For the four registers variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 4.
- <T> Is the size specifier, encoded in "size":

size	<T>
00	RESERVED
01	H
10	S
11	D

- <Zdn4> Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 4 plus 3.
- <Zdn2> Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 2 plus 1.
- <Zm1> For the two registers variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 2.
- For the four registers variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 4.
- <Zm4> Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.
- <Zm2> Is the name of the second scalable vector register of the second source multi-vector group, encoded as "Zm" times 2 plus 1.

## Operation

```

CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
array [0..3] of bits(VL) results;

for r = 0 to nreg-1
    bits(VL) operand1 = Z[dn+r, VL];
    bits(VL) operand2 = Z[m+r, VL];
    for e = 0 to elements-1
        bits(esize) element1 = Elem[operand1, e, esize];
        bits(esize) element2 = Elem[operand2, e, esize];
        Elem[results[r], e, esize] = FPAbsMin(element1, element2, FPCR);

for r = 0 to nreg-1
    Z[dn+r, VL] = results[r];

```

FCLAMP

Multi-vector floating-point clamp to minimum/maximum number

Clamp each floating-point element in the two or four destination vectors to between the floating-point minimum value in the corresponding element of the first source vector and the floating-point maximum value in the corresponding element of the second source vector and destructively place the clamped results in the corresponding elements of the two or four destination vectors.

Regardless of the value of FPCR.AH, the behavior is as follows for each minimum number and maximum number operation:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is Default NaN.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

Two registers  
(FEAT\_SME2)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

# FDOT (2-way, multiple and indexed vector, FP16 to FP32)

Multi-vector half-precision floating-point dot-product by indexed element

The instruction computes the fused sum-of-products of a pair of half-precision floating-point values held in the corresponding 32-bit elements of the two or four first source vectors and the indexed 32-bit element of the second source vector, without intermediate rounding. The single-precision sum-of-products are destructively added to the corresponding single-precision elements of the ZA single-vector groups.

The half-precision floating-point pairs within the second source vector are specified using an immediate index which selects the same pair position within each 128-bit vector segment. The element index range is from 0 to 3. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## FDOT (2-way, multiple and indexed vector, FP8 to FP16)

Multi-vector 8-bit floating-point dot-product by indexed element to half-precision

The instruction computes the fused sum-of-products of a group of two 8-bit floating-point values held in the corresponding 16-bit elements of the two or four first source vectors and the indexed 16-bit element of the second source vector. The half-precision sum-of-products are scaled by  $2^{-\text{UInt}(\text{FPMR.LSCALE}[3:0])}$ , before being destructively added without intermediate rounding to the corresponding half-precision elements of the ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

The 8-bit floating-point pairs within the second source vector are specified using an immediate index which selects the same pair position within each 128-bit vector segment.

The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors. The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

## FDOT (2-way, multiple vectors, FP8 to FP16)

Multi-vector 8-bit floating-point dot-product to half-precision

The instruction computes the fused sum-of-products of a group of two 8-bit floating-point values held in the corresponding 16-bit elements of the two or four first and second source vectors. The half-precision sum-of-products are scaled by  $2^{-\text{UInt}(\text{FPMR.LSCALE}[3:0])}$ , before being destructively added without intermediate rounding to the corresponding half-precision elements of the ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors. The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## FDOT (4-way, multiple and indexed vector)

Multi-vector 8-bit floating-point dot-product by indexed element to single-precision

The instruction computes the fused sum-of-products of a group of four 8-bit floating-point values held in the corresponding 32-bit elements of the two or four first source vectors and the indexed 32-bit element of the second source vector. The single-precision sum-of-products are scaled by  $2^{-\text{UInt}(\text{FPMR.LSCALE})}$ , before being destructively added without intermediate rounding to the corresponding single-precision elements of the ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

The 8-bit floating-point groups within the second source vector are specified using an immediate index which selects the same group position within each 128-bit vector segment.

The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors. The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

FMAX (multiple and single vector)

Multi-vector floating-point maximum by vector

Determine the maximum of floating-point elements of the second source vector and the corresponding floating-point elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

# FMAX (multiple vectors)

Multi-vector floating-point maximum

Determine the maximum of floating-point elements of the two or four second source vectors and the corresponding floating-point elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

Multi-vector floating-point minimum number by vector

Determine the minimum number value of floating-point elements of the second source vector and the corresponding floating-point elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

Regardless of the value of FPCR.AH, the behavior is as follows:

- Negative zero compares less than positive zero.
- If one element is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either element is a signaling NaN or if both elements are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a signaling NaN or if both elements are NaNs, the result is Default NaN.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

## FMLA (multiple and indexed vector)

Multi-vector floating-point fused multiply-add by indexed element

Multiply the indexed element of the second source vector by the corresponding floating-point elements of the two or four first source vectors and destructively add without intermediate rounding to the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 2 bits depending on the size of the element. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.F64F64 indicates whether the double-precision variant is implemented, and

ID\_AA64SMFR0\_EL1.F16F16 indicates whether the half-precision variant is implemented.

## FMLA (multiple vectors)

Multi-vector floating-point fused multiply-add

Multiply the corresponding floating-point elements of the two or four first and second source vectors and destructively add without intermediate rounding to the corresponding elements of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.F64F64 indicates whether the double-precision variant is implemented, and

ID\_AA64SMFR0\_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: [Two ZA single-vectors](#) , [Two ZA single-vectors of half precision elements](#) , [Four ZA single-vectors](#) and [Four ZA single-vectors of half precision elements](#)

## FMLAL (multiple and indexed vector, FP16 to FP32)

Multi-vector floating-point multiply-add long by indexed element

This half-precision floating-point multiply-add long instruction widens all 16-bit half-precision elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively adds these values without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The half-precision elements within the second source vector are specified using a 3-bit immediate index which selects the same element position within each 128-bit vector segment.

The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

```

## FMLAL (multiple and indexed vector, FP8 to FP16)

Multi-vector 8-bit floating-point multiply-add long by indexed element to half-precision

This 8-bit floating-point multiply-add long instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the indexed element of the second source vector to half-precision format and multiplies the corresponding elements. The intermediate products are scaled by  $2^{-\text{UInt}(\text{FPMR.LSCALE}[3:0])}$  before being destructively added without intermediate rounding to the overlapping 16-bit half-precision elements of the ZA double-vector groups. The 8-bit floating-point elements within the second source vector are specified using a 4-bit immediate index which selects the same element position within each 128-bit vector segment.

The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors. The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

FMLAL (multiple and single vector, FP8 to FP16)

Multi-vector 8-bit floating-point multiply-add long by vector to half-precision

This 8-bit floating-point multiply-add long instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the second source vector to half-precision format and multiplies the corresponding elements. The intermediate products are scaled by  $2^{-\text{UInt}(\text{FPMR.LSCALE}[3:0])}$  before being destructively added without intermediate rounding to the overlapping 16-bit half-precision elements of the ZA double-vector groups. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors. The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated. It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

## FMLALL (multiple and indexed vector)

Multi-vector 8-bit floating-point multiply-add long-long by indexed element to single-precision

This 8-bit floating-point multiply-add long long instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format and multiplies the corresponding elements. The intermediate products are scaled by  $2^{-\text{UInt}(\text{FPMR.LSCALE})}$  before being destructively added without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA quad-vector groups.

The 8-bit floating-point elements within the second source vector are specified using a 4-bit immediate index which selects the same element position within each 128-bit vector segment.

The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors. The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

    vec = vec + vstride;
```

## FMLALL (multiple and single vector)

Multi-vector 8-bit floating-point multiply-add long-long by vector to single-precision

This 8-bit floating-point multiply-add long long instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the second source vector to single-precision format and multiplies the corresponding elements. The intermediate products are scaled by  $2^{-\text{UInt}(\text{FPMR.LSCALE})}$  before being destructively added without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA quad-vector groups.

The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors. The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

## FMLS (multiple and indexed vector)

Multi-vector floating-point fused multiply-subtract by indexed element

Multiply the indexed element of the second source vector by the corresponding floating-point elements of the two or four first source vectors and destructively subtract without intermediate rounding from the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 2 bits depending on the size of the element. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.F64F64 indicates whether the double-precision variant is implemented, and

ID\_AA64SMFR0\_EL1.F16F16 indicates whether the half-precision variant is implemented.

## FMLS (multiple vectors)

Multi-vector floating-point fused multiply-subtract

Multiply the corresponding floating-point elements of the two or four first and second source vectors and destructively subtract without intermediate rounding from the corresponding elements of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.F64F64 indicates whether the double-precision variant is implemented, and

ID\_AA64SMFR0\_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: [Two ZA single-vectors](#) , [Two ZA single-vectors of half precision elements](#) , [Four ZA single-vectors](#) and [Four ZA single-vectors of half precision elements](#)

FMLSL (multiple and indexed vector)

Multi-vector floating-point multiply-subtract long by indexed element

This half-precision floating-point multiply-subtract long instruction widens all 16-bit half-precision elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively subtracts these values without intermediate rounding from the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The half-precision elements within the second source vector are specified using a 3-bit immediate index which selects the same element position within each 128-bit vector segment.

The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

## FMOPA (non-widening)

Floating-point outer product and accumulate

The half-precision variant works with a 16-bit element ZA tile.

The single-precision variant works with a 32-bit element ZA tile.

The double-precision variant works with a 64-bit element ZA tile.

These instructions generate an outer product of the first source vector and the second source vector. In case of the half-precision variant, the first source is  $SVL_H \times 1$  vector and the second source is  $1 \times SVL_H$  vector. In case of the single-precision variant, the first source is  $SVL_S \times 1$  vector and the second source is  $1 \times SVL_S$  vector. In case of the double-precision variant, the first source is  $SVL_D \times 1$  vector and the second source is  $1 \times SVL_D$  vector.

Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is Inactive the corresponding destination tile element remains unmodified.

The resulting outer product,  $SVL_H \times SVL_H$  in case of half-precision variant,  $SVL_S \times SVL_S$  in case of single-precision variant or  $SVL_D \times SVL_D$  in case of double-precision variant, is then destructively added to the destination tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

FMOPA (widening, 2-way, FP16 to FP32)

Half-precision floating-point sum of outer products and accumulate

The half-precision floating-point sum of outer products and accumulate instruction works with a 32-bit element ZA tile. This instruction widens the  $SVL_S \times 2$  sub-matrix of half-precision floating-point values held in the first source vector to single-precision floating-point values and multiplies it by the widened  $2 \times SVL_S$  sub-matrix of half-precision floating-point values in the second source vector to single-precision floating-point values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting  $SVL_S \times SVL_S$  single-precision floating-point sum of outer products is then destructively added to the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a  $SVL_S \times 2$  sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a  $2 \times SVL_S$  sub-matrix.

