributes

FAR_EL3 is a 64-bit register.

Field descriptions

```
63                                                                                                  32
|                   Faulting Virtual Address for synchronous exceptions taken to EL3                |

31                                                                                                   0
|                   Faulting Virtual Address for synchronous exceptions taken to EL3                |
```

VA, bits [63:0]

Faulting Virtual Address for synchronous exceptions taken to EL3. Exceptions that set the FAR_EL3 are Instruction Aborts (EC `0x20` or `0x21`), Data Aborts (EC `0x24` or `0x25`), and PC alignment faults (EC `0x22`). ESR_EL3.EC holds the EC syndrome value for the exception.

For a synchronous External abort:

- If the VA that generated the abort was from an address range for which Address tagging is enabled for the translation regime in use when the abort was generated, then bits[63:56] of FAR_EL3 are UNKNOWN.
- If the VA that generated the abort was from an address range for which Address tagging is disabled and Logical Address Tagging is enabled for the translation regime in use when the abort was generated, then bits[59:56] of FAR_EL3 are UNKNOWN.

For a synchronous External abort other than a synchronous External abort on a translation table walk, this field is valid only if ESR_EL3.FnV is 0, and FAR_EL3 is UNKNOWN if ESR_EL3.FnV is 1.

On an exception due to a Tag Check Fault caused by a data cache maintenance or other DC instruction, the address held in FAR_EL3 is IMPLEMENTATION DEFINED as one of the following:

- The lowest address that gave rise to the fault.
- The address specified in the register argument of the instruction as generated by MMU faults caused by DC ZVA.

If a memory fault that sets FAR_EL3 is generated from an STZGM instruction, the address held in FAR_EL3 is IMPLEMENTATION DEFINED as one of the following:

- The lowest address that gave rise to the fault.
- The address specified in the register argument.

If a memory fault that sets FAR_EL3, other than a Tag Check Fault, is generated from a data cache maintenance or other DC instruction, this field holds the address specified in the register argument of the instruction.

If the exception that updates FAR_EL3 is taken from an Exception level using AArch32, the top 32 bits are all zero, unless both of the following apply, in which case the top 32 bits of FAR_ELx are `0x00000001`:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The faulting address was generated by a load or store instruction that sequentially incremented from address `0xFFFFFFFF`. Such a load or store instruction is CONSTRAINED UNPREDICTABLE.
- The implementation treats such incrementing as setting bit[32] of the virtual address to 1.

When the PE sets ESR_EL3.{ISV,FnP} to {0,1} on taking a Data Abort exception, the PE sets FAR_EL3 to any address within the naturally-aligned fault granule that contains the virtual address of the memory access that generated the Data Abort exception.

The naturally-aligned fault granule is one of:

- When ESR_EL3.DFSC is `0b010001`, indicating a Synchronous Tag Check fault, it is a 16-byte tag granule.
- When ESR_EL3.DFSC is `0b11010x`, indicating an IMPLEMENTATION DEFINED fault, it is an IMPLEMENTATION DEFINED granule.
- Otherwise, it is the smallest implemented translation granule.

When FEAT_MOPS is implemented, the value in FAR_EL3 on a synchronous exception from any of the Memory Copy and Memory Set instructions is determined as follows:

- For an MMU fault reported as a Data Abort or as a Granule Protection Check Exception, the value is within the address range of the relevant translation granule, aligned to the size of the relevant translation granule of the address that generated the Data Abort. Bits[(n-1):0] of the value are UNKNOWN, where 2^n is the relevant translation granule size in bytes. For the purpose of calculating the relevant translation granule, if the MMU is disabled for a stage of translation, then the current translation granule size is equal to 2^{64} for stage 1, and the PARange for stage 2. The relevant translation granule is:
  - For MMU faults generated at stage 1, the current stage 1 translation granule.
  - For MMU faults generated at stage 2, the smaller of the current stage 1 translation granule and the current stage 2 translation granule.
  - If FEAT_RME is implemented, for a GPC fault, the smallest of the current stage 1 translation granule, the current stage 2 translation granule and the configured granule size in GPCCR_EL3.PGS.
- For a Data Abort generated by a Tag Check Fault, the value is any address that caused a Tag Check Fault within the block size of the load or store.
- Otherwise, the value is the lowest address in the block size of the load or store.

For a Data Abort exception, if address tagging is enabled for the address accessed by the data access that caused the exception, then this field includes the tag. For more information about address tagging, see ‘Address tagging’.

For a synchronous Tag Check Fault:

- If FEAT_MTE_TAGGED_FAR is implemented or Address tagging is disabled for the translation regime in use when the abort was generated, all bits of FAR_EL3 are not UNKNOWN.
- If FEAT_MTE_TAGGED_FAR is not implemented and Address tagging is enabled for the translation regime in use when the abort was generated, bits[63:60] of FAR_EL3 are UNKNOWN.

Execution at EL2, EL1, and EL0 makes FAR_EL3 become UNKNOWN.

Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that actually gave rise to the instruction or Data Abort. It is the lowest address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

For all other exceptions taken to EL3, FAR_EL3 is UNKNOWN.

FAR_EL3 is made UNKNOWN on an exception return from EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing FAR_EL3

D24.2.50 FGWTE3_EL3, Fine-Grained Write Traps EL3

The FGWTE3_EL3 characteristics are:

Purpose

Provides controls for traps of `MSR` and `MSRR` writes to specified EL3 System registers.

Configuration

This register is present only when EL3 is implemented, FEAT_FGWTE3 is implemented, and FEAT_AA64 is implemented. Otherwise, direct accesses to FGWTE3_EL3 are UNDEFINED.

Attributes

FGWTE3_EL3 is a 64-bit register.

Field descriptions

`MSR` accesses are trapped to EL3 and reported with EC syndrome value `0x18`.

`MSRR` accesses are trapped to EL3 and reported with EC syndrome value `0x14`.

The bits in this register are sticky. Writes to these bits have the following properties:

- A write of ‘0’ is ignored.
- A write of ‘1’ updates the bit to 1.

Bits [63:23]

Reserved, RES0.

GPCBW_EL3, bit [22]

When FEAT_RME_GPC3 is implemented:

Traps accesses of GPCBW_EL3 to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GPCBW_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

VBAR_EL3, bit [21]

Traps accesses of VBAR_EL3 to EL3.

VBAR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

TTBR0_EL3, bit [20]

Traps accesses of TTBR0_EL3 to EL3.

TTBR0_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

TPIDR_EL3, bit [19]

Traps accesses of TPIDR_EL3 to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TPIDR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

TCR_EL3, bit [18]

Traps accesses of TCR_EL3 to EL3.

TCR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

SPMROOTCR_EL3, bit [17]

When FEAT_RME is implemented and FEAT_SPMU is implemented:

Traps accesses of SPMROOTCR_EL3 to EL3.

SPMROOTCR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

SCTLR2_EL3, bit [16]

When FEAT_SCTLR2 is implemented:

Traps accesses of SCTLR2_EL3 to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SCTLR2_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

SCTLR_EL3, bit [15]

Traps accesses of SCTLR_EL3 to EL3.

SCTLR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

PIR_EL3, bit [14]

When FEAT_S1PIE is implemented:

Traps accesses of PIR_EL3 to EL3.

PIR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MPAM3_EL3, bit [13]

When FEAT_MPAM is implemented:

Traps accesses of MPAM3_EL3 to EL3.

MPAM3_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

MECID_RL_A_EL3, bit [12]

When FEAT_MEC is implemented:

Traps accesses of MECID_RL_A_EL3 to EL3.

MECID_RL_A_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

MDCR_EL3, bit [11]

Traps accesses of MDCR_EL3 to EL3.

MDCR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

MAIR2_EL3, bit [10]

When FEAT_AIE is implemented:

Traps accesses of MAIR2_EL3 to EL3.

MAIR2_EL3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	`MSR` write accesses to the specified register are trapped to EL3 with EC syndrome value `0x18`.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

MAIR_EL3, bit [9]

Traps accesses of MAIR_EL3 to EL3.

MAIR_EL3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	`MSR` write accesses to the specified register are trapped to EL3 with EC syndrome value `0x18`.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

GPTBR_EL3, bit [8]

When FEAT_RME is implemented:

Traps accesses of GPTBR_EL3 to EL3.

GPTBR_EL3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	`MSR` write accesses to the specified register are trapped to EL3 with EC syndrome value `0x18`.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

GPCCR_EL3, bit [7]

When FEAT_RME is implemented:

Traps accesses of GPCCR_EL3 to EL3.

GPCCR_EL3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	`MSR` write accesses to the specified register are trapped to EL3 with EC syndrome value `0x18`.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

GCSPR_EL3, bit [6]

When FEAT_GCS is implemented:

Traps accesses of GCSPR_EL3 to EL3.

GCSPR_EL3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	`MSR` write accesses to the specified register are trapped to EL3 with EC syndrome value `0x18`.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

GCSCR_EL3, bit [5]

When FEAT_GCS is implemented:

Traps accesses of GCSCR_EL3 to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GCSCR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

AMAIR2_EL3, bit [4]

When FEAT_AIE is implemented:

Traps accesses of AMAIR2_EL3 to EL3.

AMAIR2_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Otherwise:

Reserved, RES0.

AMAIR_EL3, bit [3]

Traps accesses of AMAIR_EL3 to EL3.

AMAIR_EL3	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	MSR write accesses to the specified register are trapped to EL3 with EC syndrome value 0x18.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

Access to this field is W1S.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AFSR1_EL3, bit [2]

Traps accesses of AFSR1_EL3 to EL3.

AFSR1_EL3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	`MSR` write accesses to the specified register are trapped to EL3 with EC syndrome value `0x18`.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

AFSR0_EL3, bit [1]

Traps accesses of AFSR0_EL3 to EL3.

AFSR0_EL3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	`MSR` write accesses to the specified register are trapped to EL3 with EC syndrome value `0x18`.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

ACTLR_EL3, bit [0]

Traps accesses of ACTLR_EL3 to EL3.

ACTLR_EL3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	`MSR` write accesses to the specified register are trapped to EL3 with EC syndrome value `0x18`.

The reset behavior of this field is:

- On a Warm reset, this field resets to `'0'`.

Access to this field is W1S.

Accessing FGWTE3_EL3

Accesses to this register use the following encodings in the System register encoding space:

D24.2.51 FPEXC32_EL2, Floating-Point Exception Control Register

The FPEXC32_EL2 characteristics are:

Purpose

Allows access to the AArch32 register FPEXC from AArch64 state only. Its value has no effect on execution in AArch64 state.

Configuration

If EL2 is not implemented but EL3 is implemented, and EL1 is capable of using AArch32, then this register is not RES0.

Implemented only if the implementation includes the Advanced SIMD and floating-point functionality.

AArch64 System register FPEXC32_EL2 bits [31:0] are architecturally mapped to AArch32 System register FPEXC[31:0].

This register is present only when FEAT_AA32EL1 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to FPEXC32_EL2 are UNDEFINED.

Attributes

FPEXC32_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

EX, bit [31]

Exception bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RAZ/WI.

EN, bit [30]

Enables access to the Advanced SIMD and floating-point functionality from all Exception levels, except that setting this field to 0 does not disable the following:

- VMSR accesses to the FPEXC or FPSID.
- VMRS accesses from the FPEXC, FPSID, MVFR0, MVFR1, or MVFR2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EN	Meaning
0b0	Accesses to the FPSCR, and any of the SIMD and floating-point registers Q0-Q15, including their views as D0-D31 registers or S0-S31 registers, are UNDEFINED at all Exception levels.
0b1	This control permits access to the Advanced SIMD and floating-point functionality at all Exception levels.

Execution of Advanced SIMD and floating-point instructions in AArch32 state can be disabled or trapped by the following controls:

- CPACR.cp10, or, if executing at EL0, CPACR_EL1.FPEN.
- FPEXC.EN.
- If executing in Non-secure state:
  - HCPTR.TCP10, or if EL2 is using AArch64, CPTR_EL2.TFP.
  - NSACR.cp10, or if EL3 is using AArch64, CPTR_EL3.TFP.
- For Advanced SIMD instructions only:
  - CPACR.ASEDIS.
  - If executing in Non-secure state, HCPTR.TASE and NSACR.NSASEDIS.

See the descriptions of the controls for more information.

Note

When executing at EL0 using AArch32:

- If EL1 is using AArch64, then the Effective value of FPEXC.EN is 1.
- If EL2 is using AArch64 and is enabled in the current Security state, HCR_EL2.TGE is 1, and the Effective value of HCR_EL2.RW is 1, then the Effective value of FPEXC.EN is 1. However, Arm deprecates using the value of FPEXC32_EL2.EN to determine behavior.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DEX, bit [29]

Defined synchronous exception on floating-point execution.

This field identifies whether a synchronous exception generated by the attempted execution of an instruction was generated by an unallocated encoding. The instruction must be in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()` returning TRUE. This field also indicates whether the FPEXC32_EL2.TFV field is valid.

The meaning of this bit is:

DEX	Meaning
0b0	The exception was generated by the attempted execution of an unallocated instruction in the encoding space that is identified by the pseudocode function `ExecutingCP10or11Instr()`. If FPEXC32_EL2.TFV is RW then it is invalid and UNKNOWN. If FPEXC32_EL2.{IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN.
0b1	The exception was generated during the execution of an allocated encoding. FPEXC32_EL2.TFV is valid and indicates the cause of the exception.

On an exception that sets this bit to 1 the exception-handling routine must clear this bit to 0.

On an implementation that both does not support trapping of floating-point exceptions and implements the AArch32 FPSCR.{Stride, Len} fields as RAZ, this bit is RES0.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FP2V, bit [28]

FPINST2 instruction Valid bit. From Armv8.0, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RES0.

VV, bit [27]

VECITR valid bit. From Armv8, this bit is RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RES0.

TFV, bit [26]

Trapped Fault Valid bit. Valid only when the value of FPEXC32_EL2.DEX is 1. When valid, it indicates the cause of the exception and therefore whether FPEXC32_EL2.{IDF, IXF, UFF, OFF, DZF, IOF} are valid.

TFV	Meaning
`0b0`	The exception was caused by the execution of a floating-point VABS, VADD, VDIV, VFMA, VFMS, VFNMA, VFNMS, VMLA, VMLS, VMOV, VMUL, VNEG, VNMLA, VNMLS, VNMUL, VSQRT, or VSUB instruction when one or both of FPSCR.{Stride, Len} was nonzero. If FPEXC32_EL2.{IDF, IXF, UFF, OFF, DZF, IOF} are RW then they are invalid and UNKNOWN.
`0b1`	FPEXC32_EL2.{IDF, IXF, UFF, OFF, DZF, IOF} indicate the presence of trapped floating-point exceptions that had occurred at the time of the exception. Bits are set for all trapped exceptions that had occurred at the time of the exception.

This bit returns a status value and ignores writes.

When the value of FPEXC32_EL2.DEX is 0 and this bit is RW, this bit is invalid and UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When an implementation does not implement trapping of floating-point exceptions, access to this field is RAZ/WI.
- When an implementation implements FPSCR.{Stride, Len} as RAZ, access to this field is RAO/WI.

Bits [25:11]

Reserved, RES0.

VECITR, bits [10:8]

Vector iteration count. From Armv8, this field is RES1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Access to this field is RES1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

IDF, bit [7]

Input Denormal trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Input Denormal exception occurred while FPSCR.IDE was 1:

IDF	Meaning
`0b0`	Input Denormal exception has not occurred.
`0b1`	Input Denormal exception has occurred.

Input Denormal exceptions can occur only when FPSCR.FZ is 1.

Note

A half-precision floating-point value that is flushed to zero because the value of FPSCR.FZ16 is 1 does not generate an Input Denormal exception.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC32_EL2.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Input Denormal floating-point exceptions, access to this field is RAZ/WI.

Bits [6:5]

Reserved, RES0.

IXF, bit [4]

Inexact trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Inexact exception occurred while FPSCR.IXE was 1:

IXF	Meaning
`0b0`	Inexact exception has not occurred.
`0b1`	Inexact exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Inexact floating-point exceptions, access to this field is RAZ/WI.

UFF, bit [3]

Underflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Underflow exception occurred while FPSCR.UFE was 1:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

UFF	Meaning
0b0	Underflow exception has not occurred.
0b1	Underflow exception has occurred.

Underflow trapped exceptions can occur:

- On half-precision data-processing instructions only when FPSCR.FZ16 is 0.
- Otherwise only when FPSCR.FZ is 0.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC32_EL2.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Underflow floating-point exceptions, access to this field is RAZ/WI.

OFF, bit [2]

Overflow trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Overflow exception occurred while FPSCR.OFE was 1:

OFF	Meaning
0b0	Overflow exception has not occurred.
0b1	Overflow exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Overflow floating-point exceptions, access to this field is RAZ/WI.

DZF, bit [1]

Divide by Zero trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether a Divide by Zero exception occurred while FPSCR.DZE was 1:

DZF	Meaning
0b0	Divide by Zero exception has not occurred.
0b1	Divide by Zero exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Divide by Zero floating-point exceptions, access to this field is RAZ/WI.

IOF, bit [0]

Invalid Operation trapped exception bit. Valid only when the value of FPEXC.TFV is 1. When valid, it indicates whether an Invalid Operation exception occurred while FPSCR.IOE was 1:

IOF	Meaning
0b0	Invalid Operation exception has not occurred.
0b1	Invalid Operation exception has occurred.

This bit must be cleared to 0 by the exception-handling routine.

When the value of FPEXC.TFV is 0 and this bit is RW, this bit is invalid and UNKNOWN.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When an implementation does not implement trapping of Invalid Operation floating-point exceptions, access to this field is RAZ/WI.

D24.2.52 GCR_EL1, Tag Control Register.

The GCR_EL1 characteristics are:

Purpose

Tag Control Register.

Configuration

This register is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to GCR_EL1 are UNDEFINED.

Attributes

GCR_EL1 is a 64-bit register.

Field descriptions

Bits [63:17]

Reserved, RES0.

RRND, bit [16]

Controls generation of tag values by the `IRG` instruction.

RRND	Meaning
`0b0`	`IRG` generates a tag value as defined by `RandomTag()` and `ChooseNonExcludedTag()`. This mode does not provide strong guarantees for randomness and should only be used for debugging purposes.
`0b1`	`IRG` generates an implementation-specific tag value with a distribution of tag values no worse than generated with GCR_EL1.RRND == 0.

Note

Arm recommends that IMPLEMENTATION DEFINED algorithms minimize the risk of a bias by selecting tags from a uniform distribution.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Exclude, bits [15:0]

Allocation Tag values excluded from selection by `ChooseNonExcludedTag()`.

If all bits of GCR_EL1.Exclude are 1, then the Allocation Tag value 0 will be used.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D24.2.53 GMID_EL1, Multiple tag transfer ID Register

The GMID_EL1 characteristics are:

Purpose

Indicates the block size that is accessed by the LDGM and STGM System instructions.

Configuration

This register is present only when FEAT_MTE2 is implemented. Otherwise, direct accesses to GMID_EL1 are UNDEFINED.

Attributes

GMID_EL1 is a 64-bit register.

Field descriptions

Bits [63:4]

Reserved, RES0.

BS, bits [3:0]

Log_2 of the block size in words. The minimum supported size is 16B (value == 2) and the maximum is 256B (value == 6).

This field has an IMPLEMENTATION DEFINED value.

Access to this field is RO.

Accessing GMID_EL1

Accesses to this register use the following encodings in the System register encoding space:

```

D24.2.54 GPCBW_EL3, Granule Protection Check Bypass Window Register (EL3)

The GPCBW_EL3 characteristics are:

Purpose

The control register for Granule Protection Check bypass window.

Configuration

This register is present only when FEAT_RME_GPC3 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to GPCBW_EL3 are UNDEFINED.

Attributes

GPCBW_EL3 is a 64-bit register.

Field descriptions

Bits [63:40]

Reserved, RES0.

BWSIZE, bits [39:37]

GPC Bypass Window Size.

BWSIZE defines the size of the GPC bypass memory region.

BWSIZE	Meaning
0b000	30 bits, 1GB GPC bypass window.
0b001	31 bits, 2GB GPC bypass window.
0b010	32 bits, 4GB GPC bypass window.
0b100	34 bits, 16GB GPC bypass window.
0b110	36 bits, 64GB GPC bypass window.

All other values are reserved.

This field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BWSTRIDE, bits [36:32]

GPC Bypass Window Stride.

BWSTRIDE allows creating multiple GPC bypass memory regions in the memory map across a specific stride.

BWSTRIDE	Meaning
0b00000	1TB stride.
0b00010	4TB stride.
0b00100	16TB stride.
0b00110	64TB stride.
0b00111	128TB stride.
0b01000	256TB stride.
0b01001	512TB stride.
0b01010	1PB stride.
0b10000	64PB (No stride).

All other values are reserved.

This field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [31:26]

Reserved, RES0.

BWADDR, bits [25:0]

GPC Bypass window address.

This field represents bits [55:30] of the GPC bypass window base address.

The GPC bypass window is:

- Aligned in memory to the size of the window as specified by GPCBW_EL3.BWSIZE.
- Duplicated in PA space across a stride specified using GPCBW_EL3.BWSTRIDE.

This means that only bits [gpcbwu:gpcbwl] of a PA are compared against bits [gpcbwu:gpcbwl] of the window base address derived from BWADDR when checking if a PA falls within the range of a window, where:

- gpcbwl is derived from GPCBW_EL3.BWSIZE as follows:

BWSIZE	gpcbwl
0b000	30
0b001	31
0b010	32
0b100	34
0b110	36

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- gpcbwu is derived from GPCBW_EL3.BWSTRIDE as follows:

BWSTRIDE	gpcbwu
0b00000	39
0b00010	41
0b00100	43
0b00110	45
0b00111	46
0b01000	47
0b01001	48
0b01010	49
0b10000	55

If the base address derived from BWADDR is not aligned to the size programmed in BWSIZE the configuration is invalid.

If this field is configured to a value that produces a GPC bypass window base address that is greater than or equal to the stride value configured by BWSTRIDE, the configuration is invalid.

An access to a PA falls within a GPC bypass window if the pseudocode function `PAWithinGPCBypassWindow()` returns TRUE.

This field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing GPCBW_EL3

Accesses to this register use the following encodings in the System register encoding space:

D24.2.55 GPCCR_EL3, Granule Protection Check Control Register (EL3)

The GPCCR_EL3 characteristics are:

Purpose

The control register for Granule Protection Checks.

Configuration

This register is present only when FEAT_RME is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to GPCCR_EL3 are UNDEFINED.

Attributes

GPCCR_EL3 is a 64-bit register.

Field descriptions

Bits [63:30]

Reserved, RES0.

GPCBW, bit [29]

When FEAT_RME_GPC3 is implemented:

GPC Bypass Window Enable.

This field governs the behavior of the GPC bypass windows.

GPCBW	Meaning
0b0	GPC bypass windows are disabled.
0b1	GPC bypass windows are enabled.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NA7, bit [28]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_RME_GDI is implemented:

No access 7.

This field governs the behavior of the GPI encoding for NA7.

NA7	Meaning
`0b0`	GPI encoding value of `0b0111` is reserved.
`0b1`	GPI encoding value of `0b0111` is No access from this PE.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NA6, bit [27]

When FEAT_RME_GDI is implemented:

No access 6.

This field governs the behavior of the GPI encoding for NA6.

NA6	Meaning
`0b0`	GPI encoding value of `0b0110` is reserved.
`0b1`	GPI encoding value of `0b0110` is No access from this PE.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NSP, bit [26]

When FEAT_RME_GDI is implemented:

Non-secure Protected.

This field governs the behavior of the GPI encoding for NSP.

NSP	Meaning
`0b0`	GPI encoding value of `0b0101` is reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NSP	Meaning
0b1	GPI encoding value of 0b0101 is No access from this PE.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SA, bit [25]

When FEAT_RME_GDI is implemented:

System Agent.

This field governs the behavior of the GPI encoding for SA.

SA	Meaning
0b0	GPI encoding value of 0b0100 is reserved.
0b1	GPI encoding value of 0b0100 is No access from this PE.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APPSAA, bit [24]

When FEAT_RME_GPC2 is implemented:

Above PPS All Access. This field governs the behavior of memory accesses to Secure, Realm and Root PA space, for physical addresses above the range configured by GPCCR_EL3.PPS.

APPSAA	Meaning
0b0	Accesses to addresses above the configured PPS must be to Non-secure PA space, otherwise they generate a GPF at level 0.
0b1	Accesses to addresses above the configured PPS, to any PA space, do not generate a GPF because of this control.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

L0GPTSZ, bits [23:20]

Level 0 GPT entry size.

This field advertises the number of least-significant address bits protected by each entry in the level 0 GPT.

L0GPTSZ	Meaning
`0b0000`	30-bits. Each entry covers 1GB of address space.
`0b0100`	34-bits. Each entry covers 16GB of address space.
`0b0110`	36-bits. Each entry covers 64GB of address space.
`0b1001`	39-bits. Each entry covers 512GB of address space.

All other values are reserved.

Access to this field is RO.

NSO, bit [19]

When FEAT_RME_GPC2 is implemented:

Non-secure Only. This field governs the behavior of the GPI encoding for NSO.

NSO	Meaning
`0b0`	GPI encoding value of `0b1101` is reserved.
`0b1`	GPI encoding value of `0b1101` is NSO.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TBGPCD, bit [18]

When FEAT_TRBE_EXT is implemented:

Trace Buffer Granule Protection Check Disabled. Controls whether the Trace Buffer Unit accepts or rejects trace when Granule Protection Checks are disabled.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TBGPCD	Meaning
`0b0`	The Trace Buffer Unit rejects trace when GPCCR_EL3.GPC is 0.
`0b1`	The Trace Buffer Unit accepts trace when GPCCR_EL3.GPC is 0.

When the Trace Buffer Unit rejects trace, the trace might remain buffered by the trace unit until the Trace Buffer Unit is able to accept trace. When the Trace Buffer Unit accepts trace, the Trace Buffer Unit writes the trace to memory.

Note

Setting GPCCR_EL3.{TBGPCD, GPC} to {1, 0} means that the Trace Buffer Unit might write to memory without any Granule Protection Checks. The addresses that the Trace Buffer Unit writes to can be programmed by an external agent. The physical address spaces the Trace Buffer Unit can address are restricted by an IMPLEMENTATION DEFINED debug authentication interface.
Setting GPCCR_EL3.{TBGPCD, GPC} to {1, 1} means that GPCCR_EL3.{TBGPCD, GPC} will become {1, 0} on a Warm reset.

This field is ignored by the PE and treated as one when any of the following are true:

- GPCCR_EL3.GPC == 1.
- `ExternalRootInvasiveDebugEnabled()` == TRUE.

The reset behavior of this field is:

- On a Cold reset, this field resets to `'0'`.

Otherwise:

Reserved, RES0.

GPCP, bit [17]

Granule Protection Check Priority.

This control governs behavior of granule protection checks on fetches of stage 2 Table descriptors.

GPCP	Meaning
`0b0`	GPC faults are all reported with a priority that is consistent with the GPC being performed on any access to physical address space.
`0b1`	A GPC fault for the fetch of a Table descriptor for a stage 2 translation table walk might not be generated or reported. All other GPC faults are reported with a priority consistent with the GPC being performed on all accesses to physical address spaces.

This bit is permitted to be cached in a TLB.

An implementation is permitted to treat this field as RES0, with an Effective value of 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

GPC, bit [16]

Granule Protection Check Enable.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GPC	Meaning
0b0	Granule protection checks are disabled. Accesses are not prevented by this mechanism.
0b1	All accesses to physical address spaces are subject to granule protection checks, except for fetches of GPT information and accesses governed by the GPCCR_EL3.GPCP control.

If any stage of translation is enabled, this bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to '0'.

PGS, bits [15:14]

Physical Granule size.

PGS	Meaning
0b00	4KB.
0b01	64KB.
0b10	16KB.

All other values are reserved.

The value of this field is permitted to be cached in a TLB.

Granule sizes not supported for stage 1 and not supported for stage 2, as defined in ID_AA64MMFR0_EL1, are reserved. For example, if ID_AA64MMFR0_EL1.TGran16 == 0b0000 and ID_AA64MMFR0_EL1.TGran16_2 == 0b0001, then the PGS encoding 0b10 is reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SH, bits [13:12]

GPT fetch Shareability attribute

SH	Meaning
0b00	Non-shareable.
0b10	Outer Shareable.
0b11	Inner Shareable.

All other values are reserved.

Fetches of GPT information are made with the Shareability attribute that is configured in this field.

If both ORGN and IRGN are configured with Non-cacheable attributes, it is invalid to configure this field to any value other than 0b10.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ORGN, bits [11:10]

GPT fetch Outer Cacheability attribute.

ORGN	Meaning
0b00	Normal memory, Outer Non-cacheable.
0b01	Normal memory, Outer Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Outer Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Outer Write-Back Read-Allocate No Write-Allocate Cacheable.

Fetches of GPT information are made with the Outer Cacheability attributes configured in this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IRGN, bits [9:8]

GPT fetch Inner Cacheability attribute.

IRGN	Meaning
0b00	Normal memory, Inner Non-cacheable.
0b01	Normal memory, Inner Write-Back Read-Allocate Write-Allocate Cacheable.
0b10	Normal memory, Inner Write-Through Read-Allocate No Write-Allocate Cacheable.
0b11	Normal memory, Inner Write-Back Read-Allocate No Write-Allocate Cacheable.

Fetches of GPT information are made with the Inner Cacheability attributes configured in this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SPAD, bit [7]

When FEAT_RME_GPC2 is implemented:

Secure PA space Disable. This field controls access to the Secure PA space.

SPAD	Meaning
0b0	This control has no effect on accesses.
0b1	When granule protection checks are enabled, access to the Secure Physical Address space generates a Granule Protection fault.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

NSPAD, bit [6]

When FEAT_RME_GPC2 is implemented:

Non-secure PA space Disable. This field controls access to the Non-secure PA space.

NSPAD	Meaning
0b0	This control has no effect on accesses.
0b1	When granule protection checks are enabled, access to the Non-secure Physical Address space generates a Granule Protection fault.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

RLPAD, bit [5]

When FEAT_RME_GPC2 is implemented:

Realm PA space Disable. This field controls access to the Realm PA space.

RLPAD	Meaning
0b0	This control has no effect on accesses.
0b1	When granule protection checks are enabled, access to the Realm Physical Address space generates a Granule Protection fault.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [4]

Reserved, RES0.

PPS3, bit [3]

When FEAT_RME_GPC3 is implemented:

This field extends GPCCR_EL3.PPS[2:0], creating a GPCCR_EL3.PPS[3:0] field.

For a description of the values derived by evaluating PPS, see GPCCR_EL3.PPS[2:0].

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of this field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PPS, bits [2:0]

When FEAT_RME_GPC3 is implemented:

Protected Physical Address Size.

The size of the memory region protected by GPTBR_EL3, in terms of the number of least-significant address bits.

This field is evaluated with PPS3, as {PPS3, PPS} to give PPS[3:0], interpreted as:

PPS[3:0]	Meaning
0b0000	32 bits, 4GB protected address space.
0b0001	36 bits, 64GB protected address space.
0b0010	40 bits, 1TB protected address space.
0b0011	42 bits, 4TB protected address space.
0b0100	44 bits, 16TB protected address space.
0b1000	46 bits, 64TB protected address space.
0b1001	47 bits, 128TB protected address space.
0b0101	48 bits, 256TB protected address space.
0b0110	52 bits, 4PB protected address space.
0b0111	56 bits, 64PB protected address space.

All other values are reserved.

Configuration of this field to a value exceeding the implemented physical address size is invalid.

The value of this field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Protected Physical Address Size.

The size of the memory region protected by GPTBR_EL3, in terms of the number of least-significant address bits.

PPS	Meaning
0b000	32 bits, 4GB protected address space.
0b001	36 bits, 64GB protected address space.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PPS	Meaning
0b010	40 bits, 1TB protected address space.
0b011	42 bits, 4TB protected address space.
0b100	44 bits, 16TB protected address space.
0b101	48 bits, 256TB protected address space.
0b110	52 bits, 4PB protected address space.

All other values are reserved.

Configuration of this field to a value exceeding the implemented physical address size is invalid.

The value of this field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing GPCCR_EL3

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, GPCCR_EL3
```

op0	op1	CRn	CRm	op2
0b11	0b110	0b0010	0b0001	0b110

```
if !(IsFeatureImplemented(FEAT_RME) && IsFeatureImplemented(FEAT_AA64)) then
    Undefined();

D24.2.56 GPTBR_EL3, Granule Protection Table Base Register

The GPTBR_EL3 characteristics are:

Purpose

The control register for Granule Protection Table base address.

Configuration

This register is present only when FEAT_RME is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to GPTBR_EL3 are UNDEFINED.

Attributes

GPTBR_EL3 is a 64-bit register.

Field descriptions

Bits [63:44]

Reserved, RES0.

BADDR[43:40], bits [43:40]

When FEAT_RME_GPC3 is implemented:

Extension to BADDR[39:0]. This field represents bit [55:52] of the level 0 GPT base address.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

BADDR, bits [39:0]

Base address for the level 0 GPT.

This field represents bits [51:12] of the level 0 GPT base address.

The level 0 GPT is aligned in memory to the greater of:

- The size of the level 0 GPT in bytes.
- 4KB.

Bits [x:0] of the base address are treated as zero, where:

- x = Max(pps - l0gptsz + 2, 11)
- pps is derived from GPCCR_EL3.PPS as follows:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GPCCR_EL3.PPS	pps
0b000	32
0b001	36
0b010	40
0b011	42
0b100	44
0b101	48
0b110	52

- l0gptsz is derived from GPCCR_EL3.L0GPTSZ as follows:

GPCCR_EL3.L0GPTSZ	l0gptsz
0b0000	30
0b0100	34
0b0110	36
0b1001	39

If x is greater than 11, then BADDR[x - 12:0] are RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing GPTBR_EL3

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, GPTBR_EL3
```

