C8.2.381 LD4Q (scalar plus immediate)

Contiguous load four-quadword structures to four vectors (immediate index)

This instruction performs a contiguous load of four-quadword structures, each to the same element number in four vector registers from the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 4 in the range -32 to 28 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the four vector registers, or equivalently to the four consecutive quadwords in memory that make up each structure. Inactive elements will not cause a read from Device memory or signal a fault, and the corresponding element is set to zero in each of the four destination vector registers.

C8.2.387 LDFF1B (scalar plus vector)

Gather load first-fault unsigned bytes to vector (vector index)

This instruction performs a gather load with first-faulting behavior of unsigned bytes to Active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally sign-extended or zero-extended from 32 to 64 bits. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 32-bit unpacked unscaled offset, 32-bit unscaled offset, and 64-bit unscaled offset

32-bit unpacked unscaled offset

(FEAT_SVE)

Encoding

```
LDFF1B  { <Zt>.D }, <Pg>/Z, [<Xn|SP>, <Zm>.D, <mod>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Rn);
let m : integer = UInt(Zm);
let g : integer = UInt(Pg);
let esize : integer{} = 64;
let msize : integer{} = 8;
let offs_size : integer{} = 32;
let unsigned : boolean = TRUE;
let offs_unsigned : boolean = xs == '0';
let scale : integer = 0;
```

32-bit unscaled offset

(FEAT_SVE)

Encoding

C8.2.389 LDFF1D (scalar plus scalar)

Contiguous load first-fault doublewords to vector (scalar index)

This instruction performs a contiguous load with first-faulting behavior of doublewords to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 8 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.391 LDFF1H (vector plus immediate)

Gather load first-fault unsigned halfwords to vector (immediate index)

This instruction performs a gather load with first-faulting behavior of unsigned halfwords to Active elements of a vector register from memory addresses generated by a vector base plus immediate index. The index is a multiple of 2 in the range 0 to 62. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit element and 64-bit element

32-bit element

(FEAT_SVE)

Encoding

```
LDFF1H  { <Zt>.S }, <Pg>/Z, [<Zn>.S{, #<imm>}]
```

Decode for this encoding

C8.2.392 LDFF1H (scalar plus scalar)

Contiguous load first-fault unsigned halfwords to vector (scalar index)

This instruction performs a contiguous load with first-faulting behavior of unsigned halfwords to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 2 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 16-bit element, 32-bit element, and 64-bit element

C8.2.395 LDFF1SB (scalar plus scalar)

Contiguous load first-fault signed bytes to vector (scalar index)

This instruction performs a contiguous load with first-faulting behavior of signed bytes to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 16-bit element, 32-bit element, and 64-bit element

16-bit element

C8.2.398 LDFF1SH (scalar plus scalar)

Contiguous load first-fault signed halfwords to vector (scalar index)

This instruction performs a contiguous load with first-faulting behavior of signed halfwords to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 2 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit element and 64-bit element

32-bit element

(FEAT_SVE)

31–29	28–25	24–21	20–16	15–13	12–10	9–5	4–0
1 0 1	0 0 1 0	1 0 0 1	Rm	0 1 1	Pg	Rn	Zt
		dtype					

Encoding

```
LDFF1SH  { <Zt>.S }, <Pg>/Z, [<Xn|SP>{, <Xm>, LSL #1}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt(Pg);
let esize : integer{} = 32;
let msize : integer{} = 16;
let unsigned : boolean = FALSE;
```

64-bit element

(FEAT_SVE)

31–29	28–25	24–21	20–16	15–13	12–10	9–5	4–0

C8.2.401 LDFF1SW (scalar plus scalar)

Contiguous load first-fault signed words to vector (scalar index)

This instruction performs a contiguous load with first-faulting behavior of signed words to elements of a vector register from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 4 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

SVE

(FEAT_SVE)

Encoding

```
LDFF1SW  { <Zt>.D }, <Pg>/Z, [<Xn|SP>{, <Xm>, LSL #2}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);

C8.2.402 LDFF1SW (scalar plus vector)

Gather load first-fault signed words to vector (vector index)

This instruction performs a gather load with first-faulting behavior of signed words to Active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then optionally multiplied by 4. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 4 classes: 32-bit unpacked scaled offset, 32-bit unpacked unscaled offset, 64-bit scaled offset, and 64-bit unscaled offset

32-bit unpacked scaled offset

(FEAT_SVE)

Encoding

```
LDFF1SW  { <Zt>.D }, <Pg>/Z, [<Xn|SP>, <Zm>.D, <mod> #2]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Rn);
let m : integer = UInt(Zm);
let g : integer = UInt(Pg);
let esize : integer{} = 64;
let msize : integer{} = 32;
let offs_size : integer{} = 32;
let unsigned : boolean = FALSE;

C8.2.405 LDFF1W (scalar plus vector)

Gather load first-fault unsigned words to vector (vector index)

This instruction performs a gather load with first-faulting behavior of unsigned words to Active elements of a vector register from memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then optionally multiplied by 4. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 6 classes: 32-bit scaled offset, 32-bit unpacked scaled offset, 32-bit unpacked unscaled offset, 32-bit unscaled offset, 64-bit scaled offset, and 64-bit unscaled offset

32-bit scaled offset

C8.2.409 LDNF1SB

Contiguous load non-fault signed bytes to vector (immediate index)

This instruction performs a contiguous load with non-faulting behavior of signed bytes to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 16-bit element, 32-bit element, and 64-bit element

16-bit element

C8.2.413 LDNT1B (scalar plus immediate, consecutive registers)

Contiguous load non-temporal of bytes to multiple consecutive vectors (immediate index)

This instruction performs a contiguous non-temporal load of bytes to elements of two or four consecutive vector registers from the memory address generated by a 64-bit scalar base and immediate index that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 2.

For the “Four registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 4.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” times 2 plus 1.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the “PNg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the “imm4” field.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the “imm4” field.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as “Zt” times 4 plus 3.

Operation

C8.2.415 LDNT1B (vector plus scalar)

Gather load non-temporal unsigned bytes

This instruction performs a non-temporal gather load of unsigned bytes to Active elements of a vector register from memory addresses generated by a vector base plus a 64-bit unscaled scalar register offset. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit unscaled offset and 64-bit unscaled offset

32-bit unscaled offset

(FEAT_SVE2)

Encoding

```
LDNT1B  { <Zt>.S }, <Pg>/Z, [<Zn>.S{, <Xm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) then EndOfDecode(Decode_UNDEF); end;

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 2.

For the “Four registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 4.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” times 2 plus 1.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the “PNg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the “imm4” field.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the “imm4” field.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as “Zt” times 4 plus 3.

Operation

```
if IsFeatureImplemented(FEAT_SVE2p1) then CheckSVEEnabled(); else CheckStreamingSVEEnabled(); end;

C8.2.419 LDNT1D (scalar plus scalar, consecutive registers)

Contiguous load non-temporal of doublewords to multiple consecutive vectors (scalar index)

This instruction performs a contiguous non-temporal load of doublewords to elements of two or four consecutive vector registers from the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2 || FEAT_SVE2p1)

31	30	29	28	25	24	23	22	21	20	16	15	14	13	12	10	9	5	4	1	0

C8.2.420 LDNT1D (vector plus scalar)

Gather load non-temporal unsigned doublewords

This instruction performs a non-temporal gather load of doublewords to Active elements of a vector register from memory addresses generated by a vector base plus a 64-bit unscaled scalar register offset. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.424 LDNT1H (scalar plus scalar, consecutive registers)

Contiguous load non-temporal of halfwords to multiple consecutive vectors (scalar index)

This instruction performs a contiguous non-temporal load of halfwords to elements of two or four consecutive vector registers from the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2 || FEAT_SVE2p1)

31	30	29	28	25	24	23	22	21	20	16	15	14	13	12	10	9	5	4	1	0
1	0	1	0	0	0	0	0	0	Rm		0	0	1	PNg		Rn		Zt		1
												msz								N

Encoding

```
LDNT1H  { <Zt1>.H-<Zt2>.H }, <PNg>/Z, [<Xn|SP>, <Xm>, LSL #1]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) && !IsFeatureImplemented(FEAT_SVE2p1) then
    EndOfDecode(Decode_UNDEF);
end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 2;
let t : integer = UInt(Zt::'0');
let esize : integer{} = 16;
```

Four registers

(FEAT_SME2 || FEAT_SVE2p1)

31	30	29	28	25	24	23	22	21	20	16	15	14	13	12	10	9	5	4	2	1	0
1	0	1	0	0	0	0	0	0	Rm		1	0	1	PNg		Rn		Zt		0	1
												msz									N

Encoding

```
LDNT1H  { <Zt1>.H-<Zt4>.H }, <PNg>/Z, [<Xn|SP>, <Xm>, LSL #1]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) && !IsFeatureImplemented(FEAT_SVE2p1) then
    EndOfDecode(Decode_UNDEF);
end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 4;
let t : integer = UInt(Zt::'00');
let esize : integer{} = 16;
```

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 2.

For the “Four registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 4.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” times 2 plus 1.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the “PNg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the general-purpose offset register, encoded in the “Rm” field.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as “Zt” times 4 plus 3.

Operation

```
if IsFeatureImplemented(FEAT_SVE2p1) then CheckSVEEnabled(); else CheckStreamingSVEEnabled(); end;

C8.2.426 LDNT1H (scalar plus immediate, single register)

Contiguous load non-temporal halfwords to vector (immediate index)

This instruction performs a contiguous non-temporal load of halfwords to elements of a vector register from the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

C8.2.430 LDNT1SW

Gather load non-temporal signed words

This instruction performs a non-temporal gather load of signed words to Active elements of a vector register from memory addresses generated by a vector base plus a 64-bit unscaled scalar register offset. Inactive elements will not cause a read from Device memory or signal faults, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

SVE2

(FEAT_SVE2)

Encoding

```
LDNT1SW  { <Zt>.D }, <Pg>/Z, [<Zn>.D{, <Xm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Zn);
let m : integer = UInt(Rm);
let g : integer = UInt(Pg);
let esize : integer{} = 64;
let msize : integer{} = 32;
let unsigned : boolean = FALSE;
```

Assembler Symbols

<Zt>

Is the name of the scalable vector register to be transferred, encoded in the “Zt” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the base scalable vector register, encoded in the “Zn” field.

<Xm>

Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the “Rm” field.

C8.2.436 LDR (predicate)

Load predicate register

This instruction loads a predicate register from a memory address generated by a 64-bit scalar base, plus an immediate offset in the range -256 to 255 that is multiplied by the current predicate register size in bytes. This instruction is unpredicated.

The load is performed as contiguous byte accesses, each containing 8 consecutive predicate bits in ascending element order, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then a general-purpose base register must be aligned to 2 bytes.

For programmer convenience, an assembler must also accept a predicate-as-counter register name for the destination predicate register.

C8.2.437 LDR (vector)

Load vector register

This instruction loads a vector register from a memory address generated by a 64-bit scalar base, plus an immediate offset in the range -256 to 255 that is multiplied by the current vector register size in bytes. This instruction is unpredicated.

The load is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

C8.2.444 LSR (immediate, predicated)

Logical shift right by immediate (predicated)

This instruction shifts right by immediate, inserting zeroes, each active element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate shift amount is an unsigned value in the range 1 to number of bits per element. Inactive elements in the destination vector register remain unmodified.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
LSR  <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, #<const>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let tsize : bits(4) = tszh::tszl;
if tsize == '0000' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << HighestSetBitNZ(tsize);
let g : integer = UInt(Pg);
let dn : integer = UInt(Zdn);
let shift : integer = (2 * esize) - UInt(tsize::imm3);
```

Assembler Symbols

<Zdn>

Is the name of the source and destination scalable vector register, encoded in the “Zdn” field.

<T>

Is the size specifier, encoded in “tszh:tszl”:

tszh	tszl	<T>
00	00	RESERVED
00	01	B
00	1x	H
01	xx	S
1x	xx	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<const>

Is the immediate shift amount, in the range 1 to number of bits per element, encoded in “tszh:tszl:imm3”.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let PL : integer{} = VL DIV 8;
let operand1 : bits(VL) = Z{}(dn);
let mask : bits(PL) = P{}(g);
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : bits(esize) = operand1[e*:esize];
    if ActivePredicateElement{PL}(mask, e, esize) then
        result[e*:esize] = LSR(element1, shift);
    else
        result[e*:esize] = operand1[e*:esize];
    end;

end;
Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.445 LSR (wide elements, predicated)

Logical shift right by 64-bit wide elements (predicated)

This instruction shifts right, inserting zeroes, active elements of the first source vector by the corresponding overlapping 64-bit elements of the second source vector and destructively places the results in the corresponding elements of the first source vector. The shift amount is a vector of unsigned 64-bit doubleword elements in which all bits are significant, and not used modulo the destination element size. Inactive elements in the destination vector register remain unmodified.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
LSR  <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.D
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size == '11' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let dn : integer = UInt(Zdn);
let m : integer = UInt(Zm);
```

Assembler Symbols

<Zdn>

Is the name of the first source and destination scalable vector register, encoded in the “Zdn” field.

C8.2.454 MATCH

Detect any matching elements, setting the condition flags

This instruction compares each active 8-bit or 16-bit element in the first source vector with all of the elements in the corresponding 128-bit segment of the second source vector. For each element in the first source vector, if any matching element is found in the corresponding segment of the second source vector, the corresponding element of the destination predicate is set to true, otherwise it is set to false. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.456 MLA (indexed)

Multiply-add by indexed element

This instruction multiplies all integer elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively added to the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment. This instruction is unpredicated.

It has encodings from 3 classes: 16-bit, 32-bit, and 64-bit

16-bit

            result[e*:esize] = operand3[e*:esize] - product;
        else
            result[e*:esize] = operand3[e*:esize] + product;
        end;
    else
        result[e*:esize] = operand3[e*:esize];
    end;
end;

Z{VL}(da) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.459 MLS (indexed)

Multiply-subtract by indexed element

This instruction multiplies all integer elements within each 128-bit segment of the first source vector by the specified element in the corresponding second source vector segment. The products are then destructively subtracted from the corresponding elements of the addend and destination vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment. This instruction is unpredicated.

It has encodings from 3 classes: 16-bit, 32-bit, and 64-bit

16-bit

(FEAT_SVE2 || FEAT_SME)

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “16-bit” and “32-bit” variants: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “64-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “16-bit” variant: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “32-bit” variant: is the element index, in the range 0 to 3, encoded in the “i2” field.

For the “64-bit” variant: is the element index, in the range 0 to 1, encoded in the “i1” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let eltspersegment : integer = 128 DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL) = Z{}(da);

for e = 0 to elements-1 do
    let segmentbase : integer = e - (e MOD eltspersegment);
    let s : integer = segmentbase + index;
    let element1 : integer = UInt(operand1[e*:esize]);
    let element2 : integer = UInt(operand2[s*:esize]);
    let product : bits(esize) = (element1 * element2)[esize-1:0];
    result[e*:esize] = result[e*:esize] - product;
end;

Z{VL}(da) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.460 MOV (predicate, zeroing)

Move predicates (zeroing)

This instruction reads Active elements from the source predicate and places those elements in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction does not set the condition flags.

This is an alias of AND (predicates). This means:

- The encodings in this description are named to match the encodings of AND (predicates).
- The description of AND (predicates) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Not setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
MOV  <Pd>.B, <Pg>/Z, <Pn>.B
```

is equivalent to

```
AND  <Pd>.B, <Pg>/Z, <Pn>.B, <Pn>.B
```

and is the preferred disassembly when `S == '0' && Pn == Pm`.

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the source scalable predicate register, encoded in the “Pn” field.

Operation

The description of AND (predicates) gives the operational pseudocode for this instruction.

Operational Information

The description of AND (predicates) gives the operational information for this instruction.

