
## LDNT1B (scalar plus immediate, strided registers)

Contiguous load non-temporal of bytes to multiple strided vectors (immediate index)

Contiguous load non-temporal of bytes to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

(FEAT\_SME2)

LDNT1B { <Zt1>.B, <Zt2>.B }, <PNg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 2;
integer tstride = 8;
integer t = UInt(T:'0':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

### Four registers

(FEAT\_SME2)

LDNT1B { <Zt1>.B, <Zt2>.B, <Zt3>.B, <Zt4>.B }, <PNg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 4;
integer tstride = 4;
integer t = UInt(T:'00':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

### Assembler Symbols

- <Zt1> For the two registers variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as "T:'0':Zt".  
For the four registers variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as "T:'00':Zt".
- <Zt2> For the two registers variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as "T:'1':Zt".  
For the four registers variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as "T:'01':Zt".

<Zt3>	Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".
<Zt4>	Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".
<PNg>	Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the two registers variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the "imm4" field.  For the four registers variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.

## Operation

```

CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
constant integer mbytes = esize DIV 8;
bits(64) base;
bits(PL) pred = P[g, PL];

## LDNT1H (scalar plus scalar, strided registers)

Contiguous load non-temporal of halfwords to multiple strided vectors (scalar index)

Contiguous load non-temporal of halfwords to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

## LDNT1W (scalar plus immediate, strided registers)

Contiguous load non-temporal of words to multiple strided vectors (immediate index)

Contiguous load non-temporal of words to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

LDR (vector)

Load ZA array vector

The ZA array vector is selected by the sum of the vector select register and immediate offset, modulo the number of bytes in a Streaming SVE vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base, plus the same optional immediate offset multiplied by the current vector length in bytes. This instruction is unpredicated.

The load is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

1	H

- <Zd2> Is the name of the second destination scalable vector register Z4-Z7 or Z20-Z23 of a multi-vector sequence, encoded as "D:'01':Zd".
- <Zd3> Is the name of the third destination scalable vector register Z8-Z11 or Z24-Z27 of a multi-vector sequence, encoded as "D:'10':Zd".
- <Zd4> For the consecutive variant: is the name of the fourth destination scalable vector register of a multi-vector sequence, encoded as "Zd" times 4 plus 3.  
For the strided variant: is the name of the fourth destination scalable vector register Z12-Z15 or Z28-Z31 of a multi-vector sequence, encoded as "D:'11':Zd".
- <Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.
- <index> Is the vector segment index, in the range 0 to 3, encoded in the "i2" field.

## Operation

```

CheckStreamingSVEEnabled();
CheckSMEZT0Enabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer segments = esize DIV (isize * nreg);
integer segment = imm MOD segments;
bits(VL) indexes = Z[n, VL];
bits(512) table = ZT0[512];

for r = 0 to nreg-1
    integer base = (segment * nreg + r) * elements;
    bits(VL) result;
    for e = 0 to elements-1
        integer index = UInt(Elem[indexes, base+e, isize]);
        Elem[result, e, esize] = Elem[table, index, 32]<esize-1:0>;
    Z[d, VL] = result;
    d = d + dstride;

```

MOV (array to vector, four registers)

Move four ZA single-vector groups to four vector registers

The instruction operates on four ZA single-vector groups. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This is an alias of [MOVA \(array to vector, four registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(array to vector, four registers\)](#).
- The description of [MOVA \(array to vector, four registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	Rv		0	1	1	0	0	off3			Zd		0		0

MOV { <Zd1>.D-<Zd4>.D }, ZA.D[<Wv>, <offs>{, VGx4}]

is equivalent to

MOVA { <Zd1>.D-<Zd4>.D }, ZA.D[<Wv>, <offs>{, VGx4}]

and is always the preferred disassembly.

Assembler Symbols

- <Zd1> Is the name of the first destination scalable vector register of a multi-vector sequence, encoded as "Zd" times 4.
- <Zd4> Is the name of the fourth destination scalable vector register of a multi-vector sequence, encoded as "Zd" times 4 plus 3.
- <Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
- <offs> Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.

Operation

The description of [MOVA \(array to vector, four registers\)](#) gives the operational pseudocode for this instruction.

Operational information

If FEAT\_SVE2 is implemented or FEAT\_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v33.64, AdvSIMD v29.12, pseudocode v2023-06\_rel, sve v2023-06\_rel ; Build timestamp: 2023-07-04T19:42

# MOV (array to vector, two registers)

Move two ZA single-vector groups to two vector registers

The instruction operates on two ZA single-vector groups. The vector numbers forming the single-vector group within each half of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half the number of ZA array vectors.

The VECTOR GROUP symbol VGx2 indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This is an alias of [MOVA \(array to vector, two registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(array to vector, two registers\)](#).
- The description of [MOVA \(array to vector, two registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

## MOV (tile to vector, four registers)

Move four ZA tile slices to four vector registers

The instruction operates on four consecutive horizontal or vertical slices within a named ZA tile of the specified element size.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 4 in the range 0 to the number of elements in a 128-bit vector segment minus 4.

This instruction is unpredicated.

This is an alias of [MOVA \(tile to vector, four registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(tile to vector, four registers\)](#).
- The description of [MOVA \(tile to vector, four registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

### 8-bit

MOV (vector to array, four registers)

Move four vector registers to four ZA single-vector groups

The instruction operates on four ZA single-vector groups. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This is an alias of [MOVA \(vector to array, four registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(vector to array, four registers\)](#).
- The description of [MOVA \(vector to array, four registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

and is always the preferred disassembly.

Assembler Symbols

- <Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
- <offs> Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.
- <Zn1> Is the name of the first scalable vector register of a multi-vector sequence, encoded as "Zn" times 2.
- <Zn2> Is the name of the second scalable vector register of a multi-vector sequence, encoded as "Zn" times 2 plus 1.

Operation

The description of [MOVA \(vector to array, two registers\)](#) gives the operational pseudocode for this instruction.

Operational information

- If FEAT\_SVE2 is implemented or FEAT\_SME is implemented, then if PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
  - The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

## MOV (vector to tile, four registers)

Move four vector registers to four ZA tile slices

The instruction operates on four consecutive horizontal or vertical slices within a named ZA tile of the specified element size.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 4 in the range 0 to the number of elements in a 128-bit vector segment minus 4.

This instruction is unpredicated.

This is an alias of [MOVA \(vector to tile, four registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(vector to tile, four registers\)](#).
- The description of [MOVA \(vector to tile, four registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

### 8-bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## MOVA (array to vector, four registers)

Move four ZA single-vector groups to four vector registers

The instruction operates on four ZA single-vector groups. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This instruction is used by the alias [MOV \(array to vector, four registers\)](#).

### SME2

(FEAT\_SME2)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

## MOVA (tile to vector, four registers)

Move four ZA tile slices to four vector registers

The instruction operates on four consecutive horizontal or vertical slices within a named ZA tile of the specified element size.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 4 in the range 0 to the number of elements in a 128-bit vector segment minus 4.

This instruction is unpredicated.

This instruction is used by the alias [MOV \(tile to vector, four registers\)](#).

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

## MOVA (tile to vector, single)

Move ZA tile slice to vector register

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination vector remain unmodified.

This instruction is used by the alias [MOV \(tile to vector, single\)](#).

It has encodings from 5 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) , [64-bit](#) and [128-bit](#)

# MOVA (vector to array, four registers)

Move four vector registers to four ZA single-vector groups

The instruction operates on four ZA single-vector groups. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This instruction is used by the alias [MOV \(vector to array, four registers\)](#).

## SME2 (FEAT\_SME2)

    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
  - The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

## MOVA (vector to tile, four registers)

Move four vector registers to four ZA tile slices

The instruction operates on four consecutive horizontal or vertical slices within a named ZA tile of the specified element size.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 4 in the range 0 to the number of elements in a 128-bit vector segment minus 4.

This instruction is unpredicated.

This instruction is used by the alias [MOV \(vector to tile, four registers\)](#).

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

## MOVA (vector to tile, single)

Move vector register to ZA tile slice

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination slice remain unmodified.

This instruction is used by the alias [MOV \(vector to tile, single\)](#).

It has encodings from 5 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) , [64-bit](#) and [128-bit](#)

# MOVAZ (array to vector, four registers)

Move and zero four ZA single-vector groups to vector registers

The instruction operates on four ZA single-vector groups. The ZA single-vector groups are zeroed after moving their contents to the destination vectors. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

# MOVAZ (array to vector, two registers)

Move and zero two ZA single-vector groups to vector registers

The instruction operates on two ZA single-vector groups. The ZA single-vector groups are zeroed after moving their contents to the destination vectors. The vector numbers forming the single-vector group within each half of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half the number of ZA array vectors.

The VECTOR GROUP symbol VGx2 indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

## MOVAZ (tile to vector, four registers)

Move and zero four ZA tile slices to vector registers

The instruction operates on four consecutive horizontal or vertical slices within a named ZA tile of the specified element size. The tile slices are zeroed after moving their contents to the destination vectors.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 4 in the range 0 to the number of elements in a 128-bit vector segment minus 4.

This instruction is unpredicated.

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

RDSVL

Read multiple of Streaming SVE vector register size to scalar register

Multiply the Streaming SVE vector register size in bytes by an immediate in the range -32 to 31 and place the result in the 64-bit destination general-purpose register.  
This instruction does not require the PE to be in Streaming SVE mode.

## SDOT (2-way, multiple and indexed vector)

Multi-vector signed integer dot-product by indexed element

The signed integer dot product instruction computes the dot product of two signed 16-bit integer values held in each 32-bit element of the two or four first source vectors and two signed 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## SDOT (4-way, multiple and indexed vector)

Multi-vector signed integer dot-product by indexed element

The signed integer dot product instruction computes the dot product of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 4 classes: [Two ZA single-vectors of 32-bit elements](#) , [Two ZA single-vectors of 64-bit elements](#) , [Four ZA single-vectors of 32-bit elements](#) and [Four ZA single-vectors of 64-bit elements](#)

for r = 0 to nreg-1
    Z[d+r, VL] = results[r];