op0	op1	CRn	CRm	op2
0b11	0b110	0b0010	0b0001	0b100

```

D24.2.57 HACDBSBR_EL2, Hardware Accelerator for Cleaning Dirty State Base Register

The HACDBSBR_EL2 characteristics are:

Purpose

Control register for HACDBS structure.

Configuration

This register is present only when FEAT_HACDBS is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HACDBSBR_EL2 are UNDEFINED.

Attributes

HACDBSBR_EL2 is a 64-bit register.

Field descriptions

Bits [63:56]

Reserved, RES0.

BADDR, bits [55:12]

HACDBS base address, bits [55:12].

- Bits [55:12] of the base address are the value of this field.
- Bits [11:0] of the base address are 0.

Bits of this field above the implemented physical address size, indicated in ID_AA64MMFR0_EL1.PARange, are RES0.

Based on the value of the SZ field of this register, for encodings of the SZ field greater than 4KB, bits [(SZ+12-1):12] of this field are RES0 such that the base address of the HACDBS is aligned to its size.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

EN, bit [11]

Enable use of HACDBS.

EN	Meaning
0b0	Hardware accelerator for cleaning Dirty state is disabled.
0b1	Hardware accelerator for cleaning Dirty state is enabled.

If SCR_EL3.HACDBSEn is set to 0, then this field behaves as 0 for all purposes other than a direct read of the value of this bit.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [10:4]

Reserved, RES0.

SZ, bits [3:0]

Size of the HACDBS.

SZ	Meaning
0b0000	4KB
0b0001	8KB
0b0010	16KB
0b0011	32KB
0b0100	64KB
0b0101	128KB
0b0110	256KB
0b0111	512KB
0b1000	1MB
0b1001	2MB

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HACDBSBR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HACDBSBR_EL2

D24.2.58 HACDBSCONS_EL2, Hardware Accelerator for Cleaning Dirty State Consumer Register

The HACDBSCONS_EL2 characteristics are:

Purpose

Read index for HACDBS structure.

Configuration

This register is present only when FEAT_HACDBS is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HACDBSCONS_EL2 are UNDEFINED.

Attributes

HACDBSCONS_EL2 is a 64-bit register.

Field descriptions

ERR_REASON, bits [63:62]

Reason for HACDBS error.

ERR_REASON	Meaning
0b00	The PE has not experienced an error while processing the HACDBS.
0b01	STRUCTF - A read of an entry from the HACDBS has experienced a fault.
0b10	IPAF - A stage 2 walk of an IPA from a HACDBS entry has experienced an MMU fault.
0b11	IPAHACF - An entry from the HACDBS experienced an error that is not an MMU fault.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [61:19]

Reserved, RES0.

INDEX, bits [18:0]

This field indicates the index of the HACDBS entry that will be read from next.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D24.2.59 HACR_EL2, Hypervisor Auxiliary Control Register

The HACR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of IMPLEMENTATION DEFINED aspects of EL1 or EL0 operation.

Note

Arm recommends that the values in this register do not cause unnecessary traps to EL2 when the Effective value of HCR_EL2.{E2H, TGE} == {1, 1}.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

AArch64 System register HACR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HACR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to HACR_EL2 are UNDEFINED.

Attributes

HACR_EL2 is a 64-bit register.

Field descriptions

IMPLEMENTATION DEFINED, bits [63:0]

IMPLEMENTATION DEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HACR_EL2

D24.2.60 HAFGRTR_EL2, Hypervisor Activity Monitors Fine-Grained Read Trap Register

The HAFGRTR_EL2 characteristics are:

Purpose

Provides controls for traps of MRS reads of Activity Monitors System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_AMUv1 is implemented, FEAT_FGT is implemented, and FEAT_AA64 is implemented. Otherwise, direct accesses to HAFGRTR_EL2 are UNDEFINED.

Attributes

HAFGRTR_EL2 is a 64-bit register.

Field descriptions

Bits [63:50]

Reserved, RES0.

AMEVTYPER1<x>_EL0 , bits [19+2x], for x = 15 to 0

Trap MRS reads of AMEVTYPER1<x>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVTYPER1<x> at EL0 using AArch32 when EL1 is using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AMEVTYPER1<x>_EL0	Meaning
0b0	MRS reads of AMEVTYPER1<x>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVTYPER1<x> at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then, unless the read generates a higher priority exception: • MRS reads of AMEVTYPER1<x>_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of AMEVTYPER1<x> at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When x >= UInt(AMCGCR_EL0.CG1NC), access to this field is RES0.
- When !IsG1ActivityMonitorImplemented(x), access to this field is RES0.

AMEVCNTR1<x>_EL0 , bits [18+2x], for x = 15 to 0

Trap MRS reads of AMEVCNTR1<x>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVCNTR1<x> at EL0 using AArch32 when EL1 is using AArch64 to EL2.

AMEVCNTR1<x>_EL0	Meaning
0b0	MRS reads of AMEVCNTR1<x>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVCNTR1<x> at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then, unless the read generates a higher priority exception: • MRS reads of AMEVCNTR1<x>_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of AMEVCNTR1<x> at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing this field has the following behavior:

- When x >= UInt(AMCGCR_EL0.CG1NC), access to this field is RES0.
- When !IsG1ActivityMonitorImplemented(x), access to this field is RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AMCNTEN<x> , bits [17x], for x = 1 to 0

Trap MRS reads and MRC reads of multiple System registers.

Enables a trap to EL2 the following operations:

- At EL1 and EL0 using AArch64: MRS reads of AMCNTENCLR<x>_EL0 and AMCNTENSET<x>_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: MRC reads of AMCNTENCLR<x> and AMCNTENSET<x>.

AMCNTEN<x>	Meaning
0b0	The operations listed above are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then, unless the read generates a higher priority exception: • MRS reads at EL1 and EL0 using AArch64 of AMCNTENCLR<x>_EL0 and AMCNTENSET<x>_EL0 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads at EL0 using AArch32 of AMCNTENCLR<x> and AMCNTENSET<x> are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bits [16:5]

Reserved, RES0.

AMEVCNTR0<x>_EL0 , bits [x+1], for x = 3 to 0

Trap MRS reads of AMEVCNTR0<x>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVCNTR0<x> at EL0 using AArch32 when EL1 is using AArch64 to EL2.

AMEVCNTR0<x>_EL0	Meaning
0b0	MRS reads of AMEVCNTR0<x>_EL0 at EL1 and EL0 using AArch64 and MRC reads of AMEVCNTR0<x> at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, EL1 is using AArch64, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then, unless the read generates a higher priority exception: • MRS reads of AMEVCNTR0<x>_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of AMEVCNTR0<x> at EL0 using AArch32 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

When x >= 4, access to this field is RES0.

Accessing HAFGRTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HAFGRTR_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0011	0b0001	0b110

D24.2.61 HCR_EL2, Hypervisor Configuration Register

The HCR_EL2 characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various operations are trapped to EL2.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

Unless otherwise stated, the bits in this register behave as if they are 0 for all purposes other than direct reads of the register if EL2 is not enabled in the current Security state.

AArch64 System register HCR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HCR[31:0].

AArch64 System register HCR_EL2 bits [63:32] are architecturally mapped to AArch32 System register HCR2[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to HCR_EL2 are UNDEFINED.

Attributes

HCR_EL2 is a 64-bit register.

Field descriptions

TWEDEL, bits [63:60]

When FEAT_TWED is implemented:

TWE Delay. A 4-bit unsigned number that, when HCR_EL2.TWEDEn is 1, encodes the minimum delay in taking a trap of WFE* caused by HCR_EL2.TWE as $2^{(\mathrm{TWEDEL} + 8)}$ cycles.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TWEDEn, bit [59]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_TWED is implemented:

TWE Delay Enable. Enables a configurable delayed trap of the WFE* instruction caused by HCR_EL2.TWE.

TWEDEn	Meaning
0b0	The delay for taking the trap is IMPLEMENTATION DEFINED.
0b1	The delay for taking the trap is at least the number of cycles defined in HCR_EL2.TWEDEL.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TID5, bit [58]

When FEAT_MTE2 is implemented:

Trap ID group 5. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

AArch64:

- GMID_EL1.

TID5	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	The specified EL1 accesses to ID group 5 registers are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DCT, bit [57]

When FEAT_MTE2 is implemented:

Default Cacheability Tagging. When HCR_EL2.DC is in effect, controls whether EL1&0 stage 1 translations have the Tagged attribute.

DCT	Meaning
0b0	Stage 1 translations do not have the Tagged attribute.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	Stage 1 translations have the Tagged attribute.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ATA, bit [56]

When FEAT_MTE2 is implemented:

Memory tagging enable override:

- Overrides enabling of Memory tagging at EL1 and EL0.
- If disabled by this control, accesses to the following registers at EL1 are trapped to EL2 and reported using EC syndrome value 0x18:
  - GCR_EL1.
  - RGSR_EL1.
  - TFSRE0_EL1.
  - TFSR_EL1.
  - Accesses with the register name TFSR_EL2 that are not UNDEFINED.

ATA	Meaning
0b0	Disables the use of Memory tagging at EL1 and EL0. The specified registers are trapped to EL2.
0b1	This field has no effect on the use of Memory tagging at EL1 and EL0. The field does not trap the specified registers to EL2.

The Effective value of this field is 1 if any of the following are true:

- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.
- EL2 is not implemented or not enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TTLBOS, bit [55]

When FEAT_EVT2 is implemented:

Trap TLB maintenance instructions that operate on the Outer Shareable domain. Traps execution of those TLB maintenance instructions at EL1 using AArch64 to EL2, when EL2 is enabled in the current Security state. The following instructions are trapped and reported with EC syndrome value 0x18:

- TLBI VMALLE1OS, TLBI VAE1OS, TLBI ASIDE1OS,TLBI VAAE1OS, TLBI VALE1OS, and TLBI VAALE1OS.
- If FEAT_TLBIRANGE is implemented, TLBI RVAE1OS, TLBI RVAAE1OS, TLBI RVALE1OS, and TLBI RVAALE1OS.
- If FEAT_XS is implemented, then the *OSNXS variants are also trapped.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTLBOS	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Execution of the specified instructions are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TTLBIS, bit [54]

When FEAT_EVT2 is implemented:

Trap TLB maintenance instructions that operate on the Inner Shareable domain. Traps execution of those TLB maintenance instructions at EL1 to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, then the following instructions are trapped to EL2 and reported with EC syndrome value 0x18:
  - TLBI VMALLE1IS, TLBI VAE1IS, TLBI ASIDE1IS, TLBI VAAE1IS, TLBI VALE1IS, TLBI VAALE1IS, TLBI RVAE1IS, TLBI RVAAE1IS, TLBI RVALE1IS, and TLBI RVAALE1IS.
- If EL1 is using AArch32, then the following instructions are trapped to EL2 and reported with EC syndrome value 0x03:
  - TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIMVALIS, and TLBIMVAALIS.
- If FEAT_XS is implemented, then the *ISNXS variants are also trapped.

TTLBIS	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Execution of the specified instructions are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnSCXT, bit [53]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Enable Access to the SCXTNUM_EL1 and SCXTNUM_EL0 registers. The defined values are:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EnSCXT	Meaning
0b0	When EL2 is enabled in the current Security state, EL1 accesses to SCXTNUM_EL0 and SCXTNUM_EL1 are disabled, causing an exception to EL2, and the value of the registers to be treated as 0. When the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1} and EL2 is enabled in the current Security state, EL0 access to SCXTNUM_EL0 is disabled, causing an exception to EL2, and the value of the register to be treated as 0.
0b1	This control does not cause accesses to SCXTNUM_EL0 or SCXTNUM_EL1 to be trapped.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1} and the value of this field is 0, accesses at EL0 are not trapped by this control.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TOCU, bit [52]

When FEAT_EVT is implemented:

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions at EL0 and EL1 to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL0 is using AArch64, the value of SCTLR_EL1.UCI is 1, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then the following instructions at EL0 are trapped to EL2 and reported with EC syndrome value `0x18`:
  - IC IVAU, and DC CVAU.
- If EL1 is using AArch64, then the following instructions at EL1 are trapped to EL2 and reported with EC syndrome value `0x18`:
  - IC IVAU, IC IALLU, and DC CVAU.
- If EL1 is using AArch32, then the following instructions are trapped at EL1 to EL2 and reported with EC syndrome value `0x03`:
  - ICIMVAU, ICIALLU, and DCCMVAU.

Note

When SCTLR_EL1.UCI is 0, the trap on execution of instructions at EL0 is higher priority than this control. An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- IC IALLUIS and IC IALLU are always UNDEFINED at EL0 using AArch64.
- ICIMVAU, ICIALLU, ICIALLUIS, and DCCMVAU are always UNDEFINED at EL0 using AArch32.

TOCU	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	For each of the specified instructions, if the execution of the instruction can be trapped, accesses are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

AMVOFFEN, bit [51]

When FEAT_AMUv1p1 is implemented:

Activity Monitors Virtual Offsets Enable.

AMVOFFEN	Meaning
0b0	Virtualization of the Activity Monitors is disabled. Indirect reads of the virtual offset registers are zero.
0b1	Virtualization of the Activity Monitors is enabled.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TICAB, bit [50]

When FEAT_EVT is implemented:

Trap `ICIALLUIS` and `IC IALLUIS` cache maintenance instructions. Traps execution of those cache maintenance instructions at EL1 to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, then the following instruction is trapped to EL2 and reported with EC syndrome value `0x18`:
  - IC IALLUIS.
- If EL1 is using AArch32, then the following instruction is trapped to EL2 and reported with EC syndrome value `0x03`:
  - ICIALLUIS.

TICAB	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	For each of the specified instructions, if the execution of the instruction can be trapped, EL1 access is trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TID4, bit [49]

When FEAT_EVT is implemented:

Trap ID group 4. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state:

AArch64:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EL1 reads of CCSIDR_EL1, CCSIDR2_EL1, CLIDR_EL1, and CSSELR_EL1.
- EL1 writes to CSSELR_EL1.

AArch32:

- EL1 reads of CCSIDR, CCSIDR2, CLIDR, and CSSELR.
- EL1 writes to CSSELR.

TID4	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	The specified EL1 accesses to ID group 4 registers are trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

GPF, bit [48]

When FEAT_RME is implemented:

Controls the reporting of Granule protection faults at EL0 and EL1.

GPF	Meaning
`0b0`	This control does not cause exceptions to be routed from EL0 and EL1 to EL2.
`0b1`	Instruction Abort exceptions and Data Abort exceptions due to GPFs from EL0 and EL1 are routed to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FIEN, bit [47]

When FEAT_RASv1p1 is implemented:

Fault Injection Enable. Unless this bit is set to 1, accesses to the ERXPFGCDN_EL1, ERXPFGCTL_EL1, and ERXPFGF_EL1 registers from EL1 generate a Trap exception to EL2, when EL2 is enabled in the current Security state, reported using EC syndrome value `0x18`.

FIEN	Meaning
`0b0`	Accesses to the specified registers from EL1 are trapped to EL2, when EL2 is enabled in the current Security state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FIEN	Meaning
0b1	This control does not cause any instructions to be trapped.

If EL2 is disabled in the current Security state, the Effective value of HCR_EL2.FIEN is 1.

If ERRIDR_EL1.NUM is zero, meaning no error records are implemented, or no error record accessible using System registers is owned by a node that implements the RAS Common Fault Injection Model Extension, then this bit might be RES0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FWB, bit [46]

When FEAT_S2FWB is implemented:

Forced Write-Back. Defines the combined cacheability attributes in a 2 stage translation regime.

FWB	Meaning
0b0	When this bit is 0, then the combination of stage 1 and stage 2 translations on memory type and cacheability attributes are as described in the Armv8.0 architecture. For more information, see 'Combining stage 1 and stage 2 memory type attributes'.
0b1	When this bit is 1, then the encoding of the stage 2 memory type and cacheability attributes in bits[5:2] of the stage 2 Page or Block descriptors are as described in 'Stage 2 memory type and Cacheability attributes when FEAT_S2FWB is enabled'.

In Secure state, this bit applies to both the Secure stage 2 translation and the Non-secure stage 2 translation.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NV2, bit [45]

When FEAT_NV2 is implemented:

Nested Virtualization. Changes the behaviors of HCR_EL2.{NV1, NV} to provide a mechanism for hardware to transform reads and writes from System registers into reads and writes from memory.

NV2	Meaning
0b0	This bit has no effect on the behavior of HCR_EL2.{NV1, NV}. The behavior of HCR_EL2.{NV1, NV} is as defined for FEAT_NV.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NV2	Meaning
0b1	Redefines behavior of HCR_EL2{NV1, NV} to enable: • Transformation of read/writes to registers into read/writes to memory. • Redirection of EL2 registers to EL1 registers. Any exception taken from EL1 and taken to EL1 causes SPSR_EL1.M[3:2] to be set to 0b10 and not 0b01.

When the Effective value of HCR_EL2.NV is 0, the Effective value of this field is 0 and this field is treated as 0 for all purposes other than direct reads and writes of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AT, bit [44]

When FEAT_NV is implemented:

Address Translation. EL1 execution of the following address translation instructions is trapped to EL2, when EL2 is enabled in the current Security state, reported using EC syndrome value 0x18:

- AT S1E0R, AT S1E0W, AT S1E1R, AT S1E1W, AT S1E1RP, and AT S1E1WP.
- If FEAT_ATS1A is implemented, AT S1E1A.

AT	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 execution of the specified instructions is trapped to EL2.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NV1, bit [43]

When FEAT_NV2 is implemented:

Nested Virtualization.

NV1	Meaning
0b0	If the Effective value of HCR_EL2.{NV2, NV} is {1, 1}, accesses executed from EL1 to implemented EL12, EL02, or EL2 registers are transformed to loads and stores. If the Effective value of HCR_EL2.{NV2, NV} is not {1, 1}, this control does not cause any instructions to be trapped.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NV1	Meaning
0b1	If the Effective value of HCR_EL2.NV2 is 1, accesses executed from EL1 to implemented EL2 registers are transformed to loads and stores. If the Effective value of HCR_EL2.NV2 is 0, EL1 accesses to VBAR_EL1, ELR_EL1, SPSR_EL1, and, when FEAT_CSV2_2 or FEAT_CSV2_1p2 is implemented, SCXTNUM_EL1, are trapped to EL2, when EL2 is enabled in the current Security state, and are reported using EC syndrome value 0x18.

If the Effective value of HCR_EL2.NV2 is 1, the Effective value of HCR_EL2.NV1 defines which EL1 register accesses are transformed to loads and stores.

The trapping of EL1 registers caused by other control bits has priority over the transformation of these accesses.

If a register is specified that is not implemented by an implementation, then access to that register are UNDEFINED.

For the list of registers affected, see 'Enhanced support for nested virtualization'.

If the Effective value of HCR_EL2.{NV1, NV} is {0, 1}, any exception taken from EL1, and taken to EL1, causes the SPSR_EL1.M[3:2] to be set to 0b10, and not 0b01.

If the Effective value of HCR_EL2.{NV1, NV} is {1, 1}, then:

- The EL1 translation table Block and Page descriptors:
  - Bit[54] holds the PXN instead of the UXN.
  - The Effective value of UXN is 0.
  - Bit[53] is RES0.
  - Bit[6] is treated as 0 regardless of the actual value.
- If Hierarchical Permissions are enabled, the EL1 translation table Table descriptors are as follows:
  - Bit[61] is treated as 0 regardless of the actual value.
  - Bit[60] holds the PXNTable instead of the UXNTable.
  - Bit[59] is RES0.
- When executing at EL1, the Effective value of PSTATE.PAN is 0 for all purposes except reading the value of the bit.
- When executing at EL1, the Effective value of PSTATE.UAO is 1 for all purposes except reading the value of the bit.

If the Effective value of HCR_EL2.{NV1, NV} are {1, 0}, then the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- Behaving as if the Effective value of HCR_EL2.{NV1, NV} is {1, 1} for all purposes other than reading back the value of the HCR_EL2.NV bit.
- Behaving as if the Effective value of HCR_EL2.{NV1, NV} is {0, 0} for all purposes other than reading back the value of the HCR_EL2.NV1 bit.
- Behaving with regard to the Effective value of HCR_EL2.{NV1, NV} behavior as defined in the rest of this description.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_NV is implemented:

Nested Virtualization. EL1 accesses to certain registers are trapped to EL2, when EL2 is enabled in the current Security state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NV1	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 accesses to VBAR_EL1, ELR_EL1, SPSR_EL1, and, when FEAT_CSV2_2 or FEAT_CSV2_1p2 is implemented, SCXTNUM_EL1, are trapped to EL2, when EL2 is enabled in the current Security state, and are reported using EC syndrome value 0x18.

If the Effective value of HCR_EL2.{NV1, NV} is {0, 1}, then the following effects also apply:

- Any exception taken from EL1, and taken to EL1, causes the SPSR_EL1.M[3:2] to be set to 0b10, and not 0b01.

If the Effective value of HCR_EL2.{NV1, NV} is {1, 1}, then the following effects also apply:

- The EL1 translation table Block and Page descriptors:
  - Bit[54] holds the PXN instead of the UXN.
  - The Effective value of UXN is 0.
  - Bit[53] is RES0.
  - Bit[6] is treated as 0 regardless of the actual value.
- If Hierarchical Permissions are enabled, the EL1 translation table Table descriptors are as follows:
  - Bit[61] is treated as 0 regardless of the actual value.
  - Bit[60] holds the PXNTable instead of the UXNTable.
  - Bit[59] is RES0.
- When executing at EL1, the Effective value of PSTATE.PAN is 0 for all purposes except reading the value of the bit.
- When executing at EL1, the Effective value of PSTATE.UAO is 1 for all purposes except reading the value of the bit.

If the Effective value of HCR_EL2.{NV1, NV} is {1, 0}, then the behavior is a CONSTRAINED UNPREDICTABLE choice of:

- Behaving as if the Effective value of HCR_EL2.{NV1, NV} is {1, 1} for all purposes other than reading back the value of the HCR_EL2.NV bit.
- Behaving as if the Effective value of HCR_EL2.{NV1, NV} is {0, 0} for all purposes other than reading back the value of the HCR_EL2.NV1 bit.
- Behaving with regard to the Effective value of HCR_EL2.{NV1, NV} behavior as defined in the rest of this description.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

NV, bit [42]

When FEAT_NV2 is implemented:

Nested Virtualization.

When the Effective value of HCR_EL2.NV2 is 1, redefines register accesses so that:

- Instructions accessing the Special purpose registers SPSR_EL2 and ELR_EL2 instead access SPSR_EL1 and ELR_EL1 respectively.
- Instructions accessing the System registers ESR_EL2 and FAR_EL2 instead access ESR_EL1 and FAR_EL1.

When the Effective value of HCR_EL2.NV2 is 0, traps functionality that is permitted at EL2 and would be UNDEFINED at EL1 if this field was 0, when EL2 is enabled in the current Security state. This applies to the following operations:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EL1 accesses to Special-purpose registers that are not UNDEFINED at EL2.
- EL1 accesses to System registers that are not UNDEFINED at EL2.
- Execution of EL2 or EL1 translation regime address translation and TLB maintenance instructions for EL2 and above.

NV	Meaning
0b0	When this bit is set to 0, then the PE behaves as if the Effective value of HCR_EL2.NV2 is 0 for all purposes other than reading this register. This control does not cause any instructions to be trapped. When the Effective value of HCR_EL2.NV2 is 1, no FEAT_NV2 functionality is implemented.
0b1	When the Effective value of HCR_EL2.NV2 is 0, EL1 accesses to the specified registers or the execution of the specified instructions are trapped to EL2, when EL2 is enabled in the current Security state. EL1 read accesses to the CurrentEL register return a value of 0x2. When the Effective value of HCR_EL2.NV2 is 1, this control redefines EL1 register accesses so that instructions accessing SPSR_EL2, ELR_EL2, ESR_EL2, and FAR_EL2 instead access SPSR_EL1, ELR_EL1, ESR_EL1, and FAR_EL1 respectively.

When the Effective value of HCR_EL2.NV2 is 0, then:

- The System or Special-purpose registers for which accesses are trapped and reported using EC syndrome value 0x18 are as follows:
  - Registers accessed using MRS or MSR with a name ending in _EL2, except the following:
    - SP_EL2.
    - If FEAT_MEC is implemented, MECID_A0_EL2, MECID_A1_EL2, MECID_P0_EL2, MECID_P1_EL2, MECIDR_EL2, VMECID_A_EL2, and VMECID_P_EL2.
  - Registers accessed using MRS or MSR with a name ending in _EL12.
  - Registers accessed using MRS or MSR with a name ending in _EL02.
  - Special-purpose registers SPSR_irq, SPSR_abt, SPSR_und, and SPSR_fiq, accessed using MRS or MSR.
  - Special-purpose register SP_EL1 accessed using the dedicated MRS or MSR instruction.
- The instructions for which the execution is trapped and reported using EC syndrome value 0x18 are as follows:
  - EL2 translation regime Address Translation instructions and TLB maintenance instructions.
  - EL1 translation regime Address Translation instructions and TLB maintenance instructions that are accessible only from EL2 and EL3.
- The instructions for which the execution is trapped as follows:
  - SMC in an implementation that does not include EL3 and when HCR_EL2.TSC is 1. HCR_EL2.TSC bit is not RES0 in this case. This is reported using EC syndrome value 0x17.
  - The ERET, ERETAA, and ERETAB instructions, reported using EC syndrome value 0x1A.

Note

The priority of this trap is higher than the priority of the HCR_EL2.API trap. If both of these bits are set so that EL1 execution of an ERETAA or ERETAB instruction is trapped to EL2, then the syndrome reported is 0x1A.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_NV is implemented:

Nested Virtualization. Traps functionality that is permitted at EL2 and would be UNDEFINED at EL1 if this field was 0, when EL2 is enabled in the current Security state. This applies to the following operations:

- EL1 accesses to Special-purpose registers that are not UNDEFINED at EL2.
- EL1 accesses to System registers that are not UNDEFINED at EL2.
- Execution of EL2 or EL1 translation regime address translation and TLB maintenance instructions for EL2 and above.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NV	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 accesses to the specified registers or the execution of the specified instructions are trapped to EL2, when EL2 is enabled in the current Security state. EL1 read accesses to the CurrentEL register return a value of 0x2.

The System or Special-purpose registers for which accesses are trapped and reported using EC syndrome value 0x18 are as follows:

- Registers accessed using MRS or MSR with a name ending in _EL2, except the following:
  - SP_EL2.
  - If FEAT_MEC is implemented, MECID_A0_EL2, MECID_A1_EL2, MECID_P0_EL2, MECID_P1_EL2, MECIDR_EL2, VMECID_A_EL2, and VMECID_P_EL2.
- Registers accessed using MRS or MSR with a name ending in _EL12.
- Registers accessed using MRS or MSR with a name ending in _EL02.
- Special-purpose registers SPSR_irq, SPSR_abt, SPSR_und, and SPSR_fiq, accessed using MRS or MSR.
- Special-purpose register SP_EL1 accessed using the dedicated MRS or MSR instruction.

The instructions for which the execution is trapped and reported using EC syndrome value 0x18 are as follows:

- EL2 translation regime Address Translation instructions and TLB maintenance instructions.
- EL1 translation regime Address Translation instructions and TLB maintenance instructions that are accessible only from EL2 and EL3.

The execution of the ERET, ERETAA, and ERETAB instructions are trapped and reported using EC syndrome value 0x1A.

Note

The priority of this trap is higher than the priority of the HCR_EL2.API trap. If both of these bits are set so that EL1 execution of an ERETAA or ERETAB instruction is trapped to EL2, then the syndrome reported is 0x1A.

The execution of the SMC instructions in an implementation that does not include EL3 and when HCR_EL2.TSC is 1 are trapped and reported using EC syndrome value 0x17. HCR_EL2.TSC bit is not RES0 in this case.

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

API, bit [41]

When FEAT_PAuth is implemented:

Controls the use of instructions related to Pointer Authentication:

- PACGA.
- AUTDA, AUTDB, AUTDZA, AUTDZB, AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZA, AUTIZB.
- PACDA, PACDB, PACDZA, PACDZB, PACIA, PACIA1716, PACIASP, PACIAZ, PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZA, PACIZB.
- RETAA, RETAB, BRAA, BRAB, BLRAA, BLRAB, BRAAZ, BRABZ, BLRAAZ, BLRABZ.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ERETAA, ERETAB, LDRAA, and LDRAB.
- When FEAT_PAuth_LR is implemented, AUTIASPPC, AUTIASPPCR, AUTIA171615, AUTIBSPPC, AUTIBSPPCR, AUTIB171615, PACIASPPC, PACNBIASPPC, PACIA171615, PACIBSPPC, PACNBIBSPPC, PACIB171615, RETAASPPC, RETAASPPCR, RETABSPPC, RETABSPPCR.

This field is ignored if the instruction is disabled as a result of the SCTLR_ELx.{EnIB, EnIA, EnDA, EnDB} fields.

API	Meaning
`0b0`	The instructions related to Pointer Authentication are trapped to EL2 and reported using EC syndrome value `0x09`, when EL2 is enabled in the current Security state and the instructions are enabled for the EL1&0 translation regime, from: • When the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, EL0. • EL1. If the Effective value of HCR_EL2.NV is 1, the HCR_EL2.NV trap takes precedence over the HCR_EL2.API trap for the `ERETAA` and `ERETAB` instructions. If EL2 is implemented and enabled in the current Security state and the Effective value of HFGITR_EL2.ERET is 1, execution at EL1 using AArch64 of `ERETAA` or `ERETAB` instructions is reported with EC syndrome value `0x1A` with its associated ISS field, as the fine-grained trap has higher priority than the trap enabled by HCR_EL2.API == 0.
`0b1`	This control does not cause any instructions to be trapped.

If FEAT_PAuth is implemented but EL2 is not implemented or is disabled in the current Security state, the system behaves as if this bit is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APK, bit [40]

When FEAT_PAuth is implemented:

Trap registers holding “key” values for Pointer Authentication. Traps accesses to the following registers from EL1 to EL2, when EL2 is enabled in the current Security state, reported using EC syndrome value `0x18`:

- APIAKeyLo_EL1, APIAKeyHi_EL1, APIBKeyLo_EL1, APIBKeyHi_EL1, APDAKeyLo_EL1, APDAKeyHi_EL1, APDBKeyLo_EL1, APDBKeyHi_EL1, APGAKeyLo_EL1, and APGAKeyHi_EL1.

APK	Meaning
`0b0`	Access to the registers holding “key” values for pointer authentication from EL1 are trapped to EL2, when EL2 is enabled in the current Security state.
`0b1`	This control does not cause any instructions to be trapped.

Note

If FEAT_PAuth is implemented but EL2 is not implemented or is disabled in the current Security state, the system behaves as if this bit is 1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [39:38]

Reserved, RES0.

TEA, bit [37]

When FEAT_RAS is implemented:

Route synchronous External abort exceptions to EL2.

TEA	Meaning
0b0	Synchronous External abort exceptions are unaffected by this mechanism. That is, synchronous External abort exceptions are not taken to EL2 unless routed to EL2 by another control.
0b1	When executing at Exception levels below EL2, and EL2 is enabled in the current Security state, synchronous External abort exceptions are taken to EL2, unless they are routed to EL3.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TERR, bit [36]

When FEAT_RAS is implemented:

Trap accesses of Error Record registers. Enables a trap to EL2 on accesses of Error Record registers.

TERR	Meaning
0b0	Accesses of the specified Error Record registers are not trapped by this mechanism.
0b1	Accesses of the specified Error Record registers at EL1 are trapped to EL2, unless the instruction generates a higher priority exception.

In AArch64 state, the instructions affected by this control are:

- MRS and MSR accesses to ERRSELR_EL1, ERXADDR_EL1, ERXCTLR_EL1, ERXMISC0_EL1, ERXMISC1_EL1, and ERXSTATUS_EL1.
- MRS accesses to ERRIDR_EL1 and ERXFR_EL1.
- If FEAT_RASv1p1 is implemented, MRS and MSR accesses to ERXMISC2_EL1 and ERXMISC3_EL1.
- If FEAT_RASv2 is implemented, MRS accesses to ERXGSR_EL1.

In AArch32 state, the instructions affected by this control are:

- MRC and MCR accesses to ERRSELR, ERXADDR, ERXADDR2, ERXCTLR, ERXCTLR2, ERXMISC0, ERXMISC1, ERXMISC2, ERXMISC3, and ERXSTATUS.
- MRC accesses to ERRIDR, ERXFR, and ERXFR2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_RASv1p1 is implemented, MRC and MCR accesses to ERXMISC4, ERXMISC5, ERXMISC6, and ERXMISC7.

Unless the instruction generates a higher priority exception, trapped instructions generate an exception to EL2.

Trapped AArch64 instructions are reported using EC syndrome value 0x18.

Trapped AArch32 instructions are reported using EC syndrome value 0x03.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLOR, bit [35]

When FEAT_LOR is implemented:

Trap LOR registers. Traps Non-secure and Realm EL1 accesses to LORSA_EL1, LOREA_EL1, LORN_EL1, LORC_EL1, and LORID_EL1 registers to EL2.

TLOR	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Non-secure and Realm EL1 accesses to the LOR registers are trapped to EL2.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

E2H, bit [34]

When FEAT_VHE is implemented and FEAT_E2H0 is implemented:

EL2 Host. Enables a configuration where a Host Operating System is running at EL2, and the Host Operating System's applications are running at EL0.

E2H	Meaning
0b0	The facilities to support a Host Operating System at EL2 are disabled.
0b1	The facilities to support a Host Operating System at EL2 are enabled.

For information on the behavior of this bit see 'Behavior of HCR_EL2.E2H'.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This bit is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_VHE is implemented:

EL2 Host. Enables a configuration where a Host Operating System is running at EL2, and the Host Operating System's applications are running at EL0.

E2H	Meaning
0b1	The facilities to support a Host Operating System at EL2 are enabled.

This field is RES1, regardless of whether EL2 is enabled in the current Security state.

Otherwise:

Reserved, RES0.

ID, bit [33]

Stage 2 Instruction access cacheability disable. For the EL1&0 translation regime, when EL2 is enabled in the current Security state and HCR_EL2.VM==1, this control forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable.

ID	Meaning
0b0	This control has no effect on stage 2 of the EL1&0 translation regime.
0b1	Forces all stage 2 translations for instruction accesses to Normal memory to be Non-cacheable. This applies regardless of the value of HCR_EL2.FWB.

This bit has no effect on the EL2, EL2&0, or EL3 translation regimes.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

CD, bit [32]

Stage 2 Data access cacheability disable. For the EL1&0 translation regime, when EL2 is enabled in the current Security state and HCR_EL2.VM==1, this control forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable.

CD	Meaning
0b0	This control has no effect on stage 2 of the EL1&0 translation regime for data accesses and translation table walks.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CD	Meaning
0b1	Forces all stage 2 translations for data accesses and translation table walks to Normal memory to be Non-cacheable. This applies regardless of the value of HCR_EL2.FWB.

This bit has no effect on the EL2, EL2&0, or EL3 translation regimes.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

RW, bit [31]

When FEAT_AA32EL1 is implemented:

Execution state control for lower Exception levels:

RW	Meaning
0b0	Lower levels are all AArch32.
0b1	The Execution state for EL1 is AArch64. The Execution state for EL0 is determined by the current value of PSTATE.nRW when executing at EL0.

In an implementation that includes EL3, when EL2 is not enabled in Secure state, the PE behaves as if this bit has the same value as the SCR_EL3.RW bit for all purposes other than a direct read or write access of HCR_EL2.

The RW bit is permitted to be cached in a TLB.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 1.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RAO/WI.

TRVM, bit [30]

Trap Reads of Virtual Memory controls. Traps reads of the virtual memory control registers to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, EL1 accesses to the following registers are trapped to EL2 and reported using EC syndrome value 0x18 for MRS and 0x14 for MRRS:
  - SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, and CONTEXTIDR_EL1.
  - If FEAT_AIE is implemented, MAIR2_EL1 and AMAIR2_EL1.
  - If FEAT_S1PIE is implemented, PIRE0_EL1 and PIR_EL1.
  - If FEAT_S1POE is implemented, POR_EL0 and POR_EL1.
  - If FEAT_S2POE is implemented, S2POR_EL1.
  - If FEAT_TCR2 is implemented, TCR2_EL1.
  - If FEAT_SCTLR2 is implemented, SCTLR2_EL1.
- If the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and EL0 is using AArch64, EL0 accesses to the following registers are trapped to EL2 and reported using EC syndrome value 0x18 for MRS:
  - If FEAT_S1POE is implemented, POR_EL0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If EL1 is using AArch32, EL1 accesses using MRC to the following registers are trapped to EL2 and reported using EC syndrome value `0x03`, accesses using MRRC are trapped to EL2 and reported using EC syndrome value `0x04`:
  - SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, and CONTEXTIDR.

TRVM	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	Read accesses to the specified Virtual Memory control registers are trapped to EL2, when EL2 is enabled in the current Security state.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

EL2 provides a second stage of address translation, that a hypervisor can use to remap the address map defined by a Guest OS. In addition, a hypervisor can trap attempts by a Guest OS to write to the registers that control the memory system. A hypervisor might use this trap as part of its virtualization of memory management.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

HCD, bit [29]

When EL3 is not implemented:

HVC instruction disable. Disables EL1 and EL2 execution of HVC instructions, from both Execution states, when EL2 is enabled in the current Security state, reported using EC syndrome value `0x00`.

HCD	Meaning
`0b0`	HVC instruction execution is enabled at EL2 and EL1.
`0b1`	HVC instructions are UNDEFINED at EL2 and EL1. Any resulting exception is taken to the Exception level at which the HVC instruction is executed.

Note

HVC instructions are always UNDEFINED at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TDZ, bit [28]

Traps EL0 and EL1 execution of the following instructions to EL2, when EL2 is enabled in the current Security state, from AArch64 state only, reported using EC syndrome value `0x18`:

- DC ZVA.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- If FEAT_MTE is implemented, DC GVA and DC GZVA.

TDZ	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	In AArch64 state, any attempt to execute an instruction this trap applies to at EL1, or at EL0 when the instruction is not UNDEFINED at EL0, is trapped to EL2 when EL2 is enabled in the current Security state. Reading the DCZID_EL0 returns a value that indicates that the instructions this trap applies to are not supported.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TGE, bit [27]

Trap General Exceptions, from EL0.

TGE	Meaning
0b0	This control has no effect on execution at EL0.
0b1	When EL2 is not enabled in the current Security state, the Effective value of this field is 0 and this field have no effect on execution at EL0. When EL2 is enabled in the current Security state, in all cases: • All exceptions that would be routed to EL1 are routed to EL2. • If EL1 is using AArch64, the SCTLR_EL1.M field is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR_EL1. • If EL1 is using AArch32, the SCTLR.M field is treated as being 0 for all purposes other than returning the result of a direct read of SCTLR. • All virtual interrupts and virtual exceptions are disabled. • Any IMPLEMENTATION DEFINED mechanisms for signaling virtual interrupts are disabled. • An exception return to EL1 is treated as an illegal exception return. • The MDCR_EL2.{TDRA, TDOSA, TDA, TDE} fields are treated as being 1 for all purposes other than returning the result of a direct read of MDCR_EL2. In addition, when EL2 is enabled in the current Security state, if: • The Effective value of HCR_EL2.E2H is not 1, the Effective values of the HCR_EL2.{FMO, IMO, AMO} fields are 1. • The Effective value of HCR_EL2.E2H is 1, the Effective values of the HCR_EL2.{FMO, IMO, AMO} fields are 0. For further information on the behavior of this bit when the Effective value of E2H is 1, see 'Behavior of HCR_EL2.E2H'.

HCR_EL2.TGE must not be cached in a TLB.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TVM, bit [26]

Trap Virtual Memory controls. Traps writes to the virtual memory control registers to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, the following registers are trapped to EL2 and reported using EC syndrome value `0x18` for `MSR` and `0x14` for `MSRR`:
  - SCTLR_EL1, TTBR0_EL1, TTBR1_EL1, TCR_EL1, ESR_EL1, FAR_EL1, AFSR0_EL1, AFSR1_EL1, MAIR_EL1, AMAIR_EL1, and CONTEXTIDR_EL1.
  - If FEAT_AIE is implemented, MAIR2_EL1 and AMAIR2_EL1.
  - If FEAT_S1PIE is implemented, PIRE0_EL1 and PIR_EL1.
  - If FEAT_S1POE is implemented, POR_EL0 and POR_EL1.
  - If FEAT_S2POE is implemented, S2POR_EL1.
  - If FEAT_TCR2 is implemented, TCR2_EL1.
  - If FEAT_SCTLR2 is implemented, SCTLR2_EL1.
- If the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, and EL0 is using AArch64, EL0 accesses to the following registers are trapped to EL2 and reported using EC syndrome value `0x18` for `MSR`:
  - If FEAT_S1POE is implemented, POR_EL0.
- If EL1 is using AArch32, EL1 accesses using MCR to the following registers are trapped to EL2 and reported using EC syndrome value `0x03`, accesses using MCRR are trapped to EL2 and reported using EC syndrome value `0x04`:
  - SCTLR, TTBR0, TTBR1, TTBCR, TTBCR2, DACR, DFSR, IFSR, DFAR, IFAR, ADFSR, AIFSR, PRRR, NMRR, MAIR0, MAIR1, AMAIR0, AMAIR1, and CONTEXTIDR.

TVM	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	Write accesses to the specified Virtual Memory control registers are trapped to EL2, when EL2 is enabled in the current Security state.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TTLB, bit [25]

Trap TLB maintenance instructions. Traps execution of TLB maintenance instructions at EL1 to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, then the following instructions are trapped to EL2 and reported using EC syndrome value `0x18`:
  - TLBI VMALLE1, TLBI VAE1, TLBI ASIDE1, TLBI VAAE1, TLBI VALE1, and TLBI VAALE1.
  - TLBI VMALLE1IS, TLBI VAE1IS, TLBI ASIDE1IS, TLBI VAAE1IS, TLBI VALE1IS, and TLBI VAALE1IS.
  - If FEAT_TLBIOS is implemented, TLBI VMALLE1OS, TLBI VAE1OS, TLBI ASIDE1OS, TLBI VAAE1OS, TLBI VALE1OS, and TLBI VAALE1OS.
  - If FEAT_TLBIRANGE is implemented, TLBI RVAE1, TLBI RVAAE1, TLBI RVALE1, TLBI RVAALE1, TLBI RVAE1IS, TLBI RVAAE1IS, TLBI RVALE1IS, and TLBI RVAALE1IS.
  - If FEAT_TLBIOS and FEAT_TLBIRANGE are implemented, TLBI RVAE1OS, TLBI RVAAE1OS, TLBI RVALE1OS, and TLBI RVAALE1OS.
- If EL1 is using AArch32, then the following instructions are trapped to EL2 and reported using EC syndrome value `0x03`:
  - TLBIALLIS, TLBIMVAIS, TLBIASIDIS, TLBIMVAAIS, TLBIMVALIS, and TLBIMVAALIS.
  - TLBIALL, TLBIMVA, TLBIASID, TLBIMVAA, TLBIMVAL, and TLBIMVAAL

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ITLBIALL, ITLBIMVA, and ITLBIASID.
- DTLBIALL, DTLBIMVA, and DTLBIASID.

TTLB	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	EL1 execution of the specified TLB maintenance instructions are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

The TLB maintenance instructions are UNDEFINED at EL0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TPU, bit [24]

Trap cache maintenance instructions that operate to the Point of Unification. Traps execution of those cache maintenance instructions at EL0 and EL1 to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL0 is using AArch64 and the value of SCTLR_EL1.UCI is 1, then the following instructions at EL0 are trapped to EL2 and reported with EC syndrome value 0x18:
  - IC IVAU and DC CVAU.
- If EL1 is using AArch64, then the following instructions at EL1 are trapped to EL2 and reported with EC syndrome value 0x18:
  - IC IVAU, IC IALLU, IC IALLUIS, and DC CVAU.
- If EL1 is using AArch32, then the following instructions are trapped to EL2 and reported with EC syndrome value 0x03:
  - ICIMVAU, ICIALLU, ICIALLUIS, and DCCMVAU.

Note

When SCTLR_EL1.UCI is 0, the trap on execution of instructions at EL0 is higher priority than this control. An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- IC IALLUIS and IC IALLU are always UNDEFINED at EL0 using AArch64.
- ICIMVAU, ICIALLU, ICIALLUIS, and DCCMVAU are always UNDEFINED at EL0 using AArch32.

TPU	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	For each of the specified instructions, if the execution of the instruction can be trapped, access is trapped to EL2, when EL2 is enabled in the current Security state.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TPCP, bit [23]

Trap data or unified cache maintenance instructions that operate to the Point of Coherency, Persistence, or Physical Storage. When EL2 is enabled in the current Security state, traps execution of cache maintenance instructions at EL0 and EL1 to EL2 as follows:

- If EL0 is using AArch64 and the value of SCTLR_EL1.UCI is 1, then the following instructions at EL0 are trapped to EL2 and reported using EC syndrome value `0x18`:
  - DC CIVAC and DC CVAC.
  - If FEAT_MTE is implemented, DC CIGVAC, DC CIGDVAC, DC CGVAC, and DC CGDVAC.
  - If FEAT_DPB is implemented, DC CVAP.
  - If FEAT_DPB and FEAT_MTE are implemented, DC CGVAP and DC CGDVAP.
  - If FEAT_DPB2 is implemented, DC CVADP.
  - If FEAT_DPB2 and FEAT_MTE are implemented, DC CGVADP and DC CGDVADP.
- If FEAT_OCCMO is implemented, DC CIVAOC, DC CIGDVAOC, DC CVAOC and DC CGDVAOC.
- If EL1 is using AArch64, then the following instructions at EL1 are trapped to EL2 and reported using EC syndrome value `0x18`:
  - DC IVAC, DC CIVAC and DC CVAC.
  - If FEAT_MTE is implemented, DC CIGVAC, DC CIGDVAC, DC IGVAC, DC IGDVAC, DC CGVAC, and DC CGDVAC.
  - If FEAT_DPB is implemented, DC CVAP.
  - If FEAT_DPB and FEAT_MTE are implemented, DC CGVAP and DC CGDVAP.
  - If FEAT_DPB2 is implemented, DC CVADP.
  - If FEAT_DPB2 and FEAT_MTE are implemented, DC CGVADP and DC CGDVADP.
  - If FEAT_PoPS is implemented, DC CIVAPS.
  - If FEAT_PoPS and FEAT_MTE2 are implemented, DC CIGDVAPS.
- If FEAT_OCCMO is implemented, DC CIVAOC, DC CIGDVAOC, DC CVAOC and DC CGDVAOC.
- If EL1 is using AArch32, then the following instructions at EL1 are trapped to EL2 and reported using EC syndrome value `0x03`:
  - DCIMVAC, DCCIMVAC, and DCCMVAC.

Note

This field was previously named TPC.
When SCTLR_EL1.UCI is 0, the trap on execution of instructions at EL0 is higher priority than this control.
An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2. In addition:

- AArch64 instructions which invalidate by VA to the Point of Coherency or Physical Storage are always UNDEFINED at EL0 using AArch64.
- DCIMVAC, DCCIMVAC, and DCCMVAC are always UNDEFINED at EL0 using AArch32.

TPCP	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	For each of the specified instructions, if the execution of the instruction can be trapped, it is trapped to EL2, when EL2 is enabled in the current Security state.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TSW, bit [22]

Trap data or unified cache maintenance instructions that operate by Set/Way. Traps execution of those cache maintenance instructions at EL1 to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, then the following instructions are trapped to EL2 and reported with EC syndrome value `0x18`:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

  - DC ISW, DC CSW, and DC CISW.
  - If FEAT_MTE2 is implemented, DC IGSW, DC IGDSW, DC CGSW, DC CGDW, DC CIGSW, and DC CIGDSW.
- If EL1 is using AArch32, then the following instructions are trapped to EL2 and reported with EC syndrome value `0x03`:
  - DCISW, DCCSW, and DCCISW.

Note

An exception generated because an instruction is UNDEFINED at EL0 is higher priority than this trap to EL2, and these instructions are always UNDEFINED at EL0.

TSW	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	Execution of the specified instructions is trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TACR, bit [21]

Trap Auxiliary Control Registers. Traps EL1 accesses to the Auxiliary Control Registers to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, accesses to ACTLR_EL1 to EL2, are trapped to EL2 and reported using EC syndrome value `0x18`.
- If EL1 is using AArch32, accesses to ACTLR and, if implemented, ACTLR2 are trapped to EL2 and reported using EC syndrome value `0x03`.

TACR	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	EL1 accesses to the specified registers are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

Note

ACTLR_EL1 is not accessible at EL0.
ACTLR and ACTLR2 are not accessible at EL0.
The Auxiliary Control Registers are IMPLEMENTATION DEFINED registers that might implement global control bits for the PE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TIDCP, bit [20]

Trap IMPLEMENTATION DEFINED functionality. Traps EL1 accesses to the encodings reserved for IMPLEMENTATION DEFINED functionality to EL2, when EL2 is enabled in the current Security state as follows:

- In AArch64 state, EL1 access to the encodings in the following reserved encoding spaces are trapped:
  - IMPLEMENTATION DEFINED System instructions, which are accessed using SYS and SYSL, with CRn == {11, 15}, and are reported using EC syndrome value `0x18`.
  - IMPLEMENTATION DEFINED System instructions, which are accessed using SYSP, with CRn == {11, 15}, and are reported using EC syndrome value `0x14`.
  - IMPLEMENTATION DEFINED System registers, which are accessed using MRS and MSR with the S3_<op1>_<Cn>_<Cm>_<op2> register name, and are reported using EC syndrome `0x18`.
  - IMPLEMENTATION DEFINED System registers, which are accessed using MRRS and MSRR with the S3_<op1>_<Cn>_<Cm>_<op2> register name, and are reported using EC syndrome `0x14`.
- In AArch32 state, MCR and MRC access to instructions with the following encodings are trapped and reported using EC syndrome value `0x03`:
  - All coproc==p15, CRn==c9, opc1 == {0-7}, CRm == {c0-c2, c5-c8}, opc2 == {0-7}.
  - All coproc==p15, CRn==c10, opc1 ==={0-7}, CRm == {c0, c1, c4, c8}, opc2 == {0-7}.
  - All coproc==p15, CRn==c11, opc1==={0-7}, CRm == {c0-c8, c15}, opc2 == {0-7}.

For accesses to these regions of encoding space by EL0, all of the following apply:

- If FEAT_TIDCP1 is implemented, traps caused by SCTLR_EL1.TIDCP and SCTLR_EL2.TIDCP are reported with higher priority than traps caused by this control.
- If FEAT_TIDCP1 is not implemented, or the access is not trapped by SCTLR_ELx.TIDCP, one of the following applies:
  - If HCR_EL2.TIDCP is 0 then it is IMPLEMENTATION DEFINED, for each encoding, whether the access is performed, is UNDEFINED, or is trapped by an IMPLEMENTATION DEFINED mechanism.
  - If HCR_EL2.TIDCP is 1 then it is IMPLEMENTATION DEFINED, for each encoding, whether the access is trapped to EL2. If it is not trapped it is UNDEFINED.

TIDCP	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	EL1 accesses to or execution of the specified encodings reserved for IMPLEMENTATION DEFINED functionality are trapped to EL2, when EL2 is enabled in the current Security state.

An implementation can also include IMPLEMENTATION DEFINED registers that provide additional controls, to give finer-grained control of the trapping of IMPLEMENTATION DEFINED features.

Note

The trapping of accesses to these registers from EL1 is higher priority than an exception resulting from the register access being UNDEFINED.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TSC, bit [19]

Trap `SMC` instructions. Traps EL1 execution of `SMC` instructions to EL2, when EL2 is enabled in the current Security state.

If execution is in AArch64 state, the trap is reported using EC syndrome value `0x17`.

If execution is in AArch32 state, the trap is reported using EC syndrome value `0x13`.

Note

HCR_EL2.TSC traps execution of the `SMC` instruction. It is not a routing control for the `SMC` exception. Trap exceptions and `SMC` exceptions have different preferred return addresses.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TSC	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	If EL3 is implemented, then any attempt to execute an SMC instruction at EL1 is trapped to EL2, when EL2 is enabled in the current Security state, regardless of the value of SCR_EL3.SMD. If EL3 is not implemented and the Effective value of HCR_EL2.NV is 1, then any attempt to execute an SMC instruction at EL1 using AArch64 is trapped to EL2. If EL3 is not implemented and the Effective value of HCR_EL2.NV is 0, then it is IMPLEMENTATION DEFINED whether: • Any attempt to execute an SMC instruction at EL1 is trapped to EL2, when EL2 is enabled in the current Security state. • Any attempt to execute an SMC instruction is UNDEFINED.

In AArch32 state, the Armv8-A architecture permits, but does not require, this trap to apply to conditional SMC instructions that fail their condition code check, in the same way as with traps on other conditional instructions.

SMC instructions are UNDEFINED at EL0.

If EL3 is not implemented and the Effective value of HCR_EL2.NV is 0, then it is IMPLEMENTATION DEFINED whether this bit is:

- RES0.
- Implemented with the functionality as described in HCR_EL2.TSC.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID3, bit [18]

Trap ID group 3. Traps EL1 reads of group 3 ID registers to EL2, when EL2 is enabled in the current Security state, as follows:

In AArch64 state:

- Reads of the following registers are trapped to EL2, reported using EC syndrome value 0x18:
  - ID_PFR0_EL1, ID_PFR1_EL1, ID_DFR0_EL1, ID_AFR0_EL1, ID_MMFR0_EL1, ID_MMFR1_EL1, ID_MMFR2_EL1, ID_MMFR3_EL1, ID_ISAR0_EL1, ID_ISAR1_EL1, ID_ISAR2_EL1, ID_ISAR3_EL1, ID_ISAR4_EL1, ID_ISAR5_EL1, MVFR0_EL1, MVFR1_EL1, and MVFR2_EL1.
  - ID_AA64PFR0_EL1, ID_AA64PFR1_EL1, ID_AA64DFR0_EL1, ID_AA64DFR1_EL1, ID_AA64ISAR0_EL1, ID_AA64ISAR1_EL1, ID_AA64MMFR0_EL1, ID_AA64MMFR1_EL1, ID_AA64AFR0_EL1, and ID_AA64AFR1_EL1.
  - If FEAT_FGT is implemented, reads of the following registers are trapped to EL2. If FEAT_FGT is not implemented, reads of the following registers are trapped to EL2, unless the registers are implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses are trapped to EL2.
    - ID_PFR2_EL1, ID_MMFR4_EL1 and ID_MMFR5_EL1.
    - ID_AA64MMFR3_EL1.
    - ID_AA64MMFR4_EL1.
    - ID_AA64PFR2_EL1.
    - ID_AA64MMFR2_EL1 and ID_ISAR6_EL1.
    - ID_DFR1_EL1.
    - ID_AA64ZFR0_EL1.
    - ID_AA64SMFR0_EL1.
    - ID_AA64ISAR2_EL1.
  - If FEAT_FGT is implemented, this field traps all MRS accesses to registers in the following range that are not already mentioned in this field description: op0 == 3, op1 == 0, CRn == 0, CRm == {2-7}, op2

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

== {0-7}. If FEAT_FGT is not implemented, it is IMPLEMENTATION DEFINED whether this field traps accesses to registers in the range.

In AArch32 state:

- VMRS access to MVFR0, MVFR1, and MVFR2, are trapped to EL2, reported using EC syndrome value `0x08`, unless access is also trapped by HCPTR which takes priority.
- MRC access to the following registers are trapped to EL2, reported using EC syndrome value `0x03`:
  - ID_PFR0, ID_PFR1, ID_PFR2, ID_DFR0, ID_AFR0, ID_MMFR0, ID_MMFR1, ID_MMFR2, ID_MMFR3, ID_ISAR0, ID_ISAR1, ID_ISAR2, ID_ISAR3, ID_ISAR4, and ID_ISAR5.
  - If FEAT_FGT is implemented:
    - ID_MMFR4 and ID_MMFR5.
    - ID_ISAR6.
    - ID_DFR1.
    - This field traps all MRC accesses to encodings in the following range that are not already mentioned in this field description: coproc == p15, opc1 == 0, CRn == c0, CRm == {c2-c7}, opc2 == {0-7}.
  - If FEAT_FGT is not implemented:
    - ID_MMFR4 and ID_MMFR5 are trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to ID_MMFR4 or ID_MMFR5 are trapped.
    - ID_ISAR6 is trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to ID_ISAR6 are trapped to EL2.
    - ID_DFR1 is trapped to EL2, unless implemented as RAZ, when it is IMPLEMENTATION DEFINED whether accesses to ID_DFR1 are trapped to EL2.
    - Otherwise, it is IMPLEMENTATION DEFINED whether this bit traps all MRC accesses to registers in the following range not already mentioned in this field description with coproc == p15, opc1 == 0, CRn == c0, CRm == {c2-c7}, opc2 == {0-7}.

TID3	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	The specified EL1 read accesses to ID group 3 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID2, bit [17]

Trap ID group 2. Traps the following register accesses to EL2, when EL2 is enabled in the current Security state, as follows:

- If EL1 is using AArch64, reads of CTR_EL0, CCSIDR_EL1, CCSIDR2_EL1, CLIDR_EL1, and CSSELR_EL1 are trapped to EL2, reported using EC syndrome value `0x18`.
- If EL0 is using AArch64 and the value of SCTLR_EL1.UCT is not 0, reads of CTR_EL0 are trapped to EL2, reported using EC syndrome value `0x18`. If the value of SCTLR_EL1.UCT is 0, then EL0 reads of CTR_EL0 are trapped to EL1 and the resulting exception takes precedence over this trap.
- If EL1 is using AArch64, writes to CSSELR_EL1 are trapped to EL2, reported using EC syndrome value `0x18`.
- If EL1 is using AArch32, reads of CTR, CCSIDR, CCSIDR2, CLIDR, and CSSELR are trapped to EL2, reported using EC syndrome value `0x03`.
- If EL1 is using AArch32, writes to CSSELR are trapped to EL2, reported using EC syndrome value `0x03`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TID2	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	The specified EL1 and EL0 accesses to ID group 2 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID1, bit [16]

Trap ID group 1. Traps EL1 reads of the following registers to EL2, when EL2 is enabled in the current Security state as follows:

- In AArch64 state, accesses of REVIDR_EL1 and AIDR_EL1, reported using EC syndrome value 0x18.
- When FEAT_SME is implemented, accesses of SMIDR_EL1, reported using EC syndrome value 0x18.
- In AArch32 state, accesses of TCMTR, TLBTR, REVIDR, and AIDR, reported using EC syndrome value 0x03.

TID1	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	The specified EL1 read accesses to ID group 1 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TID0, bit [15]

When FEAT_AA32 is implemented:

Trap ID group 0. Traps the following register accesses to EL2:

- EL1 reads of the JIDR, reported using EC syndrome value 0x05.
- If the JIDR is RAZ from EL0, EL0 reads of the JIDR, reported using EC syndrome value 0x05.
- EL1 accesses using VMRS of the FPSID, reported using EC syndrome value 0x08.

Note

- It is IMPLEMENTATION DEFINED whether the JIDR is RAZ or UNDEFINED at EL0. If it is UNDEFINED at EL0, then any resulting exception takes precedence over this trap.
- The FPSID is not accessible at EL0 using AArch32.
- Writes to the FPSID are ignored, and not trapped by this control.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TID0	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	The specified EL1 read accesses to ID group 0 registers are trapped to EL2, when EL2 is enabled in the current Security state.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TWE, bit [14]

Traps EL0 and EL1 execution of WFE instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states, reported using EC syndrome value 0x01.

When FEAT_WFxT is implemented, this trap also applies to the WFET instruction.

TWE	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Any attempt to execute a WFE instruction at EL1 or EL0 is trapped to EL2, when EL2 is enabled in the current Security state, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWE or SCTLR_EL1.nTWE.

In AArch32 state, the attempted execution of a conditional WFE instruction is trapped only if the instruction passes its condition code check.

Note

Since a WFE can complete at any time, even without a Wakeup event, the traps on WFE are not guaranteed to be taken, even if the WFE is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

For more information about when WFE instructions can cause the PE to enter a low-power state, see ‘Wait for Event mechanism and Send event’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

TWI, bit [13]

Traps EL0 and EL1 execution of WFI instructions to EL2, when EL2 is enabled in the current Security state, from both Execution states, reported using EC syndrome value 0x01.

When FEAT_WFxT is implemented, this trap also applies to the WFIT instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TWI	Meaning
0b0	This control does not cause any instructions to be trapped.
0b1	Any attempt to execute a WFI instruction at EL0 or EL1 is trapped to EL2, when EL2 is enabled in the current Security state, if the instruction would otherwise have caused the PE to enter a low-power state and it is not trapped by SCTLR.nTWI or SCTLR_EL1.nTWI.

In AArch32 state, the attempted execution of a conditional WFI instruction is trapped only if the instruction passes its condition code check.

Note

Since a WFI can complete at any time, even without a Wakeup event, the traps on WFI are not guaranteed to be taken, even if the WFI is executed when there is no Wakeup event. The only guarantee is that if the instruction does not complete in finite time in the absence of a Wakeup event, the trap will be taken.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

For more information about when WFI instructions can cause the PE to enter a low-power state, see 'Wait for Interrupt'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

DC, bit [12]

Default Cacheability.

DC	Meaning
0b0	This control has no effect on the EL1&0 translation regime.
0b1	In any Security state: • When EL1 is using AArch64, the PE behaves as if the value of the SCTLR_EL1.M field is 0 for all purposes other than returning the value of a direct read of SCTLR_EL1. • When EL1 is using AArch32, the PE behaves as if the value of the SCTLR.M field is 0 for all purposes other than returning the value of a direct read of SCTLR. • The PE behaves as if the value of the HCR_EL2.VM field is 1 for all purposes other than returning the value of a direct read of HCR_EL2. • The memory type produced by stage 1 of the EL10 translation regime is Normal Non-Shareable, Inner Write-Back Read-Allocate Write-Allocate, Outer Write-Back Read-Allocate Write-Allocate.

This field has no effect on the EL2, EL2&0, and EL3 translation regimes.

This bit is permitted to be cached in a TLB.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

BSU, bits [11:10]

Barrier Shareability upgrade. This field determines the minimum shareability domain that is applied to any barrier instruction executed from EL1 or EL0:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BSU	Meaning
0b00	No effect.
0b01	Inner Shareable.
0b10	Outer Shareable.
0b11	Full system.

This value is combined with the specified level of the barrier held in its instruction, using the same principles as combining the shareability attributes from two stages of address translation.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FB, bit [9]

Force broadcast. Causes the following Non-shareable invalidate instructions to be broadcast within the Inner Shareable domain when executed from EL1:

- In AArch32 state: BPIALL, TLBIALL, TLBIMVA, TLBIASID, DTLBIALL, DTLBIMVA, DTLBIASID, ITLBIALL, ITLBIMVA, ITLBIASID, TLBIMVAA, ICIALLU, TLBIMVAL, and TLBIMVAAL.
- In AArch64 state:
  - All `TLBI` instructions that are executable at EL1 and do not specify IS or OS.
  - All `TLBIP` instructions that are executable at EL1 and do not specify IS or OS.
  - `IC IALLU`.

For more information, see ‘A64 System instructions for TLB maintenance’.

FB	Meaning
0b0	The specified instructions are not affected by this control.
0b1	When one of the specified Non-shareable instructions is executed at EL1, the operation is broadcast within the Inner Shareable shareability domain.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VSE, bit [8]

Virtual SError exception.

VSE	Meaning
0b0	This mechanism is not making a virtual SError exception pending.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	A virtual SError exception is pending because of this mechanism.

The virtual SError exception is enabled only when HCR_EL2.TGE is 0 and either HCR_EL2.AMO is 1 or FEAT_DoubleFault2 is implemented and the Effective value of HCRX_EL2.TMEA is 1.

When FEAT_E3DSE is implemented, virtual SError exceptions pended by this field have priority over delegated SError exceptions pended by SCR_EL3.DSE.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VI, bit [7]

Virtual IRQ Interrupt.

VI	Meaning
0b0	This mechanism is not making a virtual IRQ pending.
0b1	A virtual IRQ is pending because of this mechanism.

The virtual IRQ is enabled only when the value of HCR_EL2.{TGE, IMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VF, bit [6]

Virtual FIQ Interrupt.

VF	Meaning
0b0	This mechanism is not making a virtual FIQ pending.
0b1	A virtual FIQ is pending because of this mechanism.

The virtual FIQ is enabled only when the value of HCR_EL2.{TGE, FMO} is {0, 1}.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

AMO, bit [5]

Physical SError exception routing.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AMO	Meaning
0b0	When executing at Exception levels below EL3 and the Effective value of HCR_EL2.TGE is 0: • The routing of physical SError exceptions is unaffected by this mechanism. • If FEAT_E3DSE is implemented, then delegated SError exceptions enabled by SCR_EL3.DSE are not taken to EL2. • Virtual SError exceptions are not enabled by this mechanism.
0b1	When executing at Exception levels below EL3, EL2 is enabled in the current Security state, and the Effective value of HCR_EL2.TGE is 0: • Physical SError exceptions are taken to EL2, unless they are routed to EL3. • If FEAT_E3DSE is implemented, then delegated SError exceptions enabled by SCR_EL3.DSE are taken to EL2. • Virtual SError exceptions are enabled.

When executing at EL3, the value of HCR_EL2.AMO has no impact on the behavior of the PE.

When executing at Exception levels below EL3, and EL2 is not enabled in the current Security state, the Effective value of HCR_EL2.AMO is 0.

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the AMO bit, all of the following are true:

- Physical SError exceptions target EL2 unless they are routed to EL3.
- If FEAT_E3DSE is implemented, delegated SError exceptions target EL2.
- Virtual SError exceptions are disabled.

When executing at EL2 and the Effective value of HCR_EL2.{E2H, TGE} is {1, 0}, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.AMO is 1 or the value programmed.

For more information, see ‘Asynchronous exception routing’.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

IMO, bit [4]

Physical IRQ Routing.

IMO	Meaning
0b0	When executing at Exception levels below EL3 and the Effective value of HCR_EL2.TGE is 0: • Physical IRQ interrupts are not taken to EL2. • Virtual IRQ interrupts are disabled.
0b1	When executing at Exception levels below EL3, EL2 is enabled in the current Security state, and the Effective value of HCR_EL2.TGE is 0: • Physical IRQ exceptions are taken to EL2, unless they are routed to EL3. • Virtual IRQ interrupts are enabled.

When executing at EL3, the Effective value of HCR_EL2.IMO has no impact on the behavior of the PE.

When executing at Exception levels below EL3, and EL2 is not enabled in the current Security state, the Effective value of HCR_EL2.IMO is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the IMO bit, all of the following are true:

- Physical IRQ Interrupts target EL2 unless they are routed to EL3.
- Virtual IRQ interrupts are disabled.

When executing at EL2 and the Effective value of HCR_EL2.{E2H, TGE} is {1, 0}, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.IMO is 1 or the value programmed.

For more information, see 'Asynchronous exception routing'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

FMO, bit [3]

Physical FIQ Routing.

FMO	Meaning
`0b0`	When executing at Exception levels below EL3 and the Effective value of HCR_EL2.TGE is 0: • Physical FIQ interrupts are not taken to EL2. • Virtual FIQ interrupts are disabled.
`0b1`	When executing at Exception levels below EL3, EL2 is enabled in the current Security state, and the Effective value of HCR_EL2.TGE is 0: • Physical FIQ exceptions are taken to EL2, unless they are routed to EL3. • Virtual FIQ interrupts are enabled.

When executing at EL3, the Effective value of HCR_EL2.FMO has no impact on the behavior of the PE.

When executing at Exception levels below EL3, and EL2 is not enabled in the current Security state, the Effective value of HCR_EL2.FMO is 0.

When the Effective value of HCR_EL2.TGE is 1, regardless of the value of the FMO bit, all of the following are true:

- Physical FIQ Interrupts target EL2 unless they are routed to EL3.
- Virtual FIQ interrupts are disabled.

When executing at EL2 and the Effective value of HCR_EL2.{E2H, TGE} is {1, 0}, it is IMPLEMENTATION DEFINED whether the Effective value of HCR_EL2.FMO is 1 or the value programmed.

For more information, see 'Asynchronous exception routing'.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

PTW, bit [2]

Protected Table Walk. In the EL1&0 translation regime, a translation table access made as part of a stage 1 translation table walk is subject to a stage 2 translation. The combining of the memory type attributes from the two stages of translation means the access might be made to a type of Device memory. If this occurs, then the value of this bit determines the behavior:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PTW	Meaning
0b0	The translation table walk occurs as if it is to Normal Non-cacheable memory. This means it can be made speculatively.
0b1	The memory access generates a stage 2 Permission fault.

This bit is permitted to be cached in a TLB.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

SWIO, bit [1]

Set/Way Invalidation Override. Causes EL1 execution of the data cache invalidate by set/way instructions to perform a data cache clean and invalidate by set/way:

SWIO	Meaning
0b0	This control has no effect on the operation of data cache invalidate by set/way instructions.
0b1	Data cache invalidate by set/way instructions perform a data cache clean and invalidate by set/way.

When the value of this bit is 1:

AArch32: DCISW performs the same invalidation as a DCCISW instruction.

AArch64: DC ISW performs the same invalidation as a DC CISW instruction.

This bit can be implemented as RES1.

When HCR_EL2.TGE is 1, the PE ignores the value of this field for all purposes other than a direct read of this field.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

VM, bit [0]

Virtualization enable. Enables stage 2 address translation for the EL1&0 translation regime, when EL2 is enabled in the current Security state.

VM	Meaning
0b0	EL1&0 stage 2 address translation disabled.
0b1	EL1&0 stage 2 address translation enabled.

When the value of this bit is 1, data cache invalidate instructions executed at EL1 perform a data cache clean and invalidate. For the invalidate by set/way instruction this behavior applies regardless of the value of the HCR_EL2.SWIO bit.

This bit is permitted to be cached in a TLB.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, the Effective value of this field is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Accessing HCR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HCR_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b000