C8.2.461 MOV (immediate, zeroing)

Move signed integer immediate to vector elements (zeroing)

This instruction moves a signed integer immediate to each Active element in the destination vector. Inactive elements in the destination vector register are set to zero.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

This is an alias of CPY (immediate, zeroing). This means:

- The encodings in this description are named to match the encodings of CPY (immediate, zeroing).
- The description of CPY (immediate, zeroing) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C8.2.462 MOV (immediate, merging)

Move signed integer immediate to vector elements (merging)

This instruction moves a signed integer immediate to each Active element in the destination vector. Inactive elements in the destination vector register remain unmodified.

The immediate operand is a signed value in the range -128 to +127, and for element widths of 16 bits or higher it may also be a signed multiple of 256 in the range -32768 to +32512 (excluding 0).

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

This is an alias of CPY (immediate, merging). This means:

- The encodings in this description are named to match the encodings of CPY (immediate, merging).
- The description of CPY (immediate, merging) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C8.2.469 MOV

Move predicate (unpredicated)

This instruction reads all elements from the source predicate and places those elements in the destination predicate. This instruction is unpredicated. This instruction does not set the condition flags.

For programmer convenience, an assembler must also accept predicate-as-counter register names for the source and destination predicate registers.

This is an alias of ORR (predicates). This means:

- The encodings in this description are named to match the encodings of ORR (predicates).
- The description of ORR (predicates) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Not setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
MOV  <Pd>.B, <Pn>.B
```

is equivalent to

```
ORR  <Pd>.B, <Pn>/Z, <Pn>.B, <Pn>.B
```

and is the preferred disassembly when `S == '0' && Pn == Pm && Pm == Pg`.

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pn>

Is the name of the source scalable predicate register, encoded in the “Pn” field.

Operation

The description of ORR (predicates) gives the operational pseudocode for this instruction.

C8.2.473 MOVPRFX (predicated)

Move prefix (predicated)

This instruction is a hint to hardware that the instruction may be combined with the destructive instruction that follows it in program order to create a single constructive operation. This instruction is also permitted to be implemented as a discrete vector copy, and the result of executing the pair of instructions with or without combining is identical. The choice of combined versus discrete operation may vary dynamically.

Unless the combination of a constructive operation with merging predication is specifically required, it is strongly recommended that for performance reasons software should prefer to use the zeroing form of predicated `MOVPRFX` or the unpredicated `MOVPRFX` instruction.

Although the operation of the instruction is defined as a simple predicated vector copy, it is required that the prefixed instruction at PC+4 must be an SVE destructive binary or ternary instruction encoding, or a unary operation with merging predication, but excluding other `MOVPRFX` instructions. The prefixed instruction must specify the same predicate register, and have the same maximum element size (ignoring a fixed 64-bit "wide vector" operand), and the same destination vector as the `MOVPRFX` instruction. The prefixed instruction must not use the destination register in any other operand position, even if they have different names but refer to the same architectural register state. Any other use is UNPREDICTABLE.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
MOVPRFX  <Zd>.<T>, <Pg>/<ZM>, <Zn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Zd);
let merging : boolean = (M == '1');
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T>

Is the size specifier, encoded in "size":

size	<T>
00	B

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

size	<T>
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<ZM>

Is the predication qualifier, encoded in “M”:

M	<ZM>
0	Z
1	M

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
let dest : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};
var result : bits(VL);

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let element : bits(esize) = operand1[e*:esize];
        result[e*:esize] = element;
    else
        result[e*:esize] = dest[e*:esize];
    end;
end;

Z{VL}(d) = result;
```

C8.2.475 MOVS (predicated)

Move predicates (zeroing), setting the condition flags

This instruction reads Active elements from the source predicate and places those elements in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This is an alias of ANDS. This means:

- The encodings in this description are named to match the encodings of ANDS.
- The description of ANDS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
MOVS  <Pd>.B, <Pg>/Z, <Pn>.B
```

is equivalent to

```
ANDS  <Pd>.B, <Pg>/Z, <Pn>.B, <Pn>.B
```

and is the preferred disassembly when `S == '1' && Pn == Pm`.

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the source scalable predicate register, encoded in the “Pn” field.

Operation

The description of ANDS gives the operational pseudocode for this instruction.

Operational Information

The description of ANDS gives the operational information for this instruction.

let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “16-bit” and “32-bit” variants: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “64-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “16-bit” variant: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “32-bit” variant: is the element index, in the range 0 to 3, encoded in the “i2” field.

For the “64-bit” variant: is the element index, in the range 0 to 1, encoded in the “i1” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let eltspersegment : integer = 128 DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL);

for e = 0 to elements-1 do
    let segmentbase : integer = e - (e MOD eltspersegment);
    let s : integer = segmentbase + index;
```

C8.2.482 NAND

Bitwise NAND predicates

This instruction performs a bitwise NAND between the active elements of the first source predicate and the corresponding elements of the second source predicate, and places the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction does not set the condition flags.

Not setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
NAND  <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8;
let g : integer = UInt(Pg);
let n : integer = UInt(Pn);
let m : integer = UInt(Pm);
let d : integer = UInt(Pd);
let setflags : boolean = FALSE;
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the first source scalable predicate register, encoded in the “Pn” field.

<Pm>

Is the name of the second source scalable predicate register, encoded in the “Pm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(PL) = P{}(n);
let operand2 : bits(PL) = P{}(m);
var result : bits(PL);

C8.2.483 NANDS

Bitwise NAND predicates, setting the condition flags

This instruction performs a bitwise NAND between the active elements of the first source predicate and the corresponding elements of the second source predicate, and places the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

Setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
NANDS  <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8;
let g : integer = UInt(Pg);
let n : integer = UInt(Pn);
let m : integer = UInt(Pm);
let d : integer = UInt(Pd);
let setflags : boolean = TRUE;
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the first source scalable predicate register, encoded in the “Pn” field.

<Pm>

Is the name of the second source scalable predicate register, encoded in the “Pm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(PL) = P{}(n);
let operand2 : bits(PL) = P{}(m);
var result : bits(PL);
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Zd);
let merging : boolean = FALSE;
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        var element : integer = SInt(operand[e*:esize]);
        element = -element;
        result[e*:esize] = element[esize-1:0];

    end;
end;
Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.486 NMATCH

Detect no matching elements, setting the condition flags

This instruction compares each active 8-bit or 16-bit element in the first source vector with all of the elements in the corresponding 128-bit segment of the second source vector. For each element in the first source vector, if no matching element is found in the corresponding segment of the second source vector, the corresponding element of the destination predicate is set to true, otherwise it is set to false. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

Byte and halfword

(FEAT_SVE2)

Encoding

```
NMATCH  <Pd>.<T>, <Pg>/Z, <Zn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(sz);
let g : integer = UInt(Pg);
let d : integer = UInt(Pd);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<T>

Is the size specifier, encoded in “sz”:

sz	<T>
0	B
1	H

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

C8.2.489 NOT (predicate)

Bitwise invert predicate

This instruction performs a bitwise invert of each active element of the source predicate, and places the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction does not set the condition flags.

This is an alias of EOR (predicates). This means:

- The encodings in this description are named to match the encodings of EOR (predicates).
- The description of EOR (predicates) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Not setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
NOT  <Pd>.B, <Pg>/Z, <Pn>.B
```

is equivalent to

```
EOR  <Pd>.B, <Pg>/Z, <Pn>.B, <Pg>.B
```

and is the preferred disassembly when `Pm == Pg`.

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the source scalable predicate register, encoded in the “Pn” field.

Operation

The description of EOR (predicates) gives the operational pseudocode for this instruction.

Operational Information

The description of EOR (predicates) gives the operational information for this instruction.

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let element : bits(esize) = operand[e*:esize];
        result[e*:esize] = NOT element;

    end;
end;
Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.491 NOTS

Bitwise invert predicate, setting the condition flags

This instruction performs a bitwise invert of each active element of the source predicate, and places the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

This is an alias of EORS. This means:

- The encodings in this description are named to match the encodings of EORS.
- The description of EORS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
NOTS  <Pd>.B, <Pg>/Z, <Pn>.B
```

is equivalent to

```
EORS  <Pd>.B, <Pg>/Z, <Pn>.B, <Pg>.B
```

and is the preferred disassembly when `Pm == Pg`.

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the source scalable predicate register, encoded in the “Pn” field.

Operation

The description of EORS gives the operational pseudocode for this instruction.

Operational Information

The description of EORS gives the operational information for this instruction.

C8.2.492 ORN (immediate)

Bitwise inclusive OR with inverted immediate (unpredicated)

This instruction performs a bitwise inclusive OR between an inverted immediate and each 64-bit element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate is a 64-bit value consisting of a single run of ones or zeros repeating every 2, 4, 8, 16, 32 or 64 bits. This instruction is unpredicated.

This is a pseudo-instruction of ORR (immediate). This means:

- The encodings in this description are named to match the encodings of ORR (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of ORR (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

C8.2.494 ORNS

Bitwise inclusive OR inverted predicate, setting the condition flags

This instruction performs a bitwise inclusive OR between the active elements of the first source predicate and the inverted corresponding elements of the second source predicate, and places the results in the corresponding elements of the destination predicate. Inactive elements in the destination predicate register are set to zero. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

Setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
ORNS  <Pd>.B, <Pg>/Z, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8;
let g : integer = UInt(Pg);
let n : integer = UInt(Pn);
let m : integer = UInt(Pm);
let d : integer = UInt(Pd);
let setflags : boolean = TRUE;
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the first source scalable predicate register, encoded in the “Pn” field.

<Pm>

Is the name of the second source scalable predicate register, encoded in the “Pm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(PL) = P{}(n);

C8.2.501 ORV

Bitwise inclusive OR reduction to scalar

This instruction performs a bitwise inclusive OR between the elements of the source vector, and places the result in the SIMD&FP scalar destination register. Inactive elements in the source vector are treated as zero.

SVE

(FEAT_SVE || FEAT_SME)

C8.2.506 PMLAL

Multi-vector polynomial multiply long and accumulate

This instruction performs a polynomial multiplication over [0, 1] of the even-numbered elements of the first source vector by the corresponding elements of the second source vector, and then performs a bitwise exclusive-OR between the result and the overlapping double-width elements of the first destination vector. The same operation is performed with odd-numbered elements of the source vectors, writing to the second destination vector. This instruction is unpredicated.

This instruction is legal when executed in Streaming SVE mode if both FEAT_SSVE_AES and FEAT_SVE_AES2 are implemented.

C8.2.507 PMOV (to predicate)

Move predicate from vector

This instruction copies a packed bitmap, where bit value `0b1` represents TRUE and bit value `0b0` represents FALSE, from a portion of the source vector register to elements of the destination SVE predicate register.

Because the number of bits in an SVE predicate element scales with the vector element size, the behavior varies according to the specified element size.

- When the predicate element specifier is B, each bit [N] from the least-significant VL/8 bits in the source vector register is copied to bit [N] of the destination predicate register. The portion index, if specified, must be 0.
- When the predicate element specifier is H, each bit [N] within the indexed block of VL/16 bits in the source vector register is copied to bit [N*2] of the destination predicate register, and the other bits in the predicate are set to zero. The portion index is in the range 0 to 1, inclusive.
- When the predicate element specifier is S, each bit [N] within the indexed block of VL/32 bits in the source vector register is copied to bit [N*4] of the destination predicate register, and the other bits in the predicate are set to zero. The portion index is in the range 0 to 3, inclusive.
- When the predicate element specifier is D, each bit [N] within the indexed block of VL/64 bits in the source vector register is copied to bit [N*8] of the destination predicate register, and the other bits in the predicate are set to zero. The portion index is in the range 0 to 7, inclusive.

The portion index is optional, defaulting to 0 if omitted.

It has encodings from 4 classes: Byte, Doubleword, Halfword, and Word

C8.2.508 PMOV (to vector)

Move predicate to vector

This instruction copies the source SVE predicate register elements into the destination vector register as a packed bitmap with one bit per predicate element, where bit value `0b1` represents a TRUE predicate element, and bit value `0b0` represents a FALSE predicate element.

Because the number of bits in an SVE predicate element scales with the vector element size, the behavior varies according to the specified element size.

- When the predicate element specifier is B, every bit in the predicate register is copied to the least-significant VL/8 bits of the destination vector register. The portion index, if specified, must be 0.
- When the predicate element specifier is H, every second bit in the predicate register is copied to the indexed block of VL/16 bits in the destination vector register, where the portion index is in the range 0 to 1, inclusive.
- When the predicate element specifier is S, every fourth bit in the predicate register is copied to the indexed block of VL/32 bits in the destination vector register, where the portion index is in the range 0 to 3, inclusive.
- When the predicate element specifier is D, every eighth bit in the predicate register is copied to the indexed block of VL/64 bits in the destination vector register, where the portion index is in the range 0 to 7, inclusive.

The portion index is optional, defaulting to 0 if omitted. When the index is zero, the instruction writes zeroes to the most significant VL-(VL/esize) bits of the destination vector register. When a non-zero index is specified, the packed bitmap is inserted into the destination vector register, and the unindexed blocks remain unchanged.

It has encodings from 4 classes: Byte, Doubleword, Halfword, and Word

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Pn>

Is the name of the source scalable predicate register, encoded in the “Pn” field.

<imm>

For the “Doubleword” variant: is the optional portion index, in the range 0 to 7, defaulting to 0, encoded in the “i3h:i3l” fields.

For the “Halfword” variant: is the optional portion index, in the range 0 to 1, defaulting to 0, encoded in the “i1” field.

For the “Word” variant: is the optional portion index, in the range 0 to 3, defaulting to 0, encoded in the “i2” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let operand : bits(PL) = P{}(n);
var result : bits(VL);

if imm == 0 then
    result = Zeros{VL};
else
    result = Z{VL}(d);
end;

for e = 0 to elements-1 do
    result[(elements * imm) + e] = PredicateElement{PL}(operand, e, esize);
end;

Z{VL}(d) = result;
```

C8.2.510 PMULL

Multi-vector polynomial multiply long

This instruction performs a polynomial multiplication over [0, 1] of the even-numbered elements of the first source vector by the corresponding elements of the second source vector, and places the results in the overlapping double-width elements of the first destination vector. The same operation is performed with odd-numbered elements of the source vectors, writing to the second destination vector. This instruction is unpredicated.

This instruction is legal when executed in Streaming SVE mode if both FEAT_SSVE_AES and FEAT_SVE_AES2 are implemented.

SVE2

(FEAT_SVE_AES2)

C8.2.513 PNEXT

Find next active predicate

This instruction constructs a loop that iterates over all true elements in the vector select predicate register. If all elements in the first source predicate register are false it determines the first true element in the vector select predicate register, otherwise it determines the next true element in the vector select predicate register that follows the last true element in the first source predicate register. All elements of the destination predicate register are set to false, except the element corresponding to the determined vector select element, if any, which is set to true. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

SVE

(FEAT_SVE || FEAT_SME)

C8.2.514 PRFB (vector plus immediate)

Gather prefetch bytes (vector plus immediate)

This instruction performs a gather prefetch of bytes from the active memory addresses generated by a vector base plus immediate index. The index is in the range 0 to 31. Inactive addresses are not prefetched from memory.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit element and 64-bit element

32-bit element

C8.2.515 PRFB (scalar plus immediate)

Contiguous prefetch bytes (immediate index)

This instruction prefetches contiguous byte elements from the memory address generated by a 64-bit scalar base and immediate index in the range -32 to 31 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

Note

Arm strongly recommends the following for this instruction:

- A PE does not perform a prefetch as a result of Inactive elements.
- Software uses the predicate operand to suppress prefetches from unwanted addresses.