```

## Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

## SMLAL (multiple and indexed vector)

Multi-vector signed integer multiply-add long by indexed element

This signed integer multiply-add long instruction multiplies each signed 16-bit element in the one, two, or four first source vectors with each signed 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

## SMLAL (multiple vectors)

Multi-vector signed integer multiply-add long

This signed integer multiply-add long instruction multiplies each signed 16-bit element in the two or four first source vectors with each signed 16-bit element in the two or four second source vectors, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups. The lowest of the two consecutive vector numbers forming the double-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

## SMLALL (multiple and indexed vector)

Multi-vector signed integer multiply-add long-long by indexed element

This signed integer multiply-add long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: [One ZA quad-vector of 32-bit elements](#) , [One ZA quad-vector of 64-bit elements](#) , [Two ZA quad-vectors of 32-bit elements](#) , [Two ZA quad-vectors of 64-bit elements](#) , [Four ZA quad-vectors of 32-bit elements](#) and [Four ZA quad-vectors of 64-bit elements](#)

SMLALL (multiple vectors)

Multi-vector signed integer multiply-add long-long

This signed integer multiply-add long-long instruction multiplies each signed 8-bit or 16-bit element in the two or four first source vectors with each signed 8-bit or 16-bit element in the one, two, or four second source vectors, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

## SMLS (multiple and indexed vector)

Multi-vector signed integer multiply-subtract long by indexed element

This signed integer multiply-subtract long instruction multiplies each signed 16-bit element in the one, two, or four first source vectors with each signed 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

# SMLSLL (multiple and indexed vector)

Multi-vector signed integer multiply-subtract long-long by indexed element

This signed integer multiply-subtract long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

## SMLSLL (multiple and single vector)

Multi-vector signed integer multiply-subtract long-long by vector

This signed integer multiply-subtract long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit element in the second source vector, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

SMOPA (2-way)

Signed integer sum of outer products and accumulate

This instruction works with a 32-bit element ZA tile.

The signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds SVLS×2 sub-matrix of signed 16-bit integer values, and the second source holds 2×SVLS sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting SVLS×SVLS widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVLS×2 sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVLS sub-matrix.

SMOPA (4-way)

Signed integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of signed 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of signed 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

        Elem[result, r*elements + e, esize] = UnsignedSat(res, esize);

Z[d, VL] = result;
```

SQRSHRUN

Multi-vector signed saturating rounding shift right unsigned narrow by immediate and interleave

Shift right by an immediate value, the signed integer value in each element of the four source vectors and place the four-way interleaved rounded results in the quarter-width destination elements. Each result element is saturated to the quarter-width N-bit element's unsigned integer range 0 to (2<sup>N</sup>)-1. The immediate shift amount is an unsigned value in the range 1 to number of bits per source element.

This instruction is unpredicated.

SME2  
(FEAT\_SME2)

```
SQRSHRUN <Zd>.<T>, { <Zn1>.<Tb>--<Zn4>.<Tb> }, #<const>
```

```
if !HaveSME2() then UNDEFINED;
if tsize == '00' then UNDEFINED;
constant integer esize = 8 << HighestSetBit(tsize);
integer n = UInt(Zn:'00');
integer d = UInt(Zd);
integer shift = (8 * esize) - UInt(tsize:imm5);
```

Assembler Symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in "tsize":

tsize	<T>
00	RESERVED
01	B
1x	H

# ST1B (scalar plus immediate, strided registers)

Contiguous store of bytes from multiple strided vectors (immediate index)

Contiguous store of bytes from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

## Two registers (FEAT\_SME2)

ST1B { <Zt1>.B, <Zt2>.B }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 2;
integer tstride = 8;
integer t = UInt(T:'0':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

## Four registers (FEAT\_SME2)

ST1B { <Zt1>.B, <Zt2>.B, <Zt3>.B, <Zt4>.B }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 4;
integer tstride = 4;
integer t = UInt(T:'00':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

## Assembler Symbols

- <Zt1> For the two registers variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as "T:'0':Zt".  
For the four registers variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as "T:'00':Zt".
- <Zt2> For the two registers variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as "T:'1':Zt".  
For the four registers variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as "T:'01':Zt".
- <Zt3> Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".

<Zt4>	Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".
<PNg>	Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the two registers variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the "imm4" field.  For the four registers variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.

## Operation

```

CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
constant integer mbytes = esize DIV 8;
bits(64) base;

ST1B (scalar plus scalar, tile slice)

Contiguous store of bytes from 8-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 8-bit elements in a vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is added to the base address. Inactive elements are not written to memory.