```
if !IsFeatureImplemented(FEAT_AA64) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if EffectiveHCR_EL2_NVx() IN {'1x1'} then
        X{64}(t) = NVMem(0x078);
    elsif EffectiveHCR_EL2_NVx() IN {'xx1'} then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        Undefined();
    end;
elsif PSTATE.EL == EL2 then
    X{64}(t) = HCR_EL2();
elsif PSTATE.EL == EL3 then
    X{64}(t) = HCR_EL2();
end;
```

```
MSR HCR_EL2, <Xt>
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0001	0b000

```
if !IsFeatureImplemented(FEAT_AA64) then
    Undefined();
elsif PSTATE.EL == EL0 then
    Undefined();
elsif PSTATE.EL == EL1 then
    if EffectiveHCR_EL2_NVx() IN {'1x1'} then
        NVMem(0x078) = X{64}(t);
    elsif EffectiveHCR_EL2_NVx() IN {'xx1'} then
        AArch64_SystemAccessTrap(EL2, 0x18);
    else
        Undefined();
    end;
elsif PSTATE.EL == EL2 then
    HCR_EL2() = X{64}(t);
elsif PSTATE.EL == EL3 then
    HCR_EL2() = X{64}(t);
end;
```

D24.2.62 HCRX_EL2, Extended Hypervisor Configuration Register

The HCRX_EL2 characteristics are:

Purpose

Provides configuration controls for virtualization, including defining whether various operations are trapped to EL2.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_HCX is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HCRX_EL2 are UNDEFINED.

Attributes

HCRX_EL2 is a 64-bit register.

Field descriptions

Bits [63:27]

Reserved, RES0.

SRMASKEn, bit [26]

When FEAT_SRMASK is implemented:

If EL1 is using AArch64, accesses to the following registers are trapped to EL2 and reported using EC syndrome value `0x18`:

- CPACRMASK_EL1.
- SCTLRMASK_EL1.
- SCTLR2MASK_EL1.
- TCRMASK_EL1.
- TCR2MASK_EL1.
- ACTLRMASK_EL1, if it is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SRMASKEn	Meaning
0b0	EL1 accesses to the specified EL1 registers are trapped to EL2. The values in the registers are treated as 0.
0b1	This control does not cause any instructions to be trapped.

Traps generated by this control have a lower priority than traps generated by the HFGRTR2_EL2 and HFGWTR2_EL2 controls.

When EL2 is not implemented or not enabled in the current Security state, the Effective value of this field is 1.

Otherwise, when the Effective value of SCR_EL3.HXEn is 0, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [25]

Reserved, RES0.

PACMEn, bit [24]

When FEAT_PAuth_LR is implemented:

PACM Enable. Controls the effect of a PACM instruction at EL1 and EL0.

PACMEn	Meaning
0b0	The effects of PACM are disabled at EL1 and EL0, regardless of the value in any other controls.
0b1	This control does not disable the effect of PACM at EL1 and EL0.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EnFPM, bit [23]

When FEAT_FPMR is implemented:

Enables direct and indirect accesses to FPMR from EL0 and EL1.

When accesses to FPMR are disabled by this control:

- Direct accesses to FPMR from EL0 and EL1 are trapped to EL2 and reported using EC syndrome value `0x18`.
- Execution of FP8 data-processing instructions that indirectly access FPMR is UNDEFINED at EL0 and EL1.

EnFPM	Meaning
`0b0`	Direct and indirect accesses to FPMR are disabled at EL1 and EL0.
`0b1`	This control does not cause any instructions to be trapped.

Traps are not taken if there is a higher priority exception generated by the access.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

GCSEn, bit [22]

When FEAT_GCS is implemented:

Guarded Control Stack enable. Controls Guarded Control Stack behavior at EL1 and EL0.

GCSEn	Meaning
`0b0`	The Guarded Control Stack is disabled at EL1 and EL0.
`0b1`	Guarded Control Stack behavior at EL1 and EL0 is not affected by mechanism.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnIDCP128, bit [21]

When FEAT_SYSREG128 is implemented:

Enables access to IMPLEMENTATION DEFINED 128-bit System registers.

EnIDCP128	Meaning
`0b0`	Accesses at EL1, EL0 to IMPLEMENTATION DEFINED 128-bit System registers are trapped to EL2 using EC syndrome value `0x14`, unless the access generates a higher priority exception. Disables the functionality of the 128-bit IMPLEMENTATION DEFINED System registers that are accessible at EL2.
`0b1`	No accesses are trapped by this control.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnSDERR, bit [20]

When FEAT_ADERR is implemented:

Enable Synchronous Device Read Error. Override SCTLR2_EL1.EnADERR.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EnSDERR	Meaning
0b0	This field has no effect on External aborts on Device memory reads in the EL1&0 translation regime.
0b1	External abort on Device memory reads generate synchronous Data Abort exceptions in the EL1&0 translation regime.

Implementation-specific exceptions to applications of this field are described in 'Taking error exceptions'.

Setting this field to 1 does not guarantee that the PE is able to take a synchronous Data Abort exception for an External abort on a Device memory read in every case. There might be implementation-specific circumstances when an error on a load cannot be taken synchronously. These circumstances should be rare enough that treating such occurrences as fatal does not cause a significant increase in failure rate.

If FEAT_SVE is implemented, HCRX_EL2.EnSDERR is 1, and the access generating the External abort is due to any Active element of an SVE Non-fault vector load instruction or an Active element that is not the First active element of an SVE First-fault vector load instruction, then no exception is generated and the External abort is reported in the FFR.

Setting this field to 1 might have a performance impact for Device memory reads.

This field is ignored by the PE and has an Effective value of 0 when any of the following are true:

- All of the following are true:
  - FEAT_ANERR is implemented.
  - ID_AA64MMFR3_EL1.ADERR reads as `0b0010`.
  - HCRX_EL2.{EnSDERR, EnSNERR} == {1, 0}.
- The Effective value of SCR_EL3.HXEn is 0.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.
- EL2 is not implemented or not enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TMEA, bit [19]

When FEAT_DoubleFault2 is implemented:

Trap Masked External Aborts. Controls whether a masked error exception at a lower Exception level is taken to EL2.

TMEA	Meaning
0b0	Synchronous External abort exceptions, physical SError exceptions, and delegated SError exceptions at EL1 and EL0 are unaffected by this mechanism. That is, these exceptions are not taken to EL2 unless routed to EL2 by another control. Virtual SError exceptions are not enabled by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TMEA	Meaning
0b1	When executing at Exception levels below EL2, if EL2 is enabled in the current Security state, then all of the following apply: • When PSTATE.A is 1, synchronous External abort exceptions are taken to EL2, unless they are routed to EL3. • Masked physical SError exceptions are taken to EL2, unless they are routed to EL3. • If FEAT_E3DSE is implemented, then masked delegated SError exceptions enabled by SCR_EL3.DSE are taken to EL2. • If HCR_EL2.TGE is 0, then virtual SError exceptions are enabled.

The Effective value of this field is 0 when any of the following are true:

- The Effective value of SCR_EL3.HXEn is 0.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.
- EL2 is not implemented or not enabled in the current Security state.

Virtual SError exceptions are disabled when the Effective value of HCR_EL2.AMO is 0 and the Effective value of HCRX_EL2.TMEA is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnSNERR, bit [18]

When FEAT_ANERR is implemented:

Enable Synchronous Normal Read Error. Override SCTLR2_EL1.EnANERR.

EnSNERR	Meaning
0b0	This field has no effect on External aborts on Normal memory reads in the EL1&0 translation regime.
0b1	External abort on Normal memory reads generate synchronous Data Abort exceptions in the EL1&0 translation regime.

Implementation-specific exceptions to applications of this field are described in ‘Taking error exceptions’.

Setting this field to 1 does not guarantee that the PE is able to take a synchronous Data Abort exception for an External abort on a Normal memory read in every case. There might be implementation-specific circumstances when an error on a load cannot be taken synchronously. These circumstances should be rare enough that treating such occurrences as fatal does not cause a significant increase in failure rate.

If FEAT_SVE is implemented, HCRX_EL2.EnSNERR is 1, and the access generating the External abort is due to any Active element of an SVE Non-fault vector load instruction or an Active element that is not the First active element of an SVE First-fault vector load instruction, then no exception is generated and the External abort is reported in the FFR.

Setting this field to 1 might have a performance impact for Normal memory reads.

This field is ignored by the PE and has an Effective value of 0 when any of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- All of the following are true:
  - FEAT_ADERR is implemented.
  - ID_AA64MMFR3_EL1.ANERR reads as `0b0010`.
  - HCRX_EL2.{EnSDERR, EnSNERR} == {0, 1}.
- The Effective value of SCR_EL3.HXEn is 0.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.
- EL2 is not implemented or not enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D128En, bit [17]

When FEAT_D128 is implemented:

128-bit System Register trap control. Enable access to 128-bit System Registers that relate to VMSAv9-128 using `MRRS`, `MSRR` instructions.

If EL1 is using AArch64, accesses to the following registers are trapped to EL2 and reported using EC syndrome value `0x14`:

- TTBR0_EL1.
- TTBR1_EL1.
- If FEAT_THE is implemented, RCWMASK_EL1, RCWSMASK_EL1.
- PAR_EL1.

D128En	Meaning
`0b0`	EL1 accesses to the specified registers are disabled, and trapped to EL2.
`0b1`	This control does not cause any instructions to be trapped.

When EL2 is not implemented or not enabled in the current Security state, the Effective value of this field is 1.

Otherwise, when the Effective value of SCR_EL3.HXEn is 0, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PTTWI, bit [16]

When FEAT_THE is implemented:

Permit Translation Table Walk Incoherence.

Permits RCWS instructions to generate writes that have the Reduced Coherence property.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PTTWI	Meaning
0b0	Write accesses generated by RCWS at EL1 and EL0 do not have the Reduced Coherence property.
0b1	Write accesses generated by RCWS at EL1 and EL0 have the Reduced Coherence property, if enabled by TCR2_EL1.PTTWI.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

This field is permitted to be cached in TLB.

This field is permitted to be implemented as a read-only field with a fixed value of 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SCTLR2En, bit [15]

When FEAT_SCTLR2 is implemented:

SCTLR2_EL1 Enable. In AArch64 state, accesses to SCTLR2_EL1 are trapped to EL2 and reported using EC syndrome value `0x18`.

SCTLR2En	Meaning
0b0	Accesses to SCTLR2_EL1 at EL1 are trapped to EL2, unless the access generates a higher priority exception. The value in SCTLR2_EL1 is treated as 0.
0b1	This control does not cause any instructions to be trapped.

When EL2 is not implemented or not enabled in the current Security state, the Effective value of this field is 1.

Otherwise, when the Effective value of SCR_EL3.HXEn is 0, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TCR2En, bit [14]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_TCR2 is implemented:

TCR2_EL1 Enable. In AArch64 state, accesses to TCR2_EL1 are trapped to EL2 and reported using EC syndrome value `0x18`.

TCR2En	Meaning
`0b0`	Accesses to TCR2_EL1 at EL1 are trapped to EL2, unless the access generates a higher priority exception. The value in TCR2_EL1 is treated as 0.
`0b1`	This control does not cause any instructions to be trapped.

When EL2 is not implemented or not enabled in the current Security state, the Effective value of this field is 1.

Otherwise, when the Effective value of SCR_EL3.HXEn is 0, the Effective value of this field is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [13:12]

Reserved, RES0.

MSCEn, bit [11]

When FEAT_MOPS is implemented:

Memory Set and Memory Copy instructions Enable. Enables execution of the CPY*, SETG*, SETP*, SETM*, and SETE* instructions at EL1 or EL0.

MSCEn	Meaning
`0b0`	Execution of the Memory Copy and Memory Set instructions is UNDEFINED at EL1 or EL0.
`0b1`	This control does not cause any instructions to be UNDEFINED.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

MCE2, bit [10]

When FEAT_MOPS is implemented:

Controls Memory Copy and Memory Set exceptions generated as part of attempting to execute the Memory Copy and Memory Set instructions from EL1.

MCE2	Meaning
0b0	Memory Copy and Memory Set exceptions generated from EL1 are taken to EL1.
0b1	Memory Copy and Memory Set exceptions generated from EL1 are taken to EL2.

The Effective value of this field is 0 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CMOW, bit [9]

When FEAT_CMOW is implemented:

Controls the required permissions for the following cache maintenance instructions executed at EL1 or EL0:

- Any DC instruction that operates by VA and performs a clean and invalidate operation.
- Any IC instruction that operates by VA.

CMOW	Meaning
0b0	This control does not cause any instructions to generate a stage 2 Permission fault.
0b1	For these instructions, when executed at EL1 or EL0, the absence of stage 2 write permission generates a stage 2 permission fault.

For more information, see:

- Stage 2 permissions.
- Implications of enabling the dirty state management mechanism.

The Effective value of this field is 0 when any of the following are true:

- The Effective value of SCR_EL3.HXEn is 0.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.
- EL2 is not implemented or not enabled in the current Security state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

This field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VFNMI, bit [8]

When FEAT_NMI is implemented:

Virtual FIQ Interrupt with Superpriority. Enables signaling of virtual FIQ interrupts with Superpriority.

VFNMI	Meaning
`0b0`	When HCR_EL2.VF is 1, a signaled pending virtual FIQ interrupt does not have Superpriority.
`0b1`	When HCR_EL2.VF is 1, a signaled pending virtual FIQ interrupt has Superpriority.

When HCR_EL2.VF is 0, this field has no effect.

The Effective value of this field is 0 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VINMI, bit [7]

When FEAT_NMI is implemented:

Virtual IRQ Interrupt with Superpriority. Enables signaling of virtual IRQ interrupts with Superpriority.

VINMI	Meaning
`0b0`	When HCR_EL2.VI is 1, a signaled pending virtual IRQ interrupt does not have Superpriority.
`0b1`	When HCR_EL2.VI is 1, a signaled pending virtual IRQ interrupt has Superpriority.

When HCR_EL2.VI is 0, this field has no effect.

The Effective value of this field is 0 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TALLINT, bit [6]

When FEAT_NMI is implemented:

Traps the following writes at EL1 using AArch64 to EL2, when EL2 is implemented and enabled:

- MSR (register) writes of ALLINT.
- MSR (immediate) writes of ALLINT with a value of 1.

TALLINT	Meaning
`0b0`	This control does not cause any instructions to be trapped.
`0b1`	The specified MSR accesses at EL1 using AArch64 are trapped to EL2.

The Effective value of this field is 0 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SMPME, bit [5]

When FEAT_SME is implemented:

Streaming Mode Priority Mapping Enable.

Controls mapping of the value of SMPRI_EL1.Priority for streaming execution priority at EL0 or EL1.

SMPME	Meaning
`0b0`	The effective priority value is taken from SMPRI_EL1.Priority.
`0b1`	The effective priority value is: • When the current Exception level is EL2 or EL3, the value of SMPRI_EL1.Priority. • When the current Exception level is EL0 or EL1, the value of the SMPRIMAP_EL2 field corresponding to the value of SMPRI_EL1.Priority.

When SMIDR_EL1.SMPS is ‘0’, this field is RES0.

The Effective value of this field is 0 when any of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Effective value of SCR_EL3.HXEn is 0.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.
- EL2 is not implemented or not enabled in the current Security state.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FGTnXS, bit [4]

When FEAT_XS is implemented:

Determines if the fine-grained traps in HFGITR_EL2 that apply to each of the TLBI maintenance instructions that are accessible at EL1 also apply to the corresponding TLBI maintenance instructions with the nXS qualifier.

FGTnXS	Meaning
`0b0`	The fine-grained trap in the HFGITR_EL2 that applies to a TLBI maintenance instruction at EL1 also applies to the corresponding TLBI instruction with the nXS qualifier at EL1.
`0b1`	The fine-grained trap in the HFGITR_EL2 that applies to a TLBI maintenance instruction at EL1 does not apply to the corresponding TLBI instruction with the nXS qualifier at EL1.

The Effective value of this field is 0 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

FnXS, bit [3]

When FEAT_XS is implemented:

Determines the behavior of TLBI instructions affected by the XS attribute.

This control field also determines whether an AArch64 DSB instruction behaves as a DSB instruction with an nXS qualifier when executed at EL0 and EL1.

FnXS	Meaning
`0b0`	This control does not have any effect on the behavior of the TLBI maintenance instructions.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FnXS	Meaning
0b1	A TLBI maintenance instruction without the nXS qualifier executed at EL1 behaves in the same way as the corresponding TLBI maintenance instruction with the nXS qualifier. An AArch64 DSB instruction that applies to both loads and stores executed at EL1 or EL0 behaves in the same way as the corresponding DSB instruction with the nXS qualifier executed at EL1 or EL0.

The Effective value of this field is 0 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of SCR_EL3.HXEn is 0.

This field is permitted to be cached in a TLB.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnASR, bit [2]

When FEAT_LS64_V is implemented:

When the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, traps execution of an ST64BV instruction at EL0 or EL1 to EL2.

EnASR	Meaning
0b0	Execution of an ST64BV instruction at EL0 is trapped to EL2 if the execution is not trapped by SCTLR_EL1.EnASR. Execution of an ST64BV instruction at EL1 is trapped to EL2.
0b1	This control does not cause any instructions to be trapped.

A trap of an ST64BV instruction is reported using EC syndrome value `0x0A`, with an ISS code of `0x0000000`.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EnALS, bit [1]

When FEAT_LS64 is implemented:

When the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, traps execution of an LD64B or ST64B instruction at EL0 or EL1 to EL2.

EnALS	Meaning
`0b0`	Execution of an LD64B or ST64B instruction at EL0 is trapped to EL2 if the execution is not trapped by SCTLR_EL1.EnALS. Execution of an LD64B or ST64B instruction at EL1 is trapped to EL2.
`0b1`	This control does not cause any instructions to be trapped.

A trap of an LD64B or ST64B instruction is reported using EC syndrome value `0x0A`, with an ISS code of `0x0000002`.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

EnAS0, bit [0]

When FEAT_LS64_ACCDATA is implemented:

When the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, traps execution of an ST64BV0 instruction at EL0 or EL1 to EL2.

EnAS0	Meaning
`0b0`	Execution of an ST64BV0 instruction at EL0 is trapped to EL2 if the execution is not trapped by SCTLR_EL1.EnAS0. Execution of an ST64BV0 instruction at EL1 is trapped to EL2.
`0b1`	This control does not cause any instructions to be trapped.

A trap of an ST64BV0 instruction is reported using EC syndrome value `0x0A`, with an ISS code of `0x0000001`.

The Effective value of this field is 1 when any of the following are true:

- EL2 is not implemented or not enabled in the current Security state.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The Effective value of HCR_EL2.{E2H, TGE} is {1, 1}.

The Effective value of this field is 0 when all of the following are true:

- EL2 is implemented and enabled in the current Security state.
- The Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}.
- The Effective value of SCR_EL3.HXEn is 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing HCRX_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HCRX_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0001	0b0010	0b010

```
if !(IsFeatureImplemented(FEAT_HCX) && IsFeatureImplemented(FEAT_AA64)) then

D24.2.63 HDBSSBR_EL2, Hardware Dirty State Tracking Structure Base Register

The HDBSSBR_EL2 characteristics are:

Purpose

Control register for HDBSS base address.

Configuration

This register is present only when FEAT_HDBSS is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HDBSSBR_EL2 are UNDEFINED.

Attributes

HDBSSBR_EL2 is a 64-bit register.

Field descriptions

Bits [63:56]

Reserved, RES0.

BADDR, bits [55:12]

HDBSS base address, bits [55:12].

- Bits [55:12] of the base address are the value of this field.
- Bits [11:0] of the base address are 0.

Bits of this field above the implemented physical address size, indicated in ID_AA64MMFR0_EL1.PARange, are RES0.

Based on the value of the SZ field of this register, for encodings of the SZ field greater than 4KB, bits [(SZ+12-1):12] of this field are RES0 such that the base address of the HDBSS is aligned to its size.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [11:4]

D24.2.64 HDBSSPROD_EL2, Hardware Dirty State Tracking Structure Producer Register

The HDBSSPROD_EL2 characteristics are:

Purpose

Allows producer to update write index for HDBSS.

Configuration

This register is present only when FEAT_HDBSS is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HDBSSPROD_EL2 are UNDEFINED.

Attributes

HDBSSPROD_EL2 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

FSC, bits [31:26]

Fault Status Code.

FSC	Meaning	Applies when
0b000000	The PE has not experienced any error on writes to the HDBSS.	
0b010000	External Abort on write to HDBSS.	
0b101000	Granule Protection Fault on write to HDBSS.	FEAT_RME is implemented

If this field is nonzero then one or more HDBSS writes have experienced a fault since this field was last set to zero, and the associated HDBSS entries have been lost.

All other values are reserved.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Bits [25:19]

Reserved, RES0.

INDEX, bits [18:0]

This field indicates the index of the HDBSS entry that will be written to next.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

D24.2.65 HDFGRTR2_EL2, Hypervisor Debug Fine-Grained Read Trap Register 2

The HDFGRTR2_EL2 characteristics are:

Purpose

Provides controls for traps of `MRS` and `MRC` reads of debug, trace, PMU, and Statistical Profiling System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT2 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HDFGRTR2_EL2 are UNDEFINED.

Attributes

HDFGRTR2_EL2 is a 64-bit register.

Field descriptions

Bits [63:25]

Reserved, RES0.

nPMBMAR_EL1, bit [24]

When FEAT_SPE_nVM is implemented:

Trap `MRS` reads of PMBMAR_EL1 at EL1 using AArch64 to EL2.

nPMBMAR_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then `MRS` reads of PMBMAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	MRS reads of PMBMAR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nMDSTEPOP_EL1, bit [23]

When FEAT_STEP2 is implemented:

Trap MRS reads of MDSTEPOP_EL1 at EL1 using AArch64 to EL2.

nMDSTEPOP_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of MDSTEPOP_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of MDSTEPOP_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTRBMPAM_EL1, bit [22]

When FEAT_TRBE_MPAM is implemented:

Trap MRS reads of TRBMPAM_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nTRBMPAM_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of TRBMPAM_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of TRBMPAM_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [21]

Reserved, RES0.

nTRCITECR_EL1, bit [20]

When FEAT_ITE is implemented:

Trap MRS reads of TRCITECR_EL1 at EL1 using AArch64 to EL2.

nTRCITECR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of TRCITECR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of TRCITECR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMSDSFR_EL1, bit [19]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SPE_FDS is implemented:

Trap MRS reads of PMSDSFR_EL1 at EL1 using AArch64 to EL2.

nPMSDSFR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of PMSDSFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PMSDSFR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMDEVAFF_EL1, bit [18]

When FEAT_SPMU is implemented:

Trap MRS reads of SPMDEVAFF_EL1 at EL1 using AArch64 to EL2.

nSPMDEVAFF_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of SPMDEVAFF_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SPMDEVAFF_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMID, bit [17]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SPMU is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMCFGR_EL1.
- SPMCGCR<n>_EL1.
- SPMDEVARCH_EL1.
- SPMIIDR_EL1.

nSPMID	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMSCR_EL1, bit [16]

When FEAT_SPMU is implemented:

Trap MRS reads of SPMSCR_EL1 at EL1 using AArch64 to EL2.

nSPMSCR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of SPMSCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SPMSCR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSPMACCESSR_EL1, bit [15]

When FEAT_SPMU is implemented:

Trap MRS reads of SPMACCESSR_EL1 at EL1 using AArch64 to EL2.

nSPMACCESSR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of SPMACCESSR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SPMACCESSR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMCR_EL0, bit [14]

When FEAT_SPMU is implemented:

Trap MRS reads of SPMCR_EL0 at EL1 and EL0 using AArch64 to EL2.

nSPMCR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MRS reads of SPMCR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SPMCR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSPMOVS, bit [13]

When FEAT_SPMU is implemented:

Trap MRS reads at EL1 and EL0 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMOVSCLR_EL0.
- SPMOVSSET_EL0.

nSPMOVS	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MRS reads at EL1 and EL0 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMINTEN, bit [12]

When FEAT_SPMU is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMINTENCLR_EL1.
- SPMINTENSET_EL1.

nSPMINTEN	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the highest implemented Exception level is EL2, this field resets to `'0'`.
- Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMCNTEN, bit [11]

When FEAT_SPMU is implemented:

Trap `MRS` reads at EL1 and EL0 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMCNTENCLR_EL0.
- SPMCNTENSET_EL0.

nSPMCNTEN	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then `MRS` reads at EL1 and EL0 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.
`0b1`	`MRS` reads of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMSELR_EL0, bit [10]

When FEAT_SPMU is implemented:

Trap `MRS` reads of SPMSELR_EL0 at EL1 and EL0 using AArch64 to EL2.

nSPMSELR_EL0	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then `MRS` reads of SPMSELR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.
`0b1`	`MRS` reads of SPMSELR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMEVTYPERn_EL0, bit [9]

When FEAT_SPMU is implemented:

Trap MRS reads at EL1 and EL0 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMEVTYPER<n>_EL0.
- SPMEVFILTR<n>_EL0.
- SPMEVFILT2R<n>_EL0.

nSPMEVTYPERn_EL0	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MRS reads at EL1 and EL0 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.
`0b1`	MRS reads of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMEVCNTRn_EL0, bit [8]

When FEAT_SPMU is implemented:

Trap MRS reads of SPMEVCNTR<n>_EL0 at EL1 and EL0 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSPMEVCNTRn_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MRS reads of SPMEVCNTR<n>_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SPMEVCNTR<n>_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMSSCR_EL1, bit [7]

When FEAT_PMUv3_SS is implemented:

Trap MRS reads of PMSSCR_EL1 at EL1 using AArch64 to EL2.

nPMSSCR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of PMSSCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PMSSCR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMSSDATA, bit [6]

When FEAT_PMUv3_SS is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- PMCCNTSVR_EL1.
- PMEVCNTSVR<n>_EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- PMICNTSVR_EL1, if FEAT_PMUv3_ICNTR is implemented.

nPMSSDATA	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nMDSELR_EL1, bit [5]

When FEAT_Debugv8p9 is implemented:

Trap MRS reads of MDSELR_EL1 at EL1 using AArch64 to EL2.

nMDSELR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of MDSELR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of MDSELR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

It is IMPLEMENTATION DEFINED whether this field is implemented or is RES0 when 16 or fewer breakpoints are implemented, 16 or fewer watchpoints are implemented, and MDSELR_EL1 is implemented as RAZ/WI.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMUACR_EL1, bit [4]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_PMUv3p9 is implemented:

Trap MRS reads of PMUACR_EL1 at EL1 using AArch64 to EL2.

nPMUACR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of PMUACR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PMUACR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMICFILTR_EL0, bit [3]

When FEAT_PMUv3_ICNTR is implemented:

Trap MRS reads of PMICFILTR_EL0 at EL1 and EL0 using AArch64 to EL2.

nPMICFILTR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then: • MRS reads of PMICFILTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception. • PMCNTENCLR_EL0.F0, PMCNTENSET_EL0.F0, PMOVSCLR_EL0.F0, and PMOVSSET_EL0.F0 read as zero at EL1 and EL0. • PMINTENCLR_EL1.F0 and PMINTENSET_EL1.F0 read as zero at EL1.
0b1	MRS reads of PMICFILTR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

nPMICNTR_EL0, bit [2]

When FEAT_PMUv3_ICNTR is implemented:

Trap MRS reads of PMICNTR_EL0 at EL1 and EL0 using AArch64 to EL2.

nPMICNTR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MRS reads of PMICNTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PMICNTR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [1]

Reserved, RES0.

nPMECR_EL1, bit [0]

When FEAT_EBEP is implemented or FEAT_PMUv3_SS is implemented:

Trap MRS reads of PMECR_EL1 at EL1 using AArch64 to EL2.

nPMECR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of PMECR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PMECR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the highest implemented Exception level is EL2, this field resets to `'0'`.
- Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing HDFGRTR2_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HDFGRTR2_EL2
```