C8.2.516 PRFB (scalar plus scalar)

Contiguous prefetch bytes (scalar index)

This instruction prefetches contiguous byte elements from the memory address generated by a 64-bit scalar base and scalar index that is added to the base address. After each element prefetch the index value is incremented, but the index register is not updated.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

Note

Arm strongly recommends the following for this instruction:

- A PE does not perform a prefetch as a result of Inactive elements.
- Software uses the predicate operand to suppress prefetches from unwanted addresses.

C8.2.518 PRFD (vector plus immediate)

Gather prefetch doublewords (vector plus immediate)

This instruction performs a gather prefetch of doublewords from the active memory addresses generated by a vector base plus immediate index. The index is a multiple of 8 in the range 0 to 248. Inactive addresses are not prefetched from memory.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit element and 64-bit element

C8.2.519 PRFD (scalar plus immediate)

Contiguous prefetch doublewords (immediate index)

This instruction prefetches contiguous doubleword elements from the memory address generated by a 64-bit scalar base and immediate index in the range -32 to 31 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

Note

Arm strongly recommends the following for this instruction:

- A PE does not perform a prefetch as a result of Inactive elements.
- Software uses the predicate operand to suppress prefetches from unwanted addresses.

C8.2.521 PRFD (scalar plus vector)

Gather prefetch doublewords (scalar plus vector)

This instruction performs a gather prefetch of doublewords from the active memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then multiplied by 8. Inactive addresses are not prefetched from memory.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

C8.2.522 PRFH (vector plus immediate)

Gather prefetch halfwords (vector plus immediate)

This instruction performs a gather prefetch of halfwords from the active memory addresses generated by a vector base plus immediate index. The index is a multiple of 2 in the range 0 to 62. Inactive addresses are not prefetched from memory.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit element and 64-bit element

C8.2.523 PRFH (scalar plus immediate)

Contiguous prefetch halfwords (immediate index)

This instruction prefetches contiguous halfword elements from the memory address generated by a 64-bit scalar base and immediate index in the range -32 to 31 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

Note

Arm strongly recommends the following for this instruction:

- A PE does not perform a prefetch as a result of Inactive elements.
- Software uses the predicate operand to suppress prefetches from unwanted addresses.

C8.2.524 PRFH (scalar plus scalar)

Contiguous prefetch halfwords (scalar index)

This instruction prefetches contiguous halfword elements from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 2 and added to the base address. After each element prefetch the index value is incremented, but the index register is not updated.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

Note

Arm strongly recommends the following for this instruction:

- A PE does not perform a prefetch as a result of Inactive elements.
- Software uses the predicate operand to suppress prefetches from unwanted addresses.

C8.2.527 PRFW (scalar plus immediate)

Contiguous prefetch words (immediate index)

This instruction prefetches contiguous word elements from the memory address generated by a 64-bit scalar base and immediate index in the range -32 to 31 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

Note

Arm strongly recommends the following for this instruction:

- A PE does not perform a prefetch as a result of Inactive elements.
- Software uses the predicate operand to suppress prefetches from unwanted addresses.

C8.2.528 PRFW (scalar plus scalar)

Contiguous prefetch words (scalar index)

This instruction prefetches contiguous word elements from the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 4 and added to the base address. After each element prefetch the index value is incremented, but the index register is not updated.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

Note

Arm strongly recommends the following for this instruction:

- A PE does not perform a prefetch as a result of Inactive elements.
- Software uses the predicate operand to suppress prefetches from unwanted addresses.

C8.2.529 PRFW (scalar plus vector)

Gather prefetch words (scalar plus vector)

This instruction performs a gather prefetch of words from the active memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then multiplied by 4. Inactive addresses are not prefetched from memory.

The `<prfop>` operand specifies the prefetch hint as follows:

- Access type:
  - PLD for prefetch for load.
  - PST for prefetch for store.
- Target cache level:
  - L1 for Level 1 cache.
  - L2 for Level 2 cache.
  - L3 for Level 3 cache.
- Policy:
  - KEEP for retained or temporal prefetch, allocated in the cache normally.
  - STRM for streaming or non-temporal prefetch, for data that is used only once.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 3 classes: 32-bit scaled offset, 32-bit unpacked scaled offset, and 64-bit scaled offset

32-bit scaled offset

(FEAT_SVE)

31 29	28 25	24 23	22	21	20 16	15	14 13	12 10	9 5	4	3 0

C8.2.530 PSEL

Predicate select between predicate register or all-false

This instruction places the contents of the first source predicate register into the destination predicate register if the indexed element of the second source predicate is true, otherwise it sets the destination predicate to all-false. The indexed element is determined by the sum of a general-purpose index register and an immediate, modulo the number of elements. This instruction does not set the condition flags. For programmer convenience, an assembler must also accept predicate-as-counter register names for the destination predicate register and the first source predicate register.

SVE2

(FEAT_SME || FEAT_SVE2p1)

C8.2.531 PTEST

Set condition flags for predicate

This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate source register, and sets the V flag to zero.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
PTEST  <Pg>, <Pn>.B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8;
let g : integer = UInt(Pg);
let n : integer = UInt(Pn);
```

Assembler Symbols

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the source scalable predicate register, encoded in the “Pn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let mask : bits(PL) = P{}(g);
let result : bits(PL) = P{}(n);

PSTATE.[N,Z,C,V] = PredTest{PL}(mask, result, esize);
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the predicate register written by this instruction might be significantly delayed.

C8.2.532 PTRUE (predicate)

Initialize predicate from named constraint

This instruction sets elements of the destination predicate to true if the element number satisfies the named predicate constraint, or to false otherwise. If the constraint specifies more elements than are available at the current vector length, then all elements of the destination predicate are set to false.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception. This instruction does not set the condition flags.

Not setting the condition flags

C8.2.533 PTRUE (predicate as counter)

Initialize predicate-as-counter to all active

This instruction sets the destination predicate as all Active elements, using the predicate-as-counter encoding.

SVE2

(FEAT_SME2 || FEAT_SVE2p1)

31 29	28 25	24	23 22	21	20 16	15 14	13 11	10 5	4	3	2 0
0 0 1	0 0 1 0	1	size	1	0 0 0 0 0	0 1	1 1 1	0 0 0 0 0 0	1	0	PNd

Encoding

```
PTRUE  <PNd>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) && !IsFeatureImplemented(FEAT_SVE2p1) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt('1'::PNd);
```

Assembler Symbols

<PNd>

Is the name of the destination scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the “PNd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

Operation

```
if IsFeatureImplemented(FEAT_SVE2p1) then CheckSVEEnabled(); else CheckStreamingSVEEnabled(); end;
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let result : bits(PL) = EncodePredCount{}(esize, elements, elements, FALSE);
P{PL}(d) = result;
```

C8.2.534 PTRUES

Initialize predicate from named constraint and set the condition flags

This instruction sets elements of the destination predicate to true if the element number satisfies the named predicate constraint, or to false otherwise. If the constraint specifies more elements than are available at the current vector length, then all elements of the destination predicate are set to false.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

Setting the condition flags

(FEAT_SVE || FEAT_SME)

Encoding

```
PTRUES  <Pd>.<T>{, <pattern>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(Pd);
let setflags : boolean = TRUE;
let pat : bits(5) = pattern;
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let element : bits(esize) = operand[e*:esize];
        result[e*:esize] = BitReverse{esize}(element);

    end;
end;
Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.546 REVB, REVH, REVW

Reverse bytes / halfwords / words within elements (predicated)

This instruction reverses the order of 8-bit bytes, 16-bit halfwords or 32-bit words within each active element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

It has encodings from 6 classes: Byte, merging, Byte, zeroing, Halfword, merging, Halfword, zeroing, Word, merging, and Word, zeroing

Byte, merging

(FEAT_SVE || FEAT_SME)

Encoding

```
REVB  <Zd>.<T>, <Pg>/M, <Zn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then

```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

For the “Byte, merging” and “Byte, zeroing” variants: is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	D

For the “Halfword, merging” and “Halfword, zeroing” variants: is the size specifier, encoded in “size<0>”:

size<0>	<T>
0	S
1	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};

for e = 0 to elements-1 do
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

```
    if ActivePredicateElement{PL}(mask, e, esize) then
        let element : bits(esize) = operand[e*:esize];
        result[e*:esize] = Reverse{esize}(element, swsize);
    end;
end;

Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL) = Z{}(da);

for e = 0 to elements-1 do
    let op1elt : bits(esize) = operand1[e*:esize];
    let op2elt : bits(esize) = operand2[e*:esize];
    let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
    let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
    let absdiff : bits(esize) = Abs(element1 - element2)[esize-1:0];
    result[e*:esize] = result[e*:esize] + absdiff;
end;

Z{VL}(da) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.562 SADDV

Signed add reduction to scalar

This instruction adds all the signed elements of the source vector, and places the result in the SIMD&FP scalar destination register. Narrow elements are first sign-extended to 64 bits. Inactive elements in the source vector are treated as zero.

SVE

(FEAT_SVE || FEAT_SME)

31–29	28–25	24	23–22	21	20–18	17	16	15–13	12–10	9–5	4–0
0 0 0	0 0 1 0	0	size	0	0 0 0	0 (op)	0 (U)	0 0 1	Pg	Zn	Vd

Encoding

```
SADDV  <Dd>, <Pg>, <Zn>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size == '11' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Vd);
```

Assembler Symbols

<Dd>

Is the 64-bit name of the destination SIMD&FP register, encoded in the “Vd” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>

C8.2.568 SCVTF (predicated)

Signed integer convert to floating-point (predicated)

This instruction converts to floating-point from the signed integer in each active element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

If the input and result types have a different size the smaller type is held unpacked in the least significant bits of elements of the larger size. When the input is the smaller type the upper bits of each source element are ignored. When the result is the smaller type the results are zero-extended to fill each destination element.

It has encodings from 14 classes: 16-bit to half-precision, merging, 16-bit to half-precision, zeroing, 32-bit to half-precision, merging, 32-bit to half-precision, zeroing, 32-bit to single-precision, merging, 32-bit to single-precision, zeroing, 32-bit to double-precision, merging, 32-bit to double-precision, zeroing, 64-bit to half-precision, merging, 64-bit to half-precision, zeroing, 64-bit to single-precision, merging, 64-bit to single-precision, zeroing, 64-bit to double-precision, merging, and 64-bit to double-precision, zeroing

C8.2.572 SDOT (2-way, indexed)

Signed integer dot product by indexed element (two-way)

This instruction calculates the dot product of a pair of signed 16-bit integer values held in each 32-bit element of the first source vector multiplied by a pair of signed 16-bit integer values in an indexed 32-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

This instruction is unpredicated.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
let operand3 : bits(VL) = Z{}(da);
var result : bits(VL);

for e = 0 to elements-1 do
    var res : bits(esize) = operand3[e*:esize];
    for i = 0 to 3 do
        let element1 : integer = SInt(operand1[(4 * e + i)*:(esize DIV 4)]);
        let element2 : integer = SInt(operand2[(4 * e + i)*:(esize DIV 4)]);
        res = res + element1 * element2;
    end;
    result[e*:esize] = res;
end;

Z{VL}(da) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.574 SDOT (4-way, indexed)

Signed integer dot product by indexed element (four-way)

This instruction calculates the dot product of a group of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the first source vector multiplied by a group of four signed 8-bit or 16-bit integer values in an indexed 32-bit or 64-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit or 64-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index that selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment.

This instruction is unpredicated.

It has encodings from 2 classes: 8-bit to 32-bit and 16-bit to 64-bit

8-bit to 32-bit

(FEAT_SVE || FEAT_SME)

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 64;
let index : integer = UInt(i1);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let da : integer = UInt(Zda);
```

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “8-bit to 32-bit” variant: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “16-bit to 64-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “8-bit to 32-bit” variant: is the immediate index of a group of four 8-bit values within each 128-bit vector segment, in the range 0 to 3, encoded in the “i2” field.

For the “16-bit to 64-bit” variant: is the immediate index of a group of four 16-bit values within each 128-bit vector segment, in the range 0 to 1, encoded in the “i1” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let eltspersegment : integer = 128 DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
let operand3 : bits(VL) = Z{}(da);
var result : bits(VL);

for e = 0 to elements-1 do
    let segmentbase : integer = e - (e MOD eltspersegment);
    let s : integer = segmentbase + index;
    var res : bits(esize) = operand3[e*:esize];
    for i = 0 to 3 do
        let element1 : integer = SInt(operand1[(4 * e + i)*:(esize DIV 4)]);
        let element2 : integer = SInt(operand2[(4 * s + i)*:(esize DIV 4)]);
        res = res + element1 * element2;
    end;
    result[e*:esize] = res;
end;

Z{VL}(da) = result;
```

C8.2.575 SEL (predicates)

Conditionally select elements from two predicates

This instruction reads Active elements from the first source predicate and Inactive elements from the second source predicate and places them in the corresponding elements of the destination predicate. This instruction does not set the condition flags.

This instruction is used by the alias MOV (predicate, merging).

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
SEL  <Pd>.B, <Pg>, <Pn>.B, <Pm>.B
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8;
let g : integer = UInt(Pg);
let n : integer = UInt(Pn);
let m : integer = UInt(Pm);
let d : integer = UInt(Pd);
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<Pg>

Is the name of the governing scalable predicate register, encoded in the “Pg” field.

<Pn>

Is the name of the first source scalable predicate register, encoded in the “Pn” field.

<Pm>

Is the name of the second source scalable predicate register, encoded in the “Pm” field.

Alias Conditions

Alias	Is preferred when
MOV (predicate, merging)	Pd == Pm

C8.2.576 SEL (vectors)

Conditionally select elements from two vectors

This instruction selects elements from the first source vector where the corresponding vector select predicate element is true, and from the second source vector where the predicate element is false, and places them in the corresponding elements of the destination vector.

This instruction is used by the alias MOV (vector, predicated).

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.583 SLI

Shift left and insert (immediate)

This instruction shifts each source vector element left by an immediate value, and inserts the result into the corresponding vector element in the destination vector register, merging the shifted bits from each source element with existing bits in each destination vector element. The immediate shift amount is an unsigned value in the range 0 to number of bits per element minus 1. This instruction is unpredicated.

C8.2.584 SM4E

SM4 encryption and decryption

This instruction reads 16 bytes of input data from each 128-bit segment of the first source vector, together with four iterations of 32-bit round keys from the corresponding 128-bit segments of the second source vector. Each block of data is encrypted by four rounds in accordance with the SM4 standard, and destructively placed in the corresponding segments of the first source vector. This instruction is unpredicated.

ID_AA64ZFR0_EL1.SM4 indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(VL) = Z{}(dn);
let operand2 : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(m) else Zeros{VL};
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : integer = SInt(operand1[e*:esize]);
    let element2 : integer = SInt(operand2[e*:esize]);
    if ActivePredicateElement{PL}(mask, e, esize) then
        let minimum : integer = Min(element1, element2);
        result[e*:esize] = minimum[esize-1:0];
    else
        result[e*:esize] = operand1[e*:esize];
    end;
end;

Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.592 SMIN (immediate)

Signed minimum with immediate (unpredicated)

This instruction determines the signed minimum of an immediate and each element of the source vector, and destructively places the results in the corresponding elements of the source vector. The immediate is a signed 8-bit value in the range -128 to +127, inclusive. This instruction is unpredicated.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
SMIN  <Zdn>.<T>, <Zdn>.<T>, #<imm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let dn : integer = UInt(Zdn);
let unsigned : boolean = FALSE;
let imm : integer = if unsigned then UInt(imm8) else SInt(imm8);
```

Assembler Symbols

<Zdn>

Is the name of the source and destination scalable vector register, encoded in the “Zdn” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<imm>

Is the signed immediate operand, in the range -128 to 127, encoded in the “imm8” field.