This instruction follows SME ZA-targeting floating-point behaviors.

ZAtile[da, esize, dim*dim*esize] = result;
```

FMOPS (widening)

Half-precision floating-point sum of outer products and subtract

The half-precision floating-point sum of outer products and subtract instruction works with a 32-bit element ZA tile. This instruction widens the  $SVL_S \times 2$  sub-matrix of half-precision floating-point values held in the first source vector to single-precision floating-point values and multiplies it by the widened  $2 \times SVL_S$  sub-matrix of half-precision floating-point values in the second source vector to single-precision floating-point values.

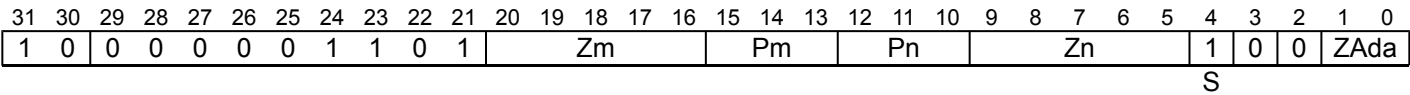

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting  $SVL_S \times SVL_S$  single-precision floating-point sum of outer products is then destructively subtracted from the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a  $SVL_S \times 2$  sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a  $2 \times SVL_S$  sub-matrix.

This instruction follows SME ZA-targeting floating-point behaviors.

FSCALE (multiple vectors)

Multi-vector floating-point adjust exponent

Multiply the floating-point elements of the two or four first source vectors by 2.0 to the power of the signed integer values in the corresponding elements of the two or four second source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

Two registers  
(FEAT\_FP8)

FSUB

Floating-point subtract multi-vector from ZA array vector accumulators

Destructively subtract all elements of the two or four source vectors from the corresponding elements of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.F64F64 indicates whether the double-precision variant is implemented, and

ID\_AA64SMFR0\_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: [Two ZA single-vectors](#) , [Two ZA single-vectors of half precision elements](#) , [Four ZA single-vectors](#) and [Four ZA single-vectors of half precision elements](#)

FVDOT (FP16 to FP32)

Multi-vector half-precision floating-point vertical dot-product by indexed element

The instruction computes the fused sum-of-products of each vertical pair of half-precision floating-point values in the corresponding elements of the two first source vectors with the pair of half-precision floating-point values in the indexed 32-bit group of the corresponding 128-bit segment of the second source vector, without intermediate rounding. The single-precision sum-of-products are destructively added to the corresponding single-precision elements of the two ZA single-vector groups.

The half-precision floating-point pairs within the second source vector are specified using an immediate index which selects the same pair position within each 128-bit vector segment. The element index range is from 0 to 3.

The vector numbers forming the single-vector group within each half of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half the number of ZA array vectors.

The VECTOR GROUP symbol VGx2 indicates that the ZA operand consists of two ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

## LD1B (scalar plus immediate, strided registers)

Contiguous load of bytes to multiple strided vectors (immediate index)

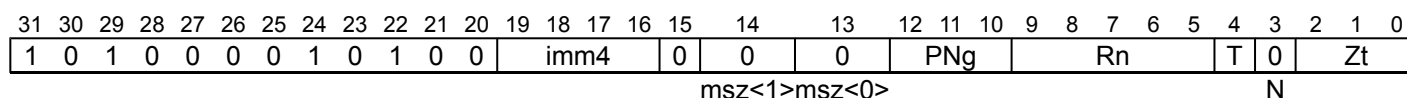

Contiguous load of unsigned bytes to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

(FEAT\_SME2)

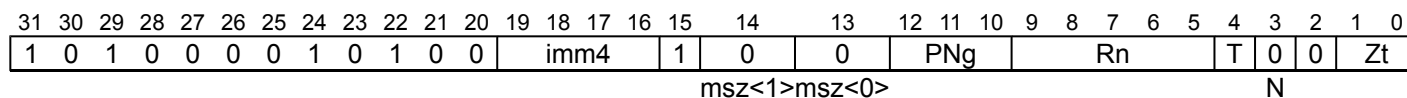

LD1B { <Zt1>.B, <Zt2>.B }, <PNg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 2;
integer tstride = 8;
integer t = UInt(T:'0':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

### Four registers

(FEAT\_SME2)

LD1B { <Zt1>.B, <Zt2>.B, <Zt3>.B, <Zt4>.B }, <PNg>/Z, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 4;
integer tstride = 4;
integer t = UInt(T:'00':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

### Assembler Symbols

- <Zt1> For the two registers variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as "T:'0':Zt".  
For the four registers variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as "T:'00':Zt".
- <Zt2> For the two registers variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as "T:'1':Zt".  
For the four registers variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as "T:'01':Zt".
- <Zt3> Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".

<Zt4>	Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".
<PNg>	Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the two registers variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the "imm4" field.  For the four registers variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.

LD1B (scalar plus scalar, tile slice)

Contiguous load of bytes to 8-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 8-bit elements in a vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

SME
(FEAT\_SME)

LD1D (scalar plus scalar, tile slice)

Contiguous load of doublewords to 64-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 64-bit elements in a vector. The immediate offset is in the range 0 to 1. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 8 and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

SME
(FEAT\_SME)

LD1D { <ZAt><HV>.D[<Ws>, <offs>] }, <Pg>/Z, [<Xn|SP>{, <Xm>, LSL #3}]

```
if !HaveSME() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt('0':Pg);
integer s = UInt('011':Rs);
integer t = UInt(ZAt);
integer offset = UInt(o1);
constant integer esize = 64;
boolean vertical = V == '1';
```

Assembler Symbols

- <ZAt> Is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAt" field.
- <HV> Is the horizontal or vertical slice indicator, encoded in "V":
Table:
V | <HV>
0 | H
1 | V
- <Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
- <offs> Is the slice index offset, in the range 0 to 1, encoded in the "o1" field.
- <Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Xm> Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the "Rm" field.

## LD1W (scalar plus scalar, strided registers)

Contiguous load of words to multiple strided vectors (scalar index)

Contiguous load of unsigned words to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

LD1W (scalar plus scalar, tile slice)

Contiguous load of words to 32-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 32-bit elements in a vector. The immediate offset is in the range 0 to 3. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 4 and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

SME
(FEAT\_SME)

LD1W { <ZAt><HV>.S[<Ws>, <offs>] }, <Pg>/Z, [<Xn|SP>{, <Xm>, LSL #2}]

```
if !HaveSME() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt('0':Pg);
integer s = UInt('011':Rs);
integer t = UInt(ZAt);
integer offset = UInt(off2);
constant integer esize = 32;
boolean vertical = V == '1';
```

Assembler Symbols

- <ZAt> Is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAt" field.
- <HV> Is the horizontal or vertical slice indicator, encoded in "V":
Table:
V | <HV>
0 | H
1 | V
- <Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
- <offs> Is the slice index offset, in the range 0 to 3, encoded in the "off2" field.
- <Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Xm> Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the "Rm" field.

## Operation

## LDNT1D (scalar plus scalar, strided registers)

Contiguous load non-temporal of doublewords to multiple strided vectors (scalar index)

Contiguous load non-temporal of doublewords to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

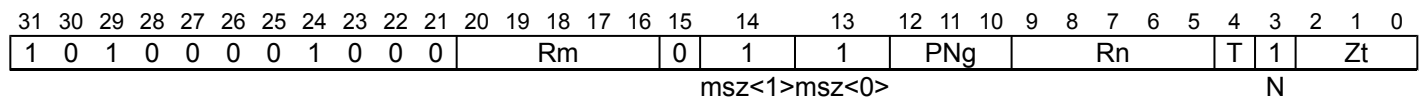

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

(FEAT\_SME2)

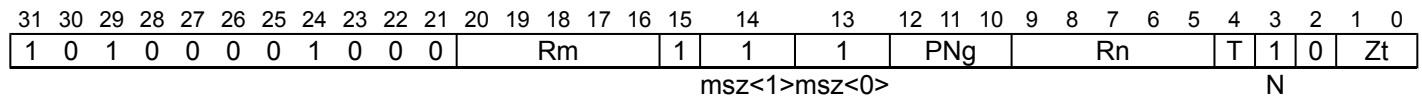

LDNT1D { <Zt1>.D, <Zt2>.D }, <PNg>/Z, [<Xn|SP>, <Xm>, LSL #3]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt('1':PNg);
constant integer nreg = 2;
integer tstride = 8;
integer t = UInt(T:'0':Zt);
constant integer esize = 64;
```

### Four registers

(FEAT\_SME2)