op0	op1	CRn	CRm	op2
0b11	0b100	0b0011	0b0001	0b000

```
if !(IsFeatureImplemented(FEAT_FGT2) && IsFeatureImplemented(FEAT_AA64)) then
    Undefined();

D24.2.66 HDFGRTR_EL2, Hypervisor Debug Fine-Grained Read Trap Register

The HDFGRTR_EL2 characteristics are:

Purpose

Provides controls for traps of `MRS` and `MRC` reads of debug, trace, PMU, and Statistical Profiling System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HDFGRTR_EL2 are UNDEFINED.

Attributes

HDFGRTR_EL2 is a 64-bit register.

Field descriptions

PMBIDR_EL1, bit [63]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SPE is implemented:

Trap MRS reads of PMBIDR_EL1 at EL1 using AArch64 to EL2.

PMBIDR_EL1	Meaning
0b0	MRS reads of PMBIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMBIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMSNEVFR_EL1, bit [62]

When FEAT_SPE_FnE is implemented:

Trap MRS reads of PMSNEVFR_EL1 at EL1 using AArch64 to EL2.

nPMSNEVFR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSNEVFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PMSNEVFR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nBRBDATA, bit [61]

When FEAT_BRBE is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- BRBINF<n>_EL1.
- BRBINFINJ_EL1.
- BRBSRC<n>_EL1.
- BRBSRCINJ_EL1.
- BRBTGT<n>_EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- BRBTGTINJ_EL1.
- BRBTS_EL1.

nBRBDATA	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of the specified System registers are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nBRBCTL, bit [60]

When FEAT_BRBE is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- BRBCR_EL1.
- BRBFCR_EL1.

nBRBCTL	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of the specified System registers are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nBRBIDR, bit [59]

When FEAT_BRBE is implemented:

Trap MRS reads of BRBIDR0_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nBRBIDR	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of BRBIDR0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of BRBIDR0_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMCEIDn_EL0, bit [58]

When FEAT_PMUv3 is implemented:

Trap MRS reads of PMCEID<n>_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMCEID<n> at EL0 using AArch32 when EL1 is using AArch64 to EL2.

PMCEIDn_EL0	Meaning
0b0	MRS reads of PMCEID<n>_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMCEID<n> at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of PMCEID<n>_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of PMCEID<n> at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMUSERENR_EL0, bit [57]

When FEAT_PMUv3 is implemented:

Trap MRS reads of PMUSERENR_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMUSERENR at EL0 using AArch32 when EL1 is using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMUSERENR_EL0	Meaning
0b0	MRS reads of PMUSERENR_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMUSERENR at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of PMUSERENR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of PMUSERENR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBTRG_EL1, bit [56]

When FEAT_TRBE is implemented:

Trap MRS reads of TRBTRG_EL1 at EL1 using AArch64 to EL2.

TRBTRG_EL1	Meaning
0b0	MRS reads of TRBTRG_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRBTRG_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBSR_EL1, bit [55]

When FEAT_TRBE is implemented:

Trap MRS reads of TRBSR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRBSR_EL1	Meaning
0b0	MRS reads of TRBSR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRBSR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBPTR_EL1, bit [54]

When FEAT_TRBE is implemented:

Trap MRS reads of TRBPTR_EL1 at EL1 using AArch64 to EL2.

TRBPTR_EL1	Meaning
0b0	MRS reads of TRBPTR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRBPTR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBMAR_EL1, bit [53]

When FEAT_TRBE is implemented:

Trap MRS reads of TRBMAR_EL1 at EL1 using AArch64 to EL2.

TRBMAR_EL1	Meaning
0b0	MRS reads of TRBMAR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRBMAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBLIMITR_EL1, bit [52]

When FEAT_TRBE is implemented:

Trap MRS reads of TRBLIMITR_EL1 at EL1 using AArch64 to EL2.

TRBLIMITR_EL1	Meaning
`0b0`	MRS reads of TRBLIMITR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRBLIMITR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBIDR_EL1, bit [51]

When FEAT_TRBE is implemented:

Trap MRS reads of TRBIDR_EL1 at EL1 using AArch64 to EL2.

TRBIDR_EL1	Meaning
`0b0`	MRS reads of TRBIDR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRBIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBBASER_EL1, bit [50]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_TRBE is implemented:

Trap MRS reads of TRBBASER_EL1 at EL1 using AArch64 to EL2.

TRBBASER_EL1	Meaning
0b0	MRS reads of TRBBASER_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRBBASER_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [49]

Reserved, RES0.

TRCVICTLR, bit [48]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MRS reads of TRCVICTLR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MRS reads of ETM TRCVICTLR at EL1 using AArch64 to EL2.

TRCVICTLR	Meaning
0b0	MRS reads of TRCVICTLR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCVICTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCSTATR, bit [47]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In an Armv9 implementation, trap MRS reads of TRCSTATR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MRS reads of ETM TRCSTATR at EL1 using AArch64 to EL2.

TRCSTATR	Meaning
0b0	MRS reads of TRCSTATR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCSTATR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCSSCSRn, bit [46]

When IsFeatureImplemented(FEAT_ETE) || ((IsFeatureImplemented(FEAT_ETMv4) && TRCSSCSR<n> are implemented) && IsFeatureImplemented(FEAT_TRC_SR)):

In an Armv9 implementation, trap MRS reads of TRCSSCSR<n> at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MRS reads of ETM TRCSSCSR<n> at EL1 using AArch64 to EL2.

TRCSSCSRn	Meaning
0b0	MRS reads of TRCSSCSR<n> are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCSSCSR<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If Single-shot Comparator n is not implementented, a read of TRCSSCSR<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCSEQSTR, bit [45]

When IsFeatureImplemented(FEAT_ETE) || ((IsFeatureImplemented(FEAT_ETMv4) && TRCSEQSTR is implemented) && IsFeatureImplemented(FEAT_TRC_SR)):

In an Armv9 implementation, trap MRS reads of TRCSEQSTR at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

In an Armv8 implementation, trap MRS reads of ETM TRCSEQSTR at EL1 using AArch64 to EL2.

TRCSEQSTR	Meaning
0b0	MRS reads of TRCSEQSTR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCSEQSTR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCPRGCTLR, bit [44]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MRS reads of TRCPRGCTLR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MRS reads of ETM TRCPRGCTLR at EL1 using AArch64 to EL2.

TRCPRGCTLR	Meaning
0b0	MRS reads of TRCPRGCTLR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCPRGCTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCOSLSR, bit [43]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MRS reads of TRCOSLSR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MRS reads of ETM TRCOSLSR at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRCOSLSR	Meaning
0b0	MRS reads of TRCOSLSR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCOSLSR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [42]

Reserved, RES0.

TRCIMSPECn, bit [41]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MRS reads of TRCIMSPEC<n> at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MRS reads of ETM TRCIMSPEC<n> at EL1 using AArch64 to EL2.

TRCIMSPECn	Meaning
0b0	MRS reads of TRCIMSPEC<n> are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCIMSPEC<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

TRCIMSPEC<1-7> are optional. If TRCIMSPEC<n> is not implemented, a read of TRCIMSPEC<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCID, bit [40]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- In an Armv9 implementation:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- TRCDEVARCH.
- TRCDEVID.
- All of the TRCIDR<n> registers.
- In an Armv8 implementation:
  - ETM TRCDEVARCH.
  - ETM TRCDEVID.
  - All of the ETM TRCIDR<n> registers.

TRCID	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [39:38]

Reserved, RES0.

TRCCNTVRn, bit [37]

When IsFeatureImplemented(FEAT_ETE) || ((IsFeatureImplemented(FEAT_ETMv4) && TRCCNTVR<n> are implemented) && IsFeatureImplemented(FEAT_TRC_SR)):

In an Armv9 implementation, trap MRS reads of TRCCNTVR<n> at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MRS reads of ETM TRCCNTVR<n> at EL1 using AArch64 to EL2.

TRCCNTVRn	Meaning
0b0	MRS reads of TRCCNTVR<n> are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCCNTVR<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If Counter n is not implemented, a read of TRCCNTVR<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRCCLAIM, bit [36]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- In an Armv9 implementation: TRCCLAIMCLR and TRCCLAIMSET.
- In an Armv8 implementation: ETM TRCCLAIMCLR and ETM TRCCLAIMSET.

TRCCLAIM	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCAUXCTLR, bit [35]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MRS reads of TRCAUXCTLR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MRS reads of ETM TRCAUXCTLR at EL1 using AArch64 to EL2.

TRCAUXCTLR	Meaning
0b0	MRS reads of TRCAUXCTLR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TRCAUXCTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCAUTHSTATUS, bit [34]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap `MRS` reads of TRCAUTHSTATUS at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap `MRS` reads of ETM TRCAUTHSTATUS at EL1 using AArch64 to EL2.

TRCAUTHSTATUS	Meaning
`0b0`	`MRS` reads of TRCAUTHSTATUS are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then `MRS` reads of TRCAUTHSTATUS at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRC, bit [33]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

Trap `MRS` reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- In an Armv9 implementation:
  - TRCACATR<n>.
  - TRCACVR<n>.
  - TRCBBCTLR.
  - TRCCCCTLR.
  - TRCCIDCCTLR0.
  - TRCCIDCCTLR1.
  - TRCCIDCVR<n>.
  - TRCCNTCTLR<n>.
  - TRCCNTRLDVR<n>.
  - TRCCONFIGR.
  - TRCEVENTCTL0R.
  - TRCEVENTCTL1R.
  - TRCEXTINSELR<n>.
  - TRCQCTLR.
  - TRCRSCTLR<n>.
  - TRCRSR.
  - TRCSEQEVR<n>.
  - TRCSEQRSTEVR.
  - TRCSSCCR<n>.
  - TRCSSPCICR<n>.
  - TRCSTALLCTLR.
  - TRCSYNCPR.
  - TRCTRACEIDR.
  - TRCTSCTLR.
  - TRCVIIECTLR.
  - TRCVIPCSSCTLR.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- TRCVISSCTLR.
- TRCVMIDCCTLR0.
- TRCVMIDCCTLR1.
- TRCVMIDCVR<n>.

- In an Armv8 implementation:

  - ETM TRCACATR<n>.
  - ETM TRCACVR<n>.
  - ETM TRCBBCTLR.
  - ETM TRCCCCTLR.
  - ETM TRCCIDCCTLR0.
  - ETM TRCCIDCCTLR1.
  - ETM TRCCIDCVR<n>.
  - ETM TRCCNTCTLR<n>.
  - ETM TRCCNTRLDVR<n>.
  - ETM TRCCONFIGR.
  - ETM TRCEVENTCTL0R.
  - ETM TRCEVENTCTL1R.
  - ETM TRCEXTINSELR.
  - ETM TRCQCTLR.
  - ETM TRCRSCTLR<n>.
  - ETM TRCSEQEVR<n>.
  - ETM TRCSEQRSTEVR.
  - ETM TRCSSCCR<n>.
  - ETM TRCSSPCICR<n>.
  - ETM TRCSTALLCTLR.
  - ETM TRCSYNCPR.
  - ETM TRCTRACEIDR.
  - ETM TRCTSCTLR.
  - ETM TRCVIIECTLR.
  - ETM TRCVIPCSSCTLR.
  - ETM TRCVISSCTLR.
  - ETM TRCVMIDCCTLR0.
  - ETM TRCVMIDCCTLR1.
  - ETM TRCVMIDCVR<n>.

TRC	Meaning
`0b0`	`MRS` reads of the specified System registers are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then `MRS` reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

A read of an unimplemented register is UNDEFINED.

TRCEXTINSELR<n> and TRCRSR are implemented only if FEAT_ETE is implemented.

TRCEXTINSELR is implemented only if FEAT_ETE is not implemented and FEAT_ETMv4 is implemented.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMSLATFR_EL1, bit [32]

When FEAT_SPE is implemented:

Trap MRS reads of PMSLATFR_EL1 at EL1 using AArch64 to EL2.

PMSLATFR_EL1	Meaning
0b0	MRS reads of PMSLATFR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSLATFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSIRR_EL1, bit [31]

When FEAT_SPE is implemented:

Trap MRS reads of PMSIRR_EL1 at EL1 using AArch64 to EL2.

PMSIRR_EL1	Meaning
0b0	MRS reads of PMSIRR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSIRR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSIDR_EL1, bit [30]

When FEAT_SPE is implemented:

Trap MRS reads of PMSIDR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMSIDR_EL1	Meaning
0b0	MRS reads of PMSIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSICR_EL1, bit [29]

When FEAT_SPE is implemented:

Trap MRS reads of PMSICR_EL1 at EL1 using AArch64 to EL2.

PMSICR_EL1	Meaning
0b0	MRS reads of PMSICR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSICR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSFCR_EL1, bit [28]

When FEAT_SPE is implemented:

Trap MRS reads of PMSFCR_EL1 at EL1 using AArch64 to EL2.

PMSFCR_EL1	Meaning
0b0	MRS reads of PMSFCR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSFCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSEVFR_EL1, bit [27]

When FEAT_SPE is implemented:

Trap MRS reads of PMSEVFR_EL1 at EL1 using AArch64 to EL2.

PMSEVFR_EL1	Meaning
`0b0`	MRS reads of PMSEVFR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSEVFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSCR_EL1, bit [26]

When FEAT_SPE is implemented:

Trap MRS reads of PMSCR_EL1 at EL1 using AArch64 to EL2.

PMSCR_EL1	Meaning
`0b0`	MRS reads of PMSCR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMSCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMBSR_EL1, bit [25]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SPE is implemented:

Trap MRS reads of PMBSR_EL1 at EL1 using AArch64 to EL2.

PMBSR_EL1	Meaning
0b0	MRS reads of PMBSR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMBSR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMBPTR_EL1, bit [24]

When FEAT_SPE is implemented:

Trap MRS reads of PMBPTR_EL1 at EL1 using AArch64 to EL2.

PMBPTR_EL1	Meaning
0b0	MRS reads of PMBPTR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMBPTR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMBLIMITR_EL1, bit [23]

When FEAT_SPE is implemented:

Trap MRS reads of PMBLIMITR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMBLIMITR_EL1	Meaning
0b0	MRS reads of PMBLIMITR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMBLIMITR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMMIR_EL1, bit [22]

When FEAT_PMUv3 is implemented:

Trap MRS reads of PMMIR_EL1 at EL1 using AArch64 to EL2.

PMMIR_EL1	Meaning
0b0	MRS reads of PMMIR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PMMIR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [21:20]

Reserved, RES0.

PMSELR_EL0, bit [19]

When FEAT_PMUv3 is implemented:

Trap MRS reads of PMSELR_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMSELR at EL0 using AArch32 when EL1 is using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMSELR_EL0	Meaning
0b0	MRS reads of PMSELR_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMSELR at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of PMSELR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of PMSELR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMOVS, bit [18]

When FEAT_PMUv3 is implemented:

Trap MRS reads and MRC reads of any of the following System registers to EL2:

- At EL1 and EL0 using AArch64: PMOVSCLR_EL0 and PMOVSSET_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: PMOVSR and PMOVSSET.

PMOVS	Meaning
0b0	MRS reads at EL1 and EL0 using AArch64 and MRC reads at EL0 using AArch32 of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads at EL1 and EL0 using AArch64 of any of the specified AArch64 System registers are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads at EL0 using AArch32 when EL1 is using AArch64 of any of the specified AArch32 System registers are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMINTEN, bit [17]

When FEAT_PMUv3 is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- PMINTENCLR_EL1.
- PMINTENSET_EL1.

PMINTEN	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMCNTEN, bit [16]

When FEAT_PMUv3 is implemented:

Trap MRS reads and MRC reads of any of the following System registers to EL2:

- At EL1 and EL0 using AArch64: PMCNTENCLR_EL0 and PMCNTENSET_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: PMCNTENCLR and PMCNTENSET.

PMCNTEN	Meaning
0b0	MRS reads at EL1 and EL0 using AArch64 and MRC reads at EL0 using AArch32 of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads at EL1 and EL0 using AArch64 of any of the specified AArch64 System registers are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads at EL0 using AArch32 when EL1 is using AArch64 of any of the specified AArch32 System registers are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMCCNTR_EL0, bit [15]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_PMUv3 is implemented:

Trap MRS reads of PMCCNTR_EL0 at EL1 and EL0 using AArch64 and MRC and MRRC reads of PMCCNTR at EL0 using AArch32 when EL1 is using AArch64 to EL2.

PMCCNTR_EL0	Meaning
0b0	MRS reads of PMCCNTR_EL0 at EL1 and EL0 using AArch64 and MRC and MRRC reads of PMCCNTR at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of PMCCNTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of PMCCNTR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03. • MRRC reads of PMCCNTR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x04.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMCCFILTR_EL0, bit [14]

When FEAT_PMUv3 is implemented:

Trap MRS reads of PMCCFILTR_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMCCFILTR at EL0 using AArch32 when EL1 is using AArch64 to EL2.

PMCCFILTR_EL0	Meaning
0b0	MRS reads of PMCCFILTR_EL0 at EL1 and EL0 using AArch64 and MRC reads of PMCCFILTR at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of PMCCFILTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of PMCCFILTR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

PMCCFILTR_EL0 can also be accessed in AArch64 state using PMXEVTYPER_EL0 when PMSELR_EL0.SEL == 31, and PMCCFILTR can also be accessed in AArch32 state using PMXEVTYPER when PMSELR.SEL == 31.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Setting this field to 1 has no effect on accesses to PMXEVTYPER_EL0 and PMXEVTYPER, regardless of the value of PMSELR_EL0.SEL or PMSELR.SEL.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMEVTYPERn_EL0, bit [13]

When FEAT_PMUv3 is implemented:

Trap `MRS` reads and `MRC` reads of any of the following System registers to EL2:

- At EL1 and EL0 using AArch64: PMEVTYPER<n>_EL0 and PMXEVTYPER_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: PMEVTYPER<n> and PMXEVTYPER.

PMEVTYPERn_EL0	Meaning
`0b0`	`MRS` reads at EL1 and EL0 using AArch64 and `MRC` reads at EL0 using AArch32 of the specified System registers are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • `MRS` reads at EL1 and EL0 using AArch64 of any of the specified AArch64 System registers are trapped to EL2 and reported with EC syndrome value `0x18`. • `MRC` reads at EL0 using AArch32 when EL1 is using AArch64 of any of the specified AArch32 System registers are trapped to EL2 and reported with EC syndrome value `0x03`.

Regardless of the value of this field, for each value n:

- If event counter n is not implemented, the following accesses are UNDEFINED:
  - In AArch64 state, a read of PMEVTYPER<n>_EL0, or, if n is not 31, a read of PMXEVTYPER_EL0 when PMSELR_EL0.SEL == n.
  - In AArch32 state, a read of PMEVTYPER<n>, or, if n is not 31, a read of PMXEVTYPER when PMSELR.SEL == n.
- If event counter n is implemented, n is greater-than-or-equal-to MDCR_EL2.HPMN, and EL2 is implemented and enabled in the current Security state, the following generate a Trap exception to EL2 from EL0 or EL1:
  - In AArch64 state, a read of PMEVTYPER<n>_EL0, or a read of PMXEVTYPER_EL0 when PMSELR_EL0.SEL == n, reported with EC syndrome value `0x18`.
  - In AArch32 state, a read of PMEVTYPER<n>, or a read of PMXEVTYPER when PMSELR.SEL == n, reported with EC syndrome value `0x03`.

See also HDFGRTR_EL2.PMCCFILTR_EL0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

PMEVCNTRn_EL0, bit [12]

When FEAT_PMUv3 is implemented:

Trap MRS reads and MRC reads of any of the following System registers to EL2:

- At EL1 and EL0 using AArch64: PMEVCNTR<n>_EL0 and PMXEVCNTR_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: PMEVCNTR<n> and PMXEVCNTR.

PMEVCNTRn_EL0	Meaning
0b0	MRS reads at EL1 and EL0 using AArch64 and MRC reads at EL0 using AArch32 of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads at EL1 and EL0 using AArch64 of any of the specified AArch64 System registers are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads at EL0 using AArch32 when EL1 is using AArch64 of any of the specified AArch32 System registers are trapped to EL2 and reported with EC syndrome value 0x03.

Regardless of the value of this field, for each value n:

- If event counter n is not implemented, the following accesses are UNDEFINED:
  - In AArch64 state, a read of PMEVCNTR<n>_EL0, or a read of PMXEVCNTR_EL0 when PMSELR_EL0.SEL is n.
  - In AArch32 state, a read of PMEVCNTR<n>, or a read of PMXEVCNTR when PMSELR.SEL is n.
- If event counter n is implemented, n is greater than or equal to MDCR_EL2.HPMN, and EL2 is implemented and enabled in the current Security state, the following generate a Trap exception to EL2 from EL0 or EL1:
  - In AArch64 state, a read of PMEVCNTR<n>_EL0, or a read of PMXEVCNTR_EL0 when PMSELR_EL0.SEL is n, reported with EC syndrome value 0x18.
  - In AArch32 state, a read of PMEVCNTR<n>, or a read of PMXEVCNTR when PMSELR.SEL is n, reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

OSDLR_EL1, bit [11]

When FEAT_DoubleLock is implemented:

Trap MRS reads of OSDLR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

OSDLR_EL1	Meaning
0b0	MRS reads of OSDLR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of OSDLR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

OSECCR_EL1, bit [10]

Trap MRS reads of OSECCR_EL1 at EL1 using AArch64 to EL2.

OSECCR_EL1	Meaning
0b0	MRS reads of OSECCR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of OSECCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

OSLSR_EL1, bit [9]

Trap MRS reads of OSLSR_EL1 at EL1 using AArch64 to EL2.

OSLSR_EL1	Meaning
0b0	MRS reads of OSLSR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of OSLSR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [8]

Reserved, RES0.

DBGPRCR_EL1, bit [7]

Trap MRS reads of DBGPRCR_EL1 at EL1 using AArch64 to EL2.

DBGPRCR_EL1	Meaning
0b0	MRS reads of DBGPRCR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of DBGPRCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGAUTHSTATUS_EL1, bit [6]

Trap MRS reads of DBGAUTHSTATUS_EL1 at EL1 using AArch64 to EL2.

DBGAUTHSTATUS_EL1	Meaning
0b0	MRS reads of DBGAUTHSTATUS_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of DBGAUTHSTATUS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGCLAIM, bit [5]

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- DBGCLAIMCLR_EL1.
- DBGCLAIMSET_EL1.

DBGCLAIM	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DBGCLAIM	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

MDSCR_EL1, bit [4]

Trap MRS reads of MDSCR_EL1 at EL1 using AArch64 to EL2.

MDSCR_EL1	Meaning
0b0	MRS reads of MDSCR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of MDSCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGWVRn_EL1, bit [3]

Trap MRS reads of DBGWVR<n>_EL1 at EL1 using AArch64 to EL2.

DBGWVRn_EL1	Meaning
0b0	MRS reads of DBGWVR<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of DBGWVR<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If watchpoint n is not implemented, a read of DBGWVR<n>_EL1 is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGWCRn_EL1, bit [2]

Trap MRS reads of DBGWCR<n>_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DBGWCRn_EL1	Meaning
0b0	MRS reads of DBGWCR<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of DBGWCR<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If watchpoint n is not implemented, a read of DBGWCR<n>_EL1 is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGBVRn_EL1, bit [1]

Trap MRS reads of DBGBVR<n>_EL1 at EL1 using AArch64 to EL2.

DBGBVRn_EL1	Meaning
0b0	MRS reads of DBGBVR<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of DBGBVR<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If breakpoint n is not implemented, a read of DBGBVR<n>_EL1 is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGBCRn_EL1, bit [0]

Trap MRS reads of DBGBCR<n>_EL1 at EL1 using AArch64 to EL2.

DBGBCRn_EL1	Meaning
0b0	MRS reads of DBGBCR<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of DBGBCR<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

If breakpoint n is not implemented, a read of DBGBCR<n>_EL1 is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

D24.2.67 HDFGWTR2_EL2, Hypervisor Debug Fine-Grained Write Trap Register 2

The HDFGWTR2_EL2 characteristics are:

Purpose

Provides controls for traps of MSR and MCR writes of debug, trace, PMU, and Statistical Profiling System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT2 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HDFGWTR2_EL2 are UNDEFINED.

Attributes

HDFGWTR2_EL2 is a 64-bit register.

Field descriptions

Bits [63:25]

Reserved, RES0.

nPMBMAR_EL1, bit [24]

When FEAT_SPE_nVM is implemented:

Trap MSR writes of PMBMAR_EL1 at EL1 using AArch64 to EL2.

nPMBMAR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of PMBMAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of PMBMAR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nMDSTEPOP_EL1, bit [23]

When FEAT_STEP2 is implemented:

Trap MSR writes of MDSTEPOP_EL1 at EL1 using AArch64 to EL2.

nMDSTEPOP_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of MDSTEPOP_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of MDSTEPOP_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTRBMPAM_EL1, bit [22]

When FEAT_TRBE_MPAM is implemented:

Trap MSR writes of TRBMPAM_EL1 at EL1 using AArch64 to EL2.

nTRBMPAM_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of TRBMPAM_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of TRBMPAM_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMZR_EL0, bit [21]

When FEAT_PMUv3p9 is implemented:

Trap MSR writes of PMZR_EL0 at EL1 and EL0 using AArch64 to EL2.

nPMZR_EL0	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MSR writes of PMZR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of PMZR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTRCITECR_EL1, bit [20]

When FEAT_ITE is implemented:

Trap MSR writes of TRCITECR_EL1 at EL1 using AArch64 to EL2.

nTRCITECR_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of TRCITECR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of TRCITECR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMSDSFR_EL1, bit [19]

When FEAT_SPE_FDS is implemented:

Trap MSR writes of PMSDSFR_EL1 at EL1 using AArch64 to EL2.

nPMSDSFR_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of PMSDSFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of PMSDSFR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [18:17]

Reserved, RES0.

nSPMSCR_EL1, bit [16]

When FEAT_SPMU is implemented:

Trap MSR writes of SPMSCR_EL1 at EL1 using AArch64 to EL2.

nSPMSCR_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of SPMSCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	MSR writes of SPMSCR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMACCESSR_EL1, bit [15]

When FEAT_SPMU is implemented:

Trap MSR writes of SPMACCESSR_EL1 at EL1 using AArch64 to EL2.

nSPMACCESSR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of SPMACCESSR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of SPMACCESSR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMCR_EL0, bit [14]

When FEAT_SPMU is implemented:

Trap MSR writes of SPMCR_EL0 at EL1 and EL0 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSPMCR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MSR writes of SPMCR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of SPMCR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMOVS, bit [13]

When FEAT_SPMU is implemented:

Trap MSR writes at EL1 and EL0 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMOVSCLR_EL0.
- SPMOVSSET_EL0.

nSPMOVS	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MSR writes at EL1 and EL0 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMINTEN, bit [12]

When FEAT_SPMU is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- SPMINTENCLR_EL1.
- SPMINTENSET_EL1.

nSPMINTEN	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMCNTEN, bit [11]

When FEAT_SPMU is implemented:

Trap MSR writes at EL1 and EL0 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMCNTENCLR_EL0.
- SPMCNTENSET_EL0.

nSPMCNTEN	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MSR writes at EL1 and EL0 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSPMSELR_EL0, bit [10]

When FEAT_SPMU is implemented:

Trap MSR writes of SPMSELR_EL0 at EL1 and EL0 using AArch64 to EL2.

nSPMSELR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MSR writes of SPMSELR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of SPMSELR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMEVTYPERn_EL0, bit [9]

When FEAT_SPMU is implemented:

Trap MSR writes at EL1 and EL0 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMEVTYPER<n>_EL0.
- SPMEVFILTR<n>_EL0.
- SPMEVFILT2R<n>_EL0.

nSPMEVTYPERn_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MSR writes at EL1 and EL0 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the highest implemented Exception level is EL2, this field resets to `'0'`.
- Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSPMEVCNTRn_EL0, bit [8]

When FEAT_SPMU is implemented:

Trap MSR writes at EL1 and EL0 using AArch64 of any of the following AArch64 System registers to EL2:

- SPMEVCNTR<n>_EL0.
- SPMZR_EL0.

nSPMEVCNTRn_EL0	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then MSR writes at EL1 and EL0 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of the specified System registers are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMSSCR_EL1, bit [7]

When FEAT_PMUv3_SS is implemented:

Trap MSR writes of PMSSCR_EL1 at EL1 using AArch64 to EL2.

nPMSSCR_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of PMSSCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of PMSSCR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [6]

Reserved, RES0.

nMDSELR_EL1, bit [5]

When FEAT_Debugv8p9 is implemented:

Trap MSR writes of MDSELR_EL1 at EL1 using AArch64 to EL2.

nMDSELR_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of MDSELR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of MDSELR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

It is IMPLEMENTATION DEFINED whether this field is implemented or is RES0 when 16 or fewer breakpoints are implemented, 16 or fewer watchpoints are implemented, and MDSELR_EL1 is implemented as RAZ/WI.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMUACR_EL1, bit [4]

When FEAT_PMUv3p9 is implemented:

Trap MSR writes of PMUACR_EL1 at EL1 using AArch64 to EL2.

nPMUACR_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of PMUACR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nPMUACR_EL1	Meaning
0b1	MSR writes of PMUACR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMICFILTR_EL0, bit [3]

When FEAT_PMUv3_ICNTR is implemented:

Trap MSR writes of PMICFILTR_EL0 at EL1 and EL0 using AArch64 to EL2.

nPMICFILTR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then: • MSR writes of PMICFILTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception. • PMCNTENCLR_EL0.F0, PMCNTENSET_EL0.F0, PMOVSCLR_EL0.F0, and PMOVSSET_EL0.F0 ignore writes at EL1 and EL0. • PMINTENCLR_EL1.F0 and PMINTENSET_EL1.F0 ignore writes at EL1.
0b1	MSR writes of PMICFILTR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPMICNTR_EL0, bit [2]

When FEAT_PMUv3_ICNTR is implemented:

Trap MSR writes of PMICNTR_EL0 at EL1 and EL0 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nPMICNTR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then: • MSR writes of PMICNTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception. • PMZR_EL0.F0 ignores writes at EL1 and EL0.
0b1	MSR writes of PMICNTR_EL0 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [1]

Reserved, RES0.

nPMECR_EL1, bit [0]

When FEAT_EBEP is implemented or FEAT_PMUv3_SS is implemented:

Trap MSR writes of PMECR_EL1 at EL1 using AArch64 to EL2.

nPMECR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of PMECR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of PMECR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D24.2.68 HDFGWTR_EL2, Hypervisor Debug Fine-Grained Write Trap Register

The HDFGWTR_EL2 characteristics are:

Purpose

Provides controls for traps of MSR and MCR writes of debug, trace, PMU, and Statistical Profiling System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HDFGWTR_EL2 are UNDEFINED.

Attributes

HDFGWTR_EL2 is a 64-bit register.

Field descriptions

Bit [63]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nPMSNEVFR_EL1, bit [62]

When FEAT_SPE_FnE is implemented:

Trap MSR writes of PMSNEVFR_EL1 at EL1 using AArch64 to EL2.

nPMSNEVFR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSNEVFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of PMSNEVFR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nBRBDATA, bit [61]

When FEAT_BRBE is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- BRBINFINJ_EL1.
- BRBSRCINJ_EL1.
- BRBTGTINJ_EL1.
- BRBTS_EL1.

nBRBDATA	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of the specified System registers are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nBRBCTL, bit [60]

When FEAT_BRBE is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- BRBCR_EL1.
- BRBFCR_EL1.

nBRBCTL	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of the specified System registers are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [59:58]

Reserved, RES0.

PMUSERENR_EL0, bit [57]

When FEAT_PMUv3 is implemented:

Trap MSR writes of PMUSERENR_EL0 at EL1 using AArch64 to EL2.

PMUSERENR_EL0	Meaning
0b0	MSR writes of PMUSERENR_EL0 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMUSERENR_EL0 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBTRG_EL1, bit [56]

When FEAT_TRBE is implemented:

Trap MSR writes of TRBTRG_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRBTRG_EL1	Meaning
0b0	MSR writes of TRBTRG_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRBTRG_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBSR_EL1, bit [55]

When FEAT_TRBE is implemented:

Trap MSR writes of TRBSR_EL1 at EL1 using AArch64 to EL2.

TRBSR_EL1	Meaning
0b0	MSR writes of TRBSR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRBSR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBPTR_EL1, bit [54]

When FEAT_TRBE is implemented:

Trap MSR writes of TRBPTR_EL1 at EL1 using AArch64 to EL2.

TRBPTR_EL1	Meaning
0b0	MSR writes of TRBPTR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRBPTR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBMAR_EL1, bit [53]

When FEAT_TRBE is implemented:

Trap MSR writes of TRBMAR_EL1 at EL1 using AArch64 to EL2.

TRBMAR_EL1	Meaning
`0b0`	MSR writes of TRBMAR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRBMAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRBLIMITR_EL1, bit [52]

When FEAT_TRBE is implemented:

Trap MSR writes of TRBLIMITR_EL1 at EL1 using AArch64 to EL2.

TRBLIMITR_EL1	Meaning
`0b0`	MSR writes of TRBLIMITR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRBLIMITR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [51]

Reserved, RES0.

TRBBASER_EL1, bit [50]

When FEAT_TRBE is implemented:

Trap MSR writes of TRBBASER_EL1 at EL1 using AArch64 to EL2.

TRBBASER_EL1	Meaning
0b0	MSR writes of TRBBASER_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRBBASER_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRFCR_EL1, bit [49]

When FEAT_TRF is implemented:

Trap MSR writes of TRFCR_EL1 at EL1 using AArch64 to EL2.

TRFCR_EL1	Meaning
0b0	MSR writes of TRFCR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRFCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCVICTLR, bit [48]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MSR writes of TRCVICTLR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MSR writes of ETM TRCVICTLR at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRCVICTLR	Meaning
0b0	MSR writes of TRCVICTLR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRCVICTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [47]

Reserved, RES0.

TRCSSCSRn, bit [46]

When IsFeatureImplemented(FEAT_ETE) || ((IsFeatureImplemented(FEAT_ETMv4) && TRCSSCSR<n> are implemented) && IsFeatureImplemented(FEAT_TRC_SR)):

In an Armv9 implementation, trap MSR writes of TRCSSCSR<n> at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MSR writes of ETM TRCSSCSR<n> at EL1 using AArch64 to EL2.

TRCSSCSRn	Meaning
0b0	MSR writes of TRCSSCSR<n> are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRCSSCSR<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If Single-shot Comparator n is not implementented, a write of TRCSSCSR<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCSEQSTR, bit [45]

When IsFeatureImplemented(FEAT_ETE) || ((IsFeatureImplemented(FEAT_ETMv4) && TRCSEQSTR is implemented) && IsFeatureImplemented(FEAT_TRC_SR)):

In an Armv9 implementation, trap MSR writes of TRCSEQSTR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MSR writes of ETM TRCSEQSTR at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRCSEQSTR	Meaning
0b0	MSR writes of TRCSEQSTR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRCSEQSTR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCPRGCTLR, bit [44]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MSR writes of TRCPRGCTLR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MSR writes of ETM TRCPRGCTLR at EL1 using AArch64 to EL2.

TRCPRGCTLR	Meaning
0b0	MSR writes of TRCPRGCTLR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRCPRGCTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [43]

Reserved, RES0.

TRCOSLAR, bit [42]

When FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented:

In an Armv8 implementation, trap MSR writes of ETM TRCOSLAR at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRCOSLAR	Meaning
0b0	MSR writes of ETM TRCOSLAR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ETM TRCOSLAR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCIMSPECn, bit [41]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MSR writes of TRCIMSPEC<n> at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MSR writes of ETM TRCIMSPEC<n> at EL1 using AArch64 to EL2.

TRCIMSPECn	Meaning
0b0	MSR writes of TRCIMSPEC<n> are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRCIMSPEC<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

TRCIMSPEC<1-7> are optional. If TRCIMSPEC<n> is not implemented, a write of TRCIMSPEC<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [40:38]

Reserved, RES0.

TRCCNTVRn, bit [37]

When IsFeatureImplemented(FEAT_ETE) || ((IsFeatureImplemented(FEAT_ETMv4) && TRCCNTVR<n> are implemented) && IsFeatureImplemented(FEAT_TRC_SR)):

In an Armv9 implementation, trap MSR writes of TRCCNTVR<n> at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MSR writes of ETM TRCCNTVR<n> at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRCCNTVRn	Meaning
0b0	MSR writes of TRCCNTVR<n> are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRCCNTVR<n> at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If Counter n is not implemented, a write of TRCCNTVR<n> is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCCLAIM, bit [36]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- In an Armv9 implementation: TRCCLAIMCLR and TRCCLAIMSET.
- In an Armv8 implementation: ETM TRCCLAIMCLR and ETM TRCCLAIMSET.

TRCCLAIM	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TRCAUXCTLR, bit [35]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

In an Armv9 implementation, trap MSR writes of TRCAUXCTLR at EL1 using AArch64 to EL2.

In an Armv8 implementation, trap MSR writes of ETM TRCAUXCTLR at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TRCAUXCTLR	Meaning
0b0	MSR writes of TRCAUXCTLR are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TRCAUXCTLR at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [34]

Reserved, RES0.

TRC, bit [33]

When FEAT_ETE is implemented or (FEAT_ETMv4 is implemented and System register access to the trace unit registers is implemented):

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- In an Armv9 implementation:
  - TRCACATR<n>.
  - TRCACVR<n>.
  - TRCBBCTLR.
  - TRCCCCTLR.
  - TRCCIDCCTLR0.
  - TRCCIDCCTLR1.
  - TRCCIDCVR<n>.
  - TRCCNTCTLR<n>.
  - TRCCNTRLDVR<n>.
  - TRCCONFIGR.
  - TRCEVENTCTL0R.
  - TRCEVENTCTL1R.
  - TRCEXTINSELR<n>.
  - TRCQCTLR.
  - TRCRSCTLR<n>.
  - TRCRSR.
  - TRCSEQEVR<n>.
  - TRCSEQRSTEVR.
  - TRCSSCCR<n>.
  - TRCSSPCICR<n>.
  - TRCSTALLCTLR.
  - TRCSYNCPR.
  - TRCTRACEIDR.
  - TRCTSCTLR.
  - TRCVIIECTLR.
  - TRCVIPCSSCTLR.
  - TRCVISSCTLR.
  - TRCVMIDCCTLR0.
  - TRCVMIDCCTLR1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- TRCVMIDCVR<n>.

- In an Armv8 implementation:

  - ETM TRCACATR<n>.
  - ETM TRCACVR<n>.
  - ETM TRCBBCTLR.
  - ETM TRCCCCTLR.
  - ETM TRCCIDCCTLR0.
  - ETM TRCCIDCCTLR1.
  - ETM TRCCIDCVR<n>.
  - ETM TRCCNTCTLR<n>.
  - ETM TRCCNTRLDVR<n>.
  - ETM TRCCONFIGR.
  - ETM TRCEVENTCTL0R.
  - ETM TRCEVENTCTL1R.
  - ETM TRCEXTINSELR.
  - ETM TRCQCTLR.
  - ETM TRCRSCTLR<n>.
  - ETM TRCSEQEVR<n>.
  - ETM TRCSEQRSTEVR.
  - ETM TRCSSCCR<n>.
  - ETM TRCSSPCICR<n>.
  - ETM TRCSTALLCTLR.
  - ETM TRCSYNCPR.
  - ETM TRCTRACEIDR.
  - ETM TRCTSCTLR.
  - ETM TRCVIIECTLR.
  - ETM TRCVIPCSSCTLR.
  - ETM TRCVISSCTLR.
  - ETM TRCVMIDCCTLR0.
  - ETM TRCVMIDCCTLR1.
  - ETM TRCVMIDCVR<n>.

TRC	Meaning
`0b0`	`MSR` writes of the specified System registers are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then `MSR` writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

A write of an unimplemented register is UNDEFINED.

TRCEXTINSELR<n> and TRCRSR are implemented only if FEAT_ETE is implemented.

TRCEXTINSELR is implemented only if FEAT_ETE is not implemented and FEAT_ETMv4 is implemented.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSLATFR_EL1, bit [32]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SPE is implemented:

Trap MSR writes of PMSLATFR_EL1 at EL1 using AArch64 to EL2.

PMSLATFR_EL1	Meaning
0b0	MSR writes of PMSLATFR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSLATFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSIRR_EL1, bit [31]

When FEAT_SPE is implemented:

Trap MSR writes of PMSIRR_EL1 at EL1 using AArch64 to EL2.

PMSIRR_EL1	Meaning
0b0	MSR writes of PMSIRR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSIRR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [30]

Reserved, RES0.

PMSICR_EL1, bit [29]

When FEAT_SPE is implemented:

Trap MSR writes of PMSICR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMSICR_EL1	Meaning
0b0	MSR writes of PMSICR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSICR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSFCR_EL1, bit [28]

When FEAT_SPE is implemented:

Trap MSR writes of PMSFCR_EL1 at EL1 using AArch64 to EL2.

PMSFCR_EL1	Meaning
0b0	MSR writes of PMSFCR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSFCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSEVFR_EL1, bit [27]

When FEAT_SPE is implemented:

Trap MSR writes of PMSEVFR_EL1 at EL1 using AArch64 to EL2.

PMSEVFR_EL1	Meaning
0b0	MSR writes of PMSEVFR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSEVFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSCR_EL1, bit [26]

When FEAT_SPE is implemented:

Trap MSR writes of PMSCR_EL1 at EL1 using AArch64 to EL2.

PMSCR_EL1	Meaning
`0b0`	MSR writes of PMSCR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMSCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMBSR_EL1, bit [25]

When FEAT_SPE is implemented:

Trap MSR writes of PMBSR_EL1 at EL1 using AArch64 to EL2.

PMBSR_EL1	Meaning
`0b0`	MSR writes of PMBSR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMBSR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMBPTR_EL1, bit [24]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SPE is implemented:

Trap MSR writes of PMBPTR_EL1 at EL1 using AArch64 to EL2.

PMBPTR_EL1	Meaning
0b0	MSR writes of PMBPTR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMBPTR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMBLIMITR_EL1, bit [23]

When FEAT_SPE is implemented:

Trap MSR writes of PMBLIMITR_EL1 at EL1 using AArch64 to EL2.

PMBLIMITR_EL1	Meaning
0b0	MSR writes of PMBLIMITR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PMBLIMITR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [22]

Reserved, RES0.

PMCR_EL0, bit [21]

When FEAT_PMUv3 is implemented:

Trap MSR writes of PMCR_EL0 at EL1 and EL0 using AArch64 and MCR writes of PMCR at EL0 using AArch32 when EL1 is using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCR_EL0	Meaning
0b0	MSR writes of PMCR_EL0 at EL1 and EL0 using AArch64 and MCR writes of PMCR at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes of PMCR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MCR writes of PMCR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSWINC_EL0, bit [20]

When FEAT_PMUv3 is implemented:

Trap MSR writes of PMSWINC_EL0 at EL1 and EL0 using AArch64 and MCR writes of PMSWINC at EL0 using AArch32 when EL1 is using AArch64 to EL2.

PMSWINC_EL0	Meaning
0b0	MSR writes of PMSWINC_EL0 at EL1 and EL0 using AArch64 and MCR writes of PMSWINC at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes of PMSWINC_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MCR writes of PMSWINC at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMSELR_EL0, bit [19]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_PMUv3 is implemented:

Trap MSR writes of PMSELR_EL0 at EL1 and EL0 using AArch64 and MCR writes of PMSELR at EL0 using AArch32 when EL1 is using AArch64 to EL2.

PMSELR_EL0	Meaning
0b0	MSR writes of PMSELR_EL0 at EL1 and EL0 using AArch64 and MCR writes of PMSELR at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes of PMSELR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MCR writes of PMSELR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMOVS, bit [18]

When FEAT_PMUv3 is implemented:

Trap MSR writes and MCR writes of any of the following System registers to EL2:

- At EL1 and EL0 using AArch64: PMOVSCLR_EL0 and PMOVSSET_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: PMOVSR and PMOVSSET.

PMOVS	Meaning
0b0	MSR writes at EL1 and EL0 using AArch64 and MCR writes at EL0 using AArch32 of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes at EL1 and EL0 using AArch64 of any of the specified AArch64 System registers are trapped to EL2 and reported with EC syndrome value 0x18. • MCR writes at EL0 using AArch32 when EL1 is using AArch64 of any of the specified AArch32 System registers are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

PMINTEN, bit [17]

When FEAT_PMUv3 is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- PMINTENCLR_EL1.
- PMINTENSET_EL1.

PMINTEN	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMCNTEN, bit [16]

When FEAT_PMUv3 is implemented:

Trap MSR writes and MCR writes of any of the following System registers to EL2:

- At EL1 and EL0 using AArch64: PMCNTENCLR_EL0 and PMCNTENSET_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: PMCNTENCLR and PMCNTENSET.

PMCNTEN	Meaning
0b0	MSR writes at EL1 and EL0 using AArch64 and MCR writes at EL0 using AArch32 of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes at EL1 and EL0 using AArch64 of any of the specified AArch64 System registers are trapped to EL2 and reported with EC syndrome value 0x18. • MCR writes at EL0 using AArch32 when EL1 is using AArch64 of any of the specified AArch32 System registers are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the highest implemented Exception level is EL2, this field resets to `'0'`.
- Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMCCNTR_EL0, bit [15]

When FEAT_PMUv3 is implemented:

Trap MSR writes of PMCCNTR_EL0 at EL1 and EL0 using AArch64 and MCR and MCRR writes of PMCCNTR at EL0 using AArch32 when EL1 is using AArch64 to EL2.

PMCCNTR_EL0	Meaning
`0b0`	MSR writes of PMCCNTR_EL0 at EL1 and EL0 using AArch64 and MCR and MCRR writes of PMCCNTR at EL0 using AArch32 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes of PMCCNTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`. • MCR writes of PMCCNTR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value `0x03`. • MCRR writes of PMCCNTR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value `0x04`.

PMCCNTR_EL0 can also be indirectly set to zero by a write of 1 to PMCR_EL0.C or PMZR_EL0.C in AArch64 state, or a write of 1 to PMCR.C in AArch32 state. Setting this field to 1 has no effect on indirect writes to PMCCNTR_EL0 using PMCR_EL0, PMZR_EL0, or PMCR.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMCCFILTR_EL0, bit [14]

When FEAT_PMUv3 is implemented:

Trap MSR writes of PMCCFILTR_EL0 at EL1 and EL0 using AArch64 and MCR writes of PMCCFILTR at EL0 using AArch32 when EL1 is using AArch64 to EL2.

PMCCFILTR_EL0	Meaning
`0b0`	MSR writes of PMCCFILTR_EL0 at EL1 and EL0 using AArch64 and MCR writes of PMCCFILTR at EL0 using AArch32 are not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMCCFILTR_EL0	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes of PMCCFILTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MCR writes of PMCCFILTR at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

PMCCFILTR_EL0 can also be accessed in AArch64 state using PMXEVTYPER_EL0 when PMSELR_EL0.SEL == 31, and PMCCFILTR can also be accessed in AArch32 state using PMXEVTYPER when PMSELR.SEL == 31.

Setting this field to 1 has no effect on accesses to PMXEVTYPER_EL0 and PMXEVTYPER, regardless of the value of PMSELR_EL0.SEL or PMSELR.SEL.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMEVTYPERn_EL0, bit [13]

When FEAT_PMUv3 is implemented:

Trap MSR writes and MCR writes of any of the following System registers to EL2:

- At EL1 and EL0 using AArch64: PMEVTYPER<n>_EL0 and PMXEVTYPER_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: PMEVTYPER<n> and PMXEVTYPER.

PMEVTYPERn_EL0	Meaning
0b0	MSR writes at EL1 and EL0 using AArch64 and MCR writes at EL0 using AArch32 of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes at EL1 and EL0 using AArch64 of any of the specified AArch64 System registers are trapped to EL2 and reported with EC syndrome value 0x18. • MCR writes at EL0 using AArch32 when EL1 is using AArch64 of any of the specified AArch32 System registers are trapped to EL2 and reported with EC syndrome value 0x03.

Regardless of the value of this field, for each value n:

- If event counter n is not implemented, the following accesses are UNDEFINED:
  - In AArch64 state, a write of PMEVTYPER<n>_EL0, or, if n is not 31, a write of PMXEVTYPER_EL0 when PMSELR_EL0.SEL == n.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- In AArch32 state, a write of PMEVTYPER<n>, or, if n is not 31, a write of PMXEVTYPER when PMSELR.SEL == n.
- If event counter n is implemented, n is greater-than-or-equal-to MDCR_EL2.HPMN, and EL2 is implemented and enabled in the current Security state, the following generate a Trap exception to EL2 from EL0 or EL1:
  - In AArch64 state, a write of PMEVTYPER<n>_EL0, or a write of PMXEVTYPER_EL0 when PMSELR_EL0.SEL == n, reported with EC syndrome value `0x18`.
  - In AArch32 state, a write of PMEVTYPER<n>, or a write of PMXEVTYPER when PMSELR.SEL == n, reported with EC syndrome value `0x03`.

See also HDFGWTR_EL2.PMCCFILTR_EL0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

PMEVCNTRn_EL0, bit [12]

When FEAT_PMUv3 is implemented:

Trap MSR writes and MCR writes of any of the following System registers to EL2:

- At EL1 and EL0 using AArch64: PMEVCNTR<n>_EL0 and PMXEVCNTR_EL0.
- At EL0 using AArch32 when EL1 is using AArch64: PMEVCNTR<n> and PMXEVCNTR.

PMEVCNTRn_EL0	Meaning
`0b0`	MSR writes at EL1 and EL0 using AArch64 and MCR writes at EL0 using AArch32 of the specified System registers are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes at EL1 and EL0 using AArch64 of any of the specified AArch64 System registers are trapped to EL2 and reported with EC syndrome value `0x18`. • MCR writes at EL0 using AArch32 when EL1 is using AArch64 of any of the specified AArch32 System registers are trapped to EL2 and reported with EC syndrome value `0x03`.

Regardless of the value of this field, for each value n:

- If event counter n is not implemented, the following accesses are UNDEFINED:
  - In AArch64 state, a write of PMEVCNTR<n>_EL0, or a write of PMXEVCNTR_EL0 when PMSELR_EL0.SEL is n.
  - In AArch32 state, a write of PMEVCNTR<n>, or a write of PMXEVCNTR when PMSELR.SEL is n.
- If event counter n is implemented, n is greater than or equal to MDCR_EL2.HPMN, and EL2 is implemented and enabled in the current Security state, the following generate a Trap exception to EL2 from EL0 or EL1:
  - In AArch64 state, a write of PMEVCNTR<n>_EL0, or a write of PMXEVCNTR_EL0 when PMSELR_EL0.SEL is n, reported with EC syndrome value `0x18`.
  - In AArch32 state, a write of PMEVCNTR<n>, or a write of PMXEVCNTR when PMSELR.SEL is n, reported with EC syndrome value `0x03`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For values of n less than MDCR_EL2.HPMN, PMEVCNTR<n>_EL0 can also be indirectly set to zero by a write of 1 to PMCR_EL0.P or PMZR_EL0.P<n> in AArch64 state, or a write of 1 to PMCR.P in AArch32 state. Setting this field to 1 has no effect on indirect writes to PMEVCNTR<n>_EL0 using PMCR_EL0, PMZR_EL0, or PMCR.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

OSDLR_EL1, bit [11]

When FEAT_DoubleLock is implemented:

Trap MSR writes of OSDLR_EL1 at EL1 using AArch64 to EL2.

OSDLR_EL1	Meaning
`0b0`	MSR writes of OSDLR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of OSDLR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

OSECCR_EL1, bit [10]

Trap MSR writes of OSECCR_EL1 at EL1 using AArch64 to EL2.

OSECCR_EL1	Meaning
`0b0`	MSR writes of OSECCR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of OSECCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [9]

Reserved, RES0.

OSLAR_EL1, bit [8]

Trap MSR writes of OSLAR_EL1 at EL1 using AArch64 to EL2.

OSLAR_EL1	Meaning
0b0	MSR writes of OSLAR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of OSLAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGPRCR_EL1, bit [7]

Trap MSR writes of DBGPRCR_EL1 at EL1 using AArch64 to EL2.

DBGPRCR_EL1	Meaning
0b0	MSR writes of DBGPRCR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of DBGPRCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bit [6]

Reserved, RES0.

DBGCLAIM, bit [5]

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- DBGCLAIMCLR_EL1.
- DBGCLAIMSET_EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DBGCLAIM	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

MDSCR_EL1, bit [4]

Trap MSR writes of MDSCR_EL1 at EL1 using AArch64 to EL2.

MDSCR_EL1	Meaning
0b0	MSR writes of MDSCR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of MDSCR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGWVRn_EL1, bit [3]

Trap MSR writes of DBGWVR<n>_EL1 at EL1 using AArch64 to EL2.

DBGWVRn_EL1	Meaning
0b0	MSR writes of DBGWVR<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of DBGWVR<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If watchpoint n is not implemented, a write of DBGWVR<n>_EL1 is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGWCRn_EL1, bit [2]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Trap MSR writes of DBGWCR<n>_EL1 at EL1 using AArch64 to EL2.

DBGWCRn_EL1	Meaning
0b0	MSR writes of DBGWCR<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of DBGWCR<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If watchpoint n is not implemented, a write of DBGWCR<n>_EL1 is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGBVRn_EL1, bit [1]

Trap MSR writes of DBGBVR<n>_EL1 at EL1 using AArch64 to EL2.

DBGBVRn_EL1	Meaning
0b0	MSR writes of DBGBVR<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of DBGBVR<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If breakpoint n is not implemented, a write of DBGBVR<n>_EL1 is UNDEFINED.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DBGBCRn_EL1, bit [0]

Trap MSR writes of DBGBCR<n>_EL1 at EL1 using AArch64 to EL2.

DBGBCRn_EL1	Meaning
0b0	MSR writes of DBGBCR<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of DBGBCR<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

If breakpoint n is not implemented, a write of DBGBCR<n>_EL1 is UNDEFINED.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

D24.2.69 HFGITR2_EL2, Hypervisor Fine-Grained Instruction Trap Register 2

The HFGITR2_EL2 characteristics are:

Purpose

Provides instruction trap controls.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT2 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HFGITR2_EL2 are UNDEFINED.

Attributes

HFGITR2_EL2 is a 64-bit register.

Field descriptions

Bits [63:2]

Reserved, RES0.

nDCCIVAPS, bit [1]

When FEAT_PoPS is implemented:

Trap execution of any of the following AArch64 instructions at EL1 to EL2:

- DC CIVAPS.
- DC CIGDVAPS, if FEAT_MTE2 is implemented.

If the Point of Physical Storage is before any level of data cache, it is IMPLEMENTATION DEFINED whether the execution of the affected instruction is trapped when the value of this control is 1.

nDCCIVAPS	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then execution at EL1 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.
0b1	Execution of the specified instructions is not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TSBCSYNC, bit [0]

When FEAT_TRBEv1p1 is implemented:

Trap execution of TSB CSYNC at EL1 and EL0 using AArch64 to EL2.

TSBCSYNC	Meaning
`0b0`	Execution of TSB CSYNC is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, then execution of TSB CSYNC at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x0A`, unless the instruction generates a higher priority exception.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing HFGITR2_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HFGITR2_EL2
```

op0	op1	CRn	CRm	op2

D24.2.70 HFGITR_EL2, Hypervisor Fine-Grained Instruction Trap Register

The HFGITR_EL2 characteristics are:

Purpose

Provides instruction trap controls.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HFGITR_EL2 are UNDEFINED.