For the “64-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “32-bit” variant: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “64-bit” variant: is the element index, in the range 0 to 3, encoded in the “i2h:i2l” fields.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV (2 * esize);
let eltspersegment : integer = 128 DIV (2 * esize);
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL) = Z{}(da);

for e = 0 to elements-1 do
    let s : integer = e - (e MOD eltspersegment);
    let element1 : integer = SInt(operand1[(2 * e + sel)*:esize]);
    let element2 : integer = SInt(operand2[(2 * s + index)*:esize]);
    let product : bits(2*esize) = (element1 * element2)[2*esize-1:0];
    result[e*:(2*esize)] = result[e*:(2*esize)] + product;
end;

Z{VL}(da) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.

C8.2.601 SMLSLB (indexed)

Signed multiply-subtract long by indexed element (bottom)

This instruction multiplies the even-numbered signed elements within each 128-bit segment of the first source vector by the specified signed element in the corresponding second source vector segment, and destructively subtracts the results from the overlapping double-width elements of the addend vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

(FEAT_SVE2 || FEAT_SME)

Encoding

```

C8.2.604 SMMLA

Signed 8-bit integer matrix multiply-accumulate to 32-bit integer

This instruction multiplies the 2×8 matrix of signed 8-bit integer values held in each 128-bit segment of the first source vector by the 8×2 matrix of signed 8-bit integer values in the corresponding segment of the second source vector. The resulting 2×2 widened 32-bit integer matrix product is then destructively added to the 32-bit integer matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing an 8-way dot product per destination element.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

SVE

(FEAT_SVE && FEAT_I8MM)

C8.2.608 SMULLB (indexed)

Signed multiply long by indexed element (bottom)

This instruction multiplies the even-numbered signed elements within each 128-bit segment of the first source vector by the specified signed element in the corresponding second source vector segment, and places the results in the overlapping double-width elements of the destination vector register.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

(FEAT_SVE2 || FEAT_SME)

Encoding

```
SMULLB  <Zd>.S, <Zn>.H, <Zm>.H[<imm>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 16;
let index : integer = UInt(i3h::i3l);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
let sel : integer = 0;
```

64-bit

(FEAT_SVE2 || FEAT_SME)

Encoding

```
SMULLB  <Zd>.D, <Zn>.S, <Zm>.S[<imm>]
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 32;
let index : integer = UInt(i2h::i2l);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
let sel : integer = 0;
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “32-bit” variant: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “64-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “32-bit” variant: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “64-bit” variant: is the element index, in the range 0 to 3, encoded in the “i2h:i2l” fields.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV (2 * esize);
let eltspersegment : integer = 128 DIV (2 * esize);
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL);

for e = 0 to elements-1 do
    let s : integer = e - (e MOD eltspersegment);
    let element1 : integer = SInt(operand1[(2 * e + sel)*:esize]);
    let element2 : integer = SInt(operand2[(2 * s + index)*:esize]);
    let res : integer = element1 * element2;
    result[e*:(2*esize)] = res[2*esize-1:0];
end;

Z{VL}(d) = result;
```

C8.2.609 SMULLT (vectors)

Signed multiply long (top)

This instruction multiplies the odd-numbered signed elements of the first source vector by the corresponding elements of the second source vector, and places the results in the overlapping double-width elements of the destination vector. This instruction is unpredicated.

SVE2

(FEAT_SVE2 || FEAT_SME)

Encoding

```
SMULLT  <Zd>.<T>, <Zn>.<Tb>, <Zm>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size == '00' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	D

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb>

Is the size specifier, encoded in “size”:

size	<Tb>
00	RESERVED
01	B
10	H
11	S

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : integer = SInt(operand1[(2*e + 1)*:(esize DIV 2)]);
    let element2 : integer = SInt(operand2[(2*e + 1)*:(esize DIV 2)]);
    let res : integer = element1 * element2;
    result[e*:esize] = res[esize-1:0];
end;

C8.2.611 SPLICE

Splice two vectors under predicate control

This instruction selects a region from the first source vector and copies it to the lowest-numbered elements of the result. Any remaining elements of the result are set to a copy of the lowest-numbered elements from the second source vector. The region is selected using the first and last true elements in the vector select predicate register. The result is destructively placed in the destination and first source vector, or constructively placed in the destination vector.

It has encodings from 2 classes: Constructive and Destructive

Constructive

(FEAT_SVE2 || FEAT_SME)

31 29	28 25	24	23 22	21	20	19 17	16	15 14	13	12 10	9 5	4 0

```

Operational Information

For the Destructive variant:

The destructive variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the destructive variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.614 SQADD (immediate)

Signed saturating add immediate (unpredicated)

This instruction performs a signed saturating addition of an unsigned immediate to each element of the source vector, and destructively places the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

SVE

(FEAT_SVE || FEAT_SME)

C8.2.615 SQADD (vectors, unpredicated)

Signed saturating add (unpredicated)

This instruction performs a signed saturating addition of all elements of the first source vector to the corresponding elements of the second source vector, and places the results in the corresponding elements of the destination vector. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

C8.2.616 SQCADD

Saturating complex integer add

This instruction adds the real and imaginary components of the integral complex numbers from the first source vector to the complex numbers from the second source vector that have first been rotated by 90 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation, equivalent to multiplying the complex numbers in the second source vector by ±j beforehand. The results are destructively placed in the corresponding elements of the first source vector. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

C8.2.619 SQDECB

Signed saturating decrement scalar by multiple of 8-bit predicate constraint element count

This instruction determines the number of active 8-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement the scalar destination. The result is saturated to the source general-purpose register's signed integer range. A 32-bit saturated result is then sign-extended to 64 bits.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

C8.2.623 SQDECH (vector)

Signed saturating decrement vector by multiple of 16-bit predicate constraint element count

This instruction determines the number of active 16-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement all destination vector elements. The results are saturated to the 16-bit
signed integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
SQDECH  <Zdn>.H{, <pattern>{, MUL #<imm>}}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 16;
let dn : integer = UInt(Zdn);
let pat : bits(5) = pattern;
let imm : integer = UInt(imm4) + 1;

let unsigned : boolean = FALSE;
```

Assembler Symbols

<Zdn>

Is the name of the source and destination scalable vector register, encoded in the “Zdn” field.

<pattern>

Is the optional pattern specifier, defaulting to ALL, encoded in “pattern”:

pattern	<pattern>
00000	POW2

C8.2.624 SQDECP (scalar)

Signed saturating decrement scalar by count of true predicate elements

This instruction determines the number of true elements in the source predicate and then uses the result to decrement the scalar destination. The result is saturated to the source general-purpose register's signed integer range. A 32-bit saturated result is then sign-extended to 64 bits.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

(FEAT_SVE || FEAT_SME)

Encoding

```
SQDECP  <Xdn>, <Pm>.<T>, <Wdn>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let m : integer = UInt(Pm);
let dn : integer = UInt(Rdn);
let unsigned : boolean = FALSE;
let  ssize : integer{} = 32;
```

64-bit

(FEAT_SVE || FEAT_SME)

Encoding

```
SQDECP  <Xdn>, <Pm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let m : integer = UInt(Pm);
let dn : integer = UInt(Rdn);
let unsigned : boolean = FALSE;
let  ssize : integer{} = 64;
```

Assembler Symbols

<Xdn>

Is the 64-bit name of the source and destination general-purpose register, encoded in the “Rdn” field.

<Pm>

Is the name of the source scalable predicate register, encoded in the “Pm” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Wdn>

Is the 32-bit name of the source and destination general-purpose register, encoded in the “Rdn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let operand1 : bits(ssize) = X{}(dn);
let operand2 : bits(PL) = P{}(m);
var result : bits(ssize);
var count : integer = 0;

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(operand2, e, esize) then
        count = count + 1;
    end;
end;

if unsigned then
    (result, -) = UnsignedSatQ{ssize}(UInt(operand1) - count);
    X{64}(dn) = ZeroExtend{64}(result);
else
    (result, -) = SignedSatQ{ssize}(SInt(operand1) - count);
    X{64}(dn) = SignExtend{64}(result);
end;
```

Operational Information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the general-purpose register written by this instruction might be significantly delayed.

C8.2.629 SQDMLALB (indexed)

Signed saturating doubling multiply-add by indexed element (bottom)

This instruction multiples the even-numbered signed elements within each 128-bit segment of the first source vector by the specified signed element in the corresponding second source vector segment and then doubles the result of the multiplication. Each intermediate value is saturated to the double-width N-bit value's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$ and is then destructively added to the overlapping double-width elements of the addend and destination vector. Each destination element is saturated to the double-width N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

C8.2.630 SQDMLALBT

Signed saturating doubling multiply-add (bottom × top)

This instruction multiplies the even-numbered signed elements of the first source vector by the corresponding odd-numbered signed elements of the second source vector, and then doubles the result of the multiplication. Each intermediate value is saturated to the double-width N-bit value's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$ and is then destructively added to the overlapping double-width elements of the addend and destination vector. Each destination element is saturated to the double-width N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

C8.2.632 SQDMLALT (indexed)

Signed saturating doubling multiply-add by indexed element (top)

This instruction multiplies the odd-numbered signed elements within each 128-bit segment of the first source vector by the specified signed element in the corresponding second source vector segment, and then doubles the result. Each intermediate value is saturated to the double-width N-bit value's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$ and is then destructively added to the overlapping double-width elements of the addend and destination vector. Each destination element is saturated to the double-width N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “32-bit” variant: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “64-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “32-bit” variant: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “64-bit” variant: is the element index, in the range 0 to 3, encoded in the “i2h:i2l” fields.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV (2 * esize);
let eltspersegment : integer = 128 DIV (2 * esize);
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL) = Z{}(da);

for e = 0 to elements-1 do
    let s : integer = e - (e MOD eltspersegment);
    let element1 : integer = SInt(operand1[(2 * e + sel)*:esize]);
    let element2 : integer = SInt(operand2[(2 * s + index)*:esize]);
    let element3 : integer = SInt(result[e*:(2*esize)]);
    let product : integer = SInt(SignedSat{2*esize}(2 * element1 * element2));
    let res : integer = element3 - product;
    result[e*:(2*esize)] = SignedSat{2*esize}(res);
end;

Z{VL}(da) = result;
```

Operational Information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.638 SQDMULH (vectors)

Signed saturating doubling multiply high (unpredicated)

This instruction multiplies the signed elements of the first source vector by the corresponding elements of the second source vector, and then doubles the result and places the most significant half of the results in the corresponding elements of the destination vector register. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

C8.2.639 SQDMULH (indexed)

Signed saturating doubling multiply high by indexed element

This instruction multiplies all signed elements within each 128-bit segment of the first source vector by the specified signed element in the corresponding second source vector segment, then doubles and places the most significant half of the result in the corresponding elements of the destination vector register. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

It has encodings from 3 classes: 16-bit, 32-bit, and 64-bit

16-bit

C8.2.644 SQINCB

Signed saturating increment scalar by multiple of 8-bit predicate constraint element count

This instruction determines the number of active 8-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination. The result is saturated to the source general-purpose register's signed integer range. A 32-bit saturated result is then sign-extended to 64 bits.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

(FEAT_SVE || FEAT_SME)

Encoding

```
SQINCB  <Xdn>, <Wdn>{, <pattern>{, MUL #<imm>}}

C8.2.645 SQINCD (scalar)

Signed saturating increment scalar by multiple of 64-bit predicate constraint element count

This instruction determines the number of active 64-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination. The result is saturated to the source general-purpose register's signed integer range. A 32-bit saturated result is then sign-extended to 64 bits.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

C8.2.651 SQINCW (scalar)

Signed saturating increment scalar by multiple of 32-bit predicate constraint element count

This instruction determines the number of active 32-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment the scalar destination. The result is saturated to the source general-purpose register's signed integer range. A 32-bit saturated result is then sign-extended to 64 bits.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 2 classes: 32-bit and 64-bit

C8.2.652 SQINCW (vector)

Signed saturating increment vector by multiple of 32-bit predicate constraint element count

This instruction determines the number of active 32-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment all destination vector elements. The results are saturated to the 32-bit
signed integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
SQINCW  <Zdn>.S{, <pattern>{, MUL #<imm>}}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then

C8.2.653 SQNEG

Signed saturating negate

This instruction negates the signed integer value in each Active element of the source vector, and places the results in the corresponding elements of the destination vector. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

It has encodings from 2 classes: Merging and Zeroing

Merging

(FEAT_SVE2 || FEAT_SME)

31–29	28–25	24	23–22	21	20	19	18	17	16	15–14	13	12–10	9–5	4–0

C8.2.654 SQRDCMLAH (vectors)

Saturating rounding doubling complex integer multiply-add high

This instruction multiplies without saturation the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the integral numbers in the first source vector by the corresponding complex number in the second source vector rotated by 0, 90, 180 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

This instruction then doubles and adds the products to the corresponding components of the complex numbers in the addend vector, and destructively places the most significant rounded half of the results in the corresponding elements of the addend vector. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

C8.2.655 SQRDCMLAH (indexed)

Saturating rounding doubling complex integer multiply-add high by indexed element

This instruction multiplies without saturation the duplicated real components for rotations 0 and 180, or imaginary components for rotations 90 and 270, of the integral numbers in each 128-bit segment of the first source vector by the specified complex number in the corresponding the second source vector segment rotated by 0, 90, 180 or 270 degrees in the direction from the positive real axis towards the positive imaginary axis, when considered in polar representation.

This instruction then doubles and adds the products to the corresponding components of the complex numbers in the addend vector, and destructively places the most significant rounded half of the results in the corresponding elements of the addend vector. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

These transformations permit the creation of a variety of multiply-add and multiply-subtract operations on complex numbers by combining two of these instructions with the same vector operands but with rotations that are 90 degrees apart.

Each complex number is represented in a vector register as an even/odd pair of elements with the real part in the even-numbered element and the imaginary part in the odd-numbered element.

It has encodings from 2 classes: 16-bit and 32-bit

C8.2.657 SQRDMLAH (indexed)

Signed saturating rounding doubling multiply-add high by indexed element

This instruction multiplies all signed elements within each 128-bit segment of the first source vector by the specified signed element of the corresponding second source vector segment, and then doubles the result and destructively adds the rounded high half of each result to the corresponding elements of the addend and destination vector. Each destination element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

It has encodings from 3 classes: 16-bit, 32-bit, and 64-bit

16-bit

(FEAT_SVE2 || FEAT_SME)

C8.2.673 SQSHLU

Signed saturating shift left unsigned by immediate

This instruction shifts left by immediate each active signed element of the source vector, and destructively places the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. The immediate shift amount is an unsigned value in the range 0 to number of bits per element minus 1. Inactive elements in the destination vector register remain unmodified.

C8.2.679 SQSUB (immediate)

Signed saturating subtract immediate (unpredicated)

This instruction performs a signed saturating subtraction of an unsigned immediate from each element of the source vector, and destructively places the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

<Zdn>

Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T>

Is the size specifier, encoded in "size":

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm>

Is the name of the second source scalable vector register, encoded in the "Zm" field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(VL) = Z{}(dn);
let operand2 : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(m) else Zeros{VL};
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : integer = SInt(operand1[e*:esize]);
    let element2 : integer = SInt(operand2[e*:esize]);
    if ActivePredicateElement{PL}(mask, e, esize) then
        result[e*:esize] = SignedSat{esize}(element2 - element1);
    else
        result[e*:esize] = operand1[e*:esize];
    end;
end;

Z{VL}(dn) = result;
```

Operational Information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.687 SRI

Shift right and insert (immediate)

This instruction shifts each source vector element right by an immediate value, and inserts the result into the corresponding vector element in the destination vector register, merging the shifted bits from each source element with existing bits in each destination vector element. The immediate shift amount is an unsigned value in the range 1 to number of bits per element. This instruction is unpredicated.