LDNT1D { <Zt1>.D, <Zt2>.D, <Zt3>.D, <Zt4>.D }, <PNg>/Z, [<Xn|SP>, <Xm>, LSL #3]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt('1':PNg);
constant integer nreg = 4;
integer tstride = 4;
integer t = UInt(T:'00':Zt);
constant integer esize = 64;
```

### Assembler Symbols

- <Zt1> For the two registers variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as "T:'0':Zt".
- For the four registers variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as "T:'00':Zt".
- <Zt2> For the two registers variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as "T:'1':Zt".
- For the four registers variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as "T:'01':Zt".

- <Zt3> Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".
- <Zt4> Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".
- <PNg> Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Xm> Is the 64-bit name of the general-purpose offset register, encoded in the "Rm" field.

LDR (array vector)

Load ZA array vector

The ZA array vector is selected by the sum of the vector select register and immediate offset, modulo the number of bytes in a Streaming SVE vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base, plus the same optional immediate offset multiplied by the current vector length in bytes. This instruction is unpredicated.

The load is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

# MOV (array to vector, four registers)

Move four ZA single-vector groups to four vector registers

The instruction operates on four ZA single-vector groups. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This is an alias of [MOVA \(array to vector, four registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(array to vector, four registers\)](#).
- The description of [MOVA \(array to vector, four registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	Rv		0	1	1	0	0	off3		Zd		0		0	

MOV { <Zd1>.D-<Zd4>.D }, ZA.D[<Wv>, <offs>{, VGx4}]

is equivalent to

MOVA { <Zd1>.D-<Zd4>.D }, ZA.D[<Wv>, <offs>{, VGx4}]

and is always the preferred disassembly.

## Assembler Symbols

- <Zd1> Is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 4.
- <Zd4> Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.

MOV (array to vector, two registers)

Move two ZA single-vector groups to two vector registers

The instruction operates on two ZA single-vector groups. The vector numbers forming the single-vector group within each half of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half the number of ZA array vectors.

The VECTOR GROUP symbol VGx2 indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This is an alias of [MOVA \(array to vector, two registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(array to vector, two registers\)](#).

    - The values of the NZCV flags.

MOV (tile to vector, four registers)

Move four ZA tile slices to four vector registers

The instruction operates on four consecutive horizontal or vertical slices within a named ZA tile of the specified element size.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 4 in the range 0 to the number of elements in a 128-bit vector segment minus 4.

This instruction is unpredicated.

This is an alias of [MOVA \(tile to vector, four registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(tile to vector, four registers\)](#).
- The description of [MOVA \(tile to vector, four registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

## Assembler Symbols

- <Zd1> Is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 4.
- <Zd4> Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.
- <ZAn> For the 16-bit variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field.  
For the 32-bit variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field.  
For the 64-bit variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.
- <HV> Is the horizontal or vertical slice indicator, encoded in "V":

V	<HV>
0	H
1	V

- <Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
- <offs1> For the 8-bit variant: is the first slice index offset, encoded as "off2" field times 4.  
For the 16-bit variant: is the first slice index offset, encoded as "o1" field times 4.  
For the 32-bit and 64-bit variant: is the first slice index offset, with implicit value 0.
- <offs4> For the 8-bit variant: is the fourth slice index offset, encoded as "off2" field times 4 plus 3.  
For the 16-bit variant: is the fourth slice index offset, encoded as "o1" field times 4 plus 3.  
For the 32-bit and 64-bit variant: is the fourth slice index offset, with implicit value 3.

## Operation

The description of [MOVA \(tile to vector, four registers\)](#) gives the operational pseudocode for this instruction.

## Operational information

If FEAT\_SVE2 is implemented or FEAT\_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

## MOV (tile to vector, single)

Move ZA tile slice to vector register

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination vector remain unmodified.

This is an alias of [MOVA \(tile to vector, single\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(tile to vector, single\)](#).
- The description of [MOVA \(tile to vector, single\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 5 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) , [64-bit](#) and [128-bit](#)

is equivalent to

MOVA <Zd>.Q, <Pg>/M, <ZAn><HV>.Q[<Ws>, <offs>]

and is always the preferred disassembly.

## Assembler Symbols

- <Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.
- <Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- <ZAn> For the 16-bit variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field.  
For the 32-bit variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field.  
For the 64-bit variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.  
For the 128-bit variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the "ZAn" field.

<HV> Is the horizontal or vertical slice indicator, encoded in "V":

V	<HV>
0	H
1	V

- <Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
- <offs> For the 8-bit variant: is the slice index offset, in the range 0 to 15, encoded in the "off4" field.  
For the 16-bit variant: is the slice index offset, in the range 0 to 7, encoded in the "off3" field.  
For the 32-bit variant: is the slice index offset, in the range 0 to 3, encoded in the "off2" field.  
For the 64-bit variant: is the slice index offset, in the range 0 to 1, encoded in the "o1" field.  
For the 128-bit variant: is the slice index offset, with implicit value 0.

## Operation

The description of [MOVA \(tile to vector, single\)](#) gives the operational pseudocode for this instruction.

## Operational information

If FEAT\_SVE2 is implemented or FEAT\_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
  - The values of the NZCV flags.

MOV (tile to vector, two registers)

Move two ZA tile slices to two vector registers

The instruction operates on two consecutive horizontal or vertical slices within a named ZA tile of the specified element size.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

This is an alias of [MOVA \(tile to vector, two registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(tile to vector, two registers\)](#).
- The description of [MOVA \(tile to vector, two registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

8-bit

MOV (vector to array, four registers)

Move four vector registers to four ZA single-vector groups

The instruction operates on four ZA single-vector groups. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This is an alias of [MOVA \(vector to array, four registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(vector to array, four registers\)](#).
- The description of [MOVA \(vector to array, four registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

# MOV (vector to tile, single)

Move vector register to ZA tile slice

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

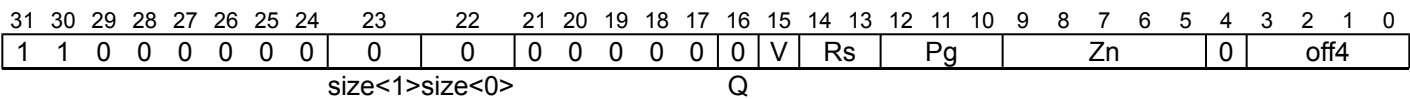

Inactive elements in the destination slice remain unmodified.

This is an alias of [MOVA \(vector to tile, single\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(vector to tile, single\)](#).
- The description of [MOVA \(vector to tile, single\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 5 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) , [64-bit](#) and [128-bit](#)

## 8-bit

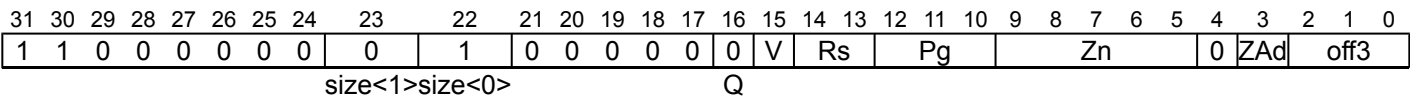

MOV ZA0<HV>.B[<Ws>, <offs>], <Pg>/M, <Zn>.B

is equivalent to

MOVA ZA0<HV>.B[<Ws>, <offs>], <Pg>/M, <Zn>.B

and is always the preferred disassembly.

## 16-bit

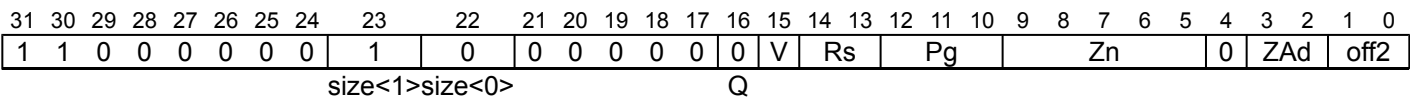

MOV <ZAd><HV>.H[<Ws>, <offs>], <Pg>/M, <Zn>.H

is equivalent to

MOVA <ZAd><HV>.H[<Ws>, <offs>], <Pg>/M, <Zn>.H

and is always the preferred disassembly.

## 32-bit

MOV <ZAd><HV>.S[<Ws>, <offs>], <Pg>/M, <Zn>.S

is equivalent to

MOVA <ZAd><HV>.S[<Ws>, <offs>], <Pg>/M, <Zn>.S

and is always the preferred disassembly.

## 64-bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

## MOV (vector to tile, two registers)

Move two vector registers to two ZA tile slices

The instruction operates on two consecutive horizontal or vertical slices within a named ZA tile of the specified element size.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

This is an alias of [MOVA \(vector to tile, two registers\)](#). This means:

- The encodings in this description are named to match the encodings of [MOVA \(vector to tile, two registers\)](#).
- The description of [MOVA \(vector to tile, two registers\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

### 8-bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	V	Rs	0	0	0	Zn			0		0	0	off3			
size<1>size<0>																															

MOV ZA0<HV>.B[<Ws>, <offs1>:<offs2>], { <Zn1>.B-<Zn2>.B }

is equivalent to

MOVA ZA0<HV>.B[<Ws>, <offs1>:<offs2>], { <Zn1>.B-<Zn2>.B }

and is always the preferred disassembly.

### 16-bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	1	0	0	0	1	0	0	V	Rs	0	0	0	Zn			0	0	0	ZAd	off2			
size<1>size<0>																															

MOV <ZAd><HV>.H[<Ws>, <offs1>:<offs2>], { <Zn1>.H-<Zn2>.H }

is equivalent to

MOVA <ZAd><HV>.H[<Ws>, <offs1>:<offs2>], { <Zn1>.H-<Zn2>.H }

and is always the preferred disassembly.

### 32-bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

size<1>size<0>																															

MOV <ZAd><HV>.S[<Ws>, <offs1>:<offs2>], { <Zn1>.S-<Zn2>.S }

is equivalent to

MOVA <ZAd><HV>.S[<Ws>, <offs1>:<offs2>], { <Zn1>.S-<Zn2>.S }

and is always the preferred disassembly.

## 64-bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	1	1	0	0	0	1	0	0	V	Rs	0	0	0	Zn			0		0	0	ZAd			

size<1>size<0>

MOV <ZAd><HV>.D[<Ws>, <offs1>:<offs2>], { <Zn1>.D-<Zn2>.D }

is equivalent to

MOVA <ZAd><HV>.D[<Ws>, <offs1>:<offs2>], { <Zn1>.D-<Zn2>.D }

and is always the preferred disassembly.

## Assembler Symbols

<ZAd> For the 16-bit variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAd" field.  
For the 32-bit variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAd" field.  
For the 64-bit variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAd" field.

<HV> Is the horizontal or vertical slice indicator, encoded in "V":

V	<HV>
0	H
1	V

<Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<offs1> For the 8-bit variant: is the first slice index offset, encoded as "off3" field times 2.  
For the 16-bit variant: is the first slice index offset, encoded as "off2" field times 2.  
For the 32-bit variant: is the first slice index offset, encoded as "o1" field times 2.  
For the 64-bit variant: is the first slice index offset, with implicit value 0.

<offs2> For the 8-bit variant: is the second slice index offset, encoded as "off3" field times 2 plus 1.  
For the 16-bit variant: is the second slice index offset, encoded as "off2" field times 2 plus 1.  
For the 32-bit variant: is the second slice index offset, encoded as "o1" field times 2 plus 1.  
For the 64-bit variant: is the second slice index offset, with implicit value 1.

<Zn1> Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 2.

<Zn2> Is the name of the second scalable vector register of the source multi-vector group, encoded as "Zn" times 2 plus 1.

## Operation

The description of [MOVA \(vector to tile, two registers\)](#) gives the operational pseudocode for this instruction.

## Operational information

If FEAT\_SVE2 is implemented or FEAT\_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

Internal version only: isa v33.74, AdvSIMD v29.23, pseudocode v2023-09\_rel, sve v2023-09\_rc3 ; Build timestamp: 2023-09-27T17:06

## MOVA (array to vector, four registers)

Move four ZA single-vector groups to four vector registers

The instruction operates on four ZA single-vector groups. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This instruction is used by the alias [MOV \(array to vector, four registers\)](#).

### SME2 (FEAT\_SME2)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	Rv		0	1	1		0	0	off3		Zd			0	0

MOVA { <Zd1>.D-<Zd4>.D }, ZA.D[<Wv>, <offs>{, VGx4}]