Attributes

HFGITR_EL2 is a 64-bit register.

Field descriptions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PSBCSYNC, bit [63]

When FEAT_SPEv1p5 is implemented:

Trap execution of PSB CSYNC at EL1 and EL0 using AArch64 to EL2.

PSBCSYNC	Meaning
`0b0`	Execution of PSB CSYNC is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of PSB CSYNC at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x0A`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ATS1E1A, bit [62]

When FEAT_ATS1A is implemented:

Trap execution of AT S1E1A at EL1 using AArch64 to EL2.

ATS1E1A	Meaning
`0b0`	Execution of AT S1E1A is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of AT S1E1A at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [61]

Reserved, RES0.

COSPRCTX, bit [60]

When FEAT_SPECRES2 is implemented:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Trap execution of COSP RCTX at EL1 and EL0 using AArch64 and execution of COSPRCTX at EL0 using AArch32 when EL1 is using AArch64 to EL2.

COSPRCTX	Meaning
0b0	Execution of COSP RCTX at EL1 and EL0 using AArch64 and execution of COSPRCTX at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the instruction generates a higher priority exception: • Execution of COSP RCTX at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18. • Execution of COSPRCTX at EL0 using AArch32 when EL1 is using AArch64 is trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nGCSEPP, bit [59]

When FEAT_GCS is implemented:

Trap execution of any of the following AArch64 instructions at EL1 to EL2:

- GCSPUSHX.
- GCSPOPCX.

nGCSEPP	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution at EL1 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.
0b1	Execution of the specified instructions is not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nGCSSTR_EL1, bit [58]

When FEAT_GCS is implemented:

Trap execution of any of the following AArch64 instructions at EL1 to EL2:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- GCSSTR.
- GCSSTTR when PSTATE.UAO is 1.
- GCSSTTR when the Effective value of HCR_EL2.{NV, NV1} is {1, 1}.

nGCSSTR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution at EL1 using AArch64 of any of the specified instructions generates a GCS exception with EC syndrome value 0x2D, unless the instruction generates a higher priority exception.
0b1	Execution of the specified instructions is not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nGCSPUSHM_EL1, bit [57]

When FEAT_GCS is implemented:

Trap execution of GCSPUSHM at EL1 using AArch64 to EL2.

nGCSPUSHM_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of GCSPUSHM at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.
0b1	Execution of GCSPUSHM is not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nBRBIALL, bit [56]

When FEAT_BRBE is implemented:

Trap execution of BRB IALL at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nBRBIALL	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of BRB IALL at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.
0b1	Execution of BRB IALL is not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nBRBINJ, bit [55]

When FEAT_BRBE is implemented:

Trap execution of BRB INJ at EL1 using AArch64 to EL2.

nBRBINJ	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of BRB INJ at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.
0b1	Execution of BRB INJ is not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DCCVAC, bit [54]

Trap execution of any of the following AArch64 instructions at EL1 and EL0 to EL2:

- DC CVAC.
- DC CGVAC, if FEAT_MTE is implemented.
- DC CGDVAC, if FEAT_MTE is implemented.
- DC CVAOC, if FEAT_OCCMO is implemented.
- DC CGDVAOC, if FEAT_OCCMO is implemented.

DCCVAC	Meaning
0b0	Execution of the specified instructions is not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DCCVAC	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution at EL1 and EL0 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

SVC_EL1, bit [53]

Trap execution of SVC at EL1 using AArch64 to EL2.

SVC_EL1	Meaning
0b0	Execution of SVC is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of SVC at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x15, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

SVC_EL0, bit [52]

Trap execution of SVC at EL0 using AArch64 and execution of SVC at EL0 using AArch32 when EL1 is using AArch64 to EL2.

SVC_EL0	Meaning
0b0	Execution of SVC at EL0 using AArch64 and execution of SVC at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the instruction generates a higher priority exception: • Execution of SVC at EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x15. • Execution of SVC at EL0 using AArch32 when EL1 is using AArch64 is trapped to EL2 and reported with EC syndrome value 0x11.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Otherwise, this field resets to an architecturally UNKNOWN value.

ERET, bit [51]

Trap execution of any of the following AArch64 instructions at EL1 to EL2:

- `ERET`.
- `ERETAA`, if FEAT_PAuth is implemented.
- `ERETAB`, if FEAT_PAuth is implemented.

ERET	Meaning
`0b0`	Execution of the specified instructions is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution at EL1 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value `0x1A`, unless the instruction generates a higher priority exception.

If EL2 is implemented and enabled in the current Security state, HCR_EL2.API == 0, and this field enables a fine-grained trap on the instruction, then execution at EL1 using AArch64 of `ERETAA` or `ERETAB` instructions is trapped to EL2 and reported with EC syndrome value `0x1A` with its associated ISS field, as the fine-grained trap has higher priority than the trap enabled by HCR_EL2.API == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

CPPRCTX, bit [50]

When FEAT_SPECRES is implemented:

Trap execution of CPP RCTX at EL1 and EL0 using AArch64 and execution of CPPRCTX at EL0 using AArch32 when EL1 is using AArch64 to EL2.

CPPRCTX	Meaning
`0b0`	Execution of CPP RCTX at EL1 and EL0 using AArch64 and execution of CPPRCTX at EL0 using AArch32 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the instruction generates a higher priority exception: • Execution of CPP RCTX at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`. • Execution of CPPRCTX at EL0 using AArch32 when EL1 is using AArch64 is trapped to EL2 and reported with EC syndrome value `0x03`.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DVPRCTX, bit [49]

When FEAT_SPECRES is implemented:

Trap execution of DVP RCTX at EL1 and EL0 using AArch64 and execution of DVPRCTX at EL0 using AArch32 when EL1 is using AArch64 to EL2.

DVPRCTX	Meaning
`0b0`	Execution of DVP RCTX at EL1 and EL0 using AArch64 and execution of DVPRCTX at EL0 using AArch32 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the instruction generates a higher priority exception: • Execution of DVP RCTX at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`. • Execution of DVPRCTX at EL0 using AArch32 when EL1 is using AArch64 is trapped to EL2 and reported with EC syndrome value `0x03`.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

CFPRCTX, bit [48]

When FEAT_SPECRES is implemented:

Trap execution of CFP RCTX at EL1 and EL0 using AArch64 and execution of CFPRCTX at EL0 using AArch32 when EL1 is using AArch64 to EL2.

CFPRCTX	Meaning
`0b0`	Execution of CFP RCTX at EL1 and EL0 using AArch64 and execution of CFPRCTX at EL0 using AArch32 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the instruction generates a higher priority exception: • Execution of CFP RCTX at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`. • Execution of CFPRCTX at EL0 using AArch32 when EL1 is using AArch64 is trapped to EL2 and reported with EC syndrome value `0x03`.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

TLBIVAALE1, bit [47]

Trap execution of TLBI VAALE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAALE1NXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAALE1.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAALE1NXS.

TLBIVAALE1	Meaning
`0b0`	Execution of TLBI VAALE1 is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAALE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIVALE1, bit [46]

Trap execution of TLBI VALE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VALE1NXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VALE1.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VALE1NXS.

TLBIVALE1	Meaning
`0b0`	Execution of TLBI VALE1 is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VALE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIVAAE1, bit [45]

Trap execution of TLBI VAAE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAAE1NXS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAAE1.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAAE1NXS.

TLBIVAAE1	Meaning
0b0	Execution of TLBI VAAE1 is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAAE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIASIDE1, bit [44]

Trap execution of TLBI ASIDE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI ASIDE1NXS.

TLBIASIDE1	Meaning
0b0	Execution of TLBI ASIDE1 is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI ASIDE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIVAE1, bit [43]

Trap execution of TLBI VAE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAE1NXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAE1.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAE1NXS.

TLBIVAE1	Meaning
0b0	Execution of TLBI VAE1 is not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TLBIVAE1	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIVMALLE1, bit [42]

Trap execution of TLBI VMALLE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VMALLE1NXS.

TLBIVMALLE1	Meaning
0b0	Execution of TLBI VMALLE1 is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VMALLE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIRVAALE1, bit [41]

When FEAT_TLBIRANGE is implemented:

Trap execution of TLBI RVAALE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAALE1NXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAALE1.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAALE1NXS.

TLBIRVAALE1	Meaning
0b0	Execution of TLBI RVAALE1 is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAALE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVALE1, bit [40]

When FEAT_TLBIRANGE is implemented:

Trap execution of TLBI RVALE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVALE1NXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVALE1.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVALE1NXS.

TLBIRVALE1	Meaning
`0b0`	Execution of TLBI RVALE1 is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVALE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVAAE1, bit [39]

When FEAT_TLBIRANGE is implemented:

Trap execution of TLBI RVAAE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAAE1NXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAAE1.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAAE1NXS.

TLBIRVAAE1	Meaning
`0b0`	Execution of TLBI RVAAE1 is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAAE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVAE1, bit [38]

When FEAT_TLBIRANGE is implemented:

Trap execution of TLBI RVAE1 at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAE1NXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAE1.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAE1NXS.

TLBIRVAE1	Meaning
`0b0`	Execution of TLBI RVAE1 is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAE1 at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVAALE1IS, bit [37]

When FEAT_TLBIRANGE is implemented:

Trap execution of TLBI RVAALE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAALE1ISNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAALE1IS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAALE1ISNXS.

TLBIRVAALE1IS	Meaning
`0b0`	Execution of TLBI RVAALE1IS is not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TLBIRVAALE1IS	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAALE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVALE1IS, bit [36]

When FEAT_TLBIRANGE is implemented:

Trap execution of TLBI RVALE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVALE1ISNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVALE1IS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVALE1ISNXS.

TLBIRVALE1IS	Meaning
0b0	Execution of TLBI RVALE1IS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVALE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVAAE1IS, bit [35]

When FEAT_TLBIRANGE is implemented:

Trap execution of TLBI RVAAE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAAE1ISNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAAE1IS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAAE1ISNXS.

Non-Confidential

TLBIRVAAE1IS	Meaning
0b0	Execution of TLBI RVAAE1IS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAAE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVAE1IS, bit [34]

When FEAT_TLBIRANGE is implemented:

Trap execution of TLBI RVAE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAE1ISNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAE1IS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAE1ISNXS.

TLBIRVAE1IS	Meaning
0b0	Execution of TLBI RVAE1IS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIVAALE1IS, bit [33]

Trap execution of TLBI VAALE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAALE1ISNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAALE1IS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAALE1ISNXS.

TLBIVAALE1IS	Meaning
0b0	Execution of TLBI VAALE1IS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAALE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIVALE1IS, bit [32]

Trap execution of TLBI VALE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VALE1ISNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VALE1IS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VALE1ISNXS.

TLBIVALE1IS	Meaning
0b0	Execution of TLBI VALE1IS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VALE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIVAAE1IS, bit [31]

Trap execution of TLBI VAAE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAAE1ISNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAAE1IS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAAE1ISNXS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TLBIVAAE1IS	Meaning
0b0	Execution of TLBI VAAE1IS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAAE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIASIDE1IS, bit [30]

Trap execution of TLBI ASIDE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI ASIDE1ISNXS.

TLBIASIDE1IS	Meaning
0b0	Execution of TLBI ASIDE1IS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI ASIDE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIVAE1IS, bit [29]

Trap execution of TLBI VAE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAE1ISNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAE1IS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAE1ISNXS.

TLBIVAE1IS	Meaning
0b0	Execution of TLBI VAE1IS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIVMALLE1IS, bit [28]

Trap execution of TLBI VMALLE1IS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VMALLE1ISNXS.

TLBIVMALLE1IS	Meaning
`0b0`	Execution of TLBI VMALLE1IS is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VMALLE1IS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TLBIRVAALE1OS, bit [27]

When FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented:

Trap execution of TLBI RVAALE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAALE1OSNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAALE1OS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAALE1OSNXS.

TLBIRVAALE1OS	Meaning
`0b0`	Execution of TLBI RVAALE1OS is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAALE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TLBIRVALE1OS, bit [26]

When FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented:

Trap execution of TLBI RVALE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVALE1OSNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVALE1OS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVALE1OSNXS.

TLBIRVALE1OS	Meaning
`0b0`	Execution of TLBI RVALE1OS is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVALE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVAAE1OS, bit [25]

When FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented:

Trap execution of TLBI RVAAE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAAE1OSNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAAE1OS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAAE1OSNXS.

TLBIRVAAE1OS	Meaning
`0b0`	Execution of TLBI RVAAE1OS is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAAE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIRVAE1OS, bit [24]

When FEAT_TLBIRANGE is implemented and FEAT_TLBIOS is implemented:

Trap execution of TLBI RVAE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI RVAE1OSNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP RVAE1OS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP RVAE1OSNXS.

TLBIRVAE1OS	Meaning
`0b0`	Execution of TLBI RVAE1OS is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI RVAE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIVAALE1OS, bit [23]

When FEAT_TLBIOS is implemented:

Trap execution of TLBI VAALE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAALE1OSNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAALE1OS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAALE1OSNXS.

TLBIVAALE1OS	Meaning
`0b0`	Execution of TLBI VAALE1OS is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAALE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

Non-Confidential

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIVALE1OS, bit [22]

When FEAT_TLBIOS is implemented:

Trap execution of TLBI VALE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VALE1OSNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VALE1OS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VALE1OSNXS.

TLBIVALE1OS	Meaning
`0b0`	Execution of TLBI VALE1OS is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VALE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIVAAE1OS, bit [21]

When FEAT_TLBIOS is implemented:

Trap execution of TLBI VAAE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAAE1OSNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAAE1OS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAAE1OSNXS.

TLBIVAAE1OS	Meaning
`0b0`	Execution of TLBI VAAE1OS is not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TLBIVAAE1OS	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAAE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIASIDE1OS, bit [20]

When FEAT_TLBIOS is implemented:

Trap execution of TLBI ASIDE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI ASIDE1OSNXS.

TLBIASIDE1OS	Meaning
0b0	Execution of TLBI ASIDE1OS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI ASIDE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIVAE1OS, bit [19]

When FEAT_TLBIOS is implemented:

Trap execution of TLBI VAE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VAE1OSNXS.

If FEAT_D128 is implemented, then this field also traps execution of TLBIP VAE1OS.

If FEAT_XS and FEAT_D128 are implemented, then this field also traps execution of TLBIP VAE1OSNXS.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TLBIVAE1OS	Meaning
0b0	Execution of TLBI VAE1OS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VAE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

TLBIVMALLE1OS, bit [18]

When FEAT_TLBIOS is implemented:

Trap execution of TLBI VMALLE1OS at EL1 using AArch64 to EL2.

If FEAT_XS is implemented and HCRX_EL2.FGTnXS == 0, this field also traps execution of TLBI VMALLE1OSNXS.

TLBIVMALLE1OS	Meaning
0b0	Execution of TLBI VMALLE1OS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of TLBI VMALLE1OS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ATS1E1WP, bit [17]

When FEAT_PAN2 is implemented:

Trap execution of AT S1E1WP at EL1 using AArch64 to EL2.

ATS1E1WP	Meaning
0b0	Execution of AT S1E1WP is not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ATS1E1WP	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of AT S1E1WP at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ATS1E1RP, bit [16]

When FEAT_PAN2 is implemented:

Trap execution of AT S1E1RP at EL1 using AArch64 to EL2.

ATS1E1RP	Meaning
0b0	Execution of AT S1E1RP is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of AT S1E1RP at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ATS1E0W, bit [15]

Trap execution of AT S1E0W at EL1 using AArch64 to EL2.

ATS1E0W	Meaning
0b0	Execution of AT S1E0W is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of AT S1E0W at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the highest implemented Exception level is EL2, this field resets to `'0'`.
- Otherwise, this field resets to an architecturally UNKNOWN value.

ATS1E0R, bit [14]

Trap execution of AT S1E0R at EL1 using AArch64 to EL2.

ATS1E0R	Meaning
`0b0`	Execution of AT S1E0R is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of AT S1E0R at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

ATS1E1W, bit [13]

Trap execution of AT S1E1W at EL1 using AArch64 to EL2.

ATS1E1W	Meaning
`0b0`	Execution of AT S1E1W is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of AT S1E1W at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

ATS1E1R, bit [12]

Trap execution of AT S1E1R at EL1 using AArch64 to EL2.

ATS1E1R	Meaning
`0b0`	Execution of AT S1E1R is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution of AT S1E1R at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DCZVA, bit [11]

Trap execution of any of the following AArch64 instructions at EL1 and EL0 to EL2:

- DC ZVA.
- DC GVA, if FEAT_MTE is implemented.
- DC GZVA, if FEAT_MTE is implemented.

Note

Unlike HCR_EL2.TDZ, this field has no effect on DCZID_EL0.DZP.

DCZVA	Meaning
`0b0`	Execution of the specified instructions is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution at EL1 and EL0 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DCCIVAC, bit [10]

Trap execution of any of the following AArch64 instructions at EL1 and EL0 to EL2:

- DC CIVAC.
- DC CIGVAC, if FEAT_MTE is implemented.
- DC CIGDVAC, if FEAT_MTE is implemented.
- DC CIVAOC, if FEAT_OCCMO is implemented.
- DC CIGDVAOC, if FEAT_OCCMO is implemented.

DCCIVAC	Meaning
`0b0`	Execution of the specified instructions is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution at EL1 and EL0 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DCCVADP, bit [9]

When FEAT_DPB2 is implemented:

Trap execution of any of the following AArch64 instructions at EL1 and EL0 to EL2:

- DC CVADP.
- DC CGVADP, if FEAT_MTE is implemented.
- DC CGDVADP, if FEAT_MTE is implemented.

DCCVADP	Meaning
`0b0`	Execution of the specified instructions is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution at EL1 and EL0 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

DCCVAP, bit [8]

Trap execution of any of the following AArch64 instructions at EL1 and EL0 to EL2:

- DC CVAP.
- DC CGVAP, if FEAT_MTE is implemented.
- DC CGDVAP, if FEAT_MTE is implemented.

DCCVAP	Meaning
`0b0`	Execution of the specified instructions is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution at EL1 and EL0 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DCCVAU, bit [7]

Trap execution of DC CVAU at EL1 and EL0 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DCCVAU	Meaning
0b0	Execution of DC CVAU is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution of DC CVAU at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DCCISW, bit [6]

Trap execution of any of the following AArch64 instructions at EL1 to EL2:

- DC CISW.
- DC CIGSW, if FEAT_MTE2 is implemented.
- DC CIGDSW, if FEAT_MTE2 is implemented.

DCCISW	Meaning
0b0	Execution of the specified instructions is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution at EL1 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DCCSW, bit [5]

Trap execution of any of the following AArch64 instructions at EL1 to EL2:

- DC CSW.
- DC CGSW, if FEAT_MTE2 is implemented.
- DC CGDSW, if FEAT_MTE2 is implemented.

DCCSW	Meaning
0b0	Execution of the specified instructions is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution at EL1 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DCISW, bit [4]

Trap execution of any of the following AArch64 instructions at EL1 to EL2:

- DC ISW.
- DC IGSW, if FEAT_MTE2 is implemented.
- DC IGDSW, if FEAT_MTE2 is implemented.

DCISW	Meaning
`0b0`	Execution of the specified instructions is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then execution at EL1 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DCIVAC, bit [3]

Trap execution of any of the following AArch64 instructions at EL1 to EL2:

- DC IVAC.
- DC IGVAC, if FEAT_MTE2 is implemented.
- DC IGDVAC, if FEAT_MTE2 is implemented.

DCIVAC	Meaning
`0b0`	Execution of the specified instructions is not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution at EL1 using AArch64 of any of the specified instructions is trapped to EL2 and reported with EC syndrome value `0x18`, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

ICIVAU, bit [2]

Trap execution of IC IVAU at EL1 and EL0 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ICIVAU	Meaning
0b0	Execution of IC IVAU is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution of IC IVAU at EL1 and EL0 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

ICIALLU, bit [1]

Trap execution of IC IALLU at EL1 using AArch64 to EL2.

ICIALLU	Meaning
0b0	Execution of IC IALLU is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution of IC IALLU at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

ICIALLUIS, bit [0]

Trap execution of IC IALLUIS at EL1 using AArch64 to EL2.

ICIALLUIS	Meaning
0b0	Execution of IC IALLUIS is not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then if the execution can be trapped, execution of IC IALLUIS at EL1 using AArch64 is trapped to EL2 and reported with EC syndrome value 0x18, unless the instruction generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

D24.2.71 HFGRTR2_EL2, Hypervisor Fine-Grained Read Trap Register 2

The HFGRTR2_EL2 characteristics are:

Purpose

Provides controls for traps of `MRRS`, `MRS` and `MRC` reads of System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT2 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HFGRTR2_EL2 are UNDEFINED.

Attributes

HFGRTR2_EL2 is a 64-bit register.

Field descriptions

Bits [63:40]

Reserved, RES0.

ACTLR_EL1, bit [39]

When FEAT_SRMASK is implemented:

Trap `MRS` reads of ACTLR_EL1 at EL1 using AArch64 to EL2.

ACTLR_EL1	Meaning
`0b0`	`MRS` reads of ACTLR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, then `MRS` reads of ACTLR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

This field is ignored by the PE and treated as zero when all of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [38:15]

Reserved, RES0.

nACTLRALIAS_EL1, bit [14]

When FEAT_SRMASK is implemented:

Trap MRS reads of ACTLRALIAS_EL1 at EL1 using AArch64 to EL2.

nACTLRALIAS_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MRS reads of ACTLRALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.
`0b1`	MRS reads of ACTLRALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nACTLRMASK_EL1, bit [13]

When FEAT_SRMASK is implemented:

Trap MRS reads of ACTLRMASK_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nACTLRMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of ACTLRMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of ACTLRMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTCR2ALIAS_EL1, bit [12]

When FEAT_SRMASK is implemented:

Trap MRS reads of TCR2ALIAS_EL1 at EL1 using AArch64 to EL2.

nTCR2ALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of TCR2ALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of TCR2ALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTCRALIAS_EL1, bit [11]

When FEAT_SRMASK is implemented:

Trap MRS reads of TCRALIAS_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nTCRALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of TCRALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of TCRALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSCTLR2ALIAS_EL1, bit [10]

When FEAT_SRMASK is implemented:

Trap MRS reads of SCTLR2ALIAS_EL1 at EL1 using AArch64 to EL2.

nSCTLR2ALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of SCTLR2ALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SCTLR2ALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSCTLRALIAS_EL1, bit [9]

When FEAT_SRMASK is implemented:

Trap MRS reads of SCTLRALIAS_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSCTLRALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of SCTLRALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SCTLRALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nCPACRALIAS_EL1, bit [8]

When FEAT_SRMASK is implemented:

Trap MRS reads of CPACRALIAS_EL1 at EL1 using AArch64 to EL2.

nCPACRALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of CPACRALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of CPACRALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTCR2MASK_EL1, bit [7]

When FEAT_SRMASK is implemented:

Trap MRS reads of TCR2MASK_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nTCR2MASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of TCR2MASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of TCR2MASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTCRMASK_EL1, bit [6]

When FEAT_SRMASK is implemented:

Trap MRS reads of TCRMASK_EL1 at EL1 using AArch64 to EL2.

nTCRMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of TCRMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of TCRMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSCTLR2MASK_EL1, bit [5]

When FEAT_SRMASK is implemented:

Trap MRS reads of SCTLR2MASK_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSCTLR2MASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of SCTLR2MASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SCTLR2MASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSCTLRMASK_EL1, bit [4]

When FEAT_SRMASK is implemented:

Trap MRS reads of SCTLRMASK_EL1 at EL1 using AArch64 to EL2.

nSCTLRMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of SCTLRMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SCTLRMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nCPACRMASK_EL1, bit [3]

When FEAT_SRMASK is implemented:

Trap MRS reads of CPACRMASK_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nCPACRMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of CPACRMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of CPACRMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nRCWSMASK_EL1, bit [2]

When FEAT_THE is implemented:

Trap MRS or MRRS reads of RCWSMASK_EL1 at EL1 using AArch64 to EL2.

nRCWSMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then unless the read generates a higher priority exception: • MRS reads of RCWSMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRRS reads of RCWSMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x14.
0b1	MRS and MRRS reads of RCWSMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nERXGSR_EL1, bit [1]

When FEAT_RASv2 is implemented:

Trap MRS reads of ERXGSR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nERXGSR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of ERXGSR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of ERXGSR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPFAR_EL1, bit [0]

When FEAT_PFAR is implemented:

Trap MRS reads of PFAR_EL1 at EL1 using AArch64 to EL2.

nPFAR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MRS reads of PFAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PFAR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

D24.2.72 HFGRTR_EL2, Hypervisor Fine-Grained Read Trap Register

The HFGRTR_EL2 characteristics are:

Purpose

Provides controls for traps of `MRRS`, `MRS` and `MRC` reads of System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HFGRTR_EL2 are UNDEFINED.

Attributes

HFGRTR_EL2 is a 64-bit register.

Field descriptions

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nAMAIR2_EL1, bit [63]

When FEAT_AIE is implemented:

Trap MRS reads of AMAIR2_EL1 at EL1 using AArch64 to EL2.

nAMAIR2_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of AMAIR2_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of AMAIR2_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nMAIR2_EL1, bit [62]

When FEAT_AIE is implemented:

Trap MRS reads of MAIR2_EL1 at EL1 using AArch64 to EL2.

nMAIR2_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of MAIR2_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of MAIR2_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nS2POR_EL1, bit [61]

When FEAT_S2POE is implemented:

Trap MRS reads of S2POR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nS2POR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of S2POR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of S2POR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPOR_EL1, bit [60]

When FEAT_S1POE is implemented:

Trap MRS reads of POR_EL1 at EL1 using AArch64 to EL2.

nPOR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of POR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of POR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPOR_EL0, bit [59]

When FEAT_S1POE is implemented:

Trap MRS reads of POR_EL0 at EL1 and EL0 using AArch64 to EL2.

nPOR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of POR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nPOR_EL0	Meaning
0b1	MRS reads of POR_EL0 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPIR_EL1, bit [58]

When FEAT_S1PIE is implemented:

Trap MRS reads of PIR_EL1 at EL1 using AArch64 to EL2.

nPIR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PIR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PIR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPIRE0_EL1, bit [57]

When FEAT_S1PIE is implemented:

Trap MRS reads of PIRE0_EL1 at EL1 using AArch64 to EL2.

nPIRE0_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of PIRE0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of PIRE0_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the highest implemented Exception level is EL2, this field resets to `'0'`.
- Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nRCWMASK_EL1, bit [56]

When FEAT_THE is implemented:

Trap `MRS` or `MRRS` reads of RCWMASK_EL1 at EL1 using AArch64 to EL2.

nRCWMASK_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • `MRS` reads of RCWMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`. • `MRRS` reads of RCWMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x14`.
`0b1`	`MRS` and `MRRS` reads of RCWMASK_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTPIDR2_EL0, bit [55]

When FEAT_SME is implemented:

Trap `MRS` reads of TPIDR2_EL0 at EL1 and EL0 using AArch64 to EL2.

nTPIDR2_EL0	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then `MRS` reads of TPIDR2_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.
`0b1`	`MRS` reads of TPIDR2_EL0 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

nSMPRI_EL1, bit [54]

When FEAT_SME is implemented:

Trap MRS reads of SMPRI_EL1 at EL1 using AArch64 to EL2.

nSMPRI_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of SMPRI_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of SMPRI_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nGCS_EL1, bit [53]

When FEAT_GCS is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- GCSCR_EL1.
- GCSPR_EL1.

nGCS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of the specified System registers are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nGCS_EL0, bit [52]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_GCS is implemented:

Trap MRS reads at EL1 and EL0 using AArch64 of any of the following AArch64 System registers to EL2:

- GCSCRE0_EL1, at EL1 only.
- GCSPR_EL0.

nGCS_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 and EL0 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of the specified System registers are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [51]

Reserved, RES0.

nACCDATA_EL1, bit [50]

When FEAT_LS64_ACCDATA is implemented:

Trap MRS reads of ACCDATA_EL1 at EL1 using AArch64 to EL2.

nACCDATA_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ACCDATA_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.
0b1	MRS reads of ACCDATA_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXADDR_EL1, bit [49]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_RAS is implemented:

Trap MRS reads of ERXADDR_EL1 at EL1 using AArch64 to EL2.

ERXADDR_EL1	Meaning
0b0	MRS reads of ERXADDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERXADDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXPFGCDN_EL1, bit [48]

When FEAT_RASv1p1 is implemented:

Trap MRS reads of ERXPFGCDN_EL1 at EL1 using AArch64 to EL2.

ERXPFGCDN_EL1	Meaning
0b0	MRS reads of ERXPFGCDN_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERXPFGCDN_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ERXPFGCTL_EL1, bit [47]

When FEAT_RASv1p1 is implemented:

Trap MRS reads of ERXPFGCTL_EL1 at EL1 using AArch64 to EL2.

ERXPFGCTL_EL1	Meaning
0b0	MRS reads of ERXPFGCTL_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERXPFGCTL_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXPFGF_EL1, bit [46]

When FEAT_RASv1p1 is implemented:

Trap MRS reads of ERXPFGF_EL1 at EL1 using AArch64 to EL2.

ERXPFGF_EL1	Meaning
0b0	MRS reads of ERXPFGF_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERXPFGF_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

ERXMISCn_EL1, bit [45]

When FEAT_RAS is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- ERXMISC0_EL1.
- ERXMISC1_EL1.
- ERXMISC2_EL1.
- ERXMISC3_EL1.

ERXMISCn_EL1	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXSTATUS_EL1, bit [44]

When FEAT_RAS is implemented:

Trap MRS reads of ERXSTATUS_EL1 at EL1 using AArch64 to EL2.

ERXSTATUS_EL1	Meaning
0b0	MRS reads of ERXSTATUS_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERXSTATUS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
- ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXCTLR_EL1, bit [43]

When FEAT_RAS is implemented:

Trap MRS reads of ERXCTLR_EL1 at EL1 using AArch64 to EL2.

ERXCTLR_EL1	Meaning
`0b0`	MRS reads of ERXCTLR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERXCTLR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXFR_EL1, bit [42]

When FEAT_RAS is implemented:

Trap MRS reads of ERXFR_EL1 at EL1 using AArch64 to EL2.

ERXFR_EL1	Meaning
`0b0`	MRS reads of ERXFR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERXFR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERRSELR_EL1, bit [41]

When FEAT_RAS is implemented:

Trap MRS reads of ERRSELR_EL1 at EL1 using AArch64 to EL2.

ERRSELR_EL1	Meaning
`0b0`	MRS reads of ERRSELR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERRSELR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERRIDR_EL1, bit [40]

When FEAT_RAS is implemented:

Trap MRS reads of ERRIDR_EL1 at EL1 using AArch64 to EL2.

ERRIDR_EL1	Meaning
`0b0`	MRS reads of ERRIDR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ERRIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

Accessing this field has the following behavior:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ICC_IGRPENn_EL1, bit [39]

When GICv3 is implemented:

Trap MRS reads of ICC_IGRPEN<n>_EL1 at EL1 using AArch64 to EL2.

ICC_IGRPENn_EL1	Meaning
`0b0`	MRS reads of ICC_IGRPEN<n>_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ICC_IGRPEN<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VBAR_EL1, bit [38]

Trap MRS reads of VBAR_EL1 at EL1 using AArch64 to EL2.

VBAR_EL1	Meaning
`0b0`	MRS reads of VBAR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of VBAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTBR1_EL1, bit [37]

Trap MRS or MRRS reads of TTBR1_EL1 at EL1 using AArch64 to EL2.

TTBR1_EL1	Meaning
0b0	MRS and MRRS reads of TTBR1_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of TTBR1_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRRS reads of TTBR1_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x14.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TTBR0_EL1, bit [36]

Trap MRS or MRRS reads of TTBR0_EL1 at EL1 using AArch64 to EL2.

TTBR0_EL1	Meaning
0b0	MRS and MRRS reads of TTBR0_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of TTBR0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRRS reads of TTBR0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x14.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TPIDR_EL0, bit [35]

Trap MRS reads of TPIDR_EL0 at EL1 and EL0 using AArch64 and MRC reads of TPIDRURW at EL0 using AArch32 when EL1 is using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TPIDR_EL0	Meaning
0b0	MRS reads of TPIDR_EL0 at EL1 and EL0 using AArch64 and MRC reads of TPIDRURW at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of TPIDR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of TPIDRURW at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TPIDRRO_EL0, bit [34]

Trap MRS reads of TPIDRRO_EL0 at EL1 and EL0 using AArch64 and MRC reads of TPIDRURO at EL0 using AArch32 when EL1 is using AArch64 to EL2.

TPIDRRO_EL0	Meaning
0b0	MRS reads of TPIDRRO_EL0 at EL1 and EL0 using AArch64 and MRC reads of TPIDRURO at EL0 using AArch32 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of TPIDRRO_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRC reads of TPIDRURO at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value 0x03.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TPIDR_EL1, bit [33]

Trap MRS reads of TPIDR_EL1 at EL1 using AArch64 to EL2.

TPIDR_EL1	Meaning
0b0	MRS reads of TPIDR_EL1 are not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TPIDR_EL1	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of TPIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TCR_EL1, bit [32]

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- TCR_EL1.
- TCR2_EL1, if FEAT_TCR2 is implemented.

TCR_EL1	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

SCXTNUM_EL0, bit [31]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Trap MRS reads of SCXTNUM_EL0 at EL1 and EL0 using AArch64 to EL2.

SCXTNUM_EL0	Meaning
0b0	MRS reads of SCXTNUM_EL0 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of SCXTNUM_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

SCXTNUM_EL1, bit [30]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Trap MRS reads of SCXTNUM_EL1 at EL1 using AArch64 to EL2.

SCXTNUM_EL1	Meaning
0b0	MRS reads of SCXTNUM_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of SCXTNUM_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SCTLR_EL1, bit [29]

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- SCTLR_EL1.
- SCTLR2_EL1, if FEAT_SCTLR2 is implemented.

SCTLR_EL1	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

REVIDR_EL1, bit [28]

Trap MRS reads of REVIDR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

REVIDR_EL1	Meaning
0b0	MRS reads of REVIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of REVIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

PAR_EL1, bit [27]

Trap MRS or MRRS reads of PAR_EL1 at EL1 using AArch64 to EL2.

PAR_EL1	Meaning
0b0	MRS and MRRS reads of PAR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the read generates a higher priority exception: • MRS reads of PAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MRRS reads of PAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x14.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

MPIDR_EL1, bit [26]

Trap MRS reads of MPIDR_EL1 at EL1 using AArch64 to EL2.

MPIDR_EL1	Meaning
0b0	MRS reads of MPIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of MPIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MIDR_EL1, bit [25]

Trap MRS reads of MIDR_EL1 at EL1 using AArch64 to EL2.

MIDR_EL1	Meaning
0b0	MRS reads of MIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of MIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

MAIR_EL1, bit [24]

Trap MRS reads of MAIR_EL1 at EL1 using AArch64 to EL2.

MAIR_EL1	Meaning
0b0	MRS reads of MAIR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of MAIR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

LORSA_EL1, bit [23]

When FEAT_LOR is implemented:

Trap MRS reads of LORSA_EL1 at EL1 using AArch64 to EL2.

LORSA_EL1	Meaning
0b0	MRS reads of LORSA_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of LORSA_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LORN_EL1, bit [22]

When FEAT_LOR is implemented:

Trap MRS reads of LORN_EL1 at EL1 using AArch64 to EL2.

LORN_EL1	Meaning
`0b0`	MRS reads of LORN_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of LORN_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LORID_EL1, bit [21]

When FEAT_LOR is implemented:

Trap MRS reads of LORID_EL1 at EL1 using AArch64 to EL2.

LORID_EL1	Meaning
`0b0`	MRS reads of LORID_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of LORID_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LOREA_EL1, bit [20]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_LOR is implemented:

Trap MRS reads of LOREA_EL1 at EL1 using AArch64 to EL2.

LOREA_EL1	Meaning
0b0	MRS reads of LOREA_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of LOREA_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LORC_EL1, bit [19]

When FEAT_LOR is implemented:

Trap MRS reads of LORC_EL1 at EL1 using AArch64 to EL2.

LORC_EL1	Meaning
0b0	MRS reads of LORC_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of LORC_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ISR_EL1, bit [18]

Trap MRS reads of ISR_EL1 at EL1 using AArch64 to EL2.

ISR_EL1	Meaning
0b0	MRS reads of ISR_EL1 are not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ISR_EL1	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ISR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

FAR_EL1, bit [17]

Trap MRS reads of FAR_EL1 at EL1 using AArch64 to EL2.

FAR_EL1	Meaning
0b0	MRS reads of FAR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of FAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

ESR_EL1, bit [16]

Trap MRS reads of ESR_EL1 at EL1 using AArch64 to EL2.

ESR_EL1	Meaning
0b0	MRS reads of ESR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of ESR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

DCZID_EL0, bit [15]

Trap MRS reads of DCZID_EL0 at EL1 and EL0 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DCZID_EL0	Meaning
0b0	MRS reads of DCZID_EL0 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of DCZID_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

CTR_EL0, bit [14]

Trap MRS reads of CTR_EL0 at EL1 and EL0 using AArch64 to EL2.

CTR_EL0	Meaning
0b0	MRS reads of CTR_EL0 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of CTR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

CSSELR_EL1, bit [13]

Trap MRS reads of CSSELR_EL1 at EL1 using AArch64 to EL2.

CSSELR_EL1	Meaning
0b0	MRS reads of CSSELR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of CSSELR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

CPACR_EL1, bit [12]

Trap MRS reads of CPACR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CPACR_EL1	Meaning
0b0	MRS reads of CPACR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of CPACR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

CONTEXTIDR_EL1, bit [11]

Trap MRS reads of CONTEXTIDR_EL1 at EL1 using AArch64 to EL2.

CONTEXTIDR_EL1	Meaning
0b0	MRS reads of CONTEXTIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of CONTEXTIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

CLIDR_EL1, bit [10]

Trap MRS reads of CLIDR_EL1 at EL1 using AArch64 to EL2.

CLIDR_EL1	Meaning
0b0	MRS reads of CLIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of CLIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CCSIDR_EL1, bit [9]

Trap MRS reads of CCSIDR_EL1 at EL1 using AArch64 to EL2.

CCSIDR_EL1	Meaning
0b0	MRS reads of CCSIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of CCSIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

APIBKey, bit [8]

When FEAT_PAuth is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APIBKeyHi_EL1.
- APIBKeyLo_EL1.

APIBKey	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APIAKey, bit [7]

When FEAT_PAuth is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APIAKeyHi_EL1.
- APIAKeyLo_EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

APIAKey	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APGAKey, bit [6]

When FEAT_PAuth is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APGAKeyHi_EL1.
- APGAKeyLo_EL1.

APGAKey	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APDBKey, bit [5]

When FEAT_PAuth is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APDBKeyHi_EL1.
- APDBKeyLo_EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

APDBKey	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APDAKey, bit [4]

When FEAT_PAuth is implemented:

Trap MRS reads at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APDAKeyHi_EL1.
- APDAKeyLo_EL1.

APDAKey	Meaning
0b0	MRS reads of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AMAIR_EL1, bit [3]

Trap MRS reads of AMAIR_EL1 at EL1 using AArch64 to EL2.

AMAIR_EL1	Meaning
0b0	MRS reads of AMAIR_EL1 are not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AMAIR_EL1	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of AMAIR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

AIDR_EL1, bit [2]

Trap MRS reads of AIDR_EL1 at EL1 using AArch64 to EL2.

AIDR_EL1	Meaning
0b0	MRS reads of AIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of AIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

AFSR1_EL1, bit [1]

Trap MRS reads of AFSR1_EL1 at EL1 using AArch64 to EL2.