<const>

Is the immediate shift amount, in the range 1 to number of bits per element, encoded in “tszh:tszl:imm3”.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(dn);
let mask : bits(PL) = P{}(g);
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : integer = SInt(operand1[e*:esize]);
    if ActivePredicateElement{PL}(mask, e, esize) then
        let res : integer = (element1 + (1 << (shift - 1))) >> shift;
        result[e*:esize] = res[esize-1:0];
    else
        result[e*:esize] = operand1[e*:esize];
    end;
end;

Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.691 SRSRA

Signed rounding shift right and accumulate (immediate)

This instruction shifts right by immediate each signed element of the source vector, preserving the sign bit, and destructively adds the rounded intermediate result to the corresponding elements of the addend vector. The immediate shift amount is an unsigned value in the range 1 to number of bits per element. This instruction is unpredicated.

Assembler Symbols

<Zt>

Is the name of the scalable vector register to be transferred, encoded in the “Zt” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Zm>

Is the name of the offset scalable vector register, encoded in the “Zm” field.

C8.2.707 ST1D (scalar plus immediate, consecutive registers)

Contiguous store of doublewords from multiple consecutive vectors (immediate index)

This instruction performs a contiguous store of doublewords from elements of two or four consecutive vector registers to the memory address generated by a 64-bit scalar base and immediate index that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2 || FEAT_SVE2p1)

Encoding

```
ST1D  { <Zt1>.D-<Zt2>.D }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) && !IsFeatureImplemented(FEAT_SVE2p1) then
    EndOfDecode(Decode_UNDEF);
end;
let n : integer = UInt(Rn);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 2;
let t : integer = UInt(Zt::'0');
let esize : integer{} = 64;
let offset : integer = SInt(imm4);
```

Four registers

(FEAT_SME2 || FEAT_SVE2p1)

Encoding

```
ST1D  { <Zt1>.D-<Zt4>.D }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME2) && !IsFeatureImplemented(FEAT_SVE2p1) then
    EndOfDecode(Decode_UNDEF);
end;
let n : integer = UInt(Rn);
let g : integer = UInt('1'::PNg);
let nreg : integer{} = 4;
let t : integer = UInt(Zt::'00');
let esize : integer{} = 64;
let offset : integer = SInt(imm4);
```

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 2.

For the “Four registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 4.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” times 2 plus 1.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the “PNg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the “imm4” field.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the “imm4” field.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as “Zt” times 4 plus 3.

Operation

```
if IsFeatureImplemented(FEAT_SVE2p1) then CheckSVEEnabled(); else CheckStreamingSVEEnabled(); end;
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;

C8.2.712 ST1D (scalar plus vector)

Scatter store doublewords from a vector (vector index)

This instruction performs a scatter store of doublewords from the Active elements of a vector register to the memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then optionally multiplied by 8. Inactive elements are not written to memory.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 4 classes: 32-bit unpacked scaled offset, 32-bit unpacked unscaled offset, 64-bit scaled offset, and 64-bit unscaled offset

32-bit unpacked scaled offset

(FEAT_SVE)

31–29	28–25	24–23	22–21	20–16	15	14	13	12–10	9–5	4–0
1 1 1	0 0 1 0	1 1 (msz)	0 1	Zm	1	xs	0	Pg	Rn	Zt

Encoding

```
ST1D  { <Zt>.D }, <Pg>, [<Xn|SP>, <Zm>.D, <mod> #3]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Rn);

```

Assembler Symbols

<Zt>

Is the name of the scalable vector register to be transferred, encoded in the “Zt” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Zm>

Is the name of the offset scalable vector register, encoded in the “Zm” field.

<mod>

Is the index extend and shift specifier, encoded in “xs”:

xs	<mod>
0	UXTW
1	SXTW

Operation

```
CheckNonStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
var base : bits(64);
let mask : bits(PL) = P{}(g);
var offset : bits(VL);
var src : bits(VL);
let mbytes : integer{} = msize DIV 8;
let contiguous : boolean = FALSE;
let nontemporal : boolean = FALSE;
let predicated : boolean = TRUE;
let tagchecked : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescSVE(MemOp_STORE, nontemporal, contiguous,
                                                  predicated, tagchecked);

if !AnyActiveElement{PL}(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool(Unpredictable_CHECKSPNONEACTIVE) then
        CheckSPAlignment();
    end;

```

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 2.

For the “Four registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 4.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” times 2 plus 1.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the “PNg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the “imm4” field.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the “imm4” field.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as “Zt” times 4 plus 3.

Assembler Symbols

<Zt>

Is the name of the scalable vector register to be transferred, encoded in the “Zt” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the general-purpose offset register, encoded in the “Rm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
var base : bits(64);
let mask : bits(PL) = P{}(g);
var offset : bits(64);
var addr : bits(64);
var src : bits(VL);
let mbytes : integer{} = msize DIV 8;
let contiguous : boolean = TRUE;
let nontemporal : boolean = FALSE;
let predicated : boolean = TRUE;
let tagchecked : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescSVE(MemOp_STORE, nontemporal, contiguous,
                                                  predicated, tagchecked);

if !AnyActiveElement{PL}(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool(Unpredictable_CHECKSPNONEACTIVE) then
        CheckSPAlignment();
    end;
else
    if n == 31 then CheckSPAlignment(); end;
    src = Z{VL}(t);
end;

base = if n == 31 then SP{64}() else X{64}(n);
offset = X{64}(m);
addr = AddressAdd(base, UInt(offset) * mbytes, accdesc);

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        Mem{msize}(addr, accdesc) = src[e*:esize][msize-1:0];
    end;
    addr = AddressIncrement(addr, mbytes, accdesc);

C8.2.718 ST1H (scalar plus vector)

Scatter store halfwords from a vector (vector index)

This instruction performs a scatter store of halfwords from the Active elements of a vector register to the memory addresses generated by a 64-bit scalar base plus vector index. The index values are optionally first sign-extended or zero-extended from 32 to 64 bits and then optionally multiplied by 2. Inactive elements are not written to memory.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 6 classes: 32-bit scaled offset, 32-bit unpacked scaled offset, 32-bit unpacked unscaled offset, 32-bit unscaled offset, 64-bit scaled offset, and 64-bit unscaled offset

32-bit scaled offset

(FEAT_SVE)

C8.2.720 ST1W (scalar plus immediate, consecutive registers)

Contiguous store of words from multiple consecutive vectors (immediate index)

This instruction performs a contiguous store of words from elements of two or four consecutive vector registers to the memory address generated by a 64-bit scalar base and immediate index that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2 || FEAT_SVE2p1)

31	30	29	28	25	24	23	22	20	19	16	15	14	13	12	10	9	5	4	1	0

C8.2.722 ST1W (vector plus immediate)

Scatter store words from a vector (immediate index)

This instruction performs a scatter store of words from the Active elements of a vector register to the memory addresses generated by a vector base plus immediate index. The index is a multiple of 4 in the range 0 to 124. Inactive elements are not written to memory.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit element and 64-bit element

32-bit element

(FEAT_SVE)

31–29	28–25	24–23	22–21	20–16	15–13	12–10	9–5	4–0
1 1 1	0 0 1 0	1 0	1 1	imm5	1 0 1	Pg	Zn	Zt

msz

Encoding

```
ST1W  { <Zt>.S }, <Pg>, [<Zn>.S{, #<imm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Zn);
let g : integer = UInt(Pg);
let esize : integer{} = 32;
let msize : integer{} = 32;
let offset : integer = UInt(imm5);
```

64-bit element

(FEAT_SVE)

31–29	28–25	24–23	22–21	20–16	15–13	12–10	9–5	4–0
1 1 1	0 0 1 0	1 0	1 0	imm5	1 0 1	Pg	Zn	Zt

msz

Encoding

```
ST1W  { <Zt>.D }, <Pg>, [<Zn>.D{, #<imm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Zn);
let g : integer = UInt(Pg);
let esize : integer{} = 64;
let msize : integer{} = 32;
let offset : integer = UInt(imm5);
```

Assembler Symbols

<Zt>

Is the name of the scalable vector register to be transferred, encoded in the “Zt” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the base scalable vector register, encoded in the “Zn” field.

<imm>

Is the optional unsigned immediate byte offset, a multiple of 4 in the range 0 to 124, defaulting to 0, encoded in the “imm5” field.

Operation

```
CheckNonStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
var base : bits(VL);
var src : bits(VL);
let mbytes : integer{} = msize DIV 8;
let contiguous : boolean = FALSE;
let nontemporal : boolean = FALSE;
let predicated : boolean = TRUE;
let tagchecked : boolean = TRUE;
let accdesc : AccessDescriptor = CreateAccDescSVE(MemOp_STORE, nontemporal, contiguous,
                                                  predicated, tagchecked);

if AnyActiveElement{PL}(mask, esize) then
    base = Z{VL}(n);
    src = Z{VL}(t);
end;

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let baddr : bits(64) = ZeroExtend{}(base[e*:esize]);
        let addr : bits(64) = AddressAdd(baddr, offset * mbytes, accdesc);
        Mem{msize}(addr, accdesc) = src[e*:esize][msize-1:0];
    end;
end;
```

C8.2.726 ST2B (scalar plus immediate)

Contiguous store two-byte structures from two vectors (immediate index)

This instruction performs a contiguous store of two-byte structures, each from the same element number in two vector registers to the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 2 in the range -16 to 14 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the two vector registers, or equivalently to the two consecutive bytes in memory that make up each structure. Inactive structures are not written to memory.

C8.2.727 ST2B (scalar plus scalar)

Contiguous store two-byte structures from two vectors (scalar index)

This instruction performs a contiguous store of two-byte structures, each from the same element number in two vector registers to the memory address generated by a 64-bit scalar base and a 64-bit scalar index register and added to the base address. After each structure access the index value is incremented by two. The index register is not updated by the instruction.

Each predicate element applies to the same element number in each of the two vector registers, or equivalently to the two consecutive bytes in memory that make up each structure. Inactive structures are not written to memory.

C8.2.728 ST2D (scalar plus immediate)

Contiguous store two-doubleword structures from two vectors (immediate index)

This instruction performs a contiguous store of two-doubleword structures, each from the same element number in two vector registers to the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 2 in the range -16 to 14 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the two vector registers, or equivalently to the two consecutive doublewords in memory that make up each structure. Inactive structures are not written to memory.

Assembler Symbols

<Zt1>

Is the name of the first scalable vector register to be transferred, encoded in the “Zt” field.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” plus 1 modulo 32.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the general-purpose offset register, encoded in the “Rm” field.

C8.2.734 ST2W (scalar plus immediate)

Contiguous store two-word structures from two vectors (immediate index)

This instruction performs a contiguous store of two-word structures, each from the same element number in two vector registers to the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 2 in the range -16 to 14 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the two vector registers, or equivalently to the two consecutive words in memory that make up each structure. Inactive structures are not written to memory.

C8.2.740 ST3H (scalar plus immediate)

Contiguous store three-halfword structures from three vectors (immediate index)

This instruction performs a contiguous store of three-halfword structures, each from the same element number in three vector registers to the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 3 in the range -24 to 21 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the three vector registers, or equivalently to the three consecutive halfwords in memory that make up each structure. Inactive structures are not written to memory.

C8.2.746 ST4B (scalar plus immediate)

Contiguous store four-byte structures from four vectors (immediate index)

This instruction performs a contiguous store of four-byte structures, each from the same element number in four vector registers to the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 4 in the range -32 to 28 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the four vector registers, or equivalently to the four consecutive bytes in memory that make up each structure. Inactive structures are not written to memory.

C8.2.752 ST4Q (scalar plus immediate)

Contiguous store four-quadword structures from four vectors (immediate index)

This instruction performs a contiguous store of four-quadword structures, each from the same element number in four vector registers to the memory address generated by a 64-bit scalar base and an immediate index that is a multiple of 4 in the range -32 to 28 that is multiplied by the vector's in-memory size, irrespective of predication.

Each predicate element applies to the same element number in each of the four vector registers, or equivalently to the four consecutive quadwords in memory that make up each structure. Inactive structures are not written to memory.

```

Assembler Symbols

<Zt1>

Is the name of the first scalable vector register to be transferred, encoded in the "Zt" field.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as "Zt" plus 1 modulo 32.

<Zt3>

Is the name of the third scalable vector register to be transferred, encoded as "Zt" plus 2 modulo 32.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as "Zt" plus 3 modulo 32.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

C8.2.753 ST4Q (scalar plus scalar)

Contiguous store four-quadword structures from four vectors (scalar index)

This instruction performs a contiguous store of four-quadword structures, each from the same element number in four vector registers to the memory address generated by a 64-bit scalar base and a 64-bit scalar index register scaled by the element size (`LSL` option) and added to the base address. After each structure access the index value is incremented by four. The index register is not updated by the instruction.

Each predicate element applies to the same element number in each of the four vector registers, or equivalently to the four consecutive quadwords in memory that make up each structure. Inactive structures are not written to memory.

C8.2.758 STNT1B (vector plus scalar)

Scatter store non-temporal bytes

This instruction performs a non-temporal scatter store of bytes from the active elements of a vector register to the memory addresses generated by a vector base plus a 64-bit unscaled scalar register offset. Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 2 classes: 32-bit unscaled offset and 64-bit unscaled offset

32-bit unscaled offset

(FEAT_SVE2)

31–29	28–25	24–23	22	21	20–16	15–13	12–10	9–5	4–0
1 1 1	0 0 1 0	0 0 (msz)	1	0	Rm	0 0 1	Pg	Zn	Zt

Encoding

```
STNT1B  { <Zt>.S }, <Pg>, [<Zn>.S{, <Xm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Zn);
let m : integer = UInt(Rm);
let g : integer = UInt(Pg);
let esize : integer{} = 32;
let msize : integer{} = 8;
```

64-bit unscaled offset

(FEAT_SVE2)

31–29	28–25	24–23	22	21	20–16	15–13	12–10	9–5	4–0
1 1 1	0 0 1 0	0 0 (msz)	0	0	Rm	0 0 1	Pg	Zn	Zt

Encoding

```
STNT1B  { <Zt>.D }, <Pg>, [<Zn>.D{, <Xm>}]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) then EndOfDecode(Decode_UNDEF); end;
let t : integer = UInt(Zt);
let n : integer = UInt(Zn);
let m : integer = UInt(Rm);
let g : integer = UInt(Pg);
let esize : integer{} = 64;
let msize : integer{} = 8;
```

C8.2.759 STNT1B (scalar plus immediate, single register)

Contiguous store non-temporal bytes from vector (immediate index)

This instruction performs a contiguous non-temporal store of bytes from elements of a vector register to the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

C8.2.764 STNT1D (scalar plus immediate, single register)

Contiguous store non-temporal doublewords from vector (immediate index)

This instruction performs a contiguous non-temporal store of doublewords from elements of a vector register to the memory address generated by a 64-bit scalar base and immediate index in the range -8 to 7 that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address. Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

C8.2.770 STNT1H (scalar plus scalar, single register)

Contiguous store non-temporal halfwords from vector (scalar index)

This instruction performs a contiguous non-temporal store of halfwords from elements of a vector register to the memory address generated by a 64-bit scalar base and scalar index that is multiplied by 2 and added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

C8.2.771 STNT1W (scalar plus immediate, consecutive registers)

Contiguous store non-temporal of words from multiple consecutive vectors (immediate index)