SME
(FEAT\_SME)

ST1B { ZA0<HV>.B[<Ws>, <offs>] }, <Pg>, [<Xn|SP>{, <Xm>}]

```
if !HaveSME() then UNDEFINED;
integer n = UInt(Rn);

ST1D (scalar plus scalar, tile slice)

Contiguous store of doublewords from 64-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 64-bit elements in a vector. The immediate offset is in the range 0 to 1. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 8 and added to the base address. Inactive elements are not written to memory.

SME
(FEAT\_SME)

ST1D { <ZAt><HV>.D[<Ws>, <offs>] }, <Pg>, [<Xn|SP>{, <Xm>, LSL #3}]

```
if !HaveSME() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt('0':Pg);
integer s = UInt('011':Rs);
integer t = UInt(ZAt);
integer offset = UInt(o1);
constant integer esize = 64;
boolean vertical = V == '1';
```

Assembler Symbols

- <ZAt> Is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAt" field.
- <HV> Is the horizontal or vertical slice indicator, encoded in "V":

V	<HV>
0	H
1	V
- <Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
- <offs> Is the slice index offset, in the range 0 to 1, encoded in the "o1" field.
- <Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Xm> Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the "Rm" field.

## Operation

```
CheckStreamingSVEAndZAAEnabled();

## ST1W (scalar plus immediate, strided registers)

Contiguous store of words from multiple strided vectors (immediate index)

Contiguous store of words from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

(FEAT\_SME2)

**ST1W** { <Zt1>.S, <Zt2>.S }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 2;
integer tstride = 8;
integer t = UInt(T:'0':Zt);
constant integer esize = 32;
integer offset = SInt(imm4);
```

### Four registers

(FEAT\_SME2)

**ST1W** { <Zt1>.S, <Zt2>.S, <Zt3>.S, <Zt4>.S }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 4;
integer tstride = 4;
integer t = UInt(T:'00':Zt);
constant integer esize = 32;
integer offset = SInt(imm4);
```

### Assembler Symbols

- <Zt1> For the two registers variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as "T:'0':Zt".  
For the four registers variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as "T:'00':Zt".
- <Zt2> For the two registers variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as "T:'1':Zt".  
For the four registers variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as "T:'01':Zt".
- <Zt3> Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".

<Zt4>	Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".
<PNg>	Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the two registers variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the "imm4" field.  For the four registers variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.

ST1W (scalar plus scalar, tile slice)

Contiguous store of words from 32-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 32-bit elements in a vector. The immediate offset is in the range 0 to 3. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 4 and added to the base address. Inactive elements are not written to memory.

SME
(FEAT\_SME)

ST1W { <ZAt><HV>.S[<Ws>, <offs>] }, <Pg>, [<Xn|SP>{, <Xm>, LSL #2}]

```
if !HaveSME() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt('0':Pg);
integer s = UInt('011':Rs);
integer t = UInt(ZAt);
integer offset = UInt(off2);
constant integer esize = 32;
boolean vertical = V == '1';
```

Assembler Symbols

- <ZAt> Is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAt" field.
- <HV> Is the horizontal or vertical slice indicator, encoded in "V":

V	<HV>
0	H
1	V
- <Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
- <offs> Is the slice index offset, in the range 0 to 3, encoded in the "off2" field.
- <Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Xm> Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the "Rm" field.

## Operation

STR (vector)

Store ZA array vector

The ZA array vector is selected by the sum of the vector select register and immediate offset, modulo the number of bytes in a Streaming SVE vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base, plus the same optional immediate offset multiplied by the current vector length in bytes. This instruction is unpredicated.

The store is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

## SUDOT (multiple and indexed vector)

Multi-vector signed by unsigned integer dot-product by indexed elements

The signed by unsigned integer dot product instruction computes the dot product of four signed 8-bit integer values held in each 32-bit element of the two or four first source vectors and four unsigned 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

SUMLALL (multiple and indexed vector)

Multi-vector signed by unsigned integer multiply-add long-long by indexed element

This signed by unsigned integer multiply-add long-long instruction multiplies each signed 8-bit element in the one, two, or four first source vectors with each unsigned 8-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The element index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 4 bits. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

SUMOPA

Signed by unsigned integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed by unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of signed 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of signed 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate registers contain the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate registers contain the same value for each execution.
  - The values of the NZCV flags.

SUMOPS

Signed by unsigned integer sum of outer products and subtract

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed by unsigned integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of signed 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of signed 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate registers contain the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate registers contain the same value for each execution.
  - The values of the NZCV flags.

SUNPK

Unpack and sign-extend multi-vector elements

Unpack elements from one or two source vectors and then sign-extend them to place in elements of twice their size within the two or four destination vectors.

This instruction is unpredicated.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

Two registers  
(FEAT\_SME2)

SUNPK { <Zd1>.<T>-<Zd2>.<T> }, <Zn>.<Tb>

```
if !HaveSME2() then UNDEFINED;
if size == '00' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn);
integer d = UInt(Zd:'0');
constant integer nreg = 2;
boolean unsigned = FALSE;
```

Four registers  
(FEAT\_SME2)

SUNPK { <Zd1>.<T>-<Zd4>.<T> }, { <Zn1>.<Tb>-<Zn2>.<Tb> }

```
if !HaveSME2() then UNDEFINED;
if size == '00' then UNDEFINED;
constant integer esize = 8 << UInt(size);
integer n = UInt(Zn:'0');
integer d = UInt(Zd:'00');
constant integer nreg = 4;
boolean unsigned = FALSE;
```

Assembler Symbols

- <Zd1>
- For the two registers variant: is the name of the first destination scalable vector register of a multi-vector sequence, encoded as "Zd" times 2.
- For the four registers variant: is the name of the first destination scalable vector register of a multi-vector sequence, encoded as "Zd" times 4.

<T> Is the size specifier, encoded in "size":

size	<T>
00	RESERVED
01	H
10	S
11	D

<Zd4> Is the name of the fourth destination scalable vector register of a multi-vector sequence, encoded as "Zd" times 4 plus 3.

- <Zn1> Is the name of the first scalable vector register of a multi-vector sequence, encoded as "Zn" times 2.
- <Zd2> Is the name of the second destination scalable vector register of a multi-vector sequence, encoded as "Zd" times 2 plus 1.
- <Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.
- <Tb> Is the size specifier, encoded in "size":

size	<Tb>
00	RESERVED
01	B
10	H
11	S

- <Zn2> Is the name of the second scalable vector register of a multi-vector sequence, encoded as "Zn" times 2 plus 1.