AFSR1_EL1	Meaning
0b0	MRS reads of AFSR1_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of AFSR1_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

AFSR0_EL1, bit [0]

Trap MRS reads of AFSR0_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

AFSR0_EL1	Meaning
0b0	MRS reads of AFSR0_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MRS reads of AFSR0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the read generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing HFGRTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HFGRTR_EL2
```

op0	op1	CRn	CRm	op2

D24.2.73 HFGWTR2_EL2, Hypervisor Fine-Grained Write Trap Register 2

The HFGWTR2_EL2 characteristics are:

Purpose

Provides controls for traps of MSRR, MSR and MCR writes of System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT2 is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HFGWTR2_EL2 are UNDEFINED.

Attributes

HFGWTR2_EL2 is a 64-bit register.

Field descriptions

Bits [63:40]

Reserved, RES0.

ACTLR_EL1, bit [39]

When FEAT_SRMASK is implemented:

Trap MSR writes of ACTLR_EL1 at EL1 using AArch64 to EL2.

ACTLR_EL1	Meaning
0b0	MSR writes of ACTLR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, then MSR writes of ACTLR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [38:15]

Reserved, RES0.

nACTLRALIAS_EL1, bit [14]

When FEAT_SRMASK is implemented:

Trap MSR writes of ACTLRALIAS_EL1 at EL1 using AArch64 to EL2.

nACTLRALIAS_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of ACTLRALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	MSR writes of ACTLRALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nACTLRMASK_EL1, bit [13]

When FEAT_SRMASK is implemented:

Trap MSR writes of ACTLRMASK_EL1 at EL1 using AArch64 to EL2.

nACTLRMASK_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, then MSR writes of ACTLRMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b1	MSR writes of ACTLRMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTCR2ALIAS_EL1, bit [12]

When FEAT_SRMASK is implemented:

Trap MSR writes of TCR2ALIAS_EL1 at EL1 using AArch64 to EL2.

nTCR2ALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of TCR2ALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of TCR2ALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTCRALIAS_EL1, bit [11]

When FEAT_SRMASK is implemented:

Trap MSR writes of TCRALIAS_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nTCRALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of TCRALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of TCRALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSCTLR2ALIAS_EL1, bit [10]

When FEAT_SRMASK is implemented:

Trap MSR writes of SCTLR2ALIAS_EL1 at EL1 using AArch64 to EL2.

nSCTLR2ALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of SCTLR2ALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of SCTLR2ALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSCTLRALIAS_EL1, bit [9]

When FEAT_SRMASK is implemented:

Trap MSR writes of SCTLRALIAS_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSCTLRALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of SCTLRALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of SCTLRALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nCPACRALIAS_EL1, bit [8]

When FEAT_SRMASK is implemented:

Trap MSR writes of CPACRALIAS_EL1 at EL1 using AArch64 to EL2.

nCPACRALIAS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of CPACRALIAS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of CPACRALIAS_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTCR2MASK_EL1, bit [7]

When FEAT_SRMASK is implemented:

Trap MSR writes of TCR2MASK_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nTCR2MASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of TCR2MASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of TCR2MASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTCRMASK_EL1, bit [6]

When FEAT_SRMASK is implemented:

Trap MSR writes of TCRMASK_EL1 at EL1 using AArch64 to EL2.

nTCRMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of TCRMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of TCRMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSCTLR2MASK_EL1, bit [5]

When FEAT_SRMASK is implemented:

Trap MSR writes of SCTLR2MASK_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nSCTLR2MASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of SCTLR2MASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of SCTLR2MASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nSCTLRMASK_EL1, bit [4]

When FEAT_SRMASK is implemented:

Trap MSR writes of SCTLRMASK_EL1 at EL1 using AArch64 to EL2.

nSCTLRMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of SCTLRMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of SCTLRMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nCPACRMASK_EL1, bit [3]

When FEAT_SRMASK is implemented:

Trap MSR writes of CPACRMASK_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nCPACRMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of CPACRMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of CPACRMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nRCWSMASK_EL1, bit [2]

When FEAT_THE is implemented:

Trap MSR or MSRR writes of RCWSMASK_EL1 at EL1 using AArch64 to EL2.

nRCWSMASK_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then unless the write generates a higher priority exception: • MSR writes of RCWSMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MSRR writes of RCWSMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x14.
0b1	MSR and MSRR writes of RCWSMASK_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [1]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nPFAR_EL1, bit [0]

When FEAT_PFAR is implemented:

Trap MSR writes of PFAR_EL1 at EL1 using AArch64 to EL2.

nPFAR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, then MSR writes of PFAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of PFAR_EL1 are not trapped by this mechanism.

This field is ignored by the PE and treated as zero when all of the following are true:

- EL3 is implemented.
- SCR_EL3.FGTEn2 == 0.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Accessing HFGWTR2_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HFGWTR2_EL2
```

op0	op1	CRn	CRm	op2

D24.2.74 HFGWTR_EL2, Hypervisor Fine-Grained Write Trap Register

The HFGWTR_EL2 characteristics are:

Purpose

Provides controls for traps of `MSRR`, `MSR` and `MCR` writes of System registers.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register is present only when FEAT_FGT is implemented and FEAT_AA64 is implemented. Otherwise, direct accesses to HFGWTR_EL2 are UNDEFINED.

Attributes

HFGWTR_EL2 is a 64-bit register.

Field descriptions

nAMAIR2_EL1, bit [63]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_AIE is implemented:

Trap MSR writes of AMAIR2_EL1 at EL1 using AArch64 to EL2.

nAMAIR2_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of AMAIR2_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of AMAIR2_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nMAIR2_EL1, bit [62]

When FEAT_AIE is implemented:

Trap MSR writes of MAIR2_EL1 at EL1 using AArch64 to EL2.

nMAIR2_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of MAIR2_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of MAIR2_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nS2POR_EL1, bit [61]

When FEAT_S2POE is implemented:

Trap MSR writes of S2POR_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nS2POR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of S2POR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of S2POR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPOR_EL1, bit [60]

When FEAT_S1POE is implemented:

Trap MSR writes of POR_EL1 at EL1 using AArch64 to EL2.

nPOR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of POR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of POR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPOR_EL0, bit [59]

When FEAT_S1POE is implemented:

Trap MSR writes of POR_EL0 at EL1 and EL0 using AArch64 to EL2.

nPOR_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of POR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

nPOR_EL0	Meaning
0b1	MSR writes of POR_EL0 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPIR_EL1, bit [58]

When FEAT_S1PIE is implemented:

Trap MSR writes of PIR_EL1 at EL1 using AArch64 to EL2.

nPIR_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PIR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of PIR_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nPIRE0_EL1, bit [57]

When FEAT_S1PIE is implemented:

Trap MSR writes of PIRE0_EL1 at EL1 using AArch64 to EL2.

nPIRE0_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of PIRE0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of PIRE0_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- When the highest implemented Exception level is EL2, this field resets to `'0'`.
- Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nRCWMASK_EL1, bit [56]

When FEAT_THE is implemented:

Trap `MSR` or `MSRR` writes of RCWMASK_EL1 at EL1 using AArch64 to EL2.

nRCWMASK_EL1	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • `MSR` writes of RCWMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`. • `MSRR` writes of RCWMASK_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x14`.
`0b1`	`MSR` and `MSRR` writes of RCWMASK_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nTPIDR2_EL0, bit [55]

When FEAT_SME is implemented:

Trap `MSR` writes of TPIDR2_EL0 at EL1 and EL0 using AArch64 to EL2.

nTPIDR2_EL0	Meaning
`0b0`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then `MSR` writes of TPIDR2_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.
`0b1`	`MSR` writes of TPIDR2_EL0 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Otherwise:

Reserved, RES0.

nSMPRI_EL1, bit [54]

When FEAT_SME is implemented:

Trap MSR writes of SMPRI_EL1 at EL1 using AArch64 to EL2.

nSMPRI_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of SMPRI_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of SMPRI_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nGCS_EL1, bit [53]

When FEAT_GCS is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- GCSCR_EL1.
- GCSPR_EL1.

nGCS_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of the specified System registers are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

nGCS_EL0, bit [52]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_GCS is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- GCSCRE0_EL1.
- GCSPR_EL0.

nGCS_EL0	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of the specified System registers are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [51]

Reserved, RES0.

nACCDATA_EL1, bit [50]

When FEAT_LS64_ACCDATA is implemented:

Trap MSR writes of ACCDATA_EL1 at EL1 using AArch64 to EL2.

nACCDATA_EL1	Meaning
0b0	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ACCDATA_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.
0b1	MSR writes of ACCDATA_EL1 are not trapped by this mechanism.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXADDR_EL1, bit [49]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_RAS is implemented:

Trap MSR writes of ERXADDR_EL1 at EL1 using AArch64 to EL2.

ERXADDR_EL1	Meaning
0b0	MSR writes of ERXADDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ERXADDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXPFGCDN_EL1, bit [48]

When FEAT_RASv1p1 is implemented:

Trap MSR writes of ERXPFGCDN_EL1 at EL1 using AArch64 to EL2.

ERXPFGCDN_EL1	Meaning
0b0	MSR writes of ERXPFGCDN_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ERXPFGCDN_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ERXPFGCTL_EL1, bit [47]

When FEAT_RASv1p1 is implemented:

Trap MSR writes of ERXPFGCTL_EL1 at EL1 using AArch64 to EL2.

ERXPFGCTL_EL1	Meaning
0b0	MSR writes of ERXPFGCTL_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ERXPFGCTL_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [46]

Reserved, RES0.

ERXMISCn_EL1, bit [45]

When FEAT_RAS is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- ERXMISC0_EL1.
- ERXMISC1_EL1.
- ERXMISC2_EL1.
- ERXMISC3_EL1.

ERXMISCn_EL1	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

Accessing this field has the following behavior:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXSTATUS_EL1, bit [44]

When FEAT_RAS is implemented:

Trap MSR writes of ERXSTATUS_EL1 at EL1 using AArch64 to EL2.

ERXSTATUS_EL1	Meaning
`0b0`	MSR writes of ERXSTATUS_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ERXSTATUS_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

ERXCTLR_EL1, bit [43]

When FEAT_RAS is implemented:

Trap MSR writes of ERXCTLR_EL1 at EL1 using AArch64 to EL2.

ERXCTLR_EL1	Meaning
`0b0`	MSR writes of ERXCTLR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ERXCTLR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

Accessing this field has the following behavior:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [42]

Reserved, RES0.

ERRSELR_EL1, bit [41]

When FEAT_RAS is implemented:

Trap MSR writes of ERRSELR_EL1 at EL1 using AArch64 to EL2.

ERRSELR_EL1	Meaning
`0b0`	MSR writes of ERRSELR_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ERRSELR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

Accessing this field has the following behavior:

- This field is permitted to be RES0 if all of the following are true:
  - ERRSELR_EL1 and all ERX* registers are implemented as UNDEFINED or RAZ/WI.
  - ERRIDR_EL1.NUM is zero.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [40]

Reserved, RES0.

ICC_IGRPENn_EL1, bit [39]

When GICv3 is implemented:

Trap MSR writes of ICC_IGRPEN<n>_EL1 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ICC_IGRPENn_EL1	Meaning
0b0	MSR writes of ICC_IGRPEN<n>_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ICC_IGRPEN<n>_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

VBAR_EL1, bit [38]

Trap MSR writes of VBAR_EL1 at EL1 using AArch64 to EL2.

VBAR_EL1	Meaning
0b0	MSR writes of VBAR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of VBAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TTBR1_EL1, bit [37]

Trap MSR or MSRR writes of TTBR1_EL1 at EL1 using AArch64 to EL2.

TTBR1_EL1	Meaning
0b0	MSR and MSRR writes of TTBR1_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes of TTBR1_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MSRR writes of TTBR1_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x14.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TTBR0_EL1, bit [36]

Trap `MSR` or `MSRR` writes of TTBR0_EL1 at EL1 using AArch64 to EL2.

TTBR0_EL1	Meaning
`0b0`	`MSR` and `MSRR` writes of TTBR0_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • `MSR` writes of TTBR0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`. • `MSRR` writes of TTBR0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x14`.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TPIDR_EL0, bit [35]

Trap `MSR` writes of TPIDR_EL0 at EL1 and EL0 using AArch64 and `MCR` writes of TPIDRURW at EL0 using AArch32 when EL1 is using AArch64 to EL2.

TPIDR_EL0	Meaning
`0b0`	`MSR` writes of TPIDR_EL0 at EL1 and EL0 using AArch64 and `MCR` writes of TPIDRURW at EL0 using AArch32 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • `MSR` writes of TPIDR_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`. • `MCR` writes of TPIDRURW at EL0 using AArch32 when EL1 is using AArch64 are trapped to EL2 and reported with EC syndrome value `0x03`.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TPIDRRO_EL0, bit [34]

Trap `MSR` writes of TPIDRRO_EL0 at EL1 using AArch64 to EL2.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TPIDRRO_EL0	Meaning
0b0	MSR writes of TPIDRRO_EL0 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TPIDRRO_EL0 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TPIDR_EL1, bit [33]

Trap MSR writes of TPIDR_EL1 at EL1 using AArch64 to EL2.

TPIDR_EL1	Meaning
0b0	MSR writes of TPIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of TPIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

TCR_EL1, bit [32]

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- TCR_EL1.
- TCR2_EL1, if FEAT_TCR2 is implemented.

TCR_EL1	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

SCXTNUM_EL0, bit [31]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Trap MSR writes of SCXTNUM_EL0 at EL1 and EL0 using AArch64 to EL2.

SCXTNUM_EL0	Meaning
0b0	MSR writes of SCXTNUM_EL0 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, the Effective value of HCR_EL2.{E2H, TGE} is not {1, 1}, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of SCXTNUM_EL0 at EL1 and EL0 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SCXTNUM_EL1, bit [30]

When FEAT_CSV2_2 is implemented or FEAT_CSV2_1p2 is implemented:

Trap MSR writes of SCXTNUM_EL1 at EL1 using AArch64 to EL2.

SCXTNUM_EL1	Meaning
0b0	MSR writes of SCXTNUM_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of SCXTNUM_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

SCTLR_EL1, bit [29]

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- SCTLR_EL1.
- SCTLR2_EL1, if FEAT_SCTLR2 is implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SCTLR_EL1	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bit [28]

Reserved, RES0.

PAR_EL1, bit [27]

Trap MSR or MSRR writes of PAR_EL1 at EL1 using AArch64 to EL2.

PAR_EL1	Meaning
0b0	MSR and MSRR writes of PAR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then unless the write generates a higher priority exception: • MSR writes of PAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18. • MSRR writes of PAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x14.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bits [26:25]

Reserved, RES0.

MAIR_EL1, bit [24]

Trap MSR writes of MAIR_EL1 at EL1 using AArch64 to EL2.

MAIR_EL1	Meaning
0b0	MSR writes of MAIR_EL1 are not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

MAIR_EL1	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of MAIR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

LORSA_EL1, bit [23]

When FEAT_LOR is implemented:

Trap MSR writes of LORSA_EL1 at EL1 using AArch64 to EL2.

LORSA_EL1	Meaning
0b0	MSR writes of LORSA_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of LORSA_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LORN_EL1, bit [22]

When FEAT_LOR is implemented:

Trap MSR writes of LORN_EL1 at EL1 using AArch64 to EL2.

LORN_EL1	Meaning
0b0	MSR writes of LORN_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of LORN_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bit [21]

Reserved, RES0.

LOREA_EL1, bit [20]

When FEAT_LOR is implemented:

Trap MSR writes of LOREA_EL1 at EL1 using AArch64 to EL2.

LOREA_EL1	Meaning
0b0	MSR writes of LOREA_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of LOREA_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

LORC_EL1, bit [19]

When FEAT_LOR is implemented:

Trap MSR writes of LORC_EL1 at EL1 using AArch64 to EL2.

LORC_EL1	Meaning
0b0	MSR writes of LORC_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of LORC_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bit [18]

Reserved, RES0.

FAR_EL1, bit [17]

Trap MSR writes of FAR_EL1 at EL1 using AArch64 to EL2.

FAR_EL1	Meaning
0b0	MSR writes of FAR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of FAR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

ESR_EL1, bit [16]

Trap MSR writes of ESR_EL1 at EL1 using AArch64 to EL2.

ESR_EL1	Meaning
0b0	MSR writes of ESR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of ESR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bits [15:14]

Reserved, RES0.

CSSELR_EL1, bit [13]

Trap MSR writes of CSSELR_EL1 at EL1 using AArch64 to EL2.

CSSELR_EL1	Meaning
0b0	MSR writes of CSSELR_EL1 are not trapped by this mechanism.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CSSELR_EL1	Meaning
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of CSSELR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

CPACR_EL1, bit [12]

Trap MSR writes of CPACR_EL1 at EL1 using AArch64 to EL2.

CPACR_EL1	Meaning
0b0	MSR writes of CPACR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of CPACR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

CONTEXTIDR_EL1, bit [11]

Trap MSR writes of CONTEXTIDR_EL1 at EL1 using AArch64 to EL2.

CONTEXTIDR_EL1	Meaning
0b0	MSR writes of CONTEXTIDR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of CONTEXTIDR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bits [10:9]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

APIBKey, bit [8]

When FEAT_PAuth is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APIBKeyHi_EL1.
- APIBKeyLo_EL1.

APIBKey	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APIAKey, bit [7]

When FEAT_PAuth is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APIAKeyHi_EL1.
- APIAKeyLo_EL1.

APIAKey	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APGAKey, bit [6]

When FEAT_PAuth is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- APGAKeyHi_EL1.
- APGAKeyLo_EL1.

APGAKey	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APDBKey, bit [5]

When FEAT_PAuth is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APDBKeyHi_EL1.
- APDBKeyLo_EL1.

APDBKey	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

APDAKey, bit [4]

When FEAT_PAuth is implemented:

Trap MSR writes at EL1 using AArch64 of any of the following AArch64 System registers to EL2:

- APDAKeyHi_EL1.
- APDAKeyLo_EL1.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

APDAKey	Meaning
0b0	MSR writes of the specified System registers are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes at EL1 using AArch64 of any of the specified System registers are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

AMAIR_EL1, bit [3]

Trap MSR writes of AMAIR_EL1 at EL1 using AArch64 to EL2.

AMAIR_EL1	Meaning
0b0	MSR writes of AMAIR_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of AMAIR_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to '0'.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Bit [2]

Reserved, RES0.

AFSR1_EL1, bit [1]

Trap MSR writes of AFSR1_EL1 at EL1 using AArch64 to EL2.

AFSR1_EL1	Meaning
0b0	MSR writes of AFSR1_EL1 are not trapped by this mechanism.
0b1	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then MSR writes of AFSR1_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value 0x18, unless the write generates a higher priority exception.

The reset behavior of this field is:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

AFSR0_EL1, bit [0]

Trap `MSR` writes of AFSR0_EL1 at EL1 using AArch64 to EL2.

AFSR0_EL1	Meaning
`0b0`	`MSR` writes of AFSR0_EL1 are not trapped by this mechanism.
`0b1`	If EL2 is implemented and enabled in the current Security state, and either EL3 is not implemented or SCR_EL3.FGTEn == 1, then `MSR` writes of AFSR0_EL1 at EL1 using AArch64 are trapped to EL2 and reported with EC syndrome value `0x18`, unless the write generates a higher priority exception.

The reset behavior of this field is:

- On a Warm reset:
  - When the highest implemented Exception level is EL2, this field resets to `'0'`.
  - Otherwise, this field resets to an architecturally UNKNOWN value.

Accessing HFGWTR_EL2

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, HFGWTR_EL2
```

op0	op1	CRn	CRm	op2
`0b11`	`0b100`	`0b0001`	`0b0001`	`0b101`

```
if !(IsFeatureImplemented(FEAT_FGT) && IsFeatureImplemented(FEAT_AA64)) then

D24.2.75 HPFAR_EL2, Hypervisor IPA Fault Address Register

The HPFAR_EL2 characteristics are:

Purpose

Holds the faulting IPA for some aborts on a stage 2 translation taken to EL2 and GPC exceptions due to a fault on an access for a stage 2 translation.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

The HPFAR_EL2 is written for:

- A Translation fault, Access Flag fault, or Address Size fault on a stage 2 translation not on a stage 1 translation table walk.
- A Translation fault, Access Flag fault, Address Size fault, or Permission fault on stage 2 translation of an address accessed in a stage 1 translation table walk.
- If FEAT_RME is implemented, a Granule Protection Check fault in the second stage of translation.

For all other exceptions taken to EL2, this register is UNKNOWN.

Note

The address held in this register is an address accessed by the instruction fetch or data access that caused the exception that gave rise to the Instruction Abort exception or Data Abort exception. It is the lower address that gave rise to the fault that is reported. Where different faults from different addresses arise from the same instruction, such as for an instruction that loads or stores an unaligned address that crosses a page boundary, the architecture does not prioritize which fault is reported.

AArch64 System register HPFAR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HPFAR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to HPFAR_EL2 are UNDEFINED.

Attributes

HPFAR_EL2 is a 64-bit register.

Field descriptions

Execution at EL1 or EL0 makes HPFAR_EL2 become UNKNOWN.

NS, bit [63]

When FEAT_SEL2 is implemented:

Faulting IPA address space.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NS	Meaning
0b0	Faulting IPA is from the Secure IPA space.
0b1	Faulting IPA is from the Non-secure IPA space.

For Data Abort exceptions or Instruction Abort exceptions taken to Non-secure EL2:

- This field is RES0.
- The address is from the Non-secure IPA space.

If FEAT_RME is implemented, for Data Abort exceptions or Instruction Abort exceptions taken to Realm EL2:

- This field is RES0.
- The address is from the Realm IPA space.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Reserved, RES0.

Bits [62:48]

Reserved, RES0.

FIPA, bits [47:4]

When FEAT_D128 is implemented:

FIPA, bits [43:0]

Bits [55:12] of the Faulting Intermediate Physical Address.

For implementations with fewer than 55 physical address bits, the corresponding upper bits in this field are RES0.

When FEAT_MOPS is implemented, the value presented in FIPA on a synchronous exception that set the HPFAR_EL2 from any of the Memory Copy and Memory Set instructions is within the address range of the current stage 2 translation granule, aligned to the size of the current stage 2 translation granule, of the address that generated the Data abort. In this case, bits[(n-1):0] of the value are UNKNOWN, where 2^n is the current stage 2 translation granule size in bytes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_LPA is implemented and FEAT_D128 is not implemented:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [43:40]

Reserved, RES0.

FIPA, bits [39:0]

Bits [51:12] of the Faulting Intermediate Physical Address.

For implementations with fewer than 52 physical address bits, the corresponding upper bits in this field are RES0.

When FEAT_MOPS is implemented, the value presented in FIPA on a synchronous exception that set the HPFAR_EL2 from any of the Memory Copy and Memory Set instructions is within the address range of the current stage 2 translation granule, aligned to the size of the current stage 2 translation granule, of the address that generated the Data abort. In this case, bits[(n-1):0] of the value are UNKNOWN, where 2^n is the current stage 2 translation granule size in bytes.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

When FEAT_LPA is not implemented:

Bits [43:36]

Reserved, RES0.

FIPA, bits [35:0]

Bits[47:12] Faulting Intermediate Physical Address.

For implementations with fewer than 48 physical address bits, the corresponding upper bits in this field are RES0.

When FEAT_MOPS is implemented, the value presented in FIPA on a synchronous exception that set the HPFAR_EL2 from any of the Memory Copy and Memory Set instructions is within the address range of the current stage 2 translation granule, aligned to the size of the current stage 2 translation granule, of the address that generated the Data abort. In this case, bits[(n-1):0] of the value are UNKNOWN, where 2^n is the current stage 2 translation granule size in bytes.

D24.2.76 HSTR_EL2, Hypervisor System Trap Register

The HSTR_EL2 characteristics are:

Purpose

Controls trapping to EL2 of EL1 or lower AArch32 accesses to the System register in the coproc == `0b1111` encoding space, by the CRn value used to access the register using MCR or MRC instruction. When the register is accessible using an MCRR or MRRC instruction, this is the CRm value used to access the register.

Configuration

If EL2 is not implemented, this register is RES0 from EL3.

This register has no effect if EL2 is not enabled in the current Security state.

AArch64 System register HSTR_EL2 bits [31:0] are architecturally mapped to AArch32 System register HSTR[31:0].

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to HSTR_EL2 are UNDEFINED.

Attributes

HSTR_EL2 is a 64-bit register.

Field descriptions

When FEAT_AA32 is implemented:

Bits [63:16, 14, 4]

Reserved, RES0.

T<n> , bits [n], for n = 15 to 15, 13 to 5, 3 to 0

The remaining fields control whether EL0 and EL1 accesses, using MCR, MRC, MCRR, and MRRC instructions, to the System registers in the coproc == `0b1111` encoding space, are trapped to EL2 as follows:

- MCR or MRC accesses to these registers that are trapped to EL2 are reported using EC syndrome value `0x03`, unless the access is UNDEFINED.
- MCRR or MRRC accesses to these registers that are trapped to EL2 are reported using EC syndrome value `0x04`, unless the access is UNDEFINED.

T<n>	Meaning
`0b0`	This control has no effect on EL0 or EL1 accesses to System registers.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

T<n>	Meaning
0b1	System registers in the coproc == 0b1111 encoding space and CRn == <n> or CRm == <n> where T<n> is the name of this field, are trapped as follows: • An EL1 MCR or MRC access is trapped to EL2. • An EL0 MCR or MRC access is trapped to EL2, if the access is not UNDEFINED when the value of this field is 0. • An EL1 MCRR or MRRC access is trapped to EL2. • An EL0 MCRR or MRRC access is trapped to EL2, if the access is not UNDEFINED when the value of this field is 0. It is IMPLEMENTATION DEFINED whether an EL0 access using AArch32 is trapped to EL2, or is UNDEFINED. If the access is UNDEFINED, and generates an exception that is taken to EL1 or EL2 using AArch64, this is reported with EC syndrome value 0x00. **Note** Arm expects that trapping to EL2 of EL0 accesses to these registers is unusual and used only when the hypervisor must virtualize EL0 operation. Arm recommends that, whenever possible, EL0 accesses to these registers behave as they would if the implementation did not include EL2. This means that, if the architecture does not support the EL0 access, then the register access instruction is treated as UNDEFINED and generates an exception that is taken to EL1.

For example, when HSTR_EL2.T7 is 1, for instructions executed at EL1:

- An MCR or MRC instruction with coproc set to 0b1111 and <CRn> set to c7 is trapped to EL2.
- An MCRR or MRRC instruction with coproc set to 0b1111 and <CRm> set to c7 is trapped to EL2.

When the Effective value of HCR_EL2.{E2H, TGE} is {1, 1}, this field behaves as 0 for all purposes other than a direct read of the value of this bit.

The reset behavior of this field is:

- On a Warm reset, this field resets to an architecturally UNKNOWN value.

Otherwise:

Bits [63:0]

Reserved, RES0.

D24.2.79 ID_AA64DFR0_EL1, AArch64 Debug Feature Register 0

The ID_AA64DFR0_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

The external register EDDFR gives information from this register.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64DFR0_EL1 are UNDEFINED.

Attributes

ID_AA64DFR0_EL1 is a 64-bit register.

Field descriptions

63:60	59:56	55:52	51:48	47:44	43:40	39:36	35:32
HPMN0	ExtTrcBuff	BRBE	MTPMU	TraceBuffer	TraceFilt	DoubleLock	PMSVer

31:28	27:24	23:20	19:16	15:12	11:8	7:4	3:0
CTX_CMPs	RES0	WRPs	PMSS	BRPs	PMUVer	TraceVer	DebugVer

HPMN0, bits [63:60]

Zero PMU event counters for a Guest operating system.

The value of this field is an IMPLEMENTATION DEFINED choice of:

HPMN0	Meaning
0b0000	Setting MDCR_EL2.HPMN to zero has CONSTRAINED UNPREDICTABLE behavior.
0b0001	Setting MDCR_EL2.HPMN to zero has defined behavior.

All other values are reserved.

FEAT_HPMN0 implements the functionality identified by the value 0b0001.

From Armv8.8, in an implementation that includes FEAT_PMUv3, FEAT_FGT, and EL2, the value 0b0000 is not permitted.

Access to this field is RO.

ExtTrcBuff, bits [59:56]

Trace Buffer External Mode Extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ExtTrcBuff	Meaning
0b0000	Trace Buffer External Mode not implemented.
0b0001	Trace Buffer External Mode implemented.

All other values are reserved.

FEAT_TRBE_EXT implements the functionality identified by the value 0b0001.

Access to this field is RO.

BRBE, bits [55:52]

Branch Record Buffer Extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BRBE	Meaning
0b0000	Branch Record Buffer Extension not implemented.
0b0001	Branch Record Buffer Extension implemented.
0b0010	As 0b0001, and adds support for branch recording at EL3.

All other values are reserved.

FEAT_BRBE implements the functionality identified by the value 0b0001.

FEAT_BRBEv1p1 implements the functionality identified by the value 0b0010.

From Armv9.3, if FEAT_BRBE is implemented, the value 0b0001 is not permitted.

Access to this field is RO.

MTPMU, bits [51:48]

Multi-threaded PMU extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MTPMU	Meaning
0b0000	FEAT_MTPMU not implemented. If FEAT_PMUv3 is implemented, it is IMPLEMENTATION DEFINED whether PMEVTYPER<n>_EL0.MT and PMEVTYPER<n>.MT are read/write or RES0.
0b0001	FEAT_MTPMU and FEAT_PMUv3 implemented. PMEVTYPER<n>_EL0.MT and PMEVTYPER<n>.MT are read/write. When FEAT_MTPMU is disabled, the Effective values of PMEVTYPER<n>_EL0.MT and PMEVTYPER<n>.MT are 0.
0b1111	FEAT_MTPMU not implemented. If FEAT_PMUv3 is implemented, PMEVTYPER<n>_EL0.MT and PMEVTYPER<n>.MT are RES0.

All other values are reserved.

FEAT_MTPMU implements the functionality identified by the value 0b0001.

From Armv8.6, in an implementation that includes FEAT_PMUv3, the value 0b0000 is not permitted.

In an implementation that does not include FEAT_PMUv3, the value 0b0001 is not permitted.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Access to this field is RO.

TraceBuffer, bits [47:44]

Trace Buffer Extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceBuffer	Meaning
0b0000	Trace Buffer Extension not implemented.
0b0001	Trace Buffer Extension implemented.
0b0010	As 0b0001, and adds: • If EL2 and FEAT_FGT are implemented, a fine-grained trap on the TSB CSYNC instruction. • If EL2 is implemented, an EL2 control to override TRBLIMITR_EL1.nVM. • The TRBE Profiling exception extension, FEAT_TRBE_EXC.

All other values are reserved.

FEAT_TRBE implements the functionality identified by the value 0b0001.

FEAT_TRBEv1p1 implements the functionality identified by the value 0b0010.

In any Armv9 implementation, if FEAT_ETE is implemented, the value 0b0000 is not permitted.

From Armv9.6, if FEAT_TRBE is implemented, the value 0b0001 is not permitted.

Access to this field is RO.

TraceFilt, bits [43:40]

Armv8.4 Self-hosted Trace Extension version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceFilt	Meaning
0b0000	Armv8.4 Self-hosted Trace Extension not implemented.
0b0001	Armv8.4 Self-hosted Trace Extension implemented.

All other values are reserved.

FEAT_TRF implements the functionality identified by the value 0b0001.

From Armv8.4, if FEAT_ETMv4 is implemented, the value 0b0000 is not permitted.

If FEAT_ETE is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

DoubleLock, bits [39:36]

OS Double Lock implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DoubleLock	Meaning
0b0000	OS Double Lock implemented. OSDLR_EL1 is RW.
0b1111	OS Double Lock not implemented. OSDLR_EL1 is RAZ/WI.

All other values are reserved.

FEAT_DoubleLock implements the functionality identified by the value 0b0000.

In Armv8.0, the only permitted value is 0b0000.

If FEAT_Debugv8p2 is implemented and FEAT_DoPD is not implemented, the permitted values are 0b0000 and 0b1111.

If FEAT_DoPD is implemented, the only permitted value is 0b1111.

Access to this field is RO.

PMSVer, bits [35:32]

Statistical Profiling Extension version.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PMSVer	Meaning
0b0000	Statistical Profiling Extension not implemented.
0b0001	Statistical Profiling Extension implemented.
0b0010	As 0b0001, and adds: • Support for the Events packet Alignment flag. • If FEAT_SVE is implemented, support for the Scalable Vector extensions to Statistical Profiling.
0b0011	As 0b0010, and adds: • Discard mode. • Extended event filtering, including the PMSNEVFR_EL1 System register. • Support for the OPTIONAL previous branch target Address packet. • If FEAT_PMUv3 is implemented, controls to freeze the PMU event counters after an SPE buffer management event occurs. • If FEAT_PMUv3 is implemented, the SAMPLE_FEED_BR, SAMPLE_FEED_EVENT, SAMPLE_FEED_LAT, SAMPLE_FEED_LD, SAMPLE_FEED_OP, and SAMPLE_FEED_ST PMU events.
0b0100	As 0b0011, and adds: • If FEAT_MOPS is implemented, Operation Type packet encodings for Memory Copy and Set operations. • If FEAT_MTE is implemented, Operation Type packet encodings for loads and stores of Allocation Tags.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMSVer	Meaning
0b0101	As 0b0100, and adds: • Support for the Events packet Level 2 Data cache access, Level 2 Data cache miss, Cached data modified, Recently fetched cache line, and Cache snoop flags. • Support for Data Source filtering.
0b0110	As 0b0101, and adds: • If EL2 and FEAT_FGT are implemented, a fine-grained trap on the PSB CSYNC instruction. • The SPE Profiling exception extension, FEAT_SPE_EXC. • The Statistical Profiling physical addressing mode extension, FEAT_SPE_nVM.

All other values are reserved.

FEAT_SPE implements the functionality identified by the value 0b0001.

FEAT_SPEv1p1 implements the functionality identified by the value 0b0010.

FEAT_SPEv1p2 implements the functionality identified by the value 0b0011.

FEAT_SPEv1p3 implements the functionality identified by the value 0b0100.

FEAT_SPEv1p4 implements the functionality identified by the value 0b0101.

FEAT_SPEv1p5 implements the functionality identified by the value 0b0110.

From Armv8.5, if FEAT_SPE is implemented, the value 0b0001 is not permitted.

From Armv8.7, if FEAT_SPE is implemented, the value 0b0010 is not permitted.

From Armv8.8, if FEAT_SPE is implemented, the value 0b0011 is not permitted.

From Armv8.9, if FEAT_SPE is implemented, the value 0b0100 is not permitted.

From Armv9.6, if FEAT_SPE is implemented, the value 0b0101 is not permitted.

Access to this field is RO.

CTX_CMPs, bits [31:28]

Number of context-aware breakpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CTX_CMPs	Meaning
0b0000..0b1110	The number of context-aware breakpoints, minus 1.
0b1111	If ID_AA64DFR1_EL1.CTX_CMPs is zero, then 16 context-aware breakpoints are implemented. Otherwise, 16 or more context-aware breakpoints are implemented and ID_AA64DFR1_EL1.CTX_CMPs indicates how many.

Values greater than ID_AA64DFR0_EL1.BRPs are not permitted.

Note

If AArch32 is supported at EL1, then the PE does not implement more than 16 breakpoints.

Access to this field is RO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Bits [27:24]

Reserved, RES0.

WRPs, bits [23:20]

Number of watchpoints, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

WRPs	Meaning
`0b0001..0b1111`	The number of watchpoints, minus 1.

If FEAT_Debugv8p9 is implemented and 16 or more watchpoints are implemented, then this field reads as `0b1111` and ID_AA64DFR1_EL1.WRPs indicates the number of watchpoints.

Note

If AArch32 is supported at EL1, then the PE does not implement more than 16 watchpoints.

The value `0b0000` is reserved.

Access to this field is RO.

PMSS, bits [19:16]

PMU Snapshot extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PMSS	Meaning
`0b0000`	PMU snapshot extension not implemented.
`0b0001`	PMU snapshot extension implemented.

All other values are reserved.

FEAT_PMUv3_SS implements the functionality identified by the value `0b0001`.

Access to this field is RO.

BRPs, bits [15:12]

Index of the highest numbered context-aware breakpoint. Identifies which of the implemented breakpoints are context-aware breakpoints.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BRPs	Meaning
`0b0001..0b1110`	Index of the highest numbered context-aware breakpoint.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BRPs	Meaning
0b1111	If ID_AA64DFR0_EL1.CTX_CMPs and ID_AA64DFR1_EL1.CTX_CMPs indicate that 16 or fewer breakpoints are context-aware, then the index of the highest context-aware breakpoint is 15. Otherwise, the context-aware breakpoints are the lowest numbered breakpoints.

If ID_AA64DFR1_EL1.BRPs is zero, then this is also the number of implemented breakpoints, minus 1, meaning the context-aware breakpoints are the highest numbered breakpoints.

The value of this field is always less than the number of implemented breakpoints.

Note

If AArch32 is supported at EL1, then the PE does not implement more than 16 breakpoints.

The value 0b0000 is reserved.

Access to this field is RO.

PMUVer, bits [11:8]

Performance Monitors Extension version.

This field does not follow the standard ID scheme, but uses the alternative ID scheme described in 'Alternative ID scheme used for the Performance Monitors Extension version'.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PMUVer	Meaning
0b0000	Performance Monitors Extension not implemented.
0b0001	Performance Monitors Extension, PMUv3 implemented.
0b0100	PMUv3 for Armv8.1. As 0b0001, and adds support for: • Extended 16-bit PMEVTYPER<n>_EL0.evtCount field. • If EL2 is implemented, the MDCR_EL2.HPMD control.
0b0101	PMUv3 for Armv8.4. As 0b0100, and adds support for the PMMIR_EL1 register.
0b0110	PMUv3 for Armv8.5. As 0b0101, and adds support for: • 64-bit event counters. • If EL2 is implemented, the MDCR_EL2.HCCD control. • If EL3 is implemented, the MDCR_EL3.SCCD control.
0b0111	PMUv3 for Armv8.7. As 0b0110, and adds support for: • The PMCR_EL0.FZO and, if EL2 is implemented, MDCR_EL2.HPMFZO controls. • If EL3 is implemented, the MDCR_EL3.{MPMX,MCCD} controls.
0b1000	PMUv3 for Armv8.8. As 0b0111, and: • Extends the Common event number space to include 0x0040 to 0x00BF and 0x4040 to 0x40BF. • Removes the CONSTRAINED UNPREDICTABLE behaviors if a reserved or unimplemented PMU event number is selected.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PMUVer	Meaning
0b1001	PMUv3 for Armv8.9. As 0b1000, and: • Updates the definitions of existing PMU events. • Adds support for the PMUSERENR_EL0.UEN control and the PMUACR_EL1 register. • Adds support for the EDECR.PME control.
0b1111	IMPLEMENTATION DEFINED form of performance monitors supported, PMUv3 not supported. Arm does not recommend this value for new implementations.

All other values are reserved.

FEAT_PMUv3 implements the functionality identified by the value 0b0001.

FEAT_PMUv3p1 implements the functionality identified by the value 0b0100.

FEAT_PMUv3p4 implements the functionality identified by the value 0b0101.

FEAT_PMUv3p5 implements the functionality identified by the value 0b0110.

FEAT_PMUv3p7 implements the functionality identified by the value 0b0111.

FEAT_PMUv3p8 implements the functionality identified by the value 0b1000.

FEAT_PMUv3p9 implements the functionality identified by the value 0b1001.

From Armv8.1, if FEAT_PMUv3 is implemented, the value 0b0001 is not permitted.

From Armv8.4, if FEAT_PMUv3 is implemented, the value 0b0100 is not permitted.

From Armv8.5, if FEAT_PMUv3 is implemented, the value 0b0101 is not permitted.

From Armv8.7, if FEAT_PMUv3 is implemented, the value 0b0110 is not permitted.

From Armv8.8, if FEAT_PMUv3 is implemented, the value 0b0111 is not permitted.

From Armv8.9, if FEAT_PMUv3 is implemented, the value 0b1000 is not permitted.

Access to this field is RO.

TraceVer, bits [7:4]

Trace support. Indicates whether System register interface to a trace unit is implemented.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TraceVer	Meaning
0b0000	Trace unit System registers not implemented.
0b0001	Trace unit System registers implemented.

All other values are reserved.

When trace unit System registers are implemented, see TRCIDR1 for tracing capabilities of the trace unit.

Access to this field is RO.

DebugVer, bits [3:0]

Debug architecture version. Indicates presence of Armv8 debug architecture.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DebugVer	Meaning
0b0110	Armv8.0 debug architecture.
0b0111	Armv8.1 debug architecture, FEAT_Debugv8p1.
0b1000	Armv8.2 debug architecture, FEAT_Debugv8p2.
0b1001	Armv8.4 debug architecture, FEAT_Debugv8p4.
0b1010	Armv8.8 debug architecture, FEAT_Debugv8p8.
0b1011	Armv8.9 debug architecture, FEAT_Debugv8p9.

All other values are reserved.

FEAT_Debugv8p1 implements the functionality identified by the value 0b0111.

FEAT_Debugv8p2 implements the functionality identified by the value 0b1000.

FEAT_Debugv8p4 implements the functionality identified by the value 0b1001.

FEAT_Debugv8p8 implements the functionality identified by the value 0b1010.

FEAT_Debugv8p9 implements the functionality identified by the value 0b1011.

From Armv8.1, when FEAT_Debugv8p1 is implemented the value 0b0110 is not permitted.

From Armv8.2, the values 0b0110 and 0b0111 are not permitted.

From Armv8.4, the value 0b1000 is not permitted.

From Armv8.8, the value 0b1001 is not permitted.

From Armv8.9, the value 0b1010 is not permitted.

Access to this field is RO.

Accessing ID_AA64DFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ID_AA64DFR0_EL1
```

op0	op1	CRn	CRm	op2

D24.2.80 ID_AA64DFR1_EL1, AArch64 Debug Feature Register 1

The ID_AA64DFR1_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch64.

Configuration

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64DFR1_EL1 are UNDEFINED.

Attributes

ID_AA64DFR1_EL1 is a 64-bit register.

Field descriptions

ABL_CMPs, bits [63:56]

When FEAT_ABLE is implemented:

Number of breakpoints that support address linking, minus 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ABL_CMPs	Meaning
`0x00..0x3F`	Number of breakpoints that support address linking minus 1.

All other values are reserved.

The number of breakpoints that support address linking is never more than either the number of breakpoints or the number of watchpoints.

Access to this field is RO.

Otherwise:

Reserved, RES0.

DPFZS, bits [55:52]

Behavior of the cycle counter when event counting is frozen by a Statistical Profiling management event.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DPFZS	Meaning
0b0000	The cycle counter PMCCNTR_EL0 is never affected by PMCR_EL0.FZS.
0b0001	The cycle counter PMCCNTR_EL0 does not count when PMCR_EL0.DP is 1 and counting by event counters accessible to EL1 is frozen by the PMCR_EL0.FZS mechanism.

FEAT_SPE_DPFZS implements the functionality identified by the value 0b0001.

Access to this field is RO.

EBEP, bits [51:48]

Exception-based event profiling.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EBEP	Meaning
0b0000	Exception-based event profiling not implemented.
0b0001	Exception-based event profiling implemented.

All other values are reserved.

FEAT_EBEP implements the functionality identified by the value 0b0001.

Access to this field is RO.

ITE, bits [47:44]

Instrumentation Trace Extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ITE	Meaning
0b0000	Instrumentation Trace Extension not implemented.
0b0001	Instrumentation Trace Extension implemented.

All other values are reserved.

FEAT_ITE implements the functionality identified by the value 0b0001.

Access to this field is RO.

ABLE, bits [43:40]

Address Breakpoint Linking Extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

ABLE	Meaning
0b0000	Address Breakpoint Linking Extension not implemented.
0b0001	Address Breakpoint Linking Extension implemented.

All other values are reserved.

FEAT_ABLE implements the functionality identified by the value 0b0001.

Access to this field is RO.

PMICNTR, bits [39:36]

PMU fixed-function instruction counter.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PMICNTR	Meaning
0b0000	PMU fixed-function instruction counter not implemented.
0b0001	PMU fixed-function instruction counter implemented.

All other values are reserved.

FEAT_PMUv3_ICNTR implements the functionality identified by the value 0b0001.

If FEAT_PMUv3 is not implemented, then the only permitted value is 0b0000.

Access to this field is RO.

SPMU, bits [35:32]

System PMU extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SPMU	Meaning
0b0000	System PMU extension not implemented.
0b0001	System PMU extension implemented.
0b0010	As 0b0001, and adds support for SPMZR_EL0.

All other values are reserved.

FEAT_SPMU implements the functionality identified by the value 0b0001.

FEAT_SPMU2 implements the functionality identified by the value 0b0010.

From Armv9.5, the value 0b0001 is not permitted.

Access to this field is RO.

CTX_CMPs, bits [31:24]

Context-aware breakpoints.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CTX_CMPs	Meaning
`0x00`	ID_AA64DFR0_EL1.CTX_CMPs is the number of context-aware breakpoints, minus 1.
`0x01..0x3F`	Number of context-aware breakpoints minus 1.

All other values are reserved.

If 16 or fewer context-aware breakpoints are implemented, then the value of this field is either `0x00` or the same as ID_AA64DFR0_EL1.CTX_CMPs. If more than 16 context-aware breakpoints are implemented, then the value `0x00` is not permitted.

Values greater than ID_AA64DFR1_EL1.BRPs are not permitted.

Access to this field is RO.

WRPs, bits [23:16]

Watchpoints.

The value of this field is an IMPLEMENTATION DEFINED choice of:

WRPs	Meaning
`0x00`	ID_AA64DFR0_EL1.WRPs is the number of watchpoints, minus 1.
`0x01..0x3F`	Number of watchpoints minus 1.

All other values are reserved.

Access to this field is RO.

BRPs, bits [15:8]

Breakpoints.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BRPs	Meaning
`0x00`	ID_AA64DFR0_EL1.BRPs is the number of breakpoints, minus 1.
`0x01..0x3F`	Number of breakpoints minus 1.

All other values are reserved.

If more than 16 breakpoints are implemented, or the index of the highest numbered context-aware breakpoint is not the number of breakpoints minus 1, then the value `0x00` is not permitted.

Nonzero values less than ID_AA64DFR0_EL1.BRPs are not permitted.

Access to this field is RO.

SYSPMUID, bits [7:0]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

When FEAT_SPMU is implemented:

System PMU ID. Indicates the largest value that can be written to SPMSELR_EL0.SYSPMUSEL.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SYSPMUID	Meaning
0x00..0x1F	The largest supported value that can be written to SPMSELR_EL0.SYSPMUSEL.

All other values are reserved.

Since System PMUs might not be contiguously accessible, this field does not necessarily indicate the total number of accessible System PMUs.

Access to this field is RO.

Otherwise:

Reserved, RES0.

Accessing ID_AA64DFR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ID_AA64DFR1_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0101	0b001

```
if !IsFeatureImplemented(FEAT_AA64) then
    UnimplementedIDRegister();
elsif HaveEL(EL3) && !(EffectivelyAtEL0InHost() || EffectivelyAtEL0NotInHost() || PSTATE.EL == EL3) &&
     ↪EL3SDDUndefPriority() && IsFeatureImplemented(FEAT_IDTE3) && SCR_EL3().TID3 == '1' then
    Undefined();
elsif PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then

D24.2.81 ID_AA64DFR2_EL1, AArch64 Debug Feature Register 2

The ID_AA64DFR2_EL1 characteristics are:

Purpose

Provides top-level information about the debug system in AArch64.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1, EL2, and EL3.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64DFR2_EL1 are UNDEFINED.

Attributes

ID_AA64DFR2_EL1 is a 64-bit register.

Field descriptions

Bits [63:28]

Reserved, RES0.

TRBE_EXC, bits [27:24]

TRBE Profiling exception extension. Describes support for reporting trace buffer management events as TRBE Profiling exceptions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TRBE_EXC	Meaning
0b0000	TRBE Profiling exception not implemented.
0b0001	TRBE Profiling exception implemented.

All other values are reserved.

FEAT_TRBE_EXC implements the functionality identified by the value 0b0001.