This instruction performs a contiguous non-temporal store of words from elements of two or four consecutive vector registers to the memory address generated by a 64-bit scalar base and immediate index that is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2 || FEAT_SVE2p1)

let offset : integer = SInt(imm4);
```

Assembler Symbols

<Zt1>

For the “Two registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 2.

For the “Four registers” variant: is the name of the first scalable vector register to be transferred, encoded as “Zt” times 4.

<Zt2>

Is the name of the second scalable vector register to be transferred, encoded as “Zt” times 2 plus 1.

<PNg>

Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the “PNg” field.

<Xn|SP>

Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the “Rn” field.

<imm>

For the “Two registers” variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the “imm4” field.

For the “Four registers” variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the “imm4” field.

<Zt4>

Is the name of the fourth scalable vector register to be transferred, encoded as “Zt” times 4 plus 3.

Operation

C8.2.776 STR (predicate)

Store predicate register

This instruction stores a predicate register to a memory address generated by a 64-bit scalar base, plus an immediate offset in the range -256 to 255 that is multiplied by the current predicate register size in bytes. This instruction is unpredicated.

The store is performed as contiguous byte accesses, each containing 8 consecutive predicate bits in ascending element order, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then a general-purpose base register must be aligned to 2 bytes.

For programmer convenience, an assembler must also accept a predicate-as-counter register name for the source predicate register.

SVE

C8.2.777 STR (vector)

Store vector register

This instruction stores a vector register to a memory address generated by a 64-bit scalar base, plus an immediate offset in the range -256 to 255 that is multiplied by the current vector register size in bytes. This instruction is unpredicated.

The store is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

C8.2.778 SUB (vectors, predicated)

Subtract (predicated)

This instruction subtracts active elements of the second source vector from the corresponding elements of the first source vector, and destructively places the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

SVE

(FEAT_SVE || FEAT_SME)

31–29	28–25	24	23–22	21	20–19	18–16	15–13	12–10	9–5	4–0
0 0 0	0 0 1 0	0	size	0	0 0	0 0 1 (opc)	0 0 0	Pg	Zm	Zdn

Encoding

```
SUB  <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let dn : integer = UInt(Zdn);
let m : integer = UInt(Zm);
```

Assembler Symbols

<Zdn>

Is the name of the first source and destination scalable vector register, encoded in the “Zdn” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(VL) = Z{}(dn);
let operand2 : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(m) else Zeros{VL};
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : bits(esize) = operand1[e*:esize];
    let element2 : bits(esize) = operand2[e*:esize];
    if ActivePredicateElement{PL}(mask, e, esize) then
        result[e*:esize] = element1 - element2;
    else
        result[e*:esize] = operand1[e*:esize];
    end;
end;

Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

Non-Confidential

C8.2.779 SUB (immediate)

Subtract immediate (unpredicated)

This instruction subtracts an unsigned immediate from each element of the source vector, and destructively places the results in the corresponding elements of the source vector. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
SUB  <Zdn>.<T>, <Zdn>.<T>, #<imm>{, <shift>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size::sh == '001' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let dn : integer = UInt(Zdn);
var imm : integer = UInt(imm8);
if sh == '1' then imm = imm << 8; end;
```

Assembler Symbols

<Zdn>

Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T>

Is the size specifier, encoded in "size":

size	<T>
00	B
01	H
10	S
11	D

<imm>

Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<shift>

Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #8

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(dn);
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : bits(esize) = operand1[e*:esize];
    result[e*:esize] = element1 - imm;

end;
Z{VL}(dn) = result;
```

Operational Information

C8.2.785 SUBR (vectors)

Reversed subtract (predicated)

This instruction performs a reversed subtraction on active elements of the first source vector from the corresponding elements of the second source vector and destructively places the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

SVE

(FEAT_SVE || FEAT_SME)

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(VL) = Z{}(dn);
let operand2 : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(m) else Zeros{VL};
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : bits(esize) = operand1[e*:esize];
    let element2 : bits(esize) = operand2[e*:esize];
    if ActivePredicateElement{PL}(mask, e, esize) then
        result[e*:esize] = element2 - element1;
    else
        result[e*:esize] = operand1[e*:esize];
    end;
end;

Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.786 SUBR (immediate)

Reversed subtract from immediate (unpredicated)

This instruction performs a reversed subtraction from an unsigned immediate each element of the source vector, and destructively places the results in the corresponding elements of the source vector. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

SVE

(FEAT_SVE || FEAT_SME)

31–29	28–25	24	23–22	21	20–19	18–16	15–14	13	12–5	4–0
0 0 1	0 0 1 0	1	size	1	0 0	0 1 1 (opc)	1 1	sh	imm8	Zdn

Encoding

```
SUBR  <Zdn>.<T>, <Zdn>.<T>, #<imm>{, <shift>}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size::sh == '001' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let dn : integer = UInt(Zdn);
var imm : integer = UInt(imm8);
if sh == '1' then imm = imm << 8; end;
```

Assembler Symbols

<Zdn>

Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T>

Is the size specifier, encoded in "size":

size	<T>
00	B
01	H
10	S
11	D

<imm>

Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.

C8.2.787 SUDOT

Signed by unsigned 8-bit integer dot product by indexed element to 32-bit integer

This instruction calculates the dot product of a group of four signed 8-bit integer values held in each 32-bit element of the first source vector multiplied by a group of four unsigned 8-bit integer values in an indexed 32-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index that selects the same group position within each 128-bit vector segment. The index range is from 0 to 3.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

SVE

((FEAT_SVE || FEAT_SME) && FEAT_I8MM)

C8.2.791 TBL

Programmable table lookup in one or two vector table (zeroing)

This instruction reads each element of the second source (index) vector and uses its value to select an indexed element from a table of elements consisting of one or two consecutive vector registers, where the first or only vector holds the lower numbered elements, and places the indexed table element in the destination vector element corresponding to the index vector element. If an index value is greater than or equal to the number of vector elements, then it places zero in the corresponding destination vector element.

Since the index values can select any element in a vector this operation is not naturally vector length agnostic.

It has encodings from 2 classes: Single register table and Two register table

Single register table

(FEAT_SVE || FEAT_SME)

31–29	28–25	24	23–22	21	20–16	15–10	9–5	4–0
0 0 0	0 0 1 0	1	size	1	Zm	0 0 1 1 0 0	Zn	Zd

Encoding

```
TBL  <Zd>.<T>, { <Zn>.<T> }, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
let double_table : boolean = FALSE;
```

Two register table

(FEAT_SVE2 || FEAT_SME)

31–29	28–25	24	23–22	21	20–16	15–11	10	9–5	4–0
0 0 0	0 0 1 0	1	size	1	Zm	0 0 1 0 1	0 (op)	Zn	Zd

Encoding

```
TBL  <Zd>.<T>, { <Zn1>.<T>, <Zn2>.<T> }, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
let double_table : boolean = TRUE;
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

<Zn1>

Is the name of the first scalable vector register of the first source multi-vector group, encoded in the “Zn” field.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let indexes : bits(VL) = Z{}(m);
var result : bits(VL);
let table_size : integer{} = if double_table then VL*2 else VL;
let table_elems : integer = table_size DIV esize;
var table : bits(table_size);

if double_table then
    let top : bits(VL) = Z{}((n + 1) MOD 32);
    let bottom : bits(VL) = Z{}(n);
    table = (top::bottom)[table_size-1:0];
else
    table = Z{table_size}(n);
end;

for e = 0 to elements-1 do
    let idx : integer = UInt(indexes[e*:esize]);
    result[e*:esize] = if idx < table_elems then table[idx*:esize] else Zeros{esize};
end;

Z{VL}(d) = result;
```

C8.2.792 TBLQ

Programmable table lookup within each quadword vector segment (zeroing)

This instruction reads, for each 128-bit destination vector segment, each element of the corresponding second source (index) vector segment and uses its value to select an indexed element from the corresponding first source (table) vector segment. The indexed table element is placed in the element of the destination vector that corresponds to the index vector element. If an index value is greater than or equal to the number of elements in a 128-bit vector segment then it places zero in the corresponding destination vector element. This instruction is unpredicated.

C8.2.796 TRN1, TRN2 (vectors)

Interleave even or odd elements from two vectors

This instruction interleaves alternating even or odd-numbered elements from the first and second source vectors, and places the values in the destination vector. This instruction is unpredicated.

The 128-bit element variant requires that the Effective SVE vector length is at least 256 bits. ID_AA64ZFR0_EL1.F64MM indicates whether the 128-bit element variant is implemented. The 128-bit element variant is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 4 classes: Even, Even (quadwords), Odd, and Odd (quadwords)

Even

```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.799 UABALT

Unsigned absolute difference and accumulate long (top)

This instruction calculates the absolute difference between odd-numbered unsigned elements of the first source vector and the corresponding elements of the second source vector, and destructively adds the results to the overlapping double-width elements of the addend vector. This instruction is unpredicated.

SVE2

(FEAT_SVE2 || FEAT_SME)

Encoding

```
UABALT  <Zda>.<T>, <Zn>.<Tb>, <Zm>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size == '00' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let da : integer = UInt(Zda);
```

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	D

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb>

Is the size specifier, encoded in “size”:

size	<Tb>
00	RESERVED
01	B
10	H
11	S

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL) = Z{}(da);

for e = 0 to elements-1 do
    let element1 : integer = UInt(operand1[(2*e + 1)*:(esize DIV 2)]);
    let element2 : integer = UInt(operand2[(2*e + 1)*:(esize DIV 2)]);
    let absdiff = Abs(element1 - element2)[esize-1:0];
    result[e*:esize] = result[e*:esize] + absdiff;
end;

Z{VL}(da) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb>

Is the size specifier, encoded in “size”:

size	<Tb>
00	RESERVED
01	B
10	H
11	S

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : integer = UInt(operand1[e*:esize]);
    let element2 : integer = UInt(operand2[(2*e + 1)*:(esize DIV 2)]);
    result[e*:esize] = (element1 + element2)[esize-1:0];
end;

Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

C8.2.809 UCLAMP

Unsigned clamp to minimum/maximum

This instruction clamps each unsigned element in the destination vector to between the unsigned minimum value in the corresponding element of the first source vector and the unsigned maximum value in the corresponding element of the second source vector and destructively writes the results in the corresponding elements of the destination vector. This instruction is unpredicated.

C8.2.810 UCVTF (predicated)

Unsigned integer convert to floating-point (predicated)

This instruction converts to floating-point from the unsigned integer in each active element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

If the input and result types have a different size the smaller type is held unpacked in the least significant bits of elements of the larger size. When the input is the smaller type the upper bits of each source element are ignored. When the result is the smaller type the results are zero-extended to fill each destination element.

It has encodings from 14 classes: 16-bit to half-precision, merging, 16-bit to half-precision, zeroing, 32-bit to half-precision, merging, 32-bit to half-precision, zeroing, 32-bit to single-precision, merging, 32-bit to single-precision, zeroing, 32-bit to double-precision, merging, 32-bit to double-precision, zeroing, 64-bit to half-precision, merging, 64-bit to half-precision, zeroing, 64-bit to single-precision, merging, 64-bit to single-precision, zeroing, 64-bit to double-precision, merging, and 64-bit to double-precision, zeroing

C8.2.812 UDIVR

Unsigned reversed divide (predicated)

This instruction performs an unsigned reversed division on active elements of the second source vector by the corresponding elements of the first source vector, and destructively places the quotient in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

SVE

(FEAT_SVE || FEAT_SME)

C8.2.816 UDOT (4-way, indexed)

Unsigned integer dot product by indexed element (four-way)

This instruction calculates the dot product of a group of four unsigned 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the first source vector multiplied by a group of four unsigned 8-bit or 16-bit integer values in an indexed 32-bit or 64-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit or 64-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index that selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment.

This instruction is unpredicated.

It has encodings from 2 classes: 8-bit to 32-bit and 16-bit to 64-bit

8-bit to 32-bit

(FEAT_SVE || FEAT_SME)

C8.2.819 UHSUBR

Unsigned halving subtract reversed

This instruction subtracts active unsigned elements of the first source vector from corresponding unsigned elements of the second source vector, shifts right one bit, and destructively places the results in the corresponding elements of the first source vector. Inactive elements in the destination vector register remain unmodified.

SVE2

(FEAT_SVE2 || FEAT_SME)

Encoding

```
UHSUBR  <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let dn : integer = UInt(Zdn);
let m : integer = UInt(Zm);
```

Assembler Symbols

<Zdn>

Is the name of the first source and destination scalable vector register, encoded in the “Zdn” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand1 : bits(VL) = Z{}(dn);
let operand2 : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(m) else Zeros{VL};
var result : bits(VL);

for e = 0 to elements-1 do
    let element1 : integer = UInt(operand1[e*:esize]);
    let element2 : integer = UInt(operand2[e*:esize]);
    if ActivePredicateElement{PL}(mask, e, esize) then
        let res : integer = (element2 - element1) >> 1;
        result[e*:esize] = res[esize-1:0];
    else
        result[e*:esize] = operand1[e*:esize];
    end;
end;

Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.828 UMINQV

Unsigned minimum reduction of quadword vector segments

This instruction determines the unsigned minimum of the elements in the same position from each 128-bit source vector segment, and places each result into the corresponding element of the 128-bit SIMD&FP destination register. Inactive elements in the source vector are treated as the maximum unsigned integer for the element size.

SVE2

C8.2.831 UMLALB (indexed)

Unsigned multiply-add long by indexed element (bottom)

This instruction multiplies the even-numbered unsigned elements within each 128-bit segment of the first source vector by the specified unsigned element in the corresponding second source vector segment, and destructively adds the results to the overlapping double-width elements of the addend vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

(FEAT_SVE2 || FEAT_SME)

Encoding

C8.2.836 UMLSLT (vectors)

Unsigned multiply-subtract long (top)

This instruction multiplies the odd-numbered unsigned elements of the first source vector by the corresponding elements of the second source vector, and destructively subtracts the results from the overlapping double-width elements of the addend vector. This instruction is unpredicated.

SVE2

(FEAT_SVE2 || FEAT_SME)

Encoding

```
UMLSLT  <Zda>.<T>, <Zn>.<Tb>, <Zm>.<Tb>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size == '00' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let da : integer = UInt(Zda);
```

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	D

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<Tb>

Is the size specifier, encoded in “size”:

size	<Tb>
00	RESERVED
01	B
10	H
11	S

<Zm>

Is the name of the second source scalable vector register, encoded in the “Zm” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL) = Z{}(da);

for e = 0 to elements-1 do
    let element1 : integer = UInt(operand1[(2*e + 1)*:(esize DIV 2)]);
    let element2 : integer = UInt(operand2[(2*e + 1)*:(esize DIV 2)]);
    let product = (element1 * element2)[esize-1:0];
    result[e*:esize] = result[e*:esize] - product;
end;

Z{VL}(da) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.837 UMLSLT (indexed)

Unsigned multiply-subtract long by indexed element (top)

This instruction multiplies the odd-numbered unsigned elements within each 128-bit segment of the first source vector by the specified unsigned element in the corresponding second source vector segment, and destructively subtracts the results from the overlapping double-width elements of the addend vector.