```
if !HaveSME2() then UNDEFINED;
integer v = UInt('010':Rv);
integer offset = UInt(off3);
integer d = UInt(Zd:'00');
constant integer nreg = 4;
```

### Assembler Symbols

- <Zd1> Is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 4.
- <Zd4> Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.
- <Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
- <offs> Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.

### Operation

```
CheckStreamingSVEAndZAAEnabled();
constant integer VL = CurrentVL;
integer vectors = VL DIV 8;
integer vstride = vectors DIV nreg;
bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;

for r = 0 to nreg-1
    bits(VL) result = ZAvector[vec, VL];
    Z[d + r, VL] = result;
    vec = vec + vstride;
```

### Operational information

- If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
  - The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

# MOVA (array to vector, two registers)

Move two ZA single-vector groups to two vector registers

The instruction operates on two ZA single-vector groups. The vector numbers forming the single-vector group within each half of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half the number of ZA array vectors.

The VECTOR GROUP symbol VGx2 indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This instruction is used by the alias [MOV \(array to vector, two registers\)](#).

## SME2 (FEAT\_SME2)

## MOVA (tile to vector, single)

Move ZA tile slice to vector register

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination vector remain unmodified.

This instruction is used by the alias [MOV \(tile to vector, single\)](#).

It has encodings from 5 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) , [64-bit](#) and [128-bit](#)

## MOVA (vector to array, four registers)

Move four vector registers to four ZA single-vector groups

The instruction operates on four ZA single-vector groups. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This instruction is used by the alias [MOV \(vector to array, four registers\)](#).

### SME2

## MOVA (vector to tile, single)

Move vector register to ZA tile slice

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination slice remain unmodified.

This instruction is used by the alias [MOV \(vector to tile, single\)](#).

It has encodings from 5 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) , [64-bit](#) and [128-bit](#)

## MOVA (vector to tile, two registers)

Move two vector registers to two ZA tile slices

The instruction operates on two consecutive horizontal or vertical slices within a named ZA tile of the specified element size.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

This instruction is used by the alias [MOV \(vector to tile, two registers\)](#).

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

## MOVAZ (array to vector, four registers)

Move and zero four ZA single-vector groups to vector registers

The instruction operates on four ZA single-vector groups. The ZA single-vector groups are zeroed after moving their contents to the destination vectors. The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

# MOVAZ (array to vector, two registers)

Move and zero two ZA single-vector groups to vector registers

The instruction operates on two ZA single-vector groups. The ZA single-vector groups are zeroed after moving their contents to the destination vectors. The vector numbers forming the single-vector group within each half of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half the number of ZA array vectors.

The VECTOR GROUP symbol VGx2 indicates that the instruction operates on two ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

```

Assembler Symbols

- <Zd>

Is the name of the destination scalable vector register, encoded in the "Zd" field.
- <ZAn>

For the 16-bit variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field.  
For the 32-bit variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field.  
For the 64-bit variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.  
For the 128-bit variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the "ZAn" field.
- <HV>

Is the horizontal or vertical slice indicator, encoded in "V":

V	<HV>
0	H
1	V
- <Ws>

Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
- <offs>

For the 8-bit variant: is the slice index offset, in the range 0 to 15, encoded in the "off4" field.  
For the 16-bit variant: is the slice index offset, in the range 0 to 7, encoded in the "off3" field.

For the 32-bit variant: is the slice index offset, in the range 0 to 3, encoded in the "off2" field.

For the 64-bit variant: is the slice index offset, in the range 0 to 1, encoded in the "o1" field.

For the 128-bit variant: is the slice index offset, with implicit value 0.

## Operation

```
CheckStreamingSVEAndZAAEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer dim = VL DIV esize;
bits(32) index = X[s, 32];
integer slice = (UInt(index) + offset) MOD dim;
bits(VL) operand = ZAslice[n, esize, vertical, slice, VL];
ZAslice[n, esize, vertical, slice, VL] = Zeros(VL);
Z[d, VL] = operand;
```

## Operational information

## MOVAZ (tile to vector, two registers)

Move and zero two ZA tile slices to vector registers

The instruction operates on two consecutive horizontal or vertical slices within a named ZA tile of the specified element size. The tile slices are zeroed after moving their contents to the destination vectors.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

It has encodings from 4 classes: [8-bit](#) , [16-bit](#) , [32-bit](#) and [64-bit](#)

### 8-bit

## SDOT (2-way, multiple and indexed vector)

Multi-vector signed integer dot-product by indexed element

The signed integer dot product instruction computes the dot product of two signed 16-bit integer values held in each 32-bit element of the two or four first source vectors and two signed 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

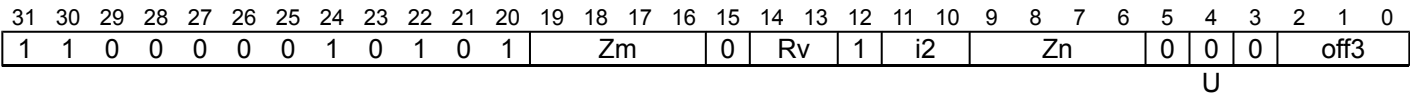

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

constant integer nreg = 4;
```

### Assembler Symbols

- <Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
- <offs> Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.
- <Zn1> For the two ZA single-vectors variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2.

For the four ZA single-vectors variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.

- <Zn4> Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.
- <Zn2> Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
- <Zm> Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.
- <index> Is the immediate index of a group of two 16-bit elements within each 128-bit vector segment, in the range 0 to 3, encoded in the "i2" field.

## Operation

```
CheckStreamingSVEAndZAEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer vectors = VL DIV 8;

## SDOT (2-way, multiple and single vector)

Multi-vector signed integer dot-product by vector

The signed integer dot product instruction computes the dot product of two signed 16-bit integer values held in each 32-bit element of the two or four first source vectors and two signed 16-bit integer values in the corresponding 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## SDOT (4-way, multiple and indexed vector)

Multi-vector signed integer dot-product by indexed element

The signed integer dot product instruction computes the dot product of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 4 classes: [Two ZA single-vectors of 32-bit elements](#) , [Two ZA single-vectors of 64-bit elements](#) , [Four ZA single-vectors of 32-bit elements](#) and [Four ZA single-vectors of 64-bit elements](#)

    vec = vec + vstride;

```

SDOT (4-way, multiple vectors)

Multi-vector signed integer dot-product

The signed integer dot product instruction computes the dot product of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding 32-bit or 64-bit element of the two or four second source vectors. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

Assembler Symbols

<T> Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the “Rv” field.

- <offs> Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.
- <Zn1> For the two ZA single-vectors variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2.  
For the four ZA single-vectors variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.
- <Tb> Is the size specifier, encoded in "sz":
- | sz | <Tb> |
|----|------|
| 0  | B    |
| 1  | H    |
- <Zn4> Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.
- <Zn2> Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
- <Zm1> For the two ZA single-vectors variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 2.  
For the four ZA single-vectors variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 4.
- <Zm4> Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.
- <Zm2> Is the name of the second scalable vector register of the second source multi-vector group, encoded as "Zm" times 2 plus 1.

## Operation

```

CheckStreamingSVEAndZAAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer vectors = VL DIV 8;
integer vstride = vectors DIV nreg;
bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;

for r = 0 to nreg-1
    bits(VL) operand1 = Z[n+r, VL];
    bits(VL) operand2 = Z[m+r, VL];
    bits(VL) operand3 = ZAvector[vec, VL];
    for e = 0 to elements-1
        bits(esize) sum = Elem[operand3, e, esize];
        for i = 0 to 3
            integer element1 = SInt(Elem[operand1, 4 * e + i, esize DIV 4]);
            integer element2 = SInt(Elem[operand2, 4 * e + i, esize DIV 4]);
            sum = sum + element1 * element2;
        Elem[result, e, esize] = sum;
    ZAvector[vec, VL] = result;
    vec = vec + vstride;

SMIN (multiple vectors)

Multi-vector signed minimum

Determine the signed minimum of elements of the two or four second source vectors and the corresponding elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

This instruction is unpredicated.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

```

Assembler Symbols

- <Zdn1> For the two registers variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 2.  
For the four registers variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 4.

<T> Is the size specifier, encoded in "size":

size	<T>
00	B
01	H
10	S
11	D

<Zdn4> Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 4 plus 3.

- <Zdn2> Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 2 plus 1.
- <Zm1> For the two registers variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 2.  
For the four registers variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 4.
- <Zm4> Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.
- <Zm2> Is the name of the second scalable vector register of the second source multi-vector group, encoded as "Zm" times 2 plus 1.

## Operation

```

CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
array [0..3] of bits(VL) results;

for r = 0 to nreg-1
    bits(VL) operand1 = Z[dn+r, VL];
    bits(VL) operand2 = Z[m+r, VL];
    for e = 0 to elements-1
        integer element1 = Int(Elem[operand1, e, esize], unsigned);
        integer element2 = Int(Elem[operand2, e, esize], unsigned);
        integer res = Min(element1, element2);
        Elem[results[r], e, esize] = res<esize-1:0>;

for r = 0 to nreg-1
    Z[dn+r, VL] = results[r];

```

## Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

# SMLAL (multiple and indexed vector)

Multi-vector signed integer multiply-add long by indexed element

This signed integer multiply-add long instruction multiplies each signed 16-bit element in the one, two, or four first source vectors with each signed 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups. The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

# SMLALL (multiple and indexed vector)

Multi-vector signed integer multiply-add long-long by indexed element

This signed integer multiply-add long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

## SMLALL (multiple and single vector)

Multi-vector signed integer multiply-add long-long by vector

This signed integer multiply-add long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit element in the second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

# SMLS (multiple and indexed vector)

Multi-vector signed integer multiply-subtract long by indexed element

This signed integer multiply-subtract long instruction multiplies each signed 16-bit element in the one, two, or four first source vectors with each signed 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

## Assembler Symbols

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs1>	For the one ZA double-vector variant: is the first vector select offset, encoded as "off3" field times 2. For the four ZA double-vectors and two ZA double-vectors variant: is the first vector select offset, encoded as "off2" field times 2.
<offs2>	For the one ZA double-vector variant: is the second vector select offset, encoded as "off3" field times 2 plus 1. For the four ZA double-vectors and two ZA double-vectors variant: is the second vector select offset, encoded as "off2" field times 2 plus 1.
<Zn>	Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zn1>	For the two ZA double-vectors variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2. For the four ZA double-vectors variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.
<Zn4>	Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.
<Zn2>	Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
<Zm>	Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.
<index>	Is the element index, in the range 0 to 7, encoded in the "i3h:i3l" fields.

## Operation