### Operation

```

CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;

SUVDOT

Multi-vector signed by unsigned integer vertical dot-product by indexed element

The signed by unsigned integer vertical dot product instruction computes the vertical dot product of the corresponding signed 8-bit elements from the four first source vectors and four unsigned 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

# SVDOT (4-way)

Multi-vector signed integer vertical dot-product by indexed element

The signed integer vertical dot product instruction computes the vertical dot product of the corresponding four signed 8-bit or 16-bit integer values held in the four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group.

The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

## 32-bit (FEAT\_SME2)

## UDOT (2-way, multiple and indexed vector)

Multi-vector unsigned integer dot-product by indexed element

The unsigned integer dot product instruction computes the dot product of two unsigned 16-bit integer values held in each 32-bit element of the two or four first source vectors and two unsigned 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

### Assembler Symbols

- <Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
- <offs> Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.
- <Zn1> For the two ZA single-vectors variant: is the name of the first scalable vector register of a multi-vector sequence, encoded as "Zn" times 2.

For the four ZA single-vectors variant: is the name of the first scalable vector register of a multi-vector sequence, encoded as "Zn" times 4.

- <Zn4> Is the name of the fourth scalable vector register of a multi-vector sequence, encoded as "Zn" times 4 plus 3.
- <Zn2> Is the name of the second scalable vector register of a multi-vector sequence, encoded as "Zn" times 2 plus 1.
- <Zm> Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.
- <index> Is the immediate index of a group of two 16-bit elements within each 128-bit vector segment, in the range 0 to 3, encoded in the "i2" field.

## Operation

## UDOT (2-way, multiple and single vector)

Multi-vector unsigned integer dot-product by vector

The unsigned integer dot product instruction computes the dot product of two unsigned 16-bit integer values held in each 32-bit element of the two or four first source vectors and two unsigned 16-bit integer values in the corresponding 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## UDOT (4-way, multiple and indexed vector)

Multi-vector unsigned integer dot-product by indexed element

The unsigned integer dot product instruction computes the dot product of four unsigned 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four unsigned 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unreplicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 4 classes: [Two ZA single-vectors of 32-bit elements](#) , [Two ZA single-vectors of 64-bit elements](#) , [Four ZA single-vectors of 32-bit elements](#) and [Four ZA single-vectors of 64-bit elements](#)

```

Assembler Symbols

<T> Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the “Rv” field.

- <offs>

Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.
- <Zn1>

Is the name of the first scalable vector register of a multi-vector sequence, encoded as "Zn".
- <Tb>

Is the size specifier, encoded in "sz":

sz	<Tb>
0	B
1	H
- <Zn4>

Is the name of the fourth scalable vector register of a multi-vector sequence, encoded as "Zn" plus 3 modulo 32.
- <Zn2>

Is the name of the second scalable vector register of a multi-vector sequence, encoded as "Zn" plus 1 modulo 32.
- <Zm>

Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.

Operation

```

CheckStreamingSVEAndZAAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer vectors = VL DIV 8;
integer vstride = vectors DIV nreg;
bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;

for r = 0 to nreg-1
  bits(VL) operand1 = Z[(n+r) MOD 32, VL];
  bits(VL) operand2 = Z[m, VL];
  bits(VL) operand3 = ZAvector[vec, VL];
  for e = 0 to elements-1
    bits(esize) sum = Elem[operand3, e, esize];
    for i = 0 to 3
      integer element1 = UInt(Elem[operand1, 4 * e + i, esize DIV 4]);
      integer element2 = UInt(Elem[operand2, 4 * e + i, esize DIV 4]);
      sum = sum + element1 * element2;
    Elem[result, e, esize] = sum;
  ZAvector[vec, VL] = result;
  vec = vec + vstride;

```

UDOT (4-way, multiple vectors)

Multi-vector unsigned integer dot-product

The unsigned integer dot product instruction computes the dot product of four unsigned 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four unsigned 8-bit or 16-bit integer values in the corresponding 32-bit or 64-bit element of the two or four second source vectors. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors. The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated. ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented. It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

Two ZA single-vectors

## UMLAL (multiple and indexed vector)

Multi-vector unsigned integer multiply-add long by indexed element

This unsigned integer multiply-add long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

## Assembler Symbols

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs1>	For the one ZA double-vector variant: is the vector select offset, pointing to first of two consecutive vectors, encoded as "off3" field times 2.  For the four ZA double-vectors and two ZA double-vectors variant: is the vector select offset, pointing to first of two consecutive vectors, encoded as "off2" field times 2.
<offs2>	For the one ZA double-vector variant: is the vector select offset, pointing to last of two consecutive vectors, encoded as "off3" field times 2 plus 1.  For the four ZA double-vectors and two ZA double-vectors variant: is the vector select offset, pointing to last of two consecutive vectors, encoded as "off2" field times 2 plus 1.
<Zn>	Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zn1>	For the two ZA double-vectors variant: is the name of the first scalable vector register of a multi-vector sequence, encoded as "Zn" times 2.  For the four ZA double-vectors variant: is the name of the first scalable vector register of a multi-vector sequence, encoded as "Zn" times 4.
<Zn4>	Is the name of the fourth scalable vector register of a multi-vector sequence, encoded as "Zn" times 4 plus 3.
<Zn2>	Is the name of the second scalable vector register of a multi-vector sequence, encoded as "Zn" times 2 plus 1.
<Zm>	Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.
<index>	Is the element index, in the range 0 to 7, encoded in the "i3h:i3l" fields.

## Operation

```
CheckStreamingSVEAndZAAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer vectors = VL DIV 8;
integer vstride = vectors DIV nreg;
integer eltspersegment = 128 DIV esize;
bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;
vec = vec - (vec MOD 2);

for r = 0 to nreg-1
  bits(VL) operand1 = Z[n+r, VL];
  bits(VL) operand2 = Z[m, VL];
  for i = 0 to 1
    bits(VL) operand3 = ZAvector[vec + i, VL];
    for e = 0 to elements-1
      integer segmentbase = e - (e MOD eltspersegment);
      integer s = 2 * segmentbase + index;
      integer element1 = UInt(Elem[operand1, 2 * e + i, esize DIV 2]);
      integer element2 = UInt(Elem[operand2, s, esize DIV 2]);
      bits(esize) product = (element1 * element2)<esize-1:0>;
      Elem[result, e, esize] = Elem[operand3, e, esize] + product;
    ZAvector[vec + i, VL] = result;
  vec = vec + vstride;
```

## Operational information

# UMLAL (multiple and single vector)

Multi-vector unsigned integer multiply-add long by vector

This unsigned integer multiply-add long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit element in the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

## UMLALL (multiple and indexed vector)

Multi-vector unsigned integer multiply-add long-long by indexed element

This unsigned integer multiply-add long-long instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors with each unsigned 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: [One ZA quad-vector of 32-bit elements](#) , [One ZA quad-vector of 64-bit elements](#) , [Two ZA quad-vectors of 32-bit elements](#) , [Two ZA quad-vectors of 64-bit elements](#) , [Four ZA quad-vectors of 32-bit elements](#) and [Four ZA quad-vectors of 64-bit elements](#)

# UMLALL (multiple and single vector)

Multi-vector unsigned integer multiply-add long-long by vector

This unsigned integer multiply-add long-long instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors with each unsigned 8-bit or 16-bit element in the second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