The elements within the second source vector are specified using an immediate index that selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

(FEAT_SVE2 || FEAT_SME)

Encoding

```
UMLSLT  <Zda>.S, <Zn>.H, <Zm>.H[<imm>]
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 16;
let index : integer = UInt(i3h::i3l);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let da : integer = UInt(Zda);
let sel : integer = 1;
```

64-bit

(FEAT_SVE2 || FEAT_SME)

Encoding

```
UMLSLT  <Zda>.D, <Zn>.S, <Zm>.S[<imm>]
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 32;
let index : integer = UInt(i2h::i2l);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let da : integer = UInt(Zda);
let sel : integer = 1;
```

Assembler Symbols

<Zda>

Is the name of the third source and destination scalable vector register, encoded in the “Zda” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “32-bit” variant: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “64-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “32-bit” variant: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “64-bit” variant: is the element index, in the range 0 to 3, encoded in the “i2h:i2l” fields.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV (2 * esize);
let eltspersegment : integer = 128 DIV (2 * esize);
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL) = Z{}(da);

for e = 0 to elements-1 do
    let s : integer = e - (e MOD eltspersegment);
    let element1 : integer = UInt(operand1[(2 * e + sel)*:esize]);
    let element2 : integer = UInt(operand2[(2 * s + index)*:esize]);
    let product : bits(2*esize) = (element1 * element2)[2*esize-1:0];
    result[e*:(2*esize)] = result[e*:(2*esize)] - product;
end;

Z{VL}(da) = result;
```

C8.2.838 UMMLA

Unsigned 8-bit integer matrix multiply-accumulate to 32-bit integer

This instruction multiplies the 2×8 matrix of unsigned 8-bit integer values held in each 128-bit segment of the first source vector by the 8×2 matrix of unsigned 8-bit integer values in the corresponding segment of the second source vector. The resulting 2×2 widened 32-bit integer matrix product is then destructively added to the 32-bit integer matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing an 8-way dot product per destination element.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

SVE

(FEAT_SVE && FEAT_I8MM)

31–29	28–25	24	23–22	21	20–16	15–14	13–10	9–5	4–0
0 1 0	0 0 1 0	1	1 1 (uns)	0	Zm	1 0	0 1 1 0	Zn	Zda

Encoding

if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 32;
let index : integer = UInt(i2h::i2l);
let n : integer = UInt(Zn);
let m : integer = UInt(Zm);
let d : integer = UInt(Zd);
let sel : integer = 1;
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

For the “32-bit” variant: is the name of the second source scalable vector register Z0-Z7, encoded in the “Zm” field.

For the “64-bit” variant: is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<imm>

For the “32-bit” variant: is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

For the “64-bit” variant: is the element index, in the range 0 to 3, encoded in the “i2h:i2l” fields.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV (2 * esize);
let eltspersegment : integer = 128 DIV (2 * esize);
let operand1 : bits(VL) = Z{}(n);
let operand2 : bits(VL) = Z{}(m);
var result : bits(VL);

for e = 0 to elements-1 do
    let s : integer = e - (e MOD eltspersegment);
    let element1 : integer = UInt(operand1[(2 * e + sel)*:esize]);
    let element2 : integer = UInt(operand2[(2 * s + index)*:esize]);
    let res : integer = element1 * element2;
    result[e*:(2*esize)] = res[2*esize-1:0];
end;

Z{VL}(d) = result;
```

Operational Information

C8.2.845 UQADD (vectors, predicated)

Unsigned saturating add (predicated)

This instruction adds active unsigned elements of the first source vector to corresponding unsigned elements of the second source vector, and destructively places the results in the corresponding elements of the first source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. Inactive elements in the destination vector register remain unmodified.

SVE2

(FEAT_SVE2 || FEAT_SME)

Encoding

```
UQADD  <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let dn : integer = UInt(Zdn);
let m : integer = UInt(Zm);
```

Assembler Symbols

<Zdn>

Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T>

Is the size specifier, encoded in "size":

size	<T>
00	B
01	H
10	S
11	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zm>

Is the name of the second source scalable vector register, encoded in the "Zm" field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.

C8.2.846 UQADD (immediate)

Unsigned saturating add immediate (unpredicated)

This instruction performs an unsigned saturating addition of an unsigned immediate to each element of the source vector, and destructively places the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

SVE

(FEAT_SVE || FEAT_SME)

C8.2.849 UQDECB

Unsigned saturating decrement scalar by multiple of 8-bit predicate constraint element count

This instruction determines the number of active 8-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement the scalar destination. The result is saturated to the general-purpose register's unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

(FEAT_SVE || FEAT_SME)

Encoding

```
UQDECB  <Wdn>{, <pattern>{, MUL #<imm>}}
```

C8.2.853 UQDECH (vector)

Unsigned saturating decrement vector by multiple of 16-bit predicate constraint element count

This instruction determines the number of active 16-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement all destination vector elements. The results are saturated to the 16-bit
unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
UQDECH  <Zdn>.H{, <pattern>{, MUL #<imm>}}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 16;
let dn : integer = UInt(Zdn);
let pat : bits(5) = pattern;
let imm : integer = UInt(imm4) + 1;

let unsigned : boolean = TRUE;
```

Assembler Symbols

<Zdn>

Is the name of the source and destination scalable vector register, encoded in the “Zdn” field.

<pattern>

Assembler Symbols

<Wdn>

Is the 32-bit name of the source and destination general-purpose register, encoded in the “Rdn” field.

<Pm>

Is the name of the source scalable predicate register, encoded in the “Pm” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Xdn>

Is the 64-bit name of the source and destination general-purpose register, encoded in the “Rdn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let operand1 : bits(ssize) = X{}(dn);
let operand2 : bits(PL) = P{}(m);
var result : bits(ssize);
var count : integer = 0;

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(operand2, e, esize) then
        count = count + 1;
    end;
end;

if unsigned then
    (result, -) = UnsignedSatQ{ssize}(UInt(operand1) - count);
    X{64}(dn) = ZeroExtend{64}(result);
else
    (result, -) = SignedSatQ{ssize}(SInt(operand1) - count);
    X{64}(dn) = SignExtend{64}(result);
end;
```

Operational Information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the general-purpose register written by this instruction might be significantly delayed.

C8.2.860 UQINCD (vector)

Unsigned saturating increment vector by multiple of 64-bit predicate constraint element count

This instruction determines the number of active 64-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment all destination vector elements. The results are saturated to the 64-bit
unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

SVE

(FEAT_SVE || FEAT_SME)

Encoding

```
UQINCD  <Zdn>.D{, <pattern>{, MUL #<imm>}}
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 64;
let dn : integer = UInt(Zdn);
let pat : bits(5) = pattern;
let imm : integer = UInt(imm4) + 1;

let unsigned : boolean = TRUE;
```

Assembler Symbols

C8.2.867 UQRSHL

Unsigned saturating rounding shift left (predicated)

This instruction shifts active unsigned elements of the first source vector by corresponding elements of the second source vector and destructively places the rounded results in the corresponding elements of the first source vector. A positive shift amount performs a left shift, otherwise a right shift by the negated shift amount is performed. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. Inactive elements in the destination vector register remain unmodified.

C8.2.876 UQSHRNT

Unsigned saturating shift right narrow by immediate (top)

This instruction shifts each unsigned integer value in the source vector elements right by an immediate value, and places the truncated results in the odd-numbered half-width destination elements, leaving the even-numbered elements unchanged. Each result element is saturated to the half-width N-bit element's unsigned integer range 0 to (2^N)-1. The immediate shift amount is an unsigned value in the range 1 to number of bits per element. This instruction is unpredicated.

```

Operational Information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.878 UQSUB (immediate)

Unsigned saturating subtract immediate (unpredicated)

This instruction performs an unsigned saturating subtraction of an unsigned immediate from each element of the source vector, and destructively places the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "`#<imm>, LSL #8`". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "`#0, LSL #8`".

SVE

(FEAT_SVE || FEAT_SME)

C8.2.883 URECPE

Unsigned reciprocal estimate (predicated)

This instruction finds the approximate reciprocal of each active unsigned element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

It has encodings from 2 classes: Merging and Zeroing

Merging

(FEAT_SVE2 || FEAT_SME)

Encoding

```
URECPE  <Zd>.S, <Pg>/M, <Zn>.S
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size != '10' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 32;
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Zd);
let merging : boolean = TRUE;
```

Zeroing

(FEAT_SVE2p2 || FEAT_SME2p2)

Encoding

```
URECPE  <Zd>.S, <Pg>/Z, <Zn>.S
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2p2) && !IsFeatureImplemented(FEAT_SME2p2) then
    EndOfDecode(Decode_UNDEF);
end;
if size != '10' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 32;
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Zd);
let merging : boolean = FALSE;
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let element : bits(esize) = operand[e*:esize];
        result[e*:esize] = UnsignedRecipEstimate{esize}(element);

    end;
end;
Z{VL}(d) = result;
```

Operational Information

For the Merging variant:

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

```

Operational Information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

C8.2.885 URSHL

Unsigned rounding shift left (predicated)

This instruction shifts active unsigned elements of the first source vector by corresponding elements of the second source vector and destructively places the rounded results in the corresponding elements of the first source vector. A positive shift amount performs a left shift, otherwise a right shift by the negated shift amount is performed. Inactive elements in the destination vector register remain unmodified.

SVE2

(FEAT_SVE2 || FEAT_SME)

Encoding

```
URSHL  <Zdn>.<T>, <Pg>/M, <Zdn>.<T>, <Zm>.<T>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let g : integer = UInt(Pg);
let m : integer = UInt(Zm);
let dn : integer = UInt(Zdn);
```

Assembler Symbols

C8.2.888 URSQRTE

Unsigned reciprocal square root estimate (predicated)

This instruction finds the approximate reciprocal square root of each active unsigned element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

It has encodings from 2 classes: Merging and Zeroing

Merging

(FEAT_SVE2 || FEAT_SME)

Encoding

```
URSQRTE  <Zd>.S, <Pg>/M, <Zn>.S
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
if size != '10' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 32;
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Zd);
let merging : boolean = TRUE;
```

Zeroing

(FEAT_SVE2p2 || FEAT_SME2p2)

Encoding

```
URSQRTE  <Zd>.S, <Pg>/Z, <Zn>.S
```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2p2) && !IsFeatureImplemented(FEAT_SME2p2) then
    EndOfDecode(Decode_UNDEF);
end;
if size != '10' then EndOfDecode(Decode_UNDEF); end;
let esize : integer{} = 32;
let g : integer = UInt(Pg);
let n : integer = UInt(Zn);
let d : integer = UInt(Zd);
let merging : boolean = FALSE;
```

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};

for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let element : bits(esize) = operand[e*:esize];
        result[e*:esize] = UnsignedRSqrtEstimate{esize}(element);

    end;
end;
Z{VL}(d) = result;
```

Operational Information

For the Merging variant:

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.894 USMMLA

Unsigned by signed 8-bit integer matrix multiply-accumulate to 32-bit integer

This instruction multiplies the 2×8 matrix of unsigned 8-bit integer values held in each 128-bit segment of the first source vector by the 8×2 matrix of signed 8-bit integer values in the corresponding segment of the second source vector. The resulting 2×2 widened 32-bit integer matrix product is then destructively added to the 32-bit integer matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing an 8-way dot product per destination element.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

SVE

C8.2.902 UXTB, UXTH, UXTW

Unsigned byte / halfword / word extend (predicated)

This instruction zero-extends the least-significant sub-element of each active element of the source vector, and places the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

It has encodings from 6 classes: Byte, merging, Byte, zeroing, Halfword, merging, Halfword, zeroing, Word, merging, and Word, zeroing

Byte, merging

Assembler Symbols

<Zd>

Is the name of the destination scalable vector register, encoded in the “Zd” field.

<T>

For the “Byte, merging” and “Byte, zeroing” variants: is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	D

For the “Halfword, merging” and “Halfword, zeroing” variants: is the size specifier, encoded in “size<0>”:

size<0>	<T>
0	S
1	D

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the “Pg” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckSVEEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let elements : integer = VL DIV esize;
let mask : bits(PL) = P{}(g);
let operand : bits(VL) = if AnyActiveElement{PL}(mask, esize) then Z{VL}(n) else Zeros{VL};
var result : bits(VL) = if merging then Z{VL}(d) else Zeros{VL};
```

Non-Confidential

```
for e = 0 to elements-1 do
    if ActivePredicateElement{PL}(mask, e, esize) then
        let element : bits(esize) = operand[e*:esize];
        result[e*:esize] = Extend{esize}(element[s_esize-1:0], unsigned);
    end;
end;

Z{VL}(d) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

C8.2.904 UZP1, UZP2 (vectors)

Concatenate even or odd elements from two vectors

This instruction concatenates adjacent even or odd-numbered elements from the first and second source vectors, and places the values in the destination vector. This instruction is unpredicated.

Note: UZP1 is equivalent to truncating and packing each element from two source vectors into a single destination vector with elements of half the size.

The 128-bit element variant requires that the Effective SVE vector length is at least 256 bits. ID_AA64ZFR0_EL1.F64MM indicates whether the 128-bit element variant is implemented. The 128-bit element variant is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 4 classes: Even, Even (quadwords), Odd, and Odd (quadwords)

Even

(FEAT_SVE || FEAT_SME)

C8.2.907 WHILEGE (predicate)

While decrementing signed scalar greater than or equal to scalar

This instruction generates a predicate that starting from the highest numbered element is true while the decrementing value of the first, signed scalar operand is greater than or equal to the second scalar operand and false thereafter down to the lowest numbered element.

If the second scalar operand is equal to the minimum signed integer value, then a condition that includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is decremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The predicate result is placed in the predicate destination register. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

C8.2.908 WHILEGE (predicate as counter)

While decrementing signed scalar greater than or equal to scalar (predicate-as-counter)

This instruction generates a predicate for a group of two or four vectors that starting from the highest numbered element of the group is true while the decrementing value of the first, signed scalar operand is greater than or equal to the second scalar operand and false thereafter down to the lowest numbered element of the group.

If the second scalar operand is equal to the minimum signed integer value, then a condition that includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is decremented by one for each destination predicate element, irrespective of the predicate result element size.

The predicate result is placed in the predicate destination register using the predicate-as-counter encoding. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

C8.2.916 WHILEHS (predicate)

While decrementing unsigned scalar higher than or same as scalar

This instruction generates a predicate that starting from the highest numbered element is true while the decrementing value of the first, unsigned scalar operand is higher than or the same as the second scalar operand and false thereafter down to the lowest numbered element.

If the second scalar operand is equal to the minimum unsigned integer value, then a condition that includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is decremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The predicate result is placed in the predicate destination register. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

C8.2.918 WHILEHS (predicate pair)

While decrementing unsigned scalar higher than or same as scalar (pair of predicates)

This instruction generates a pair of predicates that starting from the highest numbered element of the pair is true while the decrementing value of the first, unsigned scalar operand is higher than or the same as the second scalar operand and false thereafter down to the lowest numbered element of the pair.

If the second scalar operand is equal to the minimum unsigned integer value, then a condition that includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is decremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The lower-numbered elements are placed in the first predicate destination register, and the higher-numbered elements in the second predicate destination register. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

C8.2.925 WHILELS (predicate)

While incrementing unsigned scalar lower than or same as scalar

This instruction generates a predicate that starting from the lowest numbered element is true while the incrementing value of the first, unsigned scalar operand is lower than or the same as the second scalar operand and false thereafter up to the highest numbered element.

If the second scalar operand is equal to the maximum unsigned integer value, then a condition that includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is incremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The predicate result is placed in the predicate destination register. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

C8.2.931 WHILERW

While free of read-after-write conflicts

This instruction checks two addresses for a conflict or overlap between address ranges of the form [addr,addr+VL÷8), where VL is the accessible vector length in bits, that could result in a loop-carried dependency through memory due to the use of these addresses by contiguous load and store instructions within the same iteration of a loop. Generate a predicate whose elements are true while the addresses cannot conflict within the same iteration, and false thereafter. This instruction sets the First (N), None (Z), and !Last (C) condition flags based on the predicate result, and sets the V flag to zero.

SVE2

(FEAT_SVE2 || FEAT_SME)

Encoding

```
WHILERW  <Pd>.<T>, <Xn>, <Xm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SVE2) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
end;
let esize : integer{} = 8 << UInt(size);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let d : integer = UInt(Pd);
```

Assembler Symbols

<Pd>

Is the name of the destination scalable predicate register, encoded in the “Pd” field.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Xn>

Is the 64-bit name of the first source general-purpose register, encoded in the “Rn” field.

<Xm>

Is the 64-bit name of the second source general-purpose register, encoded in the “Rm” field.

C8.2.933 WRFFR

Write the first-fault register

This instruction reads the source predicate register, and writes the value in the register to the first-fault register (FFR). This instruction is intended to restore a saved FFR and is not recommended for general use by applications.