```
CheckStreamingSVEAndZAAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
integer vectors = VL DIV 8;
integer vstride = vectors DIV nreg;
integer eltsperssegment = 128 DIV esize;
bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;
vec = vec - (vec MOD 2);

for r = 0 to nreg-1
    bits(VL) operand1 = Z[n+r, VL];
    bits(VL) operand2 = Z[m, VL];
    for i = 0 to 1
        bits(VL) operand3 = ZAvector[vec + i, VL];
        for e = 0 to elements-1
            integer segmentbase = e - (e MOD eltsperssegment);
            integer s = 2 * segmentbase + index;
            integer element1 = SInt(Elem[operand1, 2 * e + i, esize DIV 2]);
            integer element2 = SInt(Elem[operand2, s, esize DIV 2]);
            bits(esize) product = (element1 * element2)<esize-1:0>;
            Elem[result, e, esize] = Elem[operand3, e, esize] - product;
        ZAvector[vec + i, VL] = result;
    vec = vec + vstride;
```

## Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

SMLSL (multiple and single vector)

Multi-vector signed integer multiply-subtract long by vector

This signed integer multiply-subtract long instruction multiplies each signed 16-bit element in the one, two, or four first source vectors with each signed 16-bit element in the second source vector, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

# SMLSLL (multiple and indexed vector)

Multi-vector signed integer multiply-subtract long-long by indexed element

This signed integer multiply-subtract long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

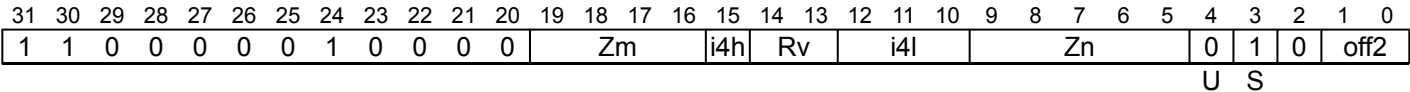

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: [One ZA quad-vector of 32-bit elements](#) , [One ZA quad-vector of 64-bit elements](#) , [Two ZA quad-vectors of 32-bit elements](#) , [Two ZA quad-vectors of 64-bit elements](#) , [Four ZA quad-vectors of 32-bit elements](#) and [Four ZA quad-vectors of 64-bit elements](#)

## SMLSLL (multiple and single vector)

Multi-vector signed integer multiply-subtract long-long by vector

This signed integer multiply-subtract long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit element in the second source vector, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

SMOPA (2-way)

Signed integer sum of outer products and accumulate

This instruction works with a 32-bit element ZA tile.

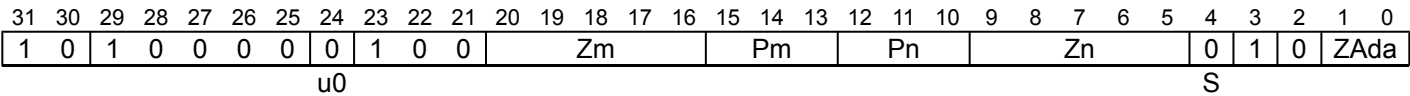

The signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds SVL<sub>S</sub>×2 sub-matrix of signed 16-bit integer values, and the second source holds 2×SVL<sub>S</sub> sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting SVL<sub>S</sub>×SVL<sub>S</sub> widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVL<sub>S</sub>×2 sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVL<sub>S</sub> sub-matrix.

SMOPA (4-way)

Signed integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of signed 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of signed 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

```

## Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its operand registers when its governing predicate registers contain the same value for each execution.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its operand registers when its governing predicate registers contain the same value for each execution.
  - The values of the NZCV flags.

SMOPS (2-way)

Signed integer sum of outer products and subtract

This instruction works with a 32-bit element ZA tile.

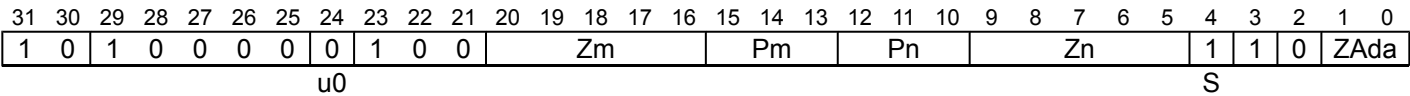

The signed integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds  $SVL_S \times 2$  sub-matrix of signed 16-bit integer values, and the second source holds  $2 \times SVL_S$  sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer sum of outer products is then destructively subtracted from the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a  $SVL_S \times 2$  sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a  $2 \times SVL_S$  sub-matrix.

SMOPS (4-way)

Signed integer sum of outer products and subtract

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of signed 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of signed 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

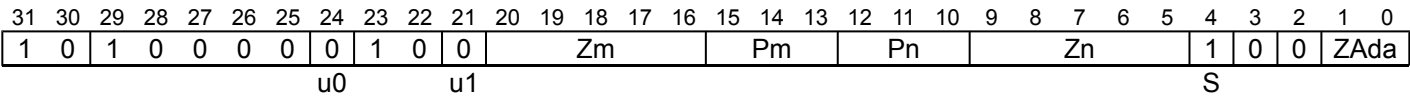

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

Assembler Symbols

- <Zdn1>

For the two registers variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 2.  
  
For the four registers variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 4.
- <T>

Is the size specifier, encoded in "size":

size	<T>
00	B
01	H
10	S
11	D
- <Zdn4>

Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 4 plus 3.
- <Zdn2>

Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 2 plus 1.
- <Zm1>

For the two registers variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 2.

For the four registers variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 4.

- <Zm4> Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.
- <Zm2> Is the name of the second scalable vector register of the second source multi-vector group, encoded as "Zm" times 2 plus 1.

## Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
array [0..3] of bits(VL) results;

for r = 0 to nreg-1
    bits(VL) operand1 = Z[dn+r, VL];
    bits(VL) operand2 = Z[m+r, VL];
    for e = 0 to elements-1

SQRSHR (four registers)

Multi-vector signed saturating rounding shift right narrow by immediate

Shift right by an immediate value, the signed integer value in each element of the four source vectors and place the rounded results in the quarter-width destination elements. Each result element is saturated to the quarter-width N-bit element's signed integer range  $-2^{(N-1)}$  to  $(2^{(N-1)})-1$ . The immediate shift amount is an unsigned value in the range 1 to number of bits per source element.  
This instruction is unpredicated.

SME2  
(FEAT\_SME2)

```
SQRSHR <Zd>.<T>, { <Zn1>.<Tb>-<Zn4>.<Tb> }, #<const>
```

```
if !HaveSME2() then UNDEFINED;

# ST1B (scalar plus immediate, strided registers)

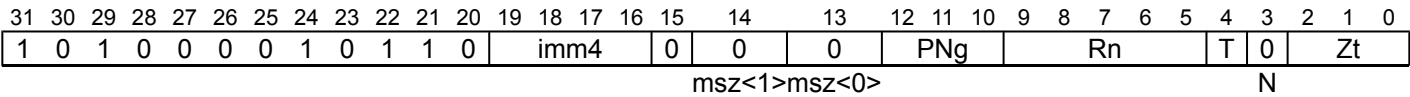

Contiguous store of bytes from multiple strided vectors (immediate index)

Contiguous store of bytes from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

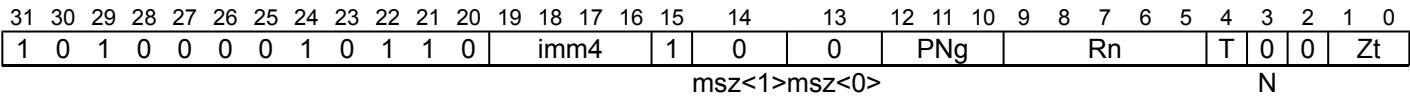

## Two registers (FEAT\_SME2)

ST1B { <Zt1>.B, <Zt2>.B }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 2;
integer tstride = 8;
integer t = UInt(T:'0':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

## Four registers (FEAT\_SME2)

ST1B { <Zt1>.B, <Zt2>.B, <Zt3>.B, <Zt4>.B }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 4;
integer tstride = 4;
integer t = UInt(T:'00':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

## Assembler Symbols

- <Zt1> For the two registers variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as "T:'0':Zt".  
For the four registers variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as "T:'00':Zt".
- <Zt2> For the two registers variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as "T:'1':Zt".  
For the four registers variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as "T:'01':Zt".
- <Zt3> Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".

<Zt4>	Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".
<PNg>	Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the two registers variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the "imm4" field.  For the four registers variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.

## Operation

```

CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
constant integer mbytes = esize DIV 8;
bits(64) base;
bits(VL) src;
bits(PL) pred = P[g, PL];
bits(PL * nreg) mask = CounterToPredicate(pred<15:0>, PL * nreg);
boolean contiguous = TRUE;
boolean nontemporal = FALSE;
boolean tagchecked = n != 31;
AccessDescriptor accdesc = CreateAccDescSVE(MemOp_STORE, nontemporal, contiguous, tagchecked);

if !AnyActiveElement(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool(Unpredictable_CHECKSPNONEACTIVE) then
        CheckSPAlignment();
    else
        if n == 31 then CheckSPAlignment();
        base = if n == 31 then SP[] else X[n, 64];

for r = 0 to nreg-1
    src = Z[t, VL];
    for e = 0 to elements-1
        if ActivePredicateElement(mask, r * elements + e, esize) then
            integer eoff = offset * nreg * elements + r * elements + e;
            bits(64) addr = GenerateAddress(base, eoff * mbytes, accdesc);
            Mem[addr, mbytes, accdesc] = Elem[src, e, esize];
        t = t + tstride;

```

## Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored when its governing predicate register contains the same value for each execution.

ST1B (scalar plus scalar, tile slice)

Contiguous store of bytes from 8-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 8-bit elements in a vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is added to the base address. Inactive elements are not written to memory.

SME
(FEAT\_SME)

ST1B { ZA0<HV>.B[<Ws>, <offs>] }, <Pg>, [<Xn|SP>{, <Xm>}]

```
if !HaveSME() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);

## ST1H (scalar plus immediate, strided registers)

Contiguous store of halfwords from multiple strided vectors (immediate index)

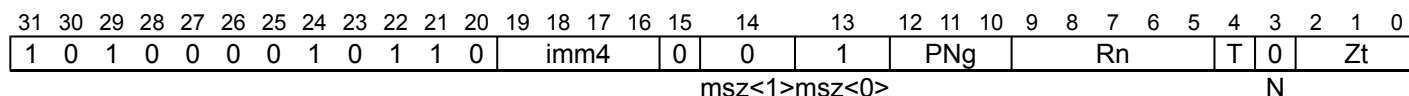

Contiguous store of halfwords from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