## UMLSL (multiple and indexed vector)

Multi-vector unsigned integer multiply-subtract long by indexed element

This unsigned integer multiply-subtract long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

## UMLSL (multiple and single vector)

Multi-vector unsigned integer multiply-subtract long by vector

This unsigned integer multiply-subtract long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit element in the second source vector, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

### One ZA double-vector

# UMLSLL (multiple and indexed vector)

Multi-vector unsigned integer multiply-subtract long-long by indexed element

This unsigned integer multiply-subtract long-long instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors with each unsigned 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: [One ZA quad-vector of 32-bit elements](#) , [One ZA quad-vector of 64-bit elements](#) , [Two ZA quad-vectors of 32-bit elements](#) , [Two ZA quad-vectors of 64-bit elements](#) , [Four ZA quad-vectors of 32-bit elements](#) and [Four ZA quad-vectors of 64-bit elements](#)

UMLSLL (multiple vectors)

Multi-vector unsigned integer multiply-subtract long-long

This unsigned integer multiply-subtract long-long instruction multiplies each unsigned 8-bit or 16-bit element in the two or four first source vectors with each unsigned 8-bit or 16-bit element in the one, two, or four second source vectors, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

UMOPA (2-way)

Unsigned integer sum of outer products and accumulate

This instruction works with a 32-bit element ZA tile.

The unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds SVLS×2 sub-matrix of unsigned 16-bit integer values, and the second source holds 2×SVLS sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting SVLS×SVLS widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVLS×2 sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVLS sub-matrix.

## UMOPA (4-way)

Unsigned integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of unsigned 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of unsigned 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

UMOPS (4-way)

Unsigned integer sum of outer products and subtract

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVL<sub>S</sub>×4 sub-matrix of unsigned 8-bit integer values, and the second source holds 4×SVL<sub>S</sub> sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVL<sub>D</sub>×4 sub-matrix of unsigned 16-bit integer values, and the second source holds 4×SVL<sub>D</sub> sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVL<sub>S</sub>×SVL<sub>S</sub> widened 32-bit integer or SVL<sub>D</sub>×SVL<sub>D</sub> widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL<sub>S</sub>×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL<sub>S</sub> sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL<sub>D</sub>×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL<sub>D</sub> sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

32-bit

# USDOT (multiple and indexed vector)

Multi-vector unsigned by signed integer dot-product by indexed element

The unsigned by signed integer dot product instruction computes the dot product of four unsigned 8-bit integer values held in each 32-bit element of the two or four first source vectors and four signed 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

## USDOT (multiple and single vector)

Multi-vector unsigned by signed integer dot-product by vector

The unsigned by signed integer dot product instruction computes the dot product of four unsigned 8-bit integer values held in each 32-bit element of the two or four first source vectors and four signed 8-bit integer values in the corresponding 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## USMLALL (multiple and indexed vector)

Multi-vector unsigned by signed integer multiply-add long-long by indexed element

This unsigned by signed integer multiply-add long-long instruction multiplies each unsigned 8-bit element in the one, two, or four first source vectors with each signed 8-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The element index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 4 bits. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

## USMLALL (multiple vectors)

Multi-vector unsigned by signed integer multiply-add long-long

This unsigned by signed integer multiply-add long-long instruction multiplies each unsigned 8-bit element in the two or four first source vectors with each signed 8-bit element in the two or four second source vectors, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

USMOPA

Unsigned by signed integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned by signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of unsigned 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of unsigned 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

USVDDOT

Multi-vector unsigned by signed integer vertical dot-product by indexed element

The unsigned by signed integer vertical dot product instruction computes the vertical dot product of corresponding unsigned 8-bit elements from the four first source vectors and four signed 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

UVDOT (2-way)

Multi-vector unsigned integer vertical dot-product by indexed element

The unsigned integer vertical dot product instruction computes the vertical dot product of the corresponding two unsigned 16-bit integer values held in the two first source vectors and two unsigned 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The vector numbers forming the single-vector group within each half of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half the number of ZA array vectors.

The VECTOR GROUP symbol VGx2 indicates that the ZA operand consists of two ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

## UVDOT (4-way)

Multi-vector unsigned integer vertical dot-product by indexed element

The unsigned integer vertical dot product instruction computes the vertical dot product of the corresponding four unsigned 8-bit or 16-bit integer values held in the four first source vectors and four unsigned 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group.

The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

### 32-bit (FEAT\_SME2)

1	1	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	Rv	0	0	0	0	0	0	0	0	0	0	0	0	0	01

**ZERO** ZA.D[<Wv>, <offs1>:<offs4>, VGx2]

```
if !HaveSME2p1() then UNDEFINED;
integer v = UInt('010':Rv);
integer offset = UInt(o1:'00');
constant integer ngrp = 2;
constant integer nvec = 4;
```

### Four ZA quad-vectors

(FEAT\_SME2p1)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	Rv	0	0	0	0	0	0	0	0	0	0	0	0	0	01

**ZERO** ZA.D[<Wv>, <offs1>:<offs4>, VGx4]

```
if !HaveSME2p1() then UNDEFINED;
integer v = UInt('010':Rv);
integer offset = UInt(o1:'00');
constant integer ngrp = 4;
constant integer nvec = 4;
```

## Assembler Symbols

- <Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
- <offs1> For the one ZA quad-vector variant: is the vector select offset, pointing to first of four consecutive vectors, encoded as "off2" field times 4.

For the four ZA quad-vectors and two ZA quad-vectors variant: is the vector select offset, pointing to first of four consecutive vectors, encoded as "o1" field times 4.

<offs4>

For the one ZA quad-vector variant: is the vector select offset, pointing to last of four consecutive vectors, encoded as "off2" field times 4 plus 3.

For the four ZA quad-vectors and two ZA quad-vectors variant: is the vector select offset, pointing to last of four consecutive vectors, encoded as "o1" field times 4 plus 3.

## Operation

```
CheckStreamingSVEAndZAAEnabled();
constant integer VL = CurrentVL;
integer vectors = VL DIV 8;
integer vstride = vectors DIV ngrp;
bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
vec = vec - (vec MOD nvec);

for r = 0 to ngrp-1
  for i = 0 to nvec-1
    ZAvector[vec + i, VL] = Zeros(VL);
  vec = vec + vstride;
```

## Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

## ZERO (single-vector)

Zero ZA single-vector groups

The instruction zeroes two or four ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

### Two ZA single-vectors

(FEAT\_SME2p1)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ZERO (tile)

Zero a list of 64-bit element ZA tiles

Zeroes all bytes within each of the up to eight listed 64-bit element tiles named ZA0.D to ZA7.D, leaving the other 64-bit element tiles unmodified.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

For programmer convenience an assembler must also accept the names of 32-bit, 16-bit, and 8-bit element tiles which are converted into the corresponding set of 64-bit element tiles.