Access to this field is RO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SPE_nVM, bits [23:20]

Profiling Buffer physical address mode supported. Describes support for defining the Profiling Buffer using physical addresses or intermediate physical addresses.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SPE_nVM	Meaning
0b0000	Profiling Buffer physical address mode not implemented.
0b0001	Profiling Buffer physical address mode implemented.

All other values are reserved.

FEAT_SPE_nVM implements the functionality identified by the value 0b0001.

Access to this field is RO.

SPE_EXC, bits [19:16]

SPE Profiling exception extension. Describes support for reporting Profiling Buffer management events as SPE Profiling exceptions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SPE_EXC	Meaning
0b0000	SPE Profiling exception not implemented.
0b0001	SPE Profiling exception implemented.

All other values are reserved.

FEAT_SPE_EXC implements the functionality identified by the value 0b0001.

Access to this field is RO.

Bits [15:8]

Reserved, RES0.

BWE, bits [7:4]

Breakpoints and watchpoint enhancements.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BWE	Meaning
0b0000	This field does not indicate whether DBGBCR<n>_EL1.MASK and address mismatch breakpoints are implemented.
0b0001	DBGBCR<n>_EL1.MASK and address mismatch breakpoints are implemented.
0b0010	As 0b0001, and address mismatch watchpoints are implemented.

All other values are reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_BWE implements the functionality identified by the value `0b0001`.

FEAT_BWE2 implements the functionality identified by the value `0b0010`.

From Armv9.5, the value `0b0001` is not permitted.

Access to this field is RO.

STEP, bits [3:0]

Enhanced Software Step Extension.

The value of this field is an IMPLEMENTATION DEFINED choice of:

STEP	Meaning
`0b0000`	Execution from MDSTEPOP_EL1 is not supported for Software Step.
`0b0001`	Execution from MDSTEPOP_EL1 is supported for Software Step.

All other values are reserved.

FEAT_STEP2 implements the functionality identified by the value `0b0001`.

Access to this field is RO.

Accessing ID_AA64DFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ID_AA64DFR2_EL1
```

op0	op1	CRn	CRm	op2
`0b11`	`0b000`	`0b0000`	`0b0101`	`0b010`

D24.2.82 ID_AA64FPFR0_EL1, AArch64 Floating-point Feature Register 0

The ID_AA64FPFR0_EL1 characteristics are:

Purpose

Provides information about floating-point formats and instructions implemented in AArch64 state.

The fields in this register do not follow the standard ID scheme. See Alternative ID scheme used for ID_AA64SMFR0_EL1 and ID_AA64FPFR0_EL1.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1, EL2, and EL3.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64FPFR0_EL1 are UNDEFINED.

Attributes

ID_AA64FPFR0_EL1 is a 64-bit register.

Field descriptions

Bits [63:32]

Reserved, RES0.

F8CVT, bit [31]

Indicates support for the following instructions:

- The Advanced SIMD floating-point scaling instruction `FSCALE`.
- The Advanced SIMD FP8 convert instructions `BF1CVTL`, `BF1CVTL2`, `BF2CVTL`, `BF2CVTL2`, `F1CVTL`, `F1CVTL2`, `F2CVTL`, `F2CVTL2`, `FCVTN`, and `FCVTN2`.
- When FEAT_SVE2 or FEAT_SME2 is implemented, the SVE2 FP8 convert instructions `BF1CVT`, `BF1CVTLT`, `BF2CVT`, `BF2CVTLT`, `F1CVT`, `F1CVTLT`, `F2CVT`, `F2CVTLT`, `BFCVTN`, `FCVTN`, `FCVTNB`, and `FCVTNT`.
- When FEAT_SME2 is implemented, the SME2 multi-vector floating-point scaling instruction `FSCALE` and the SME2 FP8 convert instructions `BF1CVT`, `BF1CVTL`, `BF2CVT`, `BF2CVTL`, `F1CVT`, `F1CVTL`, `F2CVT`, `F2CVTL`, `BFCVT`, `FCVT`, and `FCVTN`.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F8CVT	Meaning
0b0	The specified instructions are not implemented.
0b1	The specified instructions are implemented.

FEAT_FP8 implements the functionality identified by the value 1.

Access to this field is RO.

F8FMA, bit [30]

Indicates support for the following instructions:

- The Advanced SIMD FP8 to single-precision and half-precision multiply-accumulate instructions FMLALB, FMLALT, FMLALLBB, FMLALLBT, FMLALLTB, and FMLALLTT.
- When FEAT_SVE2 is implemented and the PE is not in Streaming SVE mode, the SVE2 FP8 to single-precision and half-precision multiply-accumulate instructions FMLALB, FMLALT, FMLALLBB, FMLALLBT, FMLALLTB, and FMLALLTT.

The value of this field is an IMPLEMENTATION DEFINED choice of:

F8FMA	Meaning
0b0	The specified instructions are not implemented.
0b1	The specified instructions are implemented.

FEAT_FP8FMA implements the functionality identified by the value 1.

Access to this field is RO.

F8DP4, bit [29]

Indicates support for the following instructions:

- Advanced SIMD FP8 to single-precision 4-way dot product FDOT (4-way) instructions.
- When FEAT_SVE2 is implemented and the PE is not in Streaming SVE mode, SVE FP8 to single-precision 4-way dot product FDOT (4-way) instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

F8DP4	Meaning
0b0	The specified instructions are not implemented by this feature.
0b1	The specified instructions are implemented.

Note

Other features may implement some of the specified instructions.

All other values are reserved.

FEAT_FP8DOT4 implements the functionality identified by the value 1.

Access to this field is RO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F8DP2, bit [28]

Indicates support for the following instructions:

- Advanced SIMD FP8 to half-precision 2-way dot product `FDOT` (2-way) instructions.
- When FEAT_SVE2 is implemented and the PE is not in Streaming SVE mode, SVE FP8 to half-precision 2-way dot product `FDOT` (2-way) instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

F8DP2	Meaning
`0b0`	The specified instructions are not implemented by this feature.
`0b1`	The specified instructions are implemented.

Note

Other features may implement some of the specified instructions.

FEAT_FP8DOT2 implements the functionality identified by the value 1.

Access to this field is RO.

F8MM8, bit [27]

Indicates support for the following instructions:

- Advanced SIMD FP8 to single-precision matrix multiply `FMMLA` (8-way, FP8 to FP32) instruction.
- If FEAT_SVE2 is implemented, SVE FP8 to single-precision matrix multiply `FMMLA` (widening, FP8 to FP32) instruction is implemented when the PE is not in Streaming SVE mode.

The value of this field is an IMPLEMENTATION DEFINED choice of:

F8MM8	Meaning
`0b0`	Advanced SIMD and SVE FP8 to single-precision matrix multiply instructions are not implemented by this feature.
`0b1`	The specified Advanced SIMD and SVE FP8 to single-precision matrix multiply instructions are implemented.

FEAT_F8F32MM implements the functionality identified by the value `0b0001`

Access to this field is RO.

F8MM4, bit [26]

Indicates support for the following instructions:

- Advanced SIMD FP8 to half-precision matrix multiply `FMMLA` (4-way, FP8 to FP16) instruction.
- If FEAT_SVE2 is implemented, SVE FP8 to half-precision matrix multiply `FMMLA` (widening, FP8 to FP16) instruction is implemented when the PE is not in Streaming SVE mode.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

F8MM4	Meaning
0b0	Advanced SIMD and SVE FP8 to half-precision matrix multiply instructions are not implemented by this feature.
0b1	The specified Advanced SIMD and SVE FP8 to half-precision matrix multiply instructions are implemented.

FEAT_F8F16MM implements the functionality identified by the value 0b0001

Access to this field is RO.

Bits [25:8]

Reserved, RES0.

Bits [7:2]

Reserved for data formats 2 to 7.

Reserved, RAZ.

F8E4M3, bit [1]

Indicates support for OFP8 E4M3 format and behavior for FP8 instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

F8E4M3	Meaning
0b0	OFP8 E4M3 format is not supported.
0b1	OFP8 E4M3 format is supported.

If FEAT_FP8 is implemented, the only permitted value is 1.

Otherwise, the only permitted value is 0.

For more information on OFP8 formats, see the Open Compute Project, OCP 8-bit Floating Point Specification (OFP8).

Access to this field is RO.

F8E5M2, bit [0]

Indicates support for OFP8 E5M2 format and behavior for FP8 instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

F8E5M2	Meaning
0b0	OFP8 E5M2 format is not supported.
0b1	OFP8 E5M2 format is supported.

If FEAT_FP8 is implemented, the only permitted value is 1.

Otherwise, the only permitted value is 0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

For more information on OFP8 formats, see the Open Compute Project, OCP 8-bit Floating Point Specification (OFP8).

Access to this field is RO.

D24.2.83 ID_AA64ISAR0_EL1, AArch64 Instruction Set Attribute Register 0

The ID_AA64ISAR0_EL1 characteristics are:

Purpose

Provides information about the instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64ISAR0_EL1 are UNDEFINED.

Attributes

ID_AA64ISAR0_EL1 is a 64-bit register.

Field descriptions

RNDR, bits [63:60]

Indicates support for Random Number instructions in AArch64 state.

When FEAT_RNG_TRAP is implemented, the value returned by a direct read of ID_AA64ISAR0_EL1.RNDR is further controlled by the value of SCR_EL3.TRNDR.

The value of this field is an IMPLEMENTATION DEFINED choice of:

RNDR	Meaning
0b0000	No Random Number instructions are implemented.
0b0001	RNDR and RNDRRS registers are implemented.

All other values are reserved.

FEAT_RNG implements the functionality identified by the value 0b0001.

Access to this field is RO.

TLB, bits [59:56]

Indicates support for Outer Shareable and TLB range maintenance instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TLB	Meaning
0b0000	Outer Shareable and TLB range maintenance instructions are not implemented.
0b0001	Outer Shareable TLB maintenance instructions are implemented.
0b0010	Outer Shareable and TLB range maintenance instructions are implemented.

All other values are reserved.

FEAT_TLBIOS implements the functionality identified by the values 0b0001 and 0b0010.

FEAT_TLBIRANGE implements the functionality identified by the value 0b0010.

From Armv8.4, the values 0b0000 and 0b0001 are not permitted.

Access to this field is RO.

TS, bits [55:52]

Indicates support for flag manipulation instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TS	Meaning
0b0000	No flag manipulation instructions are implemented.
0b0001	CFINV, RMIF, SETF16, and SETF8 instructions are implemented.
0b0010	CFINV, RMIF, SETF16, SETF8, AXFLAG, and XAFLAG instructions are implemented.

All other values are reserved.

FEAT_FlagM implements the functionality identified by the value 0b0001.

FEAT_FlagM2 implements the functionality identified by the value 0b0010.

In Armv8.4, the value 0b0000 is not permitted.

From Armv8.5, the value 0b0001 is not permitted.

Access to this field is RO.

FHM, bits [51:48]

Indicates support for the Advanced SIMD half-precision to single-precision multiply instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FHM	Meaning
0b0000	The Advanced SIMD half-precision to single-precision multiply instructions are not implemented.
0b0001	FMLAL and FMLSL instructions are implemented.

All other values are reserved.

FEAT_FHM implements the functionality identified by the value 0b0001.

From Armv8.4, if FEAT_FP16 is implemented, the value 0b0000 is not permitted.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Access to this field is RO.

DP, bits [47:44]

Indicates support for Dot Product instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DP	Meaning
0b0000	No Dot Product instructions implemented.
0b0001	UDOT and SDOT instructions implemented.

All other values are reserved.

FEAT_DotProd implements the functionality identified by the value 0b0001.

From Armv8.4, if FEAT_AdvSIMD is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

SM4, bits [43:40]

Indicates support for SM4 instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SM4	Meaning
0b0000	No SM4 instructions implemented.
0b0001	SM4E and SM4EKEY instructions implemented.

All other values are reserved.

If FEAT_SM4 is not implemented, the value 0b0001 is reserved.

FEAT_SM4 implements the functionality identified by the value 0b0001.

This field must have the same value as ID_AA64ISAR0_EL1.SM3.

Access to this field is RO.

SM3, bits [39:36]

Indicates support for the following SM3 instructions SM3SS1, SM3TT1A, SM3TT1B, SM3TT2A, SM3TT2B, SM3PARTW1, and SM3PARTW2 in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SM3	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

If FEAT_SM3 is not implemented, the value `0b0001` is reserved.

FEAT_SM3 implements the functionality identified by the value `0b0001`.

This field must have the same value as ID_AA64ISAR0_EL1.SM4.

Access to this field is RO.

SHA3, bits [35:32]

Indicates support for the following SHA3 instructions `EOR3`, `RAX1`, `XAR`, and `BCAX` in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA3	Meaning
`0b0000`	The specified instructions are not implemented.
`0b0001`	The specified instructions are implemented.

All other values are reserved.

If FEAT_SHA3 is not implemented, the value `0b0001` is reserved.

FEAT_SHA3 implements the functionality identified by the value `0b0001`.

If the value of ID_AA64ISAR0_EL1.SHA1 is `0b0000`, this field must have the value `0b0000`.

If the value of this field is `0b0001`, ID_AA64ISAR0_EL1.SHA2 must have the value `0b0010`.

Access to this field is RO.

RDM, bits [31:28]

Indicates support for `SQRDMLAH` and `SQRDMLSH` instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

RDM	Meaning
`0b0000`	No `RDMA` instructions implemented.
`0b0001`	`SQRDMLAH` and `SQRDMLSH` instructions implemented.

All other values are reserved.

FEAT_RDM implements the functionality identified by the value `0b0001`.

From Armv8.1, the value `0b0000` is not permitted.

Access to this field is RO.

Bits [27:24]

Reserved, RES0.

Atomic, bits [23:20]

Indicates support for Atomic instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Atomic	Meaning
0b0000	No Atomic instructions implemented.
0b0010	LDADD, LDCLR, LDEOR, LDSET, LDSMAX, LDSMIN, LDUMAX, LDUMIN, CAS, CASP, and SWP instructions implemented.
0b0011	As for 0b0010, plus 128-bit instructions LDCLRP, LDSETP, and SWPP.

All other values are reserved.

FEAT_LSE implements the functionality identified by the value 0b0010.

FEAT_LSE128 implements the functionality identified by the value 0b0011.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

CRC32, bits [19:16]

Indicates support for the following CRC32 instructions CRC32B, CRC32H, CRC32W, CRC32X, CRC32CB, CRC32CH, CRC32CW, and CRC32CX in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CRC32	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

All other values are reserved.

FEAT_CRC32 implements the functionality identified by the value 0b0001.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

SHA2, bits [15:12]

Indicates support for SHA2 instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA2	Meaning
0b0000	No SHA2 instructions implemented.
0b0001	Implements instructions: SHA256H, SHA256H2, SHA256SU0, and SHA256SU1.
0b0010	Implements instructions: • SHA256H, SHA256H2, SHA256SU0, and SHA256SU1. • SHA512H, SHA512H2, SHA512SU0, and SHA512SU1.

All other values are reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SHA256 implements the functionality identified by the value `0b0001`.

FEAT_SHA512 implements the functionality identified by the value `0b0010`.

If the value of ID_AA64ISAR0_EL1.SHA1 is `0b0000`, this field must have the value `0b0000`.

If the value of this field is `0b0010`, ID_AA64ISAR0_EL1.SHA3 must have the value `0b0001`.

Access to this field is RO.

SHA1, bits [11:8]

Indicates support for the following SHA1 instructions `SHA1C`, `SHA1P`, `SHA1M`, `SHA1H`, `SHA1SU0`, and `SHA1SU1` in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SHA1	Meaning
`0b0000`	The specified instructions are not implemented.
`0b0001`	The specified instructions are implemented.

All other values are reserved.

FEAT_SHA1 implements the functionality identified by the value `0b0001`.

If the value of ID_AA64ISAR0_EL1.SHA2 is `0b0000`, this field must have the value `0b0000`.

Access to this field is RO.

AES, bits [7:4]

Indicates support for AES instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AES	Meaning
`0b0000`	No AES instructions implemented.
`0b0001`	`AESE`, `AESD`, `AESMC`, and `AESIMC` instructions implemented.
`0b0010`	As for `0b0001`, plus `PMULL` and `PMULL2` instructions operating on 64-bit source elements.

FEAT_AES implements the functionality identified by the value `0b0001`.

FEAT_PMULL implements the functionality identified by the value `0b0010`.

All other values are reserved.

Access to this field is RO.

Bits [3:0]

Reserved, RES0.

D24.2.84 ID_AA64ISAR1_EL1, AArch64 Instruction Set Attribute Register 1

The ID_AA64ISAR1_EL1 characteristics are:

Purpose

Provides information about the features and instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64ISAR1_EL1 are UNDEFINED.

Attributes

ID_AA64ISAR1_EL1 is a 64-bit register.

Field descriptions

63:60	59:56	55:52	51:48	47:44	43:40	39:36	35:32
LS64	XS	I8MM	DGH	BF16	SPECRES	SB	FRINTTS

GPI	GPA	LRCPC	FCMA	JSCVT	API	APA	DPB

LS64, bits [63:60]

Indicates support for `LD64B` and `ST64B*` instructions, and the ACCDATA_EL1 register.

The value of this field is an IMPLEMENTATION DEFINED choice of:

LS64	Meaning
`0b0000`	No `LD64B` or `ST64B` instructions are supported.
`0b0001`	The `LD64B` and `ST64B` instructions are supported.
`0b0010`	As `0b0001`, and adds the `ST64BV` instruction and traps.
`0b0011`	As `0b0010`, and adds the `ST64BV0` instruction, ACCDATA_EL1 register, and traps.
`0b0100`	As `0b0011`, and adds support for atomic accesses to Write-back Cacheable, Shareable memory using one of the following: • `LD64B` and `ST64B` instructions. • SIMD&FP instructions that load or store a pair of 128-bit registers by generating 32-byte single-copy atomic accesses.

All other values are reserved.

FEAT_LS64 implements the functionality identified by `0b0001`.

FEAT_LS64_V implements the functionality identified by `0b0010`.

FEAT_LS64_ACCDATA implements the functionality identified by `0b0011`.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_LS64WB implements the functionality identified by `0b0100`.

Access to this field is RO.

XS, bits [59:56]

Indicates support for the XS attribute, the TLBI and DSB instructions with the nXS qualifier, and the HCRX_EL2.{FGTnXS, FnXS} fields in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

XS	Meaning
`0b0000`	The XS attribute, the TLBI and DSB instructions with the nXS qualifier, and the HCRX_EL2.{FGTnXS, FnXS} fields are not supported.
`0b0001`	The XS attribute, the TLBI and DSB instructions with the nXS qualifier, and the HCRX_EL2.{FGTnXS, FnXS} fields are supported.

All other values are reserved.

FEAT_XS implements the functionality identified by `0b0001`.

From Armv8.7, the value `0b0000` is not permitted.

Access to this field is RO.

I8MM, bits [55:52]

Indicates support for the following Advanced SIMD Int8 matrix multiplication instructions `SMMLA`, `SUDOT`, `UMMLA`, `USMMLA`, and `USDOT` in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

I8MM	Meaning
`0b0000`	The specified instructions are not implemented.
`0b0001`	The specified instructions are implemented.

All other values are reserved.

FEAT_I8MM implements the functionality identified by `0b0001`.

When Advanced SIMD and SVE are both implemented, this field must return the same value as ID_AA64ZFR0_EL1.I8MM.

From Armv8.6, the value `0b0000` is not permitted.

Access to this field is RO.

DGH, bits [51:48]

Indicates support for the Data Gathering Hint instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DGH	Meaning
0b0000	Data Gathering Hint is not implemented.
0b0001	Data Gathering Hint is implemented.

All other values are reserved.

FEAT_DGH implements the functionality identified by 0b0001.

From Armv8.0, the permitted values are 0b0000 and 0b0001.

If the DGH instruction has no effect in preventing the merging of memory accesses, the value of this field is 0b0000.

Access to this field is RO.

BF16, bits [47:44]

Indicates support for Advanced SIMD and floating-point BFloat16 instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BF16	Meaning
0b0000	BFloat16 instructions are not implemented.
0b0001	BFCVT, BFCVTN, BFCVTN2, BFDOT, BFMLALB, BFMLALT, and BFMMLA instructions are implemented.
0b0010	As 0b0001, but the FPCR.EBF field is also supported.

All other values are reserved.

FEAT_BF16 implements the functionality identified by 0b0001.

FEAT_EBF16 implements the functionality identified by 0b0010.

When FEAT_SVE or FEAT_SME is implemented, this field must return the same value as ID_AA64ZFR0_EL1.BF16.

From Armv8.6 and Armv9.1, the value 0b0000 is not permitted.

Access to this field is RO.

SPECRES, bits [43:40]

Indicates support for prediction invalidation instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SPECRES	Meaning
0b0000	Prediction invalidation instructions are not implemented.
0b0001	CFP RCTX, DVP RCTX and CPP RCTX instructions are implemented.
0b0010	As 0b0001, and COSP RCTX instruction is implemented.

All other values are reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_SPECRES implements the functionality identified by `0b0001`.

FEAT_SPECRES2 implements the functionality identified by `0b0010`.

From Armv8.5, the value `0b0000` is not permitted.

From Armv8.9, the value `0b0001` is not permitted.

Access to this field is RO.

SB, bits [39:36]

Indicates support for `SB` instruction in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SB	Meaning
`0b0000`	`SB` instruction is not implemented.
`0b0001`	`SB` instruction is implemented.

All other values are reserved.

FEAT_SB implements the functionality identified by `0b0001`.

From Armv8.5, the value `0b0000` is not permitted.

Access to this field is RO.

FRINTTS, bits [35:32]

Indicates support for `FRINT32Z`, `FRINT32X`, `FRINT64Z`, and `FRINT64X` instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FRINTTS	Meaning
`0b0000`	The specified instructions are not implemented.
`0b0001`	The specified instructions are implemented.

All other values are reserved.

FEAT_FRINTTS implements the functionality identified by `0b0001`.

From Armv8.5, the value `0b0000` is not permitted.

Access to this field is RO.

GPI, bits [31:28]

Indicates support for an IMPLEMENTATION DEFINED algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GPI	Meaning
0b0000	Generic Authentication using an IMPLEMENTATION DEFINED algorithm is not implemented.
0b0001	Generic Authentication using an IMPLEMENTATION DEFINED algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

When this field is nonzero, FEAT_PACIMP is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of ID_AA64ISAR1_EL1.GPA is nonzero, or the value of ID_AA64ISAR2_EL1.GPA3 is nonzero, this field must have the value 0b0000.

Access to this field is RO.

GPA, bits [27:24]

Indicates whether the QARMA5 algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

GPA	Meaning
0b0000	Generic Authentication using the QARMA5 algorithm is not implemented.
0b0001	Generic Authentication using the QARMA5 algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

FEAT_PACQARMA5 implements the functionality identified by 0b0001.

When this field is nonzero, FEAT_PACQARMA5 is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of ID_AA64ISAR1_EL1.GPI is nonzero, or the value of ID_AA64ISAR2_EL1.GPA3 is nonzero, this field must have the value 0b0000.

Access to this field is RO.

LRCPC, bits [23:20]

Indicates support for weaker release consistency, RCpc, based model.

The value of this field is an IMPLEMENTATION DEFINED choice of:

LRCPC	Meaning
0b0000	RCpc instructions are not implemented.
0b0001	The no offset LDAPR, LDAPRB, and LDAPRH instructions are implemented.
0b0010	As 0b0001, and the LDAPUR (unscaled), LDAPURB (unscaled), LDAPURSB (unscaled), LDAPURH (unscaled), LDAPURSH (unscaled), LDAPURSW (unscaled), STLUR (unscaled), STLURB (unscaled) and STLURH (unscaled) instructions are implemented.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

LRCPC	Meaning
0b0011	As 0b0010, and the post-index LDAPR, LDIAPP, STILP, and pre-index STLR instructions are implemented. If Advanced SIMD and floating-point is implemented, then the LDAPUR (SIMD&FP), LDAP1 (SIMD&FP), STLUR (SIMD&FP), and STL1 (SIMD&FP) instructions are implemented in Advanced SIMD and floating-point.

All other values are reserved.

FEAT_LRCPC implements the functionality identified by the value 0b0001.

FEAT_LRCPC2 implements the functionality identified by the value 0b0010.

FEAT_LRCPC3 implements the functionality identified by the value 0b0011.

From Armv8.3, the value 0b0000 is not permitted.

From Armv8.4, the value 0b0001 is not permitted.

Access to this field is RO.

FCMA, bits [19:16]

Indicates support for complex number addition and multiplication, where numbers are stored in vectors.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FCMA	Meaning
0b0000	The FCMLA and FCADD instructions are not implemented.
0b0001	The FCMLA and FCADD instructions are implemented.

All other values are reserved.

FEAT_FCMA implements the functionality identified by the value 0b0001.

From Armv8.3, if Advanced SIMD or floating-point is implemented, the value 0b0000 is not permitted.

From Armv8.3, if Advanced SIMD or floating-point is not implemented, the only permitted value is 0b0000.

Access to this field is RO.

JSCVT, bits [15:12]

Indicates support for JavaScript conversion from double-precision floating-point values to integers in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

JSCVT	Meaning
0b0000	The FJCVTZS instruction is not implemented.
0b0001	The FJCVTZS instruction is implemented.

All other values are reserved.

FEAT_JSCVT implements the functionality identified by 0b0001.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

From Armv8.3, if Advanced SIMD or floating-point is implemented, the value `0b0000` is not permitted.

From Armv8.3, if Advanced SIMD or floating-point is not implemented, the only permitted value is `0b0000`.

Access to this field is RO.

API, bits [11:8]

Indicates whether an IMPLEMENTATION DEFINED algorithm is implemented in the PE for address authentication, in AArch64 state. This applies to all Pointer Authentication instructions other than the `PACGA` instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

API	Meaning
`0b0000`	Address Authentication using an IMPLEMENTATION DEFINED algorithm is not implemented.
`0b0001`	Address Authentication using an IMPLEMENTATION DEFINED algorithm is implemented, FEAT_EPAC and FEAT_PAuth2 are not implemented.
`0b0010`	Address Authentication using an IMPLEMENTATION DEFINED algorithm is implemented, FEAT_EPAC is implemented, and FEAT_PAuth2 is not implemented.
`0b0011`	Address Authentication using an IMPLEMENTATION DEFINED algorithm is implemented, FEAT_EPAC is not implemented, and FEAT_PAuth2 is implemented.
`0b0100`	Address Authentication using an IMPLEMENTATION DEFINED algorithm is implemented, FEAT_EPAC is not implemented, FEAT_PAuth2 and FEAT_FPAC are implemented.
`0b0101`	Address Authentication using an IMPLEMENTATION DEFINED algorithm is implemented, FEAT_EPAC is not implemented, FEAT_PAuth2, FEAT_FPAC, and FEAT_FPACCOMBINE are implemented.
`0b0110`	Address Authentication using an IMPLEMENTATION DEFINED algorithm is implemented, including instructions that allow signing of LR using SP and PC as diversifiers, FEAT_EPAC is not implemented, FEAT_PAuth2, FEAT_FPAC, FEAT_FPACCOMBINE, and FEAT_PAuth_LR are implemented.

All other values are reserved.

FEAT_PAuth implements the functionality identified by `0b0001`.

FEAT_EPAC implements the functionality identified by `0b0010`.

FEAT_PAuth2 implements the functionality identified by `0b0011`.

FEAT_FPAC implements the functionality identified by `0b0100`.

FEAT_FPACCOMBINE implements the functionality identified by `0b0101`.

FEAT_PAuth_LR implements the functionality identified by `0b0110`.

When this field is nonzero, FEAT_PACIMP is implemented.

In Armv8.3, the permitted values are `0b0000`, `0b0001`, `0b0010`, `0b0011`, `0b0100`, and `0b0101`.

From Armv8.6, the permitted values are `0b0000`, `0b0011`, `0b0100`, and `0b0101`.

From Armv9.5, the permitted values are `0b0000`, `0b0011`, `0b0100`, `0b0101`, and `0b0110`.

If the value of ID_AA64ISAR1_EL1.APA is nonzero, or the value of ID_AA64ISAR2_EL1.APA3 is nonzero, this field must have the value `0b0000`.

Access to this field is RO.

APA, bits [7:4]

Indicates whether the QARMA5 algorithm is implemented in the PE for address authentication, in AArch64 state. This applies to all Pointer Authentication instructions other than the `PACGA` instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of this field is an IMPLEMENTATION DEFINED choice of:

APA	Meaning
0b0000	Address Authentication using the QARMA5 algorithm is not implemented.
0b0001	Address Authentication using the QARMA5 algorithm is implemented, FEAT_EPAC and FEAT_PAuth2 are not implemented.
0b0010	Address Authentication using the QARMA5 algorithm is implemented, FEAT_EPAC is implemented, and FEAT_PAuth2 is not implemented.
0b0011	Address Authentication using the QARMA5 algorithm is implemented, FEAT_EPAC is not implemented, and FEAT_PAuth2 is implemented.
0b0100	Address Authentication using the QARMA5 algorithm is implemented, FEAT_EPAC is not implemented, FEAT_PAuth2 and FEAT_FPAC are implemented.
0b0101	Address Authentication using the QARMA5 algorithm is implemented, FEAT_EPAC is not implemented, FEAT_PAuth2, FEAT_FPAC, and FEAT_FPACCOMBINE are implemented.
0b0110	Address Authentication using the QARMA5 algorithm is implemented, including instructions that allow signing of LR using SP and PC as diversifiers, FEAT_EPAC is not implemented, FEAT_PAuth2, FEAT_FPAC, FEAT_FPACCOMBINE, and FEAT_PAuth_LR are implemented.

All other values are reserved.

FEAT_PAuth implements the functionality identified by 0b0001.

FEAT_EPAC implements the functionality identified by 0b0010.

FEAT_PAuth2 implements the functionality identified by 0b0011.

FEAT_FPAC implements the functionality identified by 0b0100.

FEAT_FPACCOMBINE implements the functionality identified by 0b0101.

FEAT_PAuth_LR implements the functionality identified by 0b0110.

When this field is nonzero, FEAT_PACQARMA5 is implemented.

In Armv8.3, the permitted values are 0b0000, 0b0001, 0b0010, 0b0011, 0b0100, and 0b0101.

From Armv8.6, the permitted values are 0b0000, 0b0011, 0b0100, and 0b0101.

From Armv9.5, the permitted values are 0b0000, 0b0011, 0b0100, 0b0101, and 0b0110.

If the value of ID_AA64ISAR1_EL1.API is nonzero, or the value of ID_AA64ISAR2_EL1.APA3 is nonzero, this field must have the value 0b0000.

Access to this field is RO.

DPB, bits [3:0]

Data Persistence writeback. Indicates support for the DC CVAP and DC CVADP instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

DPB	Meaning
0b0000	DC CVAP not supported.
0b0001	DC CVAP supported.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

DPB	Meaning
0b0010	DC CVAP and DC CVADP supported.

All other values are reserved.

FEAT_DPB implements the functionality identified by the value 0b0001.

FEAT_DPB2 implements the functionality identified by the value 0b0010.

From Armv8.2, the value 0b0000 is not permitted.

From Armv8.5, the value 0b0001 is not permitted.

Access to this field is RO.

Accessing ID_AA64ISAR1_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ID_AA64ISAR1_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0110	0b001

```
if !IsFeatureImplemented(FEAT_AA64) then
    UnimplementedIDRegister();
elsif HaveEL(EL3) && !(EffectivelyAtEL0InHost() || EffectivelyAtEL0NotInHost() || PSTATE.EL == EL3) &&
     ↪EL3SDDUndefPriority() && IsFeatureImplemented(FEAT_IDTE3) && SCR_EL3().TID3 == '1' then

D24.2.85 ID_AA64ISAR2_EL1, AArch64 Instruction Set Attribute Register 2

The ID_AA64ISAR2_EL1 characteristics are:

Purpose

Provides information about the features and instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1, EL2, and EL3.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64ISAR2_EL1 are UNDEFINED.

Attributes

ID_AA64ISAR2_EL1 is a 64-bit register.

Field descriptions

63:60	59:56	55:52	51:48	47:44	43:40	39:36	35:32
ATS1A	LUT	CSSC	RPRFM	PCDPHINT	PRFMSLC	SYSINSTR_128	SYSREG_128

31:28	27:24	23:20	19:16	15:12	11:8	7:4	3:0
CLRBHB	PAC_frac	BC	MOPS	APA3	GPA3	RPRES	WFxT

ATS1A, bits [63:60]

Indicates support for address translation instructions, which perform stage 1 address translation for the given virtual address without checking for stage 1 permissions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ATS1A	Meaning
0b0000	Address Translate Stage 1 instructions without Permissions Checks are not implemented
0b0001	Address Translate Stage 1 instructions without Permissions Checks are implemented.

All other values are reserved.

Access to this field is RO.

LUT, bits [59:56]

Indicates support for:

- Advanced SIMD lookup table instructions with 2-bit and 4-bit indices.
- If FEAT_SVE2 or FEAT_SME2 is implemented, SVE lookup table instructions with 2-bit and 4-bit indices.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of this field is an IMPLEMENTATION DEFINED choice of:

LUT	Meaning
0b0000	The specified instructions are not implemented.
0b0001	Lookup table instructions with 2-bit indices LUTI2 and 4-bit indices LUTI4 are implemented.

All other values are reserved.

FEAT_LUT implements the functionality identified by the value 0b0001.

From Armv9.5, if FEAT_AdvSIMD is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

CSSC, bits [55:52]

Indicates support for common short sequence compression instructions.

If FEAT_CMPBR is implemented, indicates support for compare and branch instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CSSC	Meaning
0b0000	Common short sequence compression instructions are not implemented.
0b0001	The following common short sequence compression instructions are implemented: • 32-bit and 64-bit ABS, CNT, CTZ • 32-bit SMAX, UMAX, SMIN, UMIN (immediate). • 64-bit SMAX, UMAX, SMIN, UMIN (immediate). • 32-bit SMAX, UMAX, SMIN, UMIN (register). • 64-bit SMAX, UMAX, SMIN, UMIN (register).
0b0010	As 0b0001, and adds compare and branch instructions: • CBB<cc>. • CB<cc> (immediate), CB<cc> (register). • CBH<cc>.

All other values are reserved.

FEAT_CSSC implements the functionality identified by the value 0b0001.

FEAT_CMPBR implements the functionality identified by the value 0b0010.

From Armv9.4, the value 0b0000 is not permitted.

From Armv9.6, the value 0b0001 is not permitted.

Access to this field is RO.

RPRFM, bits [51:48]

RPRFM hint instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of this field is an IMPLEMENTATION DEFINED choice of:

RPRFM	Meaning
0b0000	RPRFM hint instruction is not implemented and is treated as a NOP.
0b0001	RPRFM hint instruction is implemented.

All other values are reserved.

FEAT_RPRFM implements the functionality identified by the value 0b0001.

Access to this field is RO.

PCDPHINT, bits [47:44]

Indicates support for producer-consumer data placement hints.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PCDPHINT	Meaning
0b0000	The STSHH and PRFM IR hint instructions are not implemented.
0b0001	The STSHH and PRFM IR hint instructions are implemented.

All other values are reserved.

FEAT_PCDPHINT implements the functionality identified by the value 0b0001.

Access to this field is RO.

PRFMSLC, bits [43:40]

Indicates whether the PRFM and PRFUM instructions support a system level cache option.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PRFMSLC	Meaning
0b0000	The PRFM and PRFUM instructions do not support the SLC target.
0b0001	The PRFM and PRFUM instructions support the SLC target.

All other values are reserved.

FEAT_PRFMSLC implements the functionality identified by the value 0b0001.

Access to this field is RO.

SYSINSTR_128, bits [39:36]

SYSINSTR_128. Indicates support for System instructions that can take 128-bit inputs.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SYSINSTR_128	Meaning
0b0000	System instructions that can take 128-bit inputs are not supported.
0b0001	System instructions that can take 128-bit inputs are supported.

All other values are reserved.

FEAT_SYSINSTR128 implements the functionality identified by the value 0b0001.

Access to this field is RO.

SYSREG_128, bits [35:32]

SYSREG_128. Indicates support for instructions to access 128-bit System Registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SYSREG_128	Meaning
0b0000	Instructions to access 128-bit System Registers are not supported.
0b0001	Instructions to access 128-bit System Registers are supported.

All other values are reserved.

FEAT_SYSREG128 implements the functionality identified by the value 0b0001.

Access to this field is RO.

CLRBHB, bits [31:28]

Indicates support for the CLRBHB instruction in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CLRBHB	Meaning
0b0000	CLRBHB instruction is not implemented.
0b0001	CLRBHB instruction is implemented.

All other values are reserved.

FEAT_CLRBHB implements the functionality identified by the value 0b0001.

From Armv8.9, the value 0b0000 is not permitted.

Access to this field is RO.

PAC_frac, bits [27:24]

Indicates which address bit is used to determine the size of the PAC field.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

PAC_frac	Meaning
0b0000	The address bit which is used to define the size of the PAC field is dependent on whether address tagging is used.
0b0001	The address bit which is used to define the size of the PAC field is fixed.

All other values are reserved.

FEAT_CONSTPACFIELD implements the functionality identified by the value 0b0001.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

BC, bits [23:20]

Indicates support for the BC instruction in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BC	Meaning
0b0000	BC instruction is not implemented.
0b0001	BC instruction is implemented.

All other values are reserved.

FEAT_HBC implements the functionality identified by the value 0b0001.

From Armv8.8, the value 0b0000 is not permitted.

Access to this field is RO.

MOPS, bits [19:16]

Indicates support for the Memory Copy and Memory Set instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

MOPS	Meaning
0b0000	The Memory Copy and Memory Set instructions are not implemented in AArch64 state.
0b0001	The Memory Copy and Memory Set instructions are implemented in AArch64 state with the following exception. If FEAT_MTE is implemented, then SETGP*, SETGM* and SETGE* instructions are also supported.

All other values are reserved.

FEAT_MOPS implements the functionality identified by the value 0b0001.

From Armv8.8, the value 0b0000 is not permitted.

Access to this field is RO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

APA3, bits [15:12]

Indicates whether the QARMA3 algorithm is implemented in the PE for address authentication in AArch64 state. This applies to all Pointer Authentication instructions other than the `PACGA` instruction.

The value of this field is an IMPLEMENTATION DEFINED choice of:

APA3	Meaning
`0b0000`	Address Authentication using the QARMA3 algorithm is not implemented.
`0b0001`	Address Authentication using the QARMA3 algorithm is implemented, FEAT_EPAC and FEAT_PAuth2 are not implemented.
`0b0010`	Address Authentication using the QARMA3 algorithm is implemented, FEAT_EPAC is implemented, and FEAT_PAuth2 is not implemented.
`0b0011`	Address Authentication using the QARMA3 algorithm is implemented, FEAT_EPAC is not implemented, and FEAT_PAuth2 is implemented.
`0b0100`	Address Authentication using the QARMA3 algorithm is implemented, FEAT_EPAC is not implemented, FEAT_PAuth2 and FEAT_FPAC are implemented.
`0b0101`	Address Authentication using the QARMA3 algorithm is implemented, FEAT_EPAC is not implemented, FEAT_PAuth2, FEAT_FPAC, and FEAT_FPACCOMBINE are implemented.
`0b0110`	Address Authentication using the QARMA3 algorithm is implemented, including instructions that allow signing of LR using SP and PC as diversifiers, FEAT_EPAC is not implemented, FEAT_PAuth2, FEAT_FPAC, FEAT_FPACCOMBINE, and FEAT_PAuth_LR are implemented.

All other values are reserved.

FEAT_PAuth implements the functionality identified by the value `0b0001`.

FEAT_EPAC implements the functionality identified by the value `0b0010`.

FEAT_PAuth2 implements the functionality identified by the value `0b0011`.

FEAT_FPAC implements the functionality identified by the value `0b0100`.

FEAT_FPACCOMBINE implements the functionality identified by the value `0b0101`.

FEAT_PAuth_LR implements the functionality identified by the value `0b0110`.

When this field is nonzero, FEAT_PACQARMA3 is implemented.

In Armv8.3, the permitted values are `0b0000`, `0b0001`, `0b0010`, `0b0011`, `0b0100`, and `0b0101`.

From Armv8.6, the permitted values are `0b0000`, `0b0011`, `0b0100`, and `0b0101`.

From Armv9.5, the permitted values are `0b0000`, `0b0011`, `0b0100`, `0b0101`, and `0b0110`.

If the value of ID_AA64ISAR1_EL1.API is nonzero, or the value of ID_AA64ISAR1_EL1.APA is nonzero, this field must have the value `0b0000`.

Access to this field is RO.

GPA3, bits [11:8]

Indicates whether the QARMA3 algorithm is implemented in the PE for generic code authentication in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

GPA3	Meaning
0b0000	Generic Authentication using the QARMA3 algorithm is not implemented.
0b0001	Generic Authentication using the QARMA3 algorithm is implemented. This includes the PACGA instruction.

All other values are reserved.

FEAT_PACQARMA3 implements the functionality identified by the value 0b0001.

When this field is nonzero, FEAT_PACQARMA3 is implemented.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

If the value of ID_AA64ISAR1_EL1.GPI is nonzero, or the value of ID_AA64ISAR1_EL1.GPA is nonzero, this field must have the value 0b0000.

Access to this field is RO.

RPRES, bits [7:4]

Indicates support for 12 bits of mantissa in single-precision reciprocal and reciprocal square root instructions in AArch64 state, when FPCR.AH is 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

RPRES	Meaning
0b0000	Single-precision reciprocal and reciprocal square root estimates give 8 bits of mantissa, when FPCR.AH is 1.
0b0001	Single-precision reciprocal and reciprocal square root estimates give 12 bits of mantissa, when FPCR.AH is 1.

All other values are reserved.

FEAT_RPRES implements the functionality identified by the value 0b0001.

When FPCR.AH is 0, the floating-point reciprocal estimate and reciprocal square root estimate instructions give 8 bits of mantissa.

Access to this field is RO.

WFxT, bits [3:0]

Indicates support for the WFET and WFIT instructions in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

WFxT	Meaning
0b0000	WFET and WFIT are not supported.
0b0010	WFET and WFIT are supported, and the register number is reported in the ESR_ELx on exceptions.

All other values are reserved.

FEAT_WFxT implements the functionality identified by the value 0b0010.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

From Armv8.7, the only permitted value is `0b0010`.

Access to this field is RO.