(FEAT\_SME2)

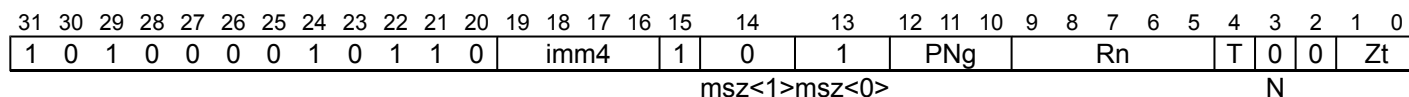

**ST1H** { <Zt1>.H, <Zt2>.H }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 2;
integer tstride = 8;
integer t = UInt(T:'0':Zt);
constant integer esize = 16;
integer offset = SInt(imm4);
```

### Four registers

(FEAT\_SME2)

**ST1H** { <Zt1>.H, <Zt2>.H, <Zt3>.H, <Zt4>.H }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;

ST1H (scalar plus scalar, tile slice)

Contiguous store of halfwords from 16-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 16-bit elements in a vector. The immediate offset is in the range 0 to 7. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 2 and added to the base address. Inactive elements are not written to memory.

SME
(FEAT\_SME)

ST1W (scalar plus scalar, tile slice)

Contiguous store of words from 32-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 32-bit elements in a vector. The immediate offset is in the range 0 to 3. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 4 and added to the base address. Inactive elements are not written to memory.

SME
(FEAT\_SME)

ST1W { <ZAt><HV>.S[<Ws>, <offs>] }, <Pg>, [<Xn|SP>{, <Xm>, LSL #2}]

```
if !HaveSME() then UNDEFINED;
integer n = UInt(Rn);
integer m = UInt(Rm);
integer g = UInt('0':Pg);
integer s = UInt('011':Rs);
integer t = UInt(ZAt);
integer offset = UInt(off2);
constant integer esize = 32;
boolean vertical = V == '1';
```

Assembler Symbols

- <ZAt> Is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAt" field.
- <HV> Is the horizontal or vertical slice indicator, encoded in "V":

V	<HV>
0	H
1	V
- <Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
- <offs> Is the slice index offset, in the range 0 to 3, encoded in the "off2" field.
- <Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.
- <Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
- <Xm> Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the "Rm" field.

## Operation

```
CheckStreamingSVEAndZAAEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer dim = VL DIV esize;
bits(64) base;
bits(64) addr;
bits(PL) mask = P[g, PL];
bits(64) moffs = X[m, 64];
bits(32) index = X[s, 32];
integer slice = (UInt(index) + offset) MOD dim;
bits(VL) src;
constant integer mbytes = esize DIV 8;
boolean contiguous = TRUE;
boolean nontemporal = FALSE;
boolean tagchecked = TRUE;
AccessDescriptor accdesc = CreateAccDescSME(MemOp\_STORE, nontemporal, contiguous, tagchecked);

if n == 31 then
    if AnyActiveElement(mask, esize) ||
        ConstrainUnpredictableBool(Unpredictable\_CHECKSPNONEACTIVE) then
        CheckSPAlignment();
    base = SP[];
else
    base = X[n, 64];

src = ZAslice[t, esize, vertical, slice, VL];
for e = 0 to dim-1
    addr = GenerateAddress(base, UInt(moffs) * mbytes, accdesc);
    if ActivePredicateElement(mask, e, esize) then
        Mem[addr, mbytes, accdesc] = Elem[src, e, esize];
    moffs = moffs + 1;
```

## STNT1B (scalar plus immediate, strided registers)

Contiguous store non-temporal of bytes from multiple strided vectors (immediate index)

Contiguous store non-temporal of bytes from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

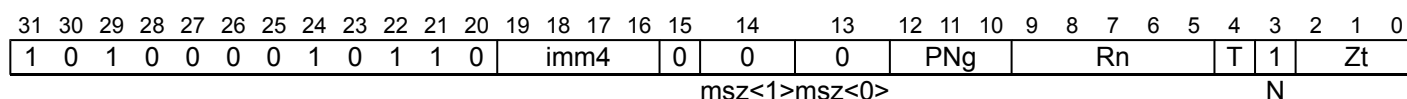

Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

### Two registers

(FEAT\_SME2)

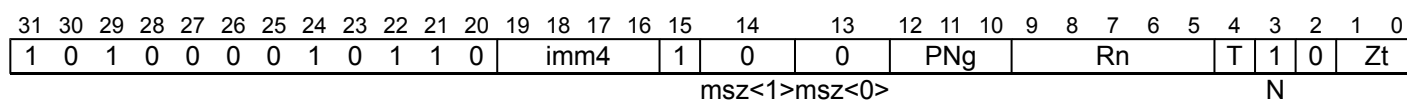

STNT1B { <Zt1>.B, <Zt2>.B }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 2;
integer tstride = 8;
integer t = UInt(T:'0':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

### Four registers

(FEAT\_SME2)

STNT1B { <Zt1>.B, <Zt2>.B, <Zt3>.B, <Zt4>.B }, <PNg>, [<Xn|SP>{, #<imm>, MUL VL}]

```
if !HaveSME2() then UNDEFINED;
integer n = UInt(Rn);
integer g = UInt('1':PNg);
constant integer nreg = 4;
integer tstride = 4;
integer t = UInt(T:'00':Zt);
constant integer esize = 8;
integer offset = SInt(imm4);
```

### Assembler Symbols

- <Zt1> For the two registers variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as "T:'0':Zt".  
For the four registers variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as "T:'00':Zt".
- <Zt2> For the two registers variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as "T:'1':Zt".  
For the four registers variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as "T:'01':Zt".
- <Zt3> Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".

<Zt4>	Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".
<PNg>	Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
<Xn SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the two registers variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the "imm4" field.  For the four registers variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.

## Operation

## STNT1H (scalar plus scalar, strided registers)

Contiguous store non-temporal of halfwords from multiple strided vectors (scalar index)

Contiguous store non-temporal of halfwords from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

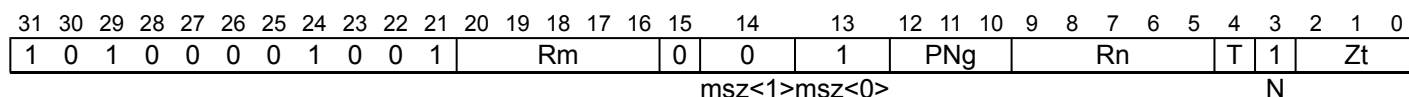

Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: [Two registers](#) and [Four registers](#)

# STR (array vector)

Store ZA array vector

The ZA array vector is selected by the sum of the vector select register and immediate offset, modulo the number of bytes in a Streaming SVE vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base, plus the same optional immediate offset multiplied by the current vector length in bytes. This instruction is unpredicated.

The store is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

## SME (FEAT\_SME)

```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

SUB (array accumulators)

Subtract multi-vector from ZA array vector accumulators

Destructively subtract all elements of the two or four source vectors from the corresponding elements of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

SUB (array results, multiple and single vector)

Subtract replicated single vector from multi-vector with ZA array vector results

Subtract all corresponding elements of the second source vector from the two or four first source vectors and place the results in the corresponding elements of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## SUDOT (multiple and indexed vector)

Multi-vector signed by unsigned integer dot-product by indexed elements

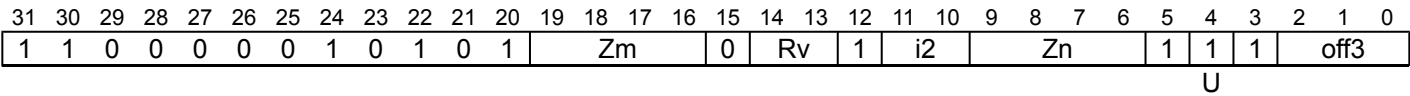

The signed by unsigned integer dot product instruction computes the dot product of four signed 8-bit integer values held in each 32-bit element of the two or four first source vectors and four unsigned 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

SUMLALL (multiple and indexed vector)

Multi-vector signed by unsigned integer multiply-add long-long by indexed element

This signed by unsigned integer multiply-add long-long instruction multiplies each signed 8-bit element in the one, two, or four first source vectors with each unsigned 8-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The element index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 4 bits. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

# SUMLALL (multiple and single vector)

Multi-vector signed by unsigned integer multiply-add long-long by vector

This signed by unsigned integer multiply-add long-long instruction multiplies each signed 8-bit element in the two or four first source vectors with each unsigned 8-bit element in the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

# SUMOPA

Signed by unsigned integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed by unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of signed 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of signed 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

SUMOPS

Signed by unsigned integer sum of outer products and subtract

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed by unsigned integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of signed 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of signed 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

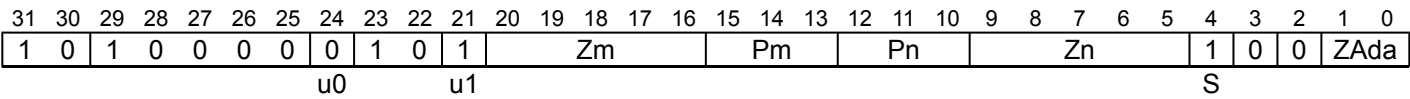

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

SUVDOT

Multi-vector signed by unsigned integer vertical dot-product by indexed element

The signed by unsigned integer vertical dot product instruction computes the vertical dot product of the corresponding signed 8-bit elements from the four first source vectors and four unsigned 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

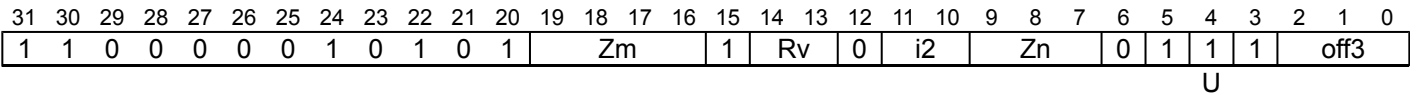

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

SME2

SVDOT (2-way)

Multi-vector signed integer vertical dot-product by indexed element

The signed integer vertical dot product instruction computes the vertical dot product of the corresponding two signed 16-bit integer values held in the two first source vectors and two signed 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The vector numbers forming the single-vector group within each half of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half the number of ZA array vectors.