This instruction requires that the source predicate contains a monotonic predicate value, in which starting from bit 0 there are zero or more 1 bits, followed only by 0 bits in any remaining bit positions. If the source is not a monotonic predicate value, then the resulting value in the FFR will be UNPREDICTABLE. It is not possible to generate a non-monotonic value in FFR when using SETFFR followed by first-fault or non-fault loads.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

SVE

    let element2 : bits(esize) = operand2[e*:esize];
    result[e*:esize] = ROR(element1 XOR element2, rot);
end;
Z{VL}(dn) = result;
```

Operational Information

This instruction is a data-independent-time instruction as described in About PSTATE.DIT.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

Assembler Symbols

<Zdn1>

For the “Two registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4.

<T>

Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Zdn2>

Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<Zdn4>

Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV esize;
var results : array [[4]] of bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(dn+r);
    let operand2 : bits(VL) = Z{}(m);
    for e = 0 to elements-1 do
        let element1 : bits(esize) = operand1[e*:esize];
        let element2 : bits(esize) = operand2[e*:esize];
        results[[r]][e*:esize] = element1 + element2;
    end;
end;

for r = 0 to nreg-1 do
    Z{VL}(dn+r) = results[[r]];
end;
```

C9.2.2 ADD (to array, array and multiple vectors)

Multi-vector accumulate to ZA array vectors

This instruction destructively adds all elements of the two or four source vectors to the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

(FEAT_SME2 && (sz == '0' || FEAT_SME_I16I64))

C9.2.5 ADDHA

Add horizontally vector elements to ZA tile

This instruction adds each element of the source vector to the corresponding Active element of each horizontal slice of a ZA tile. The tile elements are predicated by a pair of governing predicates. An element of a horizontal slice is considered active if its corresponding element in the second governing predicate is TRUE and the element corresponding to its horizontal slice number in the first governing predicate is TRUE. Inactive elements in the destination tile remain unmodified.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

C9.2.7 ADDSVL

Add multiple of Streaming SVE vector register size to scalar register

This instruction adds the Streaming SVE vector register size in bytes multiplied by an immediate in the range -32 to 31 to the 64-bit source general-purpose register or current stack pointer, and places the result in the 64-bit destination general-purpose register or current stack pointer.

This instruction does not require the PE to be in Streaming SVE mode.

SME

(FEAT_SME)

31–29	28–25	24	23	22	21	20–16	15–12	11	10–5	4–0
0 0 0	0 0 1 0	0	0	0	1	Rn	0 1 0 1	1	imm6	Rd
				op						

Encoding

```
ADDSVL  <Xd|SP>, <Xn|SP>, #<imm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME) then EndOfDecode(Decode_UNDEF); end;
let n : integer = UInt(Rn);
let d : integer = UInt(Rd);
let imm : integer = SInt(imm6);
```

Assembler Symbols

<Xd|SP>

Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the “Rd” field.

<Xn|SP>

Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the “Rn” field.

<imm>

Is the signed immediate operand, in the range -32 to 31, encoded in the “imm6” field.

Operation

```
CheckSMEEnabled();
let SVL : integer = CurrentSVL();
let len : integer = imm * (SVL DIV 8);
let operand1 : bits(64) = if n == 31 then SP{64}() else X{64}(n);
let result : bits(64) = operand1 + len;

if d == 31 then
    SP{64}() = result;
else
    X{64}(d) = result;
end;
```

C9.2.8 ADDVA

Add vertically vector elements to ZA tile

This instruction adds each element of the source vector to the corresponding Active element of each vertical slice of a ZA tile. The tile elements are predicated by a pair of governing predicates. An element of a vertical slice is considered active if its corresponding element in the first governing predicate is TRUE and the element corresponding to its vertical slice number in the second governing predicate is TRUE. Inactive elements in the destination tile remain unmodified.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

Assembler Symbols

<ZAda>

For the “32-bit” variant: is the name of the ZA tile ZA0-ZA3, encoded in the “ZAda” field.

For the “64-bit” variant: is the name of the ZA tile ZA0-ZA7, encoded in the “ZAda” field.

<Pn>

Is the name of the first governing scalable predicate register P0-P7, encoded in the “Pn” field.

<Pm>

Is the name of the second governing scalable predicate register P0-P7, encoded in the “Pm” field.

<Zn>

Is the name of the source scalable vector register, encoded in the “Zn” field.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let PL : integer{} = VL DIV 8;
let dim : integer{} = VL DIV esize;
let mask1 : bits(PL) = P{}(a);
let mask2 : bits(PL) = P{}(b);
let operand_src : bits(VL) = Z{}(n);
let operand_acc : bits(dim*dim*esize) = ZAtile{}(da, esize);
var result : bits(dim*dim*esize);

for row = 0 to dim-1 do
    let element : bits(esize) = operand_src[row*:esize];
    for col = 0 to dim-1 do
        var res : bits(esize) = operand_acc[(row*dim+col)*:esize];
        if (ActivePredicateElement{PL}(mask1, row, esize) &&
              ActivePredicateElement{PL}(mask2, col, esize)) then
            res = res + element;
        end;
        result[(row*dim+col)*:esize] = res;
    end;
end;

ZAtile{dim*dim*esize}(da, esize) = result;
```

C9.2.11 BFADD

Multi-vector BFloat16 accumulate to ZA array vectors

This instruction destructively adds all elements of the two or four source vectors to the corresponding BFloat16 elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

(FEAT_SME_B16B16)

31	30	29	28			25	24	23	22	21	20	19	18	17	16	15	14	13	12		10	9		6	5	4	3	2		0

```

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SME_B16B16) then EndOfDecode(Decode_UNDEF); end;
let v : integer = UInt('010'::Rv);
let m : integer = UInt(Zm::'00');
let offset : integer = UInt(off3);
let nreg : integer{} = 4;
```

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded in the “Rv” field.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zm1>

For the “Two ZA single-vectors” variant: is the name of the first scalable vector register of the source multi-vector group, encoded as “Zm” times 2.

For the “Four ZA single-vectors” variant: is the name of the first scalable vector register of the source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zm4>

Is the name of the fourth scalable vector register of the source multi-vector group, encoded as “Zm” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV 16;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = ZAvector{}(vec);
    let operand2 : bits(VL) = Z{}(m+r);
    for e = 0 to elements-1 do
        let element1 : bits(16) = operand1[e*:16];
        let element2 : bits(16) = operand2[e*:16];
        result[e*:16] = BFAdd_ZA(element1, element2, FPCR());
    end;
    ZAvector{VL}(vec) = result;
    vec = vec + vstride;
end;
```

C9.2.12 BFCLAMP

Multi-vector BFloat16 clamp to minimum/maximum number

This instruction clamps each BFloat16 element in the two or four destination vectors to between the BFloat16 minimum value in the corresponding element of the first source vector and the BFloat16 maximum value in the corresponding element of the second source vector and destructively places the clamped results in the corresponding elements of the two or four destination vectors.

Regardless of the value of FPCR.AH, the behavior is as follows for each minimum number and maximum number operation:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is Default NaN.

This instruction follows SME2 non-widening BFloat16 numerical behaviors corresponding to instructions that place their results in two or four SVE Z vectors.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two registers and Four registers

C9.2.15 BFCVTN

Multi-vector single-precision convert to interleaved BFloat16

This instruction converts each element of the two source vectors from single-precision to BFloat16 floating-point, and places the two-way interleaved results in the half-width destination elements.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

C9.2.16 BFDOT (multiple and indexed vector)

Multi-vector BFloat16 dot product by indexed element to single-precision

This instruction calculates the dot product of a pair of BF16 values held in the corresponding 32-bit elements of the two or four first source vectors and the indexed 32-bit element of the second source vector. The single-precision dot product results are destructively added to the corresponding single-precision elements of the ZA single-vector groups.

The BF16 pairs within the second source vector are specified using an immediate index that selects the same BF16 pair position within each 128-bit vector segment. The element index range is from 0 to 3.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

C9.2.19 BFMAX (multiple and single vector)

Multi-vector BFloat16 maximum by vector

This instruction determines the maximum of BFloat16 elements of the second source vector and the corresponding BFloat16 elements of the two or four first source vectors and destructively places the results in the corresponding elements of the two or four first source vectors.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction follows SME2 non-widening BFloat16 numerical behaviors corresponding to instructions that place their results in two or four SVE Z vectors.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two registers and Four registers

<Zdn1>

For the “Two registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2.

For the “Four registers” variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4.

<Zdn2>

Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 2 plus 1.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

<Zdn4>

Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as “Zdn” times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV 16;
var results : array [[4]] of bits(VL);

for r = 0 to nreg-1 do
    let operand1 : bits(VL) = Z{}(dn+r);
    let operand2 : bits(VL) = Z{}(m);
    for e = 0 to elements-1 do
        let element1 : bits(16) = operand1[e*:16];
        let element2 : bits(16) = operand2[e*:16];
        results[[r]][e*:16] = BFMinNum{16}(element1, element2, FPCR());
    end;
end;

for r = 0 to nreg-1 do
    Z{VL}(dn+r) = results[[r]];
end;
```

C9.2.26 BFMINNM (multiple vectors)

Multi-vector BFloat16 minimum number

This instruction determines the minimum number value of BFloat16 elements of the two or four second source vectors and the corresponding BFloat16 elements of the two or four first source vectors and destructively places the results in the corresponding elements of the two or four first source vectors.

Regardless of the value of FPCR.AH, the behavior is as follows:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is Default NaN.

This instruction follows SME2 non-widening BFloat16 numerical behaviors corresponding to instructions that place their results in two or four SVE Z vectors.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two registers and Four registers

C9.2.27 BFMLA (multiple and indexed vector)

Multi-vector BFloat16 fused multiply-add by indexed element

This instruction multiplies the indexed element of the second source vector by the corresponding BFloat16 elements of the two or four first source vectors and destructively adds these values without intermediate rounding to the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to 7.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded in the “Rv” field.

<offs1>

For the “One ZA double-vector” variant: is the first vector select offset, encoded as “off3” field times 2.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the first vector select offset, encoded as “off2” field times 2.

<offs2>

For the “One ZA double-vector” variant: is the second vector select offset, encoded as “off3” field times 2 plus 1.

For the “Four ZA double-vectors” and “Two ZA double-vectors” variants: is the second vector select offset, encoded as “off2” field times 2 plus 1.

<Zn>

Is the name of the first source scalable vector register, encoded in the “Zn” field.

<Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the “Zm” field.

Copyright © 2013-2026 Arm Limited or its affiliates. All rights reserved.
Non-Confidential

<index>

Is the element index, in the range 0 to 7, encoded in the “i3h:i3l” fields.

<Zn1>

For the “Two ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA double-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV 32;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let eltspersegment : integer = 128 DIV 32;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);
vec = vec - (vec MOD 2);

for r = 0 to nreg-1 do
    let op1 : bits(VL) = Z{}(n+r);
    let op2 : bits(VL) = Z{}(m);
    for i = 0 to 1 do
        let op3 : bits(VL) = ZAvector{}(vec + i);
        for e = 0 to elements-1 do
            let segmentbase : integer = e - (e MOD eltspersegment);
            let s : integer = 2 * segmentbase + index;
            let elem1 : bits(16) = op1[(2 * e + i)*:16];
            let elem2 : bits(16) = op2[s*:16];
            let elem3 : bits(32) = op3[e*:32];
            result[e*:32] = BFMulAddH_ZA(elem3, elem1, elem2, FPCR());
        end;
        ZAvector{VL}(vec + i) = result;
    end;
    vec = vec + vstride;
end;
```

C9.2.31 BFMLAL (multiple and single vector)

Multi-vector BFloat16 multiply-add by vector to single-precision

This instruction widens all 16-bit BFloat16 elements in the one, two, or four first source vectors and the second source vector to single-precision format, then multiplies the corresponding elements and destructively adds these values without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

C9.2.33 BFMLS (multiple and indexed vector)

Multi-vector BFloat16 fused multiply-subtract by indexed element

This instruction multiplies the indexed element of the second source vector by the corresponding BFloat16 elements of the two or four first source vectors and destructively subtracts these values without intermediate rounding from the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index that selects the same element position within each 128-bit vector segment. The index range is from 0 to 7.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo half or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

let nreg : integer{} = 4;
```

Assembler Symbols

<Wv>

Is the 32-bit name of the vector select register W8-W11, encoded in the “Rv” field.

<offs>

Is the vector select offset, in the range 0 to 7, encoded in the “off3” field.

<Zn1>

For the “Two ZA single-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 2.

For the “Four ZA single-vectors” variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as “Zn” times 4.

<Zn2>

Is the name of the second scalable vector register of the first source multi-vector group, encoded as “Zn” times 2 plus 1.

<Zm1>

For the “Two ZA single-vectors” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 2.

For the “Four ZA single-vectors” variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as “Zm” times 4.

<Zm2>

Is the name of the second scalable vector register of the second source multi-vector group, encoded as “Zm” times 2 plus 1.

<Zn4>

Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as “Zn” times 4 plus 3.

<Zm4>

Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as “Zm” times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
let VL : integer{} = CurrentVL();
let elements : integer = VL DIV 16;
let vectors : integer = VL DIV 8;
let vstride : integer = vectors DIV nreg;
let vbase : bits(32) = X{}(v);
var vec : integer = (UInt(vbase) + offset) MOD vstride;
var result : bits(VL);

for r = 0 to nreg-1 do

C9.2.36 BFMLSL (multiple and indexed vector)

Multi-vector BFloat16 multiply-subtract by indexed element from single-precision

This instruction widens all 16-bit BFloat16 elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively subtracts these values without intermediate rounding from the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The BF16 elements within the second source vector are specified using a 3-bit immediate index that selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The `vector group` symbol, `VGx2` or `VGx4`, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector, Two ZA double-vectors, and Four ZA double-vectors

One ZA double-vector

C9.2.39 BFMOP4A (widening)

BFloat16 quarter-tile sum of outer products to single-precision, accumulating

This instruction generates four independent quarter-tile BFloat16 sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of BFloat16 values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of BFloat16 values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix.

The instruction widens the sub-matrices of BFloat16 values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of BFloat16 values in the second source vectors to single-precision values. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ single-precision sums of outer products are then destructively added to the single-precision destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction follows SME BFloat16 numerical behaviors.

This instruction is unpredicated.

C9.2.40 BFMOP4A (non-widening)

BFloat16 quarter-tile outer product, accumulating

This instruction generates four independent quarter-tile BFloat16 outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 16-bit element ZA tile.

Each of the quarter-tile outer products is generated by multiplying the $SVL_H \div 2 \times 1$ sub-matrix of BFloat16 values held in the half-vectors of the first source vectors by the $1 \times SVL_H \div 2$ sub-matrix of BFloat16 values held in the half-vectors of the second source vectors.

The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ BFloat16 outer products are destructively added to the destination ZA tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

C9.2.41 BFMOP4S (widening)

BFloat16 quarter-tile sum of outer products to single-precision, subtracting

This instruction generates four independent quarter-tile BFloat16 sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of BFloat16 values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of BFloat16 values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix.

The instruction widens the sub-matrices of BFloat16 values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of BFloat16 values in the second source vectors to single-precision values. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ single-precision sums of outer products are then destructively subtracted from the single-precision destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

This instruction follows SME BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors, Single vectors, Multiple and single vectors, and Multiple vectors

BFloat16 quarter-tile outer product, subtracting

This instruction generates four independent quarter-tile BFloat16 outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 16-bit element ZA tile.

Each of the quarter-tile outer products is generated by multiplying the $SVL_H \div 2 \times 1$ sub-matrix of BFloat16 values held in the half-vectors of the first source vectors by the $1 \times SVL_H \div 2$ sub-matrix of BFloat16 values held in the half-vectors of the second source vectors.

The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ BFloat16 outer products are destructively subtracted from the destination ZA tile. This is equivalent to performing a single multiply-subtract from each of the destination tile elements.