In accordance with the architecturally defined mapping between different element size tiles:

- Zeroing the 8-bit element tile name ZA0.B, or the entire array name ZA, is equivalent to zeroing all eight 64-bit element tiles named ZA0.D to ZA7.D.
- Zeroing the 16-bit element tile name ZA0.H is equivalent to zeroing 64-bit element tiles named ZA0.D, ZA2.D, ZA4.D, and ZA6.D.
- Zeroing the 16-bit element tile name ZA1.H is equivalent to zeroing 64-bit element tiles named ZA1.D, ZA3.D, ZA5.D, and ZA7.D.
- Zeroing the 32-bit element tile name ZA0.S is equivalent to zeroing 64-bit element tiles named ZA0.D and ZA4.D.
- Zeroing the 32-bit element tile name ZA1.S is equivalent to zeroing 64-bit element tiles named ZA1.D and ZA5.D.
- Zeroing the 32-bit element tile name ZA2.S is equivalent to zeroing 64-bit element tiles named ZA2.D and ZA6.D.
- Zeroing the 32-bit element tile name ZA3.S is equivalent to zeroing 64-bit element tiles named ZA3.D and ZA7.D.

The preferred disassembly of this instruction uses the shortest list of tile names that represent the encoded immediate mask.

For example:

- An immediate which encodes 64-bit element tiles ZA0.D, ZA1.D, ZA4.D, and ZA5.D is disassembled as {ZA0.S, ZA1.S}.
- An immediate which encodes 64-bit element tiles ZA0.D, ZA2.D, ZA4.D, and ZA6.D is disassembled as {ZA0.H}.
- An all-ones immediate is disassembled as {ZA}.
- An all-zeros immediate is disassembled as an empty list { }.

SME  
(FEAT\_SME)

## Library pseudocode for shared/functions/exclusive/ClearExclusiveByAddress

```
// ClearExclusiveByAddress()
// =====
// Clear the global Exclusives monitors for all PEs EXCEPT processorid if they
// record any part of the physical address region of size bytes starting at paddress.
// It is IMPLEMENTATION DEFINED whether the global Exclusives monitor for processorid
// is also cleared if it records any part of the address region.

ClearExclusiveByAddress(FullAddress paddress, integer processorid, integer size);
```

## Library pseudocode for shared/functions/exclusive/ClearExclusiveLocal

```
// ClearExclusiveLocal()
// =====
// Clear the local Exclusives monitor for the specified processorid.

ClearExclusiveLocal(integer processorid);
```

## Library pseudocode for shared/functions/exclusive/ExclusiveMonitorsStatus

```
// ExclusiveMonitorsStatus()
// =====
// Returns '0' to indicate success if the last memory write by this PE was to
// the same physical address region endorsed by ExclusiveMonitorsPass().
// Returns '1' to indicate failure if address translation resulted in a different
// physical address.

bit ExclusiveMonitorsStatus();
```

### Library pseudocode for shared/functions/exclusive/IsExclusiveGlobal

```
// IsExclusiveGlobal()
// =====
// Return TRUE if the global Exclusives monitor for processorid includes all of
// the physical address region of size bytes starting at paddress.

boolean IsExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

### Library pseudocode for shared/functions/exclusive/IsExclusiveLocal

```
// IsExclusiveLocal()
// =====
// Return TRUE if the local Exclusives monitor for processorid includes all of
// the physical address region of size bytes starting at paddress.

boolean IsExclusiveLocal(FullAddress paddress, integer processorid, integer size);
```

### Library pseudocode for shared/functions/exclusive/MarkExclusiveGlobal

```
// MarkExclusiveGlobal()
// =====
// Record the physical address region of size bytes starting at paddress in
// the global Exclusives monitor for processorid.

MarkExclusiveGlobal(FullAddress paddress, integer processorid, integer size);
```

### Library pseudocode for shared/functions/exclusive/MarkExclusiveLocal

```
// MarkExclusiveLocal()
// =====
// Record the physical address region of size bytes starting at paddress in
// the local Exclusives monitor for processorid.

MarkExclusiveLocal(FullAddress paddress, integer processorid, integer size);
```

### Library pseudocode for shared/functions/exclusive/ProcessorID

```
// ProcessorID()
// =====
// Return the ID of the currently executing PE.

integer ProcessorID();

// =====
// Returns TRUE if Data Gathering Hint instruction support is implemented, and
// FALSE otherwise.

boolean HaveDGHExt()
    return IsFeatureImplemented(FEAT_DGH);
```

### Library pseudocode for shared/functions/extension/HaveDITExt

```
// HaveDITExt()
// =====

boolean HaveDITExt()
    return IsFeatureImplemented(FEAT_DIT);
```

### Library pseudocode for shared/functions/extension/HaveDOTPExt

```
// HaveDOTPExt()
// =====
// Returns TRUE if Dot Product feature support is implemented, and FALSE otherwise.

boolean HaveDOTPExt()
    return IsFeatureImplemented(FEAT_DotProd);
```

### Library pseudocode for shared/functions/extension/HaveDirtyBitModifierExt

```
// HaveDirtyBitModifierExt()
// =====

boolean HaveDirtyBitModifierExt()
    return IsFeatureImplemented(FEAT_HAFDBS);
```

### Library pseudocode for shared/functions/extension/HaveDoPD

```
// HaveDoPD()
// =====
// Returns TRUE if Debug Over Power Down extension
// support is implemented and FALSE otherwise.

boolean HaveDoPD()
    return IsFeatureImplemented(FEAT_DoPD);
```

### Library pseudocode for shared/functions/extension/HaveDoubleFault2Ext

```
// HaveDoubleFault2Ext()
// =====
// Returns TRUE if support for the DoubleFault2 feature is implemented, and FALSE otherwise.

boolean HaveDoubleFault2Ext()
    return IsFeatureImplemented(FEAT_DoubleFault2);
```

### Library pseudocode for shared/functions/extension/HaveDoubleFaultExt

```
// HaveDoubleFaultExt()
// =====

boolean HaveDoubleFaultExt()
    return IsFeatureImplemented(FEAT_DoubleFault);
```

### Library pseudocode for shared/functions/extension/HaveDoubleLock

```
// HaveDoubleLock()
// =====
// Returns TRUE if support for the OS Double Lock is implemented.

boolean HaveDoubleLock()
    return IsFeatureImplemented(FEAT_DoubleLock);
```

### Library pseudocode for shared/functions/extension/HaveE0PDExt

```
// HaveE0PDExt()
// =====
// Returns TRUE if support for constant fault times for unprivileged accesses
// to the memory map is implemented.

boolean HaveE0PDExt()
    return IsFeatureImplemented(FEAT_E0PD);
```

### Library pseudocode for shared/functions/extension/HaveEBF16

```
// HaveEBF16()
// =====
// Returns TRUE if the EBF16 extension is implemented, FALSE otherwise.

boolean HaveEBF16()
    return IsFeatureImplemented(FEAT_EBF16);
```

### Library pseudocode for shared/functions/extension/HaveECVExt

```
// HaveECVExt()
// =====
// Returns TRUE if Enhanced Counter Virtualization extension
// support is implemented, and FALSE otherwise.

boolean HaveECVExt()
    return IsFeatureImplemented(FEAT_ECV);
```

### Library pseudocode for shared/functions/extension/HaveETExt

```
// HaveETExt()
// =====
// Returns TRUE if Embedded Trace Extension is implemented, and FALSE otherwise.