The VECTOR GROUP symbol VGx2 indicates that the ZA operand consists of two ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

SME2

# SVDOT (4-way)

Multi-vector signed integer vertical dot-product by indexed element

The signed integer vertical dot product instruction computes the vertical dot product of the corresponding four signed 8-bit or 16-bit integer values held in the four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group.

The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

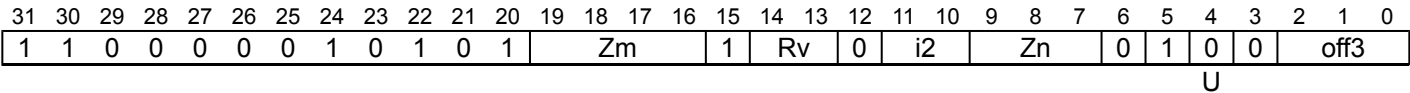

The VECTOR GROUP symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

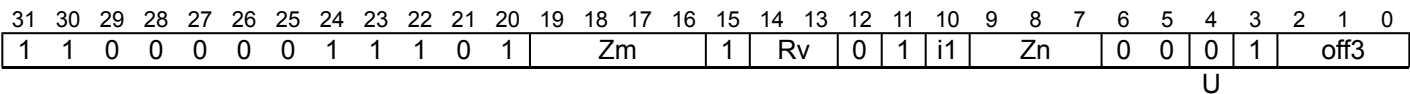

## 32-bit (FEAT\_SME2)

## UDOT (2-way, multiple and indexed vector)

Multi-vector unsigned integer dot-product by indexed element

The unsigned integer dot product instruction computes the dot product of two unsigned 16-bit integer values held in each 32-bit element of the two or four first source vectors and two unsigned 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## UDOT (2-way, multiple vectors)

Multi-vector unsigned integer dot-product

The unsigned integer dot product instruction computes the dot product of two unsigned 16-bit integer values held in each 32-bit element of the two or four first source vectors and two unsigned 16-bit integer values in the corresponding 32-bit element of the two or four second source vectors. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

## UDOT (4-way, multiple and indexed vector)

Multi-vector unsigned integer dot-product by indexed element

The unsigned integer dot product instruction computes the dot product of four unsigned 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four unsigned 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unreplicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 4 classes: [Two ZA single-vectors of 32-bit elements](#) , [Two ZA single-vectors of 64-bit elements](#) , [Four ZA single-vectors of 32-bit elements](#) and [Four ZA single-vectors of 64-bit elements](#)

## UMLAL (multiple and indexed vector)

Multi-vector unsigned integer multiply-add long by indexed element

This unsigned integer multiply-add long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

### One ZA double-vector

UMLAL (multiple and single vector)

Multi-vector unsigned integer multiply-add long by vector

This unsigned integer multiply-add long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit element in the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

# UMLALL (multiple and indexed vector)

Multi-vector unsigned integer multiply-add long-long by indexed element

This unsigned integer multiply-add long-long instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors with each unsigned 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: [One ZA quad-vector of 32-bit elements](#) , [One ZA quad-vector of 64-bit elements](#) , [Two ZA quad-vectors of 32-bit elements](#) , [Two ZA quad-vectors of 64-bit elements](#) , [Four ZA quad-vectors of 32-bit elements](#) and [Four ZA quad-vectors of 64-bit elements](#)

UMLALL (multiple vectors)

Multi-vector unsigned integer multiply-add long-long

This unsigned integer multiply-add long-long instruction multiplies each unsigned 8-bit or 16-bit element in the two or four first source vectors with each unsigned 8-bit or 16-bit element in the one, two, or four second source vectors, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

## UMLSL (multiple and indexed vector)

Multi-vector unsigned integer multiply-subtract long by indexed element

This unsigned integer multiply-subtract long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits. The lowest of the two consecutive vector numbers forming the double-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA double-vector](#) , [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

# UMLSL (multiple vectors)

Multi-vector unsigned integer multiply-subtract long

This unsigned integer multiply-subtract long instruction multiplies each unsigned 16-bit element in the two or four first source vectors with each unsigned 16-bit element in the two or four second source vectors, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups. The lowest of the two consecutive vector numbers forming the double-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA double-vectors](#) and [Four ZA double-vectors](#)

## UMLSLL (multiple and indexed vector)

Multi-vector unsigned integer multiply-subtract long-long by indexed element

This unsigned integer multiply-subtract long-long instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors with each unsigned 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: [One ZA quad-vector of 32-bit elements](#) , [One ZA quad-vector of 64-bit elements](#) , [Two ZA quad-vectors of 32-bit elements](#) , [Two ZA quad-vectors of 64-bit elements](#) , [Four ZA quad-vectors of 32-bit elements](#) and [Four ZA quad-vectors of 64-bit elements](#)

UMLSLL (multiple vectors)

Multi-vector unsigned integer multiply-subtract long-long

This unsigned integer multiply-subtract long-long instruction multiplies each unsigned 8-bit or 16-bit element in the two or four first source vectors with each unsigned 8-bit or 16-bit element in the one, two, or four second source vectors, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups. The lowest of the four consecutive vector numbers forming the quad-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

UMOPA (2-way)

Unsigned integer sum of outer products and accumulate

This instruction works with a 32-bit element ZA tile.

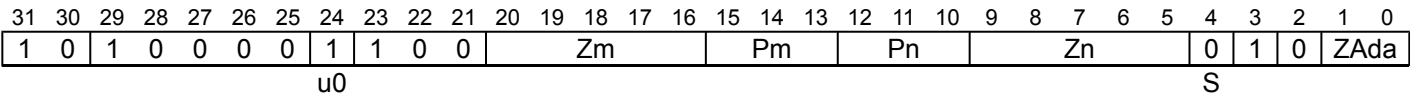

The unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds SVL<sub>S</sub>×2 sub-matrix of unsigned 16-bit integer values, and the second source holds 2×SVL<sub>S</sub> sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting SVL<sub>S</sub>×SVL<sub>S</sub> widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVL<sub>S</sub>×2 sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVL<sub>S</sub> sub-matrix.

UMOPA (4-way)

Unsigned integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of unsigned 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of unsigned 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

Multi-vector unsigned saturating extract narrow

Saturate the unsigned integer value in each element of the four source vectors to quarter the original source element width, and place the results in the quarter-width destination elements.  
This instruction is unpredicated.

SME2  
(FEAT\_SME2)

```
UQCVT <Zd>.<T>, { <Zn1>.<Tb>-<Zn4>.<Tb> }
```

```
if !HaveSME2() then UNDEFINED;
constant integer esize = 8 << UInt(sz);
integer n = UInt(Zn:'00');
integer d = UInt(Zd);
```

Assembler Symbols

- <Zd>

Is the name of the destination scalable vector register, encoded in the "Zd" field.
- <T>

Is the size specifier, encoded in "sz":

sz	<T>
0	B
1	H
- <Zn1>

Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 4.
- <Tb>

Is the size specifier, encoded in "sz":

sz	<Tb>
0	S
1	D
- <Zn4>

Is the name of the fourth scalable vector register of the source multi-vector group, encoded as "Zn" times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV (4 * esize);
bits(VL) result;

for r = 0 to 3
  bits(VL) operand = Z[n+r, VL];
  for e = 0 to elements-1
    integer element = UInt(Elem[operand, e, 4 * esize]);
    Elem[result, r*elements + e, esize] = UnsignedSat(element, esize);

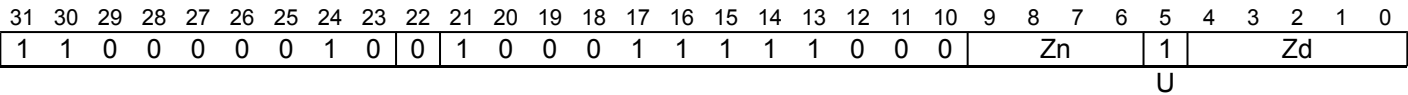

Z[d, VL] = result;
```

UQCVT (two registers)

Multi-vector unsigned saturating extract narrow

Saturate the unsigned integer value in each element of the two source vectors to half the original source element width, and place the results in the half-width destination elements.  
This instruction is unpredicated.

SME2  
(FEAT\_SME2)

```
UQCVT <Zd>.H, { <Zn1>.S-<Zn2>.S }
```

```
if !HaveSME2() then UNDEFINED;
constant integer esize = 16;
integer n = UInt(Zn:'0');
integer d = UInt(Zd);
```

Assembler Symbols

- <Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.
- <Zn1> Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 2.
- <Zn2> Is the name of the second scalable vector register of the source multi-vector group, encoded as "Zn" times 2 plus 1.

Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV (2 * esize);
bits(VL) result;

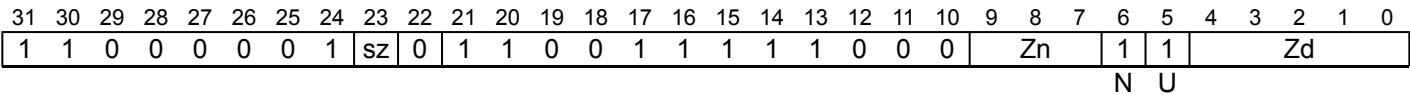

for r = 0 to 1
  bits(VL) operand = Z[n+r, VL];
  for e = 0 to elements-1
    integer element = UInt(Elem[operand, e, 2 * esize]);
    Elem[result, r*elements + e, esize] = UnsignedSat(element, esize);
Z[d, VL] = result;
```

UQCVTN

Multi-vector unsigned saturating extract narrow and interleave

Saturate the unsigned integer value in each element of the four source vectors to quarter the original source element width, and place the four-way interleaved results in the quarter-width destination elements.  
This instruction is unpredicated.