Accessing ID_AA64ISAR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ID_AA64ISAR2_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0110	0b010

```
if !IsFeatureImplemented(FEAT_AA64) then
    UnimplementedIDRegister();
elsif HaveEL(EL3) && !(Effectively AtEL0InHost() || EffectivelyAtEL0NotInHost() || PSTATE.EL == EL3) &&
     ↪EL3SDDUndefPriority() && IsFeatureImplemented(FEAT_IDTE3) && SCR_EL3().TID3 == '1' then
    Undefined();
elsif PSTATE.EL == EL0 then
    if IsFeatureImplemented(FEAT_IDST) then
        AArch64_SystemAccessTraptoEL1orEL2(0x18);

D24.2.86 ID_AA64ISAR3_EL1, AArch64 Instruction Set Attribute Register 3

The ID_AA64ISAR3_EL1 characteristics are:

Purpose

Provides information about the features and instructions implemented in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1, EL2, and EL3.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64ISAR3_EL1 are UNDEFINED.

Attributes

ID_AA64ISAR3_EL1 is a 64-bit register.

Field descriptions

Bits [63:60]

Reserved, RES0.

HINTE, bits [59:56]

Indicates support for the A64 extended hint space.

The value of this field is an IMPLEMENTATION DEFINED choice of:

HINTE	Meaning
0b0000	The A64 extended hint space is not implemented.
0b0001	The A64 base HINTE is implemented.

FEAT_HINTE implements the functionality identified by the value 0b0001.

Access to this field is RO.

Bits [55:32]

Reserved, RES0.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FPRCVT, bits [31:28]

Indicates support for the following conversion between floating-point and integer instructions with only scalar SIMD&FP register operands and results, and with different input and output register sizes, when the PE is not in Streaming SVE mode:

- `FCVTAS` (scalar SIMD&FP), `FCVTAU` (scalar SIMD&FP).
- `FCVTMS` (scalar SIMD&FP), `FCVTMU` (scalar SIMD&FP).
- `FCVTNS` (scalar SIMD&FP), `FCVTNU` (scalar SIMD&FP).
- `FCVTPS` (scalar SIMD&FP), `FCVTPU` (scalar SIMD&FP).
- `FCVTZS` (scalar SIMD&FP), `FCVTZU` (scalar SIMD&FP).
- `SCVTF` (scalar SIMD&FP), `UCVTF` (scalar SIMD&FP).

If FEAT_SME is implemented, indicates support for the above instructions, as well as the following conversion between floating-point and integer instructions with only scalar SIMD&FP register operands and results, and with the same input and output register sizes, when the PE is in Streaming SVE mode:

- `FCVTAS` (vector), `FCVTAU` (vector).
- `FCVTMS` (vector), `FCVTMU` (vector).
- `FCVTNS` (vector), `FCVTNU` (vector).
- `FCVTPS` (vector), `FCVTPU` (vector).
- `FCVTZS` (vector), `FCVTZU` (vector).
- `SCVTF` (vector), `UCVTF` (vector).

The value of this field is an IMPLEMENTATION DEFINED choice of:

FPRCVT	Meaning
`0b0000`	The specified instructions are not implemented.
`0b0001`	The specified instructions are implemented.

FEAT_FPRCVT implements the functionality identified by the value `0b0001`.

From Armv9.6, if FEAT_FP is implemented, the value `0b0000` is not permitted.

Access to this field is RO.

LSUI, bits [27:24]

Support for the following load and store unprivileged instructions:

- `LDTXR`, `STTXR`.
- `LDATXR`, `STLTXR`.
- `CAST`, `CASAT`, `CASALT`, `CASLT`.
- `CASPT`, `CASPAT`, `CASPALT`, `CASPLT`.
- `LDTP`, `STTP`.
- `LDTP (SIMD&FP)`, `STTP (SIMD&FP)`.
- `LDTNP`, `STTNP`.
- `LDTNP (SIMD&FP)`, `STTNP (SIMD&FP)`.
- `SWPT`, `SWPTA`, `SWPTL`, `SWPTAL`.
- `LDTADD`, `LDTADDA`, `LDTADDAL`, `LDTADDL`.
- `LDTSET`, `LDTSETA`, `LDTSETAL`, `LDTSETL`.
- `LDTCLR`, `LDTCLRA`, `LDTCLRAL`, `LDTCLRL`.
- `STTADD`, `STTADDL`.
- `STTSET`, `STTSETL`.
- `STTCLR`, `STTCLRL`.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

LSUI	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

FEAT_LSUI implements the functionality identified by the value 0b0001.

Access to this field is RO.

OCCMO, bits [23:20]

Indicates support for the following cache maintenance operation to the Outer cache level instructions:

- DC CIVAOC.
- DC CVAOC.

If FEAT_MTE is implemented:

- DC CIGDVAOC.
- DC CGDVAOC.

The value of this field is an IMPLEMENTATION DEFINED choice of:

OCCMO	Meaning
0b0000	The specified instructions are not implemented.
0b0001	The specified instructions are implemented.

FEAT_OCCMO implements the functionality identified by the value 0b0001.

From Armv9.6, the value 0b0000 is not permitted.

Access to this field is RO.

LSFE, bits [19:16]

Indicates support for the following A64 Base atomic floating-point in-memory instructions:

- Floating-point atomic add in memory: LDFADD, LDFADDA, LDFADDAL, and LDFADDL.
- BFloat16 atomic add in memory: LDBFADD, LDBFADDA, LDBFADDAL, and LDBFADDL.
- Floating-point atomic maximum in memory: LDFMAX, LDFMAXA, LDFMAXAL, and LDFMAXL.
- BFloat16 atomic maximum in memory: LDBFMAX, LDBFMAXA, LDBFMAXAL, and LDBFMAXL.
- Floating-point atomic maximum number in memory: LDFMAXNM, LDFMAXNMA, LDFMAXNMAL, and LDFMAXNML.
- BFloat16 atomic maximum number in memory: LDBFMAXNM, LDBFMAXNMA, LDBFMAXNMAL, and LDBFMAXNML.
- Floating-point atomic minimum in memory: LDFMIN, LDFMINA, LDFMINAL, and LDFMINL.
- BFloat16 atomic minimum in memory: LDBFMIN, LDBFMINA, LDBFMINAL, and LDBFMINL.
- Floating-point atomic minimum number in memory: LDFMINNM, LDFMINNMA, LDFMINNMAL, and LDFMINNML.
- BFloat16 atomic minimum number in memory: LDBFMINNM, LDBFMINNMA, LDBFMINNMAL, and LDBFMINNML.
- Floating-point atomic add in memory, without return: STFADD and STFADDL.
- BFloat16 atomic add in memory, without return: STBFADD and STBFADDL.
- Floating-point atomic maximum in memory, without return: STFMAX and STFMAXL.
- BFloat16 atomic maximum in memory, without return: STBFMAX and STBFMAXL.
- Floating-point atomic maximum number in memory, without return: STFMAXNM and STFMAXNML.
- BFloat16 atomic maximum number in memory, without return: STBFMAXNM and STBFMAXNML.
- Floating-point atomic minimum in memory, without return: STFMIN and STFMINL.
- BFloat16 atomic minimum in memory, without return: STBFMIN and STBFMINL.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- Floating-point atomic minimum number in memory, without return: `STFMINNM` and `STFMINNML`.
- BFloat16 atomic minimum number in memory, without return: `STBFMINNM` and `STBFMINNML`.

The value of this field is an IMPLEMENTATION DEFINED choice of:

LSFE	Meaning
`0b0000`	Atomic floating-point in-memory instructions are not implemented.
`0b0001`	The specified Atomic floating-point in-memory instructions are implemented.

FEAT_LSFE implements the functionality identified by the value `0b0001`

Access to this field is RO.

PACM, bits [15:12]

Indicates the implementation of PSTATE.PACM.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PACM	Meaning
`0b0000`	PSTATE.PACM is not implemented.
`0b0001`	Trivial implementation of PSTATE.PACM.
`0b0010`	Full implementation of PSTATE.PACM.

All other values are reserved.

FEAT_PAuth_LR implements the functionality identified by the values `0b0001` and `0b0010`.

If FEAT_PAuth_LR is implemented, the value `0b0000` is not permitted.

If ID_AA64ISAR1_EL1.API is `0b0000`, the value `0b0001` is not permitted.

If one of FEAT_PACQARMA3 or FEAT_PACQARMA5 are implemented, the value `0b0001` is not permitted.

Access to this field is RO.

TLBIW, bits [11:8]

Support for `TLBI VMALL` for Dirty state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TLBIW	Meaning
`0b0000`	`TLBI VMALL` for Dirty state is not supported.
`0b0001`	`TLBI VMALL` for Dirty state is supported.

All other values are reserved.

FEAT_TLBIW implements the functionality identified by the value `0b0001`.

Access to this field is RO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FAMINMAX, bits [7:4]

Indicates support for the following Advanced SIMD, SVE2, and SME2 instructions that calculate maximum and minimum absolute value:

- When Advanced SIMD is implemented, the Advanced SIMD instructions `FAMAX` and `FAMIN`.
- When FEAT_SVE2 or FEAT_SME2 is implemented, the SVE2 instructions `FAMAX` and `FAMIN`.
- When FEAT_SME2 is implemented, the SME2 instructions `FAMAX` (multiple and single vectors), `FAMIN` (multiple and single vectors), `FAMAX` (multiple vectors), and `FAMIN` (multiple vectors).

The value of this field is an IMPLEMENTATION DEFINED choice of:

FAMINMAX	Meaning
`0b0000`	The specified instructions are not implemented.
`0b0001`	The specified instructions are implemented.

All other values are reserved.

FEAT_FAMINMAX implements the functionality identified by the value `0b0001`.

Access to this field is RO.

CPA, bits [3:0]

Indicates support for Checked Pointer Arithmetic instructions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CPA	Meaning
`0b0000`	Checked Pointer Arithmetic instructions are not implemented.
`0b0001`	Checked Pointer Arithmetic instructions are implemented.
`0b0010`	Checked Pointer Arithmetic instructions are implemented, and Checked Pointer Arithmetic can be enabled.

All other values are reserved.

FEAT_CPA implements the functionality identified by the value `0b0001`.

FEAT_CPA2 implements the functionality identified by the value `0b0010`.

From Armv9.5, the value `0b0000` is not permitted.

Access to this field is RO.

Accessing ID_AA64ISAR3_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ID_AA64ISAR3_EL1
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

D24.2.87 ID_AA64MMFR0_EL1, AArch64 Memory Model Feature Register 0

The ID_AA64MMFR0_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64MMFR0_EL1 are UNDEFINED.

Attributes

ID_AA64MMFR0_EL1 is a 64-bit register.

Field descriptions

ECV, bits [63:60]

Indicates presence of Enhanced Counter Virtualization.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ECV	Meaning
`0b0000`	Enhanced Counter Virtualization is not implemented.
`0b0001`	Enhanced Counter Virtualization is implemented. Supports CNTHCTL_EL2.{EL1TVT, EL1TVCT, EL1NVPCT, EL1NVVCT, EVNTIS}, CNTKCTL_EL1.EVNTIS, CNTPCTSS_EL0 counter views, and CNTVCTSS_EL0 counter views. Extends the PMSCR_EL1.PCT, PMSCR_EL2.PCT, TRFCR_EL1.TS, and TRFCR_EL2.TS fields.
`0b0010`	As `0b0001`, and the CNTPOFF_EL2 register and the CNTHCTL_EL2.ECV and SCR_EL3.ECVEn fields are implemented.

All other values are reserved.

FEAT_ECV implements the functionality identified by the value `0b0001`.

FEAT_ECV_POFF implements the functionality identified by the value `0b0010`.

From Armv8.6, the value `0b0000` is not permitted.

Access to this field is RO.

FGT, bits [59:56]

Indicates presence of the Fine-Grained Trap controls.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of this field is an IMPLEMENTATION DEFINED choice of:

FGT	Meaning
0b0000	Fine-grained trap controls are not implemented.
0b0001	Fine-grained trap controls are implemented. Supports: • If EL2 is implemented, the HAFGRTR_EL2, HDFGRTR_EL2, HDFGWTR_EL2, HFGRTR_EL2, HFGITR_EL2 and HFGWTR_EL2 registers, and their associated traps. • If EL2 is implemented, MDCR_EL2.TDCC. • If EL3 is implemented, MDCR_EL3.TDCC. • If both EL2 and EL3 are implemented, SCR_EL3.FGTEn.
0b0010	As 0b0001, and also includes support for: • If EL2 is implemented, the HDFGRTR2_EL2, HDFGWTR2_EL2, HFGITR2_EL2, HFGRTR2_EL2, and HFGWTR2_EL2 registers, and their associated traps. • If both EL2 and EL3 are implemented, SCR_EL3.FGTEn2.

All other values are reserved.

FEAT_FGT implements the functionality identified by the value 0b0001.

FEAT_FGT2 implements the functionality identified by the value 0b0010.

From Armv8.6, the value 0b0000 is not permitted.

From Armv8.9, the value 0b0001 is not permitted.

Access to this field is RO.

Bits [55:48]

Reserved, RES0.

ExS, bits [47:44]

Indicates support for disabling context synchronizing exception entry and exit.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ExS	Meaning
0b0000	All exception entries and exits are context synchronization events.
0b0001	Non-context synchronizing exception entry and exit are supported.

All other values are reserved.

FEAT_ExS implements the functionality identified by the value 0b0001.

Access to this field is RO.

TGran4_2, bits [43:40]

Indicates support for 4KB memory granule size at stage 2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TGran4_2	Meaning	Applies when
0b0000	Support for 4KB granule at stage 2 is identified in the ID_AA64MMFR0_EL1.TGran4 field.	
0b0001	4KB granule not supported at stage 2.	
0b0010	4KB granule supported at stage 2.	
0b0011	4KB granule at stage 2 supports 52-bit input addresses and can describe 52-bit output addresses.	FEAT_LPA2 is implemented

All other values are reserved.

If EL2 is not implemented, this field is 0b0000. Otherwise, the value 0b0000 is deprecated.

Note

This field does not follow the standard ID scheme. See Alternative ID scheme used for ID_AA64MMFR0_EL1 stage 2 granule sizes for more information.

Access to this field is RO.

TGran64_2, bits [39:36]

Indicates support for 64KB memory granule size at stage 2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TGran64_2	Meaning
0b0000	Support for 64KB granule at stage 2 is identified in the ID_AA64MMFR0_EL1.TGran64 field.
0b0001	64KB granule not supported at stage 2.
0b0010	64KB granule supported at stage 2.

All other values are reserved.

If EL2 is not implemented, this field is 0b0000. Otherwise, the value 0b0000 is deprecated.

Note

This field does not follow the standard ID scheme. See Alternative ID scheme used for ID_AA64MMFR0_EL1 stage 2 granule sizes for more information.

Access to this field is RO.

TGran16_2, bits [35:32]

Indicates support for 16KB memory granule size at stage 2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TGran16_2	Meaning	Applies when
0b0000	Support for 16KB granule at stage 2 is identified in the ID_AA64MMFR0_EL1.TGran16 field.	
0b0001	16KB granule not supported at stage 2.	
0b0010	16KB granule supported at stage 2.	
0b0011	16KB granule at stage 2 supports 52-bit input addresses and can describe 52-bit output addresses.	FEAT_LPA2 is implemented

All other values are reserved.

If EL2 is not implemented, this field is 0b0000. Otherwise, the value 0b0000 is deprecated.

Note

This field does not follow the standard ID scheme. See Alternative ID scheme used for ID_AA64MMFR0_EL1 stage 2 granule sizes for more information.

Access to this field is RO.

TGran4, bits [31:28]

Indicates support for 4KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TGran4	Meaning	Applies when
0b0000	4KB granule supported.	
0b0001	4KB granule supports 52-bit input addresses and can describe 52-bit output addresses.	FEAT_LPA2 is implemented
0b1111	4KB granule not supported.	

All other values are reserved.

Access to this field is RO.

TGran64, bits [27:24]

Indicates support for 64KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TGran64	Meaning
0b0000	64KB granule supported.
0b1111	64KB granule not supported.

All other values are reserved.

Access to this field is RO.

TGran16, bits [23:20]

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Indicates support for 16KB memory translation granule size.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TGran16	Meaning	Applies when
0b0000	16KB granule not supported.	
0b0001	16KB granule supported.	
0b0010	16KB granule supports 52-bit input addresses and can describe 52-bit output addresses.	FEAT_LPA2 is implemented

All other values are reserved.

Access to this field is RO.

BigEndEL0, bits [19:16]

Indicates support for mixed-endian at EL0 only.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BigEndEL0	Meaning
0b0000	No mixed-endian support at EL0. The SCTLR_EL1.E0E bit has a fixed value.
0b0001	Mixed-endian support at EL0. The SCTLR_EL1.E0E bit can be configured.

FEAT_MixedEndEL0 implements the functionality identified by the value 0b0001.

All other values are reserved.

This field is invalid and is RES0 if ID_AA64MMFR0_EL1.BigEnd is not 0b0000.

Access to this field is RO.

SNSMem, bits [15:12]

Indicates support for a distinction between Secure and Non-secure Memory.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SNSMem	Meaning
0b0000	Does not support a distinction between Secure and Non-secure Memory.
0b0001	Does support a distinction between Secure and Non-secure Memory.

Note

If EL3 is implemented, the value 0b0000 is not permitted.

All other values are reserved.

Access to this field is RO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

BigEnd, bits [11:8]

Indicates support for mixed-endian configuration.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BigEnd	Meaning
0b0000	No mixed-endian support. The SCTLR_ELx.EE bits have a fixed value. See the BigEndEL0 field, bits[19:16], for whether EL0 supports mixed-endian.
0b0001	Mixed-endian support. The SCTLR_ELx.EE and SCTLR_EL1.E0E bits can be configured.

FEAT_MixedEnd implements the functionality identified by the value 0b0001.

If this field is 0b0001, FEAT_MixedEndEL0 is also implemented.

All other values are reserved.

Access to this field is RO.

ASIDBits, bits [7:4]

Number of ASID bits.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ASIDBits	Meaning
0b0000	8 bits.
0b0010	16 bits.

All other values are reserved.

Access to this field is RO.

PARange, bits [3:0]

Physical Address range supported.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PARange	Meaning	Applies when
0b0000	32 bits, 4GB.	
0b0001	36 bits, 64GB.	
0b0010	40 bits, 1TB.	
0b0011	42 bits, 4TB.	
0b0100	44 bits, 16TB.	
0b0101	48 bits, 256TB.	
0b0110	52 bits, 4PB.	FEAT_LPA is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

0b0111	56 bits, 64PB.	FEAT_D128 is implemented

All other values are reserved.

Access to this field is RO.

Accessing ID_AA64MMFR0_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ID_AA64MMFR0_EL1

D24.2.88 ID_AA64MMFR1_EL1, AArch64 Memory Model Feature Register 1

The ID_AA64MMFR1_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64MMFR1_EL1 are UNDEFINED.

Attributes

ID_AA64MMFR1_EL1 is a 64-bit register.

Field descriptions

ECBHB, bits [63:60]

Indicates support for restrictions on branch history speculation around exceptions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ECBHB	Meaning
`0b0000`	The implementation does not disclose whether restrictions are imposed on branch history speculation around exceptions.
`0b0001`	The implementation imposes restrictions on branch history speculation around exceptions.

All other values are reserved.

FEAT_ECBHB implements the functionality identified by the value `0b0001`.

From Armv8.9, the value `0b0000` is not permitted.

Access to this field is RO.

CMOW, bits [59:56]

Indicates support for cache maintenance instruction permission.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

CMOW	Meaning
0b0000	SCTLR_EL1.CMOW, SCTLR_EL2.CMOW, and HCRX_EL2.CMOW bits are not implemented.
0b0001	SCTLR_EL1.CMOW is implemented. If EL2 is implemented, SCTLR_EL2.CMOW and HCRX_EL2.CMOW bits are implemented.

All other values are reserved.

FEAT_CMOW implements the functionality identified by the value 0b0001.

From Armv8.8, the value 0b0000 is not permitted.

Access to this field is RO.

TIDCP1, bits [55:52]

Indicates whether SCTLR_EL1.TIDCP and SCTLR_EL2.TIDCP are implemented in AArch64 state.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TIDCP1	Meaning
0b0000	SCTLR_EL1.TIDCP and SCTLR_EL2.TIDCP bits are not implemented and are RES0.
0b0001	SCTLR_EL1.TIDCP bit is implemented. If EL2 is implemented, SCTLR_EL2.TIDCP bit is implemented.

All other values are reserved.

FEAT_TIDCP1 implements the functionality identified by the value 0b0001.

From Armv8.8, the value 0b0000 is not permitted.

Access to this field is RO.

nTLBPA, bits [51:48]

Indicates support for intermediate caching of translation table walks.

The value of this field is an IMPLEMENTATION DEFINED choice of:

nTLBPA	Meaning
0b0000	The intermediate caching of translation table walks might include non-coherent physical translation caches.
0b0001	The intermediate caching of translation table walks does not include non-coherent physical translation caches.

Non-coherent physical translation caches are non-coherent caches of previous valid translation table entries since the last completed relevant TLBI applicable to the PE, where either:

- The caching is indexed by the physical address of the location holding the translation table entry.
- The caching is used for stage 1 translations and is indexed by the intermediate physical address of the location holding the translation table entry.

All other values are reserved.

FEAT_nTLBPA implements the functionality identified by the value 0b0001.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Access to this field is RO.

AFP, bits [47:44]

Indicates support for FPCR.{AH, FIZ, NEP}.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AFP	Meaning
0b0000	The FPCR.{AH, FIZ, NEP} fields are not supported.
0b0001	The FPCR.{AH, FIZ, NEP} fields are supported.

All other values are reserved.

FEAT_AFP implements the functionality identified by the value 0b0001.

From Armv8.7, if Advanced SIMD and floating-point is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

HCX, bits [43:40]

Indicates support for HCRX_EL2 and its associated EL3 trap.

The value of this field is an IMPLEMENTATION DEFINED choice of:

HCX	Meaning
0b0000	HCRX_EL2 and its associated EL3 trap are not supported.
0b0001	HCRX_EL2 and its associated EL3 trap are supported.

All other values are reserved.

FEAT_HCX implements the functionality identified by the value 0b0001.

From Armv8.7, if EL2 is implemented, the value 0b0000 is not permitted.

Access to this field is RO.

ETS, bits [39:36]

Indicates support for Enhanced Translation Synchronization.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ETS	Meaning
0b0000	Enhanced Translation Synchronization is not supported.
0b0001	Enhanced Translation Synchronization is not supported.
0b0010	FEAT_ETS2 is implemented.
0b0011	FEAT_ETS3 is implemented.

All other values are reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

FEAT_ETS2 implements the functionality identified by the value `0b0010`.

FEAT_ETS3 implements the functionality identified by the value `0b0011`.

From Armv8.8, the values `0b0000` and `0b0001` are not permitted.

From Armv9.5, the value `0b0010` is not permitted.

Access to this field is RO.

TWED, bits [35:32]

Indicates support for the configurable delayed trapping of WFE and WFET.

The value of this field is an IMPLEMENTATION DEFINED choice of:

TWED	Meaning
`0b0000`	Configurable delayed trapping of WFE and WFET are not supported.
`0b0001`	Configurable delayed trapping of WFE and WFET are supported.

All other values are reserved.

FEAT_TWED implements the functionality identified by the value `0b0001`.

Access to this field is RO.

XNX, bits [31:28]

Indicates support for execute-never control distinction by Exception level at stage 2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

XNX	Meaning
`0b0000`	Distinction between EL0 and EL1 execute-never control at stage 2 not supported.
`0b0001`	Distinction between EL0 and EL1 execute-never control at stage 2 supported.

All other values are reserved.

FEAT_XNX implements the functionality identified by the value `0b0001`.

From Armv8.2, the value `0b0000` is not permitted.

Access to this field is RO.

SpecSEI, bits [27:24]

When FEAT_RAS is implemented:

Describes whether the PE can generate SError exceptions from speculative reads of memory, including speculative instruction fetches.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SpecSEI	Meaning
0b0000	The PE never generates an SError exception due to an External abort on a speculative read.
0b0001	The PE might generate an SError exception due to an External abort on a speculative read.

All other values are reserved.

FEAT_SpecSEI implements the functionality identified by the value 0b0001.

Access to this field is RO.

Otherwise:

Reserved, RES0.

PAN, bits [23:20]

Privileged Access Never. Indicates support for the PAN bit in PSTATE, SPSR_EL1, SPSR_EL2, SPSR_EL3, and DSPSR_EL0.

The value of this field is an IMPLEMENTATION DEFINED choice of:

PAN	Meaning
0b0000	PAN not supported.
0b0001	PAN supported.
0b0010	PAN supported and AT S1E1RP and AT S1E1WP instructions supported.
0b0011	PAN supported, AT S1E1RP and AT S1E1WP instructions supported, and SCTLR_EL1.EPAN and SCTLR_EL2.EPAN bits supported.

All other values are reserved.

FEAT_PAN implements the functionality identified by the value 0b0001.

FEAT_PAN2 implements the functionality added by the value 0b0010.

FEAT_PAN3 implements the functionality added by the value 0b0011.

From Armv8.1, the value 0b0000 is not permitted.

From Armv8.2, the value 0b0001 is not permitted.

From Armv8.7, the value 0b0010 is not permitted.

Access to this field is RO.

LO, bits [19:16]

LORegions. Indicates support for LORegions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

LO	Meaning
0b0000	LORegions not supported.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

LO	Meaning
0b0001	LORegions supported.

All other values are reserved.

FEAT_LOR implements the functionality identified by the value 0b0001.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

HPDS, bits [15:12]

Hierarchical Permission Disables. Indicates support for disabling hierarchical controls in translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

HPDS	Meaning
0b0000	Disabling of hierarchical controls not supported.
0b0001	Disabling of hierarchical controls supported with the TCR_EL1.{HPD1, HPD0}, TCR_EL2.HPD or TCR_EL2.{HPD1, HPD0}, and TCR_EL3.HPD bits.
0b0010	As for value 0b0001, and adds possible hardware allocation of bits[62:59] of the Translation table descriptors from the final lookup level for IMPLEMENTATION DEFINED use.

All other values are reserved.

FEAT_HPDS implements the functionality identified by the value 0b0001.

FEAT_HPDS2 implements the functionality identified by the value 0b0010.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

VH, bits [11:8]

Virtualization Host Extensions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

VH	Meaning
0b0000	Virtualization Host Extensions not supported.
0b0001	Virtualization Host Extensions supported.

All other values are reserved.

FEAT_VHE implements the functionality identified by the value 0b0001.

From Armv8.1, the value 0b0000 is not permitted.

Access to this field is RO.

VMIDBits, bits [7:4]

Number of VMID bits.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

The value of this field is an IMPLEMENTATION DEFINED choice of:

VMIDBits	Meaning
0b0000	8 bits
0b0010	16 bits

All other values are reserved.

FEAT_VMID16 implements the functionality identified by the value 0b0010.

Access to this field is RO.

HAFDBS, bits [3:0]

Hardware updates to Access flag and Dirty state in translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

HAFDBS	Meaning
0b0000	Hardware update of the Access flag and dirty state are not supported.
0b0001	Support for hardware update of the Access flag for Block and Page descriptors.
0b0010	As 0b0001, and adds support for hardware update of dirty state.
0b0011	As 0b0010, and adds support for hardware update of the Access flag for Table descriptors.
0b0100	As 0b0011, and adds support for hardware tracking of Dirty state Structure.

All other values are reserved.

FEAT_HAF implements the functionality identified by the value 0b0001.

FEAT_HAFDBS implements the functionality identified by the value 0b0010.

FEAT_HAFT implements the functionality identified by the value 0b0011.

FEAT_HDBSS implements the functionality identified by the value 0b0100.

Access to this field is RO.

Accessing ID_AA64MMFR1_EL1

D24.2.89 ID_AA64MMFR2_EL1, AArch64 Memory Model Feature Register 2

The ID_AA64MMFR2_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

For general information about the interpretation of the ID registers, see 'Principles of the ID scheme for fields in ID registers'.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1, EL2, and EL3.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64MMFR2_EL1 are UNDEFINED.

Attributes

ID_AA64MMFR2_EL1 is a 64-bit register.

Field descriptions

63:60	59:56	55:52	51:48	47:44	43:40	39:36	35:32
E0PD	EVT	BBM	TTL	RES0	FWB	IDS	AT

31:28	27:24	23:20	19:16	15:12	11:8	7:4	3:0
ST	NV	CCIDX	VARange	IESB	LSM	UAO	CnP

E0PD, bits [63:60]

Indicates support for the E0PD mechanism.

The value of this field is an IMPLEMENTATION DEFINED choice of:

E0PD	Meaning
0b0000	E0PDx mechanism is not implemented.
0b0001	E0PDx mechanism is implemented.

All other values are reserved.

FEAT_E0PD implements the functionality identified by the value 0b0001.

In Armv8.4, the permitted values are 0b0000 and 0b0001.

From Armv8.5, the only permitted value is 0b0001.

If FEAT_E0PD is implemented, FEAT_CSV3 must be implemented.

Access to this field is RO.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

EVT, bits [59:56]

Enhanced Virtualization Traps. If EL2 is implemented, indicates support for the HCR_EL2.{TTLBOS, TTLBIS, TOCU, TICAB, TID4} traps.

The value of this field is an IMPLEMENTATION DEFINED choice of:

EVT	Meaning
0b0000	HCR_EL2.{TTLBOS, TTLBIS, TOCU, TICAB, TID4} traps are not supported.
0b0001	HCR_EL2.{TOCU, TICAB, TID4} traps are supported.
0b0010	As 0b0001, and HCR_EL2.{TTLBOS, TTLBIS} traps are supported.

All other values are reserved.

FEAT_EVT implements the functionality identified by the value 0b0001.

FEAT_EVT2 implements the functionality identified by the value 0b0010.

If EL2 is not implemented, the only permitted value is 0b0000.

From Armv8.5, if EL2 is implemented, the value 0b0001 is not permitted.

Access to this field is RO.

BBM, bits [55:52]

Allows identification of the requirements of the hardware to have break-before-make sequences when changing block or table size for a translation.

The value of this field is an IMPLEMENTATION DEFINED choice of:

BBM	Meaning
0b0000	Break-before-make sequence must be used.
0b0001	Level 1 support for changing block size is supported.
0b0010	Level 2 support for changing block size is supported.

All other values are reserved.

FEAT_BBML1 implements the functionality identified by the value 0b0001.

FEAT_BBML2 implements the functionality identified by the value 0b0010.

Access to this field is RO.

TTL, bits [51:48]

Indicates support for TTL field in address operations.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

TTL	Meaning
0b0000	TLB maintenance instructions by address have bits[47:44] as RES0.
0b0001	TLB maintenance instructions by address have bits[47:44] holding the TTL field.

All other values are reserved.

FEAT_TTL implements the functionality identified by the value 0b0001.

This field affects TLBI IPAS2E1, TLBI IPAS2E1IS, TLBI IPAS2E1OS, TLBI IPAS2LE1, TLBI IPAS2LE1IS, TLBI IPAS2LE1OS, TLBI VAAE1, TLBI VAAE1IS, TLBI VAAE1OS, TLBI VAALE1, TLBI VAALE1IS, TLBI VAALE1OS, TLBI VAE1, TLBI VAE1IS, TLBI VAE1OS, TLBI VAE2, TLBI VAE2IS, TLBI VAE2OS, TLBI VAE3, TLBI VAE3IS, TLBI VAE3OS,TLBI VALE1, TLBI VALE1IS, TLBI VALE1OS, TLBI VALE2, TLBI VALE2IS, TLBI VALE2OS, TLBI VALE3, TLBI VALE3IS, TLBI VALE3OS.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

Bits [47:44]

Reserved, RES0.

FWB, bits [43:40]

Indicates support for HCR_EL2.FWB.

The value of this field is an IMPLEMENTATION DEFINED choice of:

FWB	Meaning
0b0000	HCR_EL2.FWB bit is not supported.
0b0001	HCR_EL2.FWB is supported.

All other values are reserved.

FEAT_S2FWB implements the functionality identified by the value 0b0001.

From Armv8.4, the value 0b0000 is not permitted.

Access to this field is RO.

IDS, bits [39:36]

Indicates the EC syndrome value in ESR_ELx.EC that is reported if an exception is generated by a read access to the feature ID space.

The value of this field is an IMPLEMENTATION DEFINED choice of:

IDS	Meaning
0b0000	An exception which is generated by a read access to the feature ID space, other than a trap caused by HCR_EL2.TIDx, SCTLR_EL1.UCT, or SCTLR_EL2.UCT is reported by ESR_ELx.EC == 0x0.
0b0001	All exceptions generated by an AArch64 read access to the feature ID space are reported by ESR_ELx.EC == 0x18.
0b0010	As 0b0001 and introduces support for trapping ID register accesses to EL3.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

The Feature ID space is defined as the System register space in AArch64 with op0==3, op1=={0, 1, 3}, CRn==0, CRm=={0-7}, op2=={0-7}.

FEAT_IDST implements the functionality identified by the value `0b0001`.

FEAT_IDTE3 implements the functionality identified by `0b0010`.

From Armv8.4, the value `0b0000` is not permitted.

From Armv9.6, if EL3 is implemented, the value `0b0001` is not permitted.

Access to this field is RO.

AT, bits [35:32]

Identifies support for unaligned single-copy atomicity and atomic functions.

The value of this field is an IMPLEMENTATION DEFINED choice of:

AT	Meaning
`0b0000`	Unaligned single-copy atomicity and atomic functions are not supported.
`0b0001`	Unaligned single-copy atomicity and atomic functions with a 16-byte address range aligned to 16-bytes are supported.

All other values are reserved.

FEAT_LSE2 implements the functionality identified by the value `0b0001`.

From Armv8.4, the value `0b0000` is not permitted.

Access to this field is RO.

ST, bits [31:28]

Identifies support for small translation tables.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ST	Meaning
`0b0000`	The maximum value of the TCR_ELx.{T0SZ,T1SZ} and VTCR_EL2.T0SZ fields is 39.
`0b0001`	The maximum value of the TCR_ELx.{T0SZ,T1SZ} and VTCR_EL2.T0SZ fields is 48 for 4KB and 16KB granules, and 47 for 64KB granules.

All other values are reserved.

FEAT_TTST implements the functionality identified by the value `0b0001`.

When FEAT_SEL2 is implemented, the value `0b0000` is not permitted.

Access to this field is RO.

NV, bits [27:24]

Nested Virtualization. If EL2 is implemented, indicates support for the use of nested virtualization.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

NV	Meaning
0b0000	If ID_AA64MMFR4_EL1.NV_frac != 0b0000, support for nested virtualization is described in ID_AA64MMFR4_EL1.NV_frac. Otherwise, nested virtualization is not supported.
0b0001	The HCR_EL2.{AT, NV1, NV} bits are implemented.
0b0010	The VNCR_EL2 register and the HCR_EL2.{NV2, AT, NV1, NV} bits are implemented.

All other values are reserved.

If EL2 is not implemented, the only permitted value is 0b0000.

FEAT_NV implements the functionality identified by the value 0b0001.

FEAT_NV2 implements the functionality identified by the value 0b0010.

In Armv8.3, if EL2 is implemented, the permitted values are 0b0000 and 0b0001.

From Armv8.4, if EL2 is implemented, the permitted values are 0b0000, 0b0001, and 0b0010.

Access to this field is RO.

CCIDX, bits [23:20]

Support for the use of revised CCSIDR_EL1 register format.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CCIDX	Meaning
0b0000	32-bit format implemented for all levels of the CCSIDR_EL1.
0b0001	64-bit format implemented for all levels of the CCSIDR_EL1.

All other values are reserved.

FEAT_CCIDX implements the functionality identified by the value 0b0001.

From Armv8.3, the permitted values are 0b0000 and 0b0001.

Access to this field is RO.

VARange, bits [19:16]

Indicates support for a larger virtual address.

The value of this field is an IMPLEMENTATION DEFINED choice of:

VARange	Meaning	Applies when
0b0000	VMSAv8-64 supports 48-bit VAs.	
0b0001	VMSAv8-64 supports 52-bit VAs when using the 64KB translation granule. The size for other translation granules is not defined by this field.	
0b0010	VMSAv9-128 supports 56-bit VAs.	FEAT_D128 is implemented

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

All other values are reserved.

FEAT_LVA implements the functionality identified by the value `0b0001`.

FEAT_LVA3 implements the functionality identified by the value `0b0010`.

Access to this field is RO.

IESB, bits [15:12]

Indicates support for the IESB fields in the SCTLR_ELx and ESR_ELx registers.

The value of this field is an IMPLEMENTATION DEFINED choice of:

IESB	Meaning
`0b0000`	IESB fields in the SCTLR_ELx and ESR_ELx registers is not supported.
`0b0001`	IESB fields in the SCTLR_ELx and ESR_ELx registers is supported. If an SError exception is taken ELx as a result of the error synchronization event generated on exception entry by the FEAT_IESB mechanism, then the PE sets ESR_ELx.IESB bit in the SError exception syndrome to `0b1`. If an SError exception is taken to ELx as a result of the error synchronization event generated on exception return by the FEAT_IESB mechanism, then the PE sets the ESR_ELx.IESB bit in the SError exception syndrome to an IMPLEMENTATION DEFINED choice of `0b0` or `0b1`.

All other values are reserved.

FEAT_IESB implements the functionality identified by the value `0b0001`.

Access to this field is RO.

LSM, bits [11:8]

Indicates support for LSMAOE and nTLSMD bits in SCTLR_EL1 and SCTLR_EL2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

LSM	Meaning
`0b0000`	LSMAOE and nTLSMD bits not supported.
`0b0001`	LSMAOE and nTLSMD bits supported.

All other values are reserved.

FEAT_LSMAOC implements the functionality identified by the value `0b0001`.

Access to this field is RO.

UAO, bits [7:4]

User Access Override.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

UAO	Meaning
0b0000	UAO not supported.
0b0001	UAO supported.

All other values are reserved.

FEAT_UAO implements the functionality identified by the value 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

Access to this field is RO.

CnP, bits [3:0]

Indicates support for Common not Private translations.

The value of this field is an IMPLEMENTATION DEFINED choice of:

CnP	Meaning
0b0000	Common not Private translations not supported.
0b0001	Common not Private translations supported.

All other values are reserved.

FEAT_TTCNP implements the functionality identified by the value 0b0001.

From Armv8.2, the value 0b0000 is not permitted.

Access to this field is RO.

Accessing ID_AA64MMFR2_EL1

Accesses to this register use the following encodings in the System register encoding space:

```
MRS <Xt>, ID_AA64MMFR2_EL1
```

op0	op1	CRn	CRm	op2
0b11	0b000	0b0000	0b0111	0b010

```
if !IsFeatureImplemented(FEAT_AA64) then
    UnimplementedIDRegister();
elsif HaveEL(EL3) && !(EffectivelyAtEL0InHost() || EffectivelyAtEL0NotInHost() || PSTATE.EL == EL3) &&

D24.2.90 ID_AA64MMFR3_EL1, AArch64 Memory Model Feature Register 3

The ID_AA64MMFR3_EL1 characteristics are:

Purpose

Provides information about the implemented memory model and memory management support in AArch64 state.

Configuration

Note

Prior to the introduction of the features described by this register, this register was unnamed and reserved, RES0 from EL1, EL2, and EL3.

This register is present only when FEAT_AA64 is implemented. Otherwise, direct accesses to ID_AA64MMFR3_EL1 are UNDEFINED.

Attributes

ID_AA64MMFR3_EL1 is a 64-bit register.

Field descriptions

63:60	59:56	55:52	51:48	47:44	43:40	39:36	35:32
Spec_FPACC	ADERR	SDERR	RES0	ANERR	SNERR	D128_2	D128

31:28	27:24	23:20	19:16	15:12	11:8	7:4	3:0
MEC	AIE	S2POE	S1POE	S2PIE	S1PIE	SCTLRX	TCRX

Spec_FPACC, bits [63:60]

When FEAT_FPACCOMBINE is implemented:

Speculative behavior in the event of a PAC authentication failure in an implementation that includes FEAT_FPACCOMBINE.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Spec_FPACC	Meaning
0b0000	The implementation does not disclose whether the speculative use of pointers processed by a PAC Authentication is materially different in terms of the impact on cached microarchitectural state between passing and failing of the PAC Authentication.
0b0001	The speculative use of pointers processed by a PAC Authentication is not materially different in terms of the impact on cached microarchitectural state between passing and failing of the PAC Authentication.

All other values are reserved.

For the purpose of this definition, cached microarchitecture state is the state of caching agents such as instruction caches, data caches and TLBs which can be altered as a result of speculation caused by a mispredicted execution, but is not restored to the state prior to the speculation when the misprediction is corrected.

Access to this field is RO.

Non-Confidential

Otherwise:

Reserved, RES0.

ADERR, bits [59:56]

Asynchronous Device error exceptions. With ID_AA64MMFR3_EL1.SDERR, describes the PE behavior for External aborts signaled on Device memory loads.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ADERR	Meaning
0b0000	If FEAT_RASv2 is not implemented and ID_AA64MMFR3_EL1.SDERR is 0b0000, then the behavior is not described. Otherwise, the behavior is described by ID_AA64MMFR3_EL1.SDERR.
0b0001	Some External aborts on Device memory loads are handled asynchronously.
0b0010	FEAT_ADERR is implemented. SCTLR2_ELx.EnADERR and HCRX_EL2.EnSDERR are implemented. If FEAT_ANERR is also implemented, then software should ensure that all the following apply: • SCTLR2_ELx.EnADERR is set to the value of SCTLR2_ELx.EnANERR. • HCRX_EL2.EnSDERR is set to the value of HCRX_EL2.EnSNERR.
0b0011	FEAT_ADERR is implemented. SCTLR2_ELx.EnADERR and HCRX_EL2.EnSDERR are implemented. If FEAT_ANERR is also implemented, then SCTLR2_ELx.EnADERR and HCRX_EL2.EnSDERR operate independently of SCTLR2_ELx.EnANERR and HCRX_EL2.EnSNERR.

All other values are reserved.

Implementation-specific exceptions to applications of this field are described in 'Taking error exceptions'.

When FEAT_RASv2 is implemented and ID_AA64MMFR3_EL1.SDERR is 0b0000, the value of this field is 0b0001.

When ID_AA64MMFR3_EL1.SDERR is 0b0001, the value of this field is 0b0000.

When ID_AA64MMFR3_EL1.SDERR is 0b0010, the value of this field is 0b0010.

When ID_AA64MMFR3_EL1.SDERR is 0b0011, the value of this field is 0b0011.

FEAT_ADERR implements the functionality described by the value 0b0010.

Access to this field is RO.

SDERR, bits [55:52]

Synchronous Device error exceptions. With ID_AA64MMFR3_EL1.ADERR, describes the PE behavior for External aborts signaled on Device memory loads.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SDERR	Meaning
0b0000	If FEAT_RASv2 is not implemented and ID_AA64MMFR3_EL1.ADERR is 0b0000, then the behavior is not described. Otherwise, the behavior is described by ID_AA64MMFR3_EL1.ADERR.
0b0001	All External aborts on Device memory loads are handled synchronously.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

SDERR	Meaning
0b0010	FEAT_ADERR is implemented. SCTLR2_ELx.EnADERR and HCRX_EL2.EnSDERR are implemented. If FEAT_ANERR is also implemented, then software should ensure that all the following apply: • SCTLR2_ELx.EnADERR is set to the value of SCTLR2_ELx.EnANERR. • HCRX_EL2.EnSDERR is set to the value of HCRX_EL2.EnSNERR.
0b0011	FEAT_ADERR is implemented. SCTLR2_ELx.EnADERR and HCRX_EL2.EnSDERR are implemented. If FEAT_ANERR is also implemented, then SCTLR2_ELx.EnADERR and HCRX_EL2.EnSDERR operate independently of SCTLR2_ELx.EnANERR and HCRX_EL2.EnSNERR.

All other values are reserved.

Implementation-specific exceptions to applications of this field are described in 'Taking error exceptions'.

When FEAT_RASv2 is implemented and ID_AA64MMFR3_EL1.ADERR is 0b0000, the value of this field is 0b0001.

When ID_AA64MMFR3_EL1.ADERR is 0b0001, the value of this field is 0b0000.

When ID_AA64MMFR3_EL1.ADERR is 0b0010, the value of this field is 0b0010.

When ID_AA64MMFR3_EL1.ADERR is 0b0011, the value of this field is 0b0011.

FEAT_ADERR implements the functionality described by the value 0b0010.

Access to this field is RO.

Bits [51:48]

Reserved, RES0.

ANERR, bits [47:44]

Asynchronous Normal error exceptions. With ID_AA64MMFR3_EL1.SNERR, describes the PE behavior for External aborts signaled on Normal memory loads.

The value of this field is an IMPLEMENTATION DEFINED choice of:

ANERR	Meaning
0b0000	If FEAT_RASv2 is not implemented and ID_AA64MMFR3_EL1.SNERR is 0b0000, then the behavior is not described. Otherwise, the behavior is described by ID_AA64MMFR3_EL1.SNERR.
0b0001	Some External aborts on Normal memory loads are handled asynchronously.
0b0010	FEAT_ANERR is implemented. SCTLR2_ELx.EnANERR and HCRX_EL2.EnSNERR are implemented. If FEAT_ADERR is also implemented, then software should ensure that all the following apply: • SCTLR2_ELx.EnANERR is set to the value of SCTLR2_ELx.EnADERR. • HCRX_EL2.EnSNERR is set to the value of HCRX_EL2.EnSDERR.
0b0011	FEAT_ANERR is implemented. SCTLR2_ELx.EnANERR and HCRX_EL2.EnSNERR are implemented. If FEAT_ADERR is also implemented, then SCTLR2_ELx.EnANERR and HCRX_EL2.EnSNERR operate independently of SCTLR2_ELx.EnADERR and HCRX_EL2.EnSDERR.

All other values are reserved.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Implementation-specific exceptions to applications of this field are described in 'Taking error exceptions'.

When FEAT_RASv2 is implemented and ID_AA64MMFR3_EL1.SNERR is `0b0000`, the value of this field is `0b0001`.

When ID_AA64MMFR3_EL1.SNERR is `0b0001`, the value of this field is `0b0000`.

When ID_AA64MMFR3_EL1.SNERR is `0b0010`, the value of this field is `0b0010`.

When ID_AA64MMFR3_EL1.SNERR is `0b0011`, the value of this field is `0b0011`.

FEAT_ANERR implements the functionality described by the value `0b0010`.

Access to this field is RO.

SNERR, bits [43:40]

Synchronous Normal error exceptions. With ID_AA64MMFR3_EL1.ANERR, describes the PE behavior for External aborts signaled on Normal memory loads.

The value of this field is an IMPLEMENTATION DEFINED choice of:

SNERR	Meaning
`0b0000`	If FEAT_RASv2 is not implemented and ID_AA64MMFR3_EL1.ANERR is `0b0000`, then the behavior is not described. Otherwise, the behavior is described by ID_AA64MMFR3_EL1.ANERR.
`0b0001`	All External aborts on Normal memory loads are handled synchronously.
`0b0010`	FEAT_ANERR is implemented. SCTLR2_ELx.EnANERR and HCRX_EL2.EnSNERR are implemented. If FEAT_ADERR is also implemented, then software should ensure that all the following apply: • SCTLR2_ELx.EnANERR is set to the value of SCTLR2_ELx.EnADERR. • HCRX_EL2.EnSNERR is set to the value of HCRX_EL2.EnSDERR.
`0b0011`	FEAT_ANERR is implemented. SCTLR2_ELx.EnANERR and HCRX_EL2.EnSNERR are implemented. If FEAT_ADERR is also implemented, then SCTLR2_ELx.EnANERR and HCRX_EL2.EnSNERR operate independently of SCTLR2_ELx.EnADERR and HCRX_EL2.EnSDERR.

All other values are reserved.

Implementation-specific exceptions to applications of this field are described in 'Taking error exceptions'.

When FEAT_RASv2 is implemented and ID_AA64MMFR3_EL1.ANERR is `0b0000`, the value of this field is `0b0001`.

When ID_AA64MMFR3_EL1.ANERR is `0b0001`, the value of this field is `0b0000`.

When ID_AA64MMFR3_EL1.ANERR is `0b0010`, the value of this field is `0b0010`.

When ID_AA64MMFR3_EL1.ANERR is `0b0011`, the value of this field is `0b0011`.

FEAT_ANERR implements the functionality described by the value `0b0010`.

Access to this field is RO.

D128_2, bits [39:36]

128-bit translation table descriptor at stage 2. Indicates support for 128-bit translation table descriptor at stage 2.

The value of this field is an IMPLEMENTATION DEFINED choice of:

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

D128_2	Meaning
0b0000	128-bit translation table descriptor Extension at stage 2 is not supported.
0b0001	128-bit translation table descriptor Extension at stage 2 is supported.

All other values are reserved.

Note

FEAT_D128 allows a hypervisor to support VMSAv9-128 independently for stage 2 and stage 1 translation, and the ID_AA64MMFR3_EL1.D128_2 field allows a nested hypervisor to determine what stage 2 translation table formats are available.

Access to this field is RO.

D128, bits [35:32]

128-bit translation table descriptor at stage 1. Indicates support for 128-bit translation table descriptor at stage 1.

The value of this field is an IMPLEMENTATION DEFINED choice of:

D128	Meaning
0b0000	128-bit translation table descriptor at stage 1 is not supported.
0b0001	128-bit translation table descriptor at stage 1 is supported.

All other values are reserved.

Note