boolean HaveETExt()
    return IsFeatureImplemented(FEAT_ETE);
```

### Library pseudocode for shared/functions/extension/HaveExtendedCacheSets

```
// HaveExtendedCacheSets()
// =====

### Library pseudocode for shared/functions/extension/HaveFeatMEC

```
// HaveFeatMEC()
// =====
// Returns TRUE if Memory Encryption Contexts are implemented, and FALSE otherwise.

boolean HaveFeatMEC()
    return IsFeatureImplemented(FEAT_MEC);
```

### Library pseudocode for shared/functions/extension/HaveFeatMOPS

```
// HaveFeatMOPS()
// =====
// Returns TRUE if the CPY* and SET* instructions are supported, and FALSE otherwise.

boolean HaveFeatMOPS()
    return IsFeatureImplemented(FEAT_MOPS);
```

### Library pseudocode for shared/functions/extension/HaveFeatNMI

```
// HaveFeatNMI()
// =====
// Returns TRUE if the Non-Maskable Interrupt extension is
// implemented, and FALSE otherwise.

boolean HaveFeatNMI()
    return IsFeatureImplemented(FEAT_NMI);
```

### Library pseudocode for shared/functions/extension/HaveFeatRPRES

```
// HaveFeatRPRES()
// =====
// Returns TRUE if reciprocal estimate implements 12-bit precision
// when FPCR.AH=1, and FALSE otherwise.

boolean HaveFeatRPRES()
    return IsFeatureImplemented(FEAT_RPRES);
```

### Library pseudocode for shared/functions/extension/HaveFeatSCTLR2

```
// HaveFeatSCTLR2()
// =====
// Returns TRUE if SCTLR2 extension
// support is implemented and FALSE otherwise.

boolean HaveFeatSCTLR2()
    return IsFeatureImplemented(FEAT_SCTLR2);
```

### Library pseudocode for shared/functions/extension/HaveFeatTCR2

```
// HaveFeatTCR2()
// =====
// Returns TRUE if TCR2 extension
// support is implemented and FALSE otherwise.

boolean HaveFeatTCR2()
    return IsFeatureImplemented(FEAT_TCR2);
```

### Library pseudocode for shared/functions/extension/HaveFeatTIDCP1

```
// HaveFeatTIDCP1()
// =====
// Returns TRUE if the SCTLR_EL1.TIDCP bit is implemented and the SCTLR_EL2.TIDCP bit
// is implemented if EL2 is implemented.

boolean HaveFeatTIDCP1()
    return IsFeatureImplemented(FEAT_TIDCP1);
```

### Library pseudocode for shared/functions/extension/HaveFeatTRBEEExt

```
// HaveFeatTRBEEExt()
// =====
// Returns TRUE if the Trace Buffer Extension external mode is implemented, and FALSE otherwise.

boolean HaveFeatTRBEEExt()
    return IsFeatureImplemented(FEAT_TRBE_EXT);
```

### Library pseudocode for shared/functions/extension/HaveFeatWFxT

```
// HaveFeatWFxT()
// =====
// Returns TRUE if WFET and WFIT instruction support is implemented,
// and FALSE otherwise.

boolean HaveFeatWFxT()
    return IsFeatureImplemented(FEAT_WFxT);
```

### Library pseudocode for shared/functions/extension/HaveFeatXS

```
// HaveFeatXS()
// =====
// Returns TRUE if XS attribute and the TLBI and DSB instructions with nXS qualifier
// are supported, and FALSE otherwise.

boolean HaveFeatXS()
    return IsFeatureImplemented(FEAT_XS);
```

### Library pseudocode for shared/functions/extension/HaveFlagFormatExt

```
// HaveFlagFormatExt()
// =====
// Returns TRUE if flag format conversion instructions implemented.

boolean HaveFlagFormatExt()
    return IsFeatureImplemented(FEAT_FlagM2);
```

### Library pseudocode for shared/functions/extension/HaveFlagManipulateExt

```
// HaveFlagManipulateExt()
// =====
// Returns TRUE if flag manipulate instructions are implemented.

boolean HaveFlagManipulateExt()
    return IsFeatureImplemented(FEAT_FlagM);
```

### Library pseudocode for shared/functions/extension/HaveFrintExt

```
// HaveFrintExt()
// =====
// Returns TRUE if FRINT instructions are implemented.

boolean HaveFrintExt()
    return IsFeatureImplemented(FEAT_FRINTTS);
```

### Library pseudocode for shared/functions/extension/HaveGCS

```
// HaveGCS()
// =====
// Returns TRUE if support for Guarded Control Stack is
// implemented, and FALSE otherwise.

boolean HaveGCS()
    return IsFeatureImplemented(FEAT_GCS);
```

### Library pseudocode for shared/functions/extension/HaveGTGExt

```
// HaveGTGExt()
// =====
// Returns TRUE if support for guest translation granule size is implemented.

boolean HaveGTGExt()
    return IsFeatureImplemented(FEAT_GTG);
```

### Library pseudocode for shared/functions/extension/HaveHPMDExt

```
// HaveHPMDExt()
// =====

### Library pseudocode for shared/functions/extension/HaveIDSExt

```
// HaveIDSExt()
// =====
// Returns TRUE if ID register handling feature is implemented.

boolean HaveIDSExt()
    return IsFeatureImplemented(FEAT_IDST);
```

### Library pseudocode for shared/functions/extension/HaveIESB

```
// HaveIESB()
// =====

boolean HaveIESB()
    return IsFeatureImplemented(FEAT_IESB);
```

### Library pseudocode for shared/functions/extension/HaveInt8MatMulExt

```
// HaveInt8MatMulExt()
// =====
// Returns TRUE if AArch64 8-bit integer matrix multiply instruction support
// implemented, and FALSE otherwise.

boolean HaveInt8MatMulExt()
    return IsFeatureImplemented(FEAT_I8MM);
```

### Library pseudocode for shared/functions/extension/HaveLRCPC3Ext

```
// HaveLRCPC3Ext()
// =====
// Returns TRUE if FEAT_LRCPC3 instructions are supported, and FALSE otherwise.

boolean HaveLRCPC3Ext()
    return IsFeatureImplemented(FEAT_LRCPC3);
```

### Library pseudocode for shared/functions/extension/HaveLSE128

```
// HaveLSE128()
// =====
// Returns TRUE if LSE128 is implemented, and FALSE otherwise.

boolean HaveLSE128()
    return IsFeatureImplemented(FEAT_LSE128);
```

### Library pseudocode for shared/functions/extension/HaveLSE2Ext

```
// HaveLSE2Ext()
// =====
// Returns TRUE if LSE2 is implemented, and FALSE otherwise.

boolean HaveLSE2Ext()
    return IsFeatureImplemented(FEAT_LSE2);
```

### Library pseudocode for shared/functions/extension/HaveMPAMExt

```
// HaveMPAMExt()
// =====
// Returns TRUE if MPAM is implemented, and FALSE otherwise.

boolean HaveMPAMExt()
    return IsFeatureImplemented(FEAT_MPAM);
```

### Library pseudocode for shared/functions/extension/HaveMPAMv0p1Ext

```
// HaveMPAMv0p1Ext()
// =====
// Returns TRUE if MPAMv0p1 is implemented, and FALSE otherwise.