SME2  
(FEAT\_SME2)

```
UQCVTN <Zd>.<T>, { <Zn1>.<Tb>-<Zn4>.<Tb> }
```

```
if !HaveSME2() then UNDEFINED;
constant integer esize = 8 << UInt(sz);
integer n = UInt(Zn:'00');
integer d = UInt(Zd);
```

Assembler Symbols

- <Zd>

Is the name of the destination scalable vector register, encoded in the "Zd" field.
- <T>

Is the size specifier, encoded in "sz":

sz	<T>
0	B
1	H
- <Zn1>

Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 4.
- <Tb>

Is the size specifier, encoded in "sz":

sz	<Tb>
0	S
1	D
- <Zn4>

Is the name of the fourth scalable vector register of the source multi-vector group, encoded as "Zn" times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV (4 * esize);
bits(VL) result;

for e = 0 to elements-1
  for i = 0 to 3
    bits(VL) operand = Z[n+i, VL];
    integer element = UInt(Elem[operand, e, 4 * esize]);
    Elem[result, 4*e + i, esize] = UnsignedSat(element, esize);

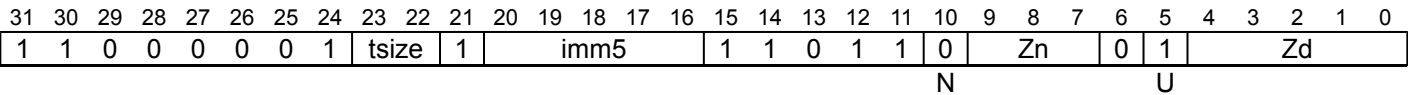

Z[d, VL] = result;
```

UQRSHR (four registers)

Multi-vector unsigned saturating rounding shift right narrow by immediate

Shift right by an immediate value, the unsigned integer value in each element of the four source vectors and place the rounded results in the quarter-width destination elements. Each result element is saturated to the quarter-width N-bit element's unsigned integer range 0 to (2<sup>N</sup>)-1. The immediate shift amount is an unsigned value in the range 1 to number of bits per source element.  
This instruction is unpredicated.

SME2  
(FEAT\_SME2)

UQRSHR <Zd>.<T>, { <Zn1>.<Tb>-<Zn4>.<Tb> }, #<const>

```
if !HaveSME2() then UNDEFINED;
if tsize == '00' then UNDEFINED;
constant integer esize = 8 << HighestSetBit(tsize);
integer n = UInt(Zn:'00');
integer d = UInt(Zd);
integer shift = (8 * esize) - UInt(tsize:imm5);
```

Assembler Symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> Is the size specifier, encoded in "tsize":

tsize	<T>
00	RESERVED
01	B
1x	H

<Zn1> Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 4.

<Tb> Is the size specifier, encoded in "tsize":

tsize	<Tb>
00	RESERVED
01	S
1x	D

<Zn4> Is the name of the fourth scalable vector register of the source multi-vector group, encoded as "Zn" times 4 plus 3.

<const> Is the immediate shift amount, in the range 1 to number of bits per source element, encoded in "tsize:imm5".

## Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV (4 * esize);
bits(VL) result;

for r = 0 to 3
    bits(VL) operand = Z[n+r, VL];
    for e = 0 to elements-1
        bits(4 * esize) element = Elem[operand, e, 4 * esize];
        integer res = (UInt(element) + (1 << (shift-1))) >> shift;
        Elem[result, r*elements + e, esize] = UnsignedSat(res, esize);

Z[d, VL] = result;
```

## USDOT (multiple and indexed vector)

Multi-vector unsigned by signed integer dot-product by indexed element

The unsigned by signed integer dot product instruction computes the dot product of four unsigned 8-bit integer values held in each 32-bit element of the two or four first source vectors and four signed 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

### Two ZA single-vectors

(FEAT\_SME2)

## USDOT (multiple and single vector)

Multi-vector unsigned by signed integer dot-product by vector

The unsigned by signed integer dot product instruction computes the dot product of four unsigned 8-bit integer values held in each 32-bit element of the two or four first source vectors and four signed 8-bit integer values in the corresponding 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code. This instruction is unpredicated.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

USMLALL (multiple and indexed vector)

Multi-vector unsigned by signed integer multiply-add long-long by indexed element

This unsigned by signed integer multiply-add long-long instruction multiplies each unsigned 8-bit element in the one, two, or four first source vectors with each signed 8-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The element index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 4 bits. The lowest of the four consecutive vector numbers forming the quad-vector group within all of, each half of, or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo all, half, or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: [One ZA quad-vector](#) , [Two ZA quad-vectors](#) and [Four ZA quad-vectors](#)

USMOPA

Unsigned by signed integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned by signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds  $SVL_S \times 4$  sub-matrix of unsigned 8-bit integer values, and the second source holds  $4 \times SVL_S$  sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds  $SVL_D \times 4$  sub-matrix of unsigned 16-bit integer values, and the second source holds  $4 \times SVL_D$  sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting  $SVL_S \times SVL_S$  widened 32-bit integer or  $SVL_D \times SVL_D$  widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_S \times 4$  sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_S$  sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a  $SVL_D \times 4$  sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a  $4 \times SVL_D$  sub-matrix.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

USVDDOT

Multi-vector unsigned by signed integer vertical dot-product by indexed element

The unsigned by signed integer vertical dot product instruction computes the vertical dot product of corresponding unsigned 8-bit elements from the four first source vectors and four signed 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

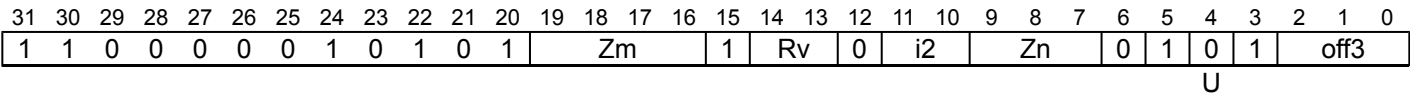

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

## UVDOT (4-way)

Multi-vector unsigned integer vertical dot-product by indexed element

The unsigned integer vertical dot product instruction computes the vertical dot product of the corresponding four unsigned 8-bit or 16-bit integer values held in the four first source vectors and four unsigned 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product results are destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group.

The vector numbers forming the single-vector group within each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo quarter the number of ZA array vectors.

The VECTOR GROUP symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The VECTOR GROUP symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID\_AA64SMFR0\_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: [32-bit](#) and [64-bit](#)

### 32-bit

## ZERO (single-vector)

Zero ZA single-vector groups

The instruction zeroes two or four ZA single-vector groups. The vector numbers forming the single-vector group within each half of or each quarter of the ZA array are selected by the sum of the vector select register and immediate offset, modulo half or quarter the number of ZA array vectors.

The VECTOR GROUP symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively.

It has encodings from 2 classes: [Two ZA single-vectors](#) and [Four ZA single-vectors](#)

### Two ZA single-vectors

(FEAT\_SME2p1)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	Rv	0	0	0	0	0	0	0	0	0	0	0	off3		

**ZERO** ZA.D[<Wv>, <offs>, VGx2]

```
if !HaveSME2p1() then UNDEFINED;
integer v = UInt('010':Rv);
integer offset = UInt(off3);
constant integer ngrp = 2;
```

### Four ZA single-vectors

(FEAT\_SME2p1)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	0	0	0	1	1	1	0	0	Rv	0	0	0	0	0	0	0	0	0	0	0	off3		

**ZERO** ZA.D[<Wv>, <offs>, VGx4]

```
if !HaveSME2p1() then UNDEFINED;
integer v = UInt('010':Rv);
integer offset = UInt(off3);
constant integer ngrp = 4;
```

### Assembler Symbols

- <Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
- <offs> Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.

### Operation

```
CheckStreamingSVEAndZAEEnabled();
constant integer VL = CurrentVL;
integer vectors = VL DIV 8;
integer vstride = vectors DIV ngrp;
bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;

for r = 0 to ngrp-1
    ZAvector[vec, VL] = Zeros(VL);
    vec = vec + vstride;
```

### Operational information

ZERO (table)

Zero ZT0

Zero all bytes of the ZT0 register.  
This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

SME2  
(FEAT\_SME2)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	1	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

ZERO { ZT0 }

```
if !HaveSME2() then UNDEFINED;
```

Operation

```
CheckSMEEnabled();  
CheckSMEZT0Enabled();  
  
if HaveTME() && TSTATE.depth > 0 then  
    FailTransaction(TMFailure_ERR, FALSE);  
  
ZT0[512] = Zeros(512);
```

Operational information

- If PSTATE.DIT is 1:
- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
  - The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

ZERO (tiles)

Zero a list of 64-bit element ZA tiles

Zeroes all bytes within each of the up to eight listed 64-bit element tiles named ZA0.D to ZA7.D, leaving the other 64-bit element tiles unmodified.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

For programmer convenience an assembler must also accept the names of 32-bit, 16-bit, and 8-bit element tiles which are converted into the corresponding set of 64-bit element tiles.

In accordance with the architecturally defined mapping between different element size tiles:

- Zeroing the 8-bit element tile name ZA0.B, or the entire array name ZA, is equivalent to zeroing all eight 64-bit element tiles named ZA0.D to ZA7.D.
- Zeroing the 16-bit element tile name ZA0.H is equivalent to zeroing 64-bit element tiles named ZA0.D, ZA2.D, ZA4.D, and ZA6.D.
- Zeroing the 16-bit element tile name ZA1.H is equivalent to zeroing 64-bit element tiles named ZA1.D, ZA3.D, ZA5.D, and ZA7.D.
- Zeroing the 32-bit element tile name ZA0.S is equivalent to zeroing 64-bit element tiles named ZA0.D and ZA4.D.
- Zeroing the 32-bit element tile name ZA1.S is equivalent to zeroing 64-bit element tiles named ZA1.D and ZA5.D.
- Zeroing the 32-bit element tile name ZA2.S is equivalent to zeroing 64-bit element tiles named ZA2.D and ZA6.D.
- Zeroing the 32-bit element tile name ZA3.S is equivalent to zeroing 64-bit element tiles named ZA3.D and ZA7.D.

The preferred disassembly of this instruction uses the shortest list of tile names that represent the encoded immediate mask.

For example:

- An immediate which encodes 64-bit element tiles ZA0.D, ZA1.D, ZA4.D, and ZA5.D is disassembled as {ZA0.S, ZA1.S}.
- An immediate which encodes 64-bit element tiles ZA0.D, ZA2.D, ZA4.D, and ZA6.D is disassembled as {ZA0.H}.
- An all-ones immediate is disassembled as {ZA}.
- An all-zeros immediate is disassembled as an empty list { }.

SME  
(FEAT\_SME)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
1	1	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	imm8									

ZERO { <mask> }

```
if !HaveSME() then UNDEFINED;
bits(8) mask = imm8;
constant integer esize = 64;
```

Assembler Symbols

<mask> Is a list of up to eight 64-bit element tile names separated by commas, encoded in the "imm8" field.

## Operation

```
CheckSMEAndZAEnabled();  
constant integer SVL = CurrentSVL;  
constant integer dim = SVL DIV esize;  
bits(dim*dim*esize) result = Zeros(dim*dim*esize);  
  
if HaveTME() && TSTATE.depth > 0 then  
    FailTransaction(TMFailure_ERR, FALSE);  
  
for i = 0 to 7  
    if mask<i> == '1' then ZAtile[i, esize, dim*dim*esize] = result;
```