boolean HaveMPAMv0p1Ext()
    return IsFeatureImplemented(FEAT_MPAMv0p1);
```

### Library pseudocode for shared/functions/extension/HaveMPAMv1p1Ext

```
// HaveMPAMv1p1Ext()
// =====
// Returns TRUE if MPAMv1p1 is implemented, and FALSE otherwise.

boolean HaveMPAMv1p1Ext()
    return IsFeatureImplemented(FEAT_MPAMv1p1);
```

### Library pseudocode for shared/functions/extension/HaveMTE2Ext

```
// HaveMTE2Ext()
// =====
// Returns TRUE if MTE support is beyond EL0, and FALSE otherwise.

boolean HaveMTE2Ext()
    return IsFeatureImplemented(FEAT_MTE2);
```

### Library pseudocode for shared/functions/extension/HaveMTE4Ext

```
// HaveMTE4Ext()
// =====
// Returns TRUE if functionality in FEAT_MTE4 is implemented, and FALSE otherwise.

boolean HaveMTE4Ext()
    return IsFeatureImplemented(FEAT_MTE4);
```

### Library pseudocode for shared/functions/extension/HaveMTEAsymFaultExt

```
// HaveMTEAsymFaultExt()
// =====
// Returns TRUE if MTE Asymmetric Fault Handling support is
// implemented, and FALSE otherwise.

boolean HaveMTEAsymFaultExt()
    return IsFeatureImplemented(FEAT_MTE4);
```

### Library pseudocode for shared/functions/extension/HaveMTEAsyncExt

```
// HaveMTEAsyncExt()
// =====
// Returns TRUE if MTE supports Asynchronous faulting, and FALSE otherwise.

boolean HaveMTEAsyncExt()
    return IsFeatureImplemented(FEAT_MTE4);
```

### Library pseudocode for shared/functions/extension/HaveMTECanonicalTagCheckingExt

```
// HaveMTECanonicalTagCheckingExt()
// =====
// Returns TRUE if MTE Canonical Tag Checking functionality is
// implemented, and FALSE otherwise.

boolean HaveMTECanonicalTagCheckingExt()
    return IsFeatureImplemented(FEAT_MTE_CANONICAL_TAGS);
```

### Library pseudocode for shared/functions/extension/HaveMTEExt

```
// HaveMTEExt()
// =====
// Returns TRUE if instruction-only MTE implemented, and FALSE otherwise.

boolean HaveMTEExt()
    return IsFeatureImplemented(FEAT_MTE);
```

### Library pseudocode for shared/functions/extension/HaveMTEPermExt

```
// HaveMTEPermExt()
// =====
// Returns TRUE if MTE_PERM implemented, and FALSE otherwise.

boolean HaveMTEPermExt()
    return IsFeatureImplemented(FEAT_MTE_PERM);
```

### Library pseudocode for shared/functions/extension/HaveMTEStoreOnlyExt

```
// HaveMTEStoreOnlyExt()
// =====
// Returns TRUE if MTE Store-only Tag Checking functionality is
// implemented, and FALSE otherwise.

boolean HaveMTEStoreOnlyExt()
    return IsFeatureImplemented(FEAT_MTE_STORE_ONLY);
```

### Library pseudocode for shared/functions/extension/HaveNV2Ext

```
// HaveNV2Ext()
// =====
// Returns TRUE if Enhanced Nested Virtualization is implemented.

boolean HaveNV2Ext()
    return IsFeatureImplemented(FEAT_NV2);
```

### Library pseudocode for shared/functions/extension/HaveNVExt

```
// HaveNVExt()
// =====
// Returns TRUE if Nested Virtualization is implemented.

boolean HaveNVExt()

## Library pseudocode for shared/functions/memory/Hint\_Prefetch

```
// Hint_Prefetch()
// =====
// Signals the memory system that memory accesses of type HINT to or from the specified address are
// likely in the near future. The memory system may take some action to speed up the memory
// accesses when they do occur, such as pre-loading the specified address into one or more
// caches as indicated by the innermost cache level target (0=L1, 1=L2, etc) and non-temporal hint
// stream. Any or all prefetch hints may be treated as a NOP. A prefetch hint must not cause a
// synchronous abort due to Alignment or Translation faults and the like. Its only effect on
// software-visible state should be on caches and TLBs associated with address, which must be
// accessible by reads, writes or execution, as defined in the translation regime of the current
// Exception level. It is guaranteed not to access Device memory.
// A Prefetch_EXEC hint must not result in an access that could not be performed by a speculative
// instruction fetch, therefore if all associated MMUs are disabled, then it cannot access any
// memory location that cannot be accessed by instruction fetches.

Hint_Prefetch(bits(64) address, PrefetchHint hint, integer target, boolean stream);

## Library pseudocode for shared/functions/unpredictable/ConstrainUnpredictable

```
// ConstrainUnpredictable()
// =====
// Return the appropriate Constraint result to control the caller's behavior.
// The return value is IMPLEMENTATION DEFINED within a permitted list for each
// UNPREDICTABLE case.
// (The permitted list is determined by an assert or case statement at the call site.)

Constraint ConstrainUnpredictable(Unpredictable which);
```

### Library pseudocode for shared/functions/unpredictable/ConstrainUnpredictableBits

```
// ConstrainUnpredictableBits()
// =====

// This is a variant of ConstrainUnpredictable for when the result can be Constraint_UNKNOWN.
// If the result is Constraint_UNKNOWN then the function also returns UNKNOWN value, but that
// value is always an allocated value; that is, one for which the behavior is not itself
// CONSTRAINED.

(Constraint,bits(width)) ConstrainUnpredictableBits(Unpredictable which, integer width);
```

### Library pseudocode for shared/functions/unpredictable/ConstrainUnpredictableBool

```
// ConstrainUnpredictableBool()
// =====
// This is a variant of the ConstrainUnpredictable function where the result is either
// Constraint_TRUE or Constraint_FALSE.

boolean ConstrainUnpredictableBool(Unpredictable which);
```

### Library pseudocode for shared/functions/unpredictable/ConstrainUnpredictableInteger

```
// ConstrainUnpredictableInteger()
// =====
// This is a variant of ConstrainUnpredictable for when the result can be Constraint_UNKNOWN.
// If the result is Constraint_UNKNOWN then the function also returns an UNKNOWN
// value in the range low to high, inclusive.

(Constraint,integer) ConstrainUnpredictableInteger(integer low, integer high,
Unpredictable which);
```

### Library pseudocode for shared/functions/unpredictable/ConstrainUnpredictableProcedure

```
// ConstrainUnpredictableProcedure()
// =====
// This is a variant of ConstrainUnpredictable that implements a Constrained
// Unpredictable behavior for a given Unpredictable situation.
// The behavior is within permitted behaviors for a given Unpredictable situation,
// these are documented in the textual part of the architecture specification.
//
// This function is expected to be refined in an IMPLEMENTATION DEFINED manner.
// The details of possible outcomes may not be present in the code and must be interpreted
// for each use with respect to the CONSTRAINED UNPREDICTABLE specifications
// for the specific area.

ConstrainUnpredictableProcedure(Unpredictable which);
```
