UMMLA

Unsigned integer matrix multiply-accumulate

The unsigned integer matrix multiply-accumulate instruction multiplies the 2×8 matrix of unsigned 8-bit integer values held in each 128-bit segment of the first source vector by the 8×2 matrix of unsigned 8-bit integer values in the corresponding segment of the second source vector. The resulting 2×2 widened 32-bit integer matrix product is then destructively added to the 32-bit integer matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing an 8-way dot product per destination element.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

UQADD (immediate)

Unsigned saturating add immediate (unpredicated)

Unsigned saturating add of an unsigned immediate to each element of the source vector, and destructively place the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<uimm8>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

															U																

```
UQADD <Zdn>.<T>, <Zdn>.<T>, #<imm>{, <shift>}
```

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
if size:sh == '001' then EndOfDecode(Decode_UNDEF);
constant integer esize = 8 << UInt(size);
constant integer dn = UInt(Zdn);
integer imm = UInt(imm8);
if sh == '1' then imm = imm << 8;
constant boolean unsigned = TRUE;
```

Assembler Symbols

<Zdn> Is the name of the source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<imm> Is an unsigned immediate in the range 0 to 255, encoded in the "imm8" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #8

Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant bits(VL) operand1 = Z[dn, VL];
bits(VL) result;

for e = 0 to elements-1
    constant integer element1 = Int(Elem[operand1, e, esize], unsigned);
    (Elem[result, e, esize], -) = SatQ(element1 + imm, esize, unsigned);

Z[dn, VL] = result;
```

Operational information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

UQDECB

Unsigned saturating decrement scalar by multiple of 8-bit predicate constraint element count

Determines the number of active 8-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement the scalar destination. The result is saturated to the general-purpose register's unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

It has encodings from 2 classes: 32-bit and 64-bit

32-bit

UQDECH (vector)

Unsigned saturating decrement vector by multiple of 16-bit predicate constraint element count

Determines the number of active 16-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to decrement all destination vector elements. The results are saturated to the 16-bit unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

UQINCD (vector)

Unsigned saturating increment vector by multiple of 64-bit predicate constraint element count

Determines the number of active 64-bit elements implied by the named predicate constraint, multiplies that by an immediate in the range 1 to 16 inclusive, and then uses the result to increment all destination vector elements. The results are saturated to the 64-bit unsigned integer range.

The named predicate constraint limits the number of active elements in a single predicate to:

- A fixed number (VL1 to VL256)
- The largest power of two (POW2)
- The largest multiple of three or four (MUL3 or MUL4)
- All available, implicitly a multiple of two (ALL).

Unspecified or out of range constraint encodings generate an empty predicate or zero element count rather than Undefined Instruction exception.

<imm> Is the immediate multiplier, in the range 1 to 16, defaulting to 1, encoded in the "imm4" field.

Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant integer count = DecodePredCount(pat, esize);
constant bits(VL) operand1 = Z[dn, VL];
bits(VL) result;

for e = 0 to elements-1
    constant integer element1 = Int(Elem[operand1, e, esize], unsigned);
    (Elem[result, e, esize], -) = SatQ(element1 + (count * imm), esize, unsigned);

Z[dn, VL] = result;
```

Operational information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

```

Operational information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of this instruction.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

    Elem[result, 2*e + 1, esize] = UnsignedSat(res, esize);

Z[d, VL] = result;
```

UQSUB (immediate)

Unsigned saturating subtract immediate (unpredicated)

Unsigned saturating subtract an unsigned immediate from each element of the source vector, and destructively place the results in the corresponding elements of the source vector. Each result element is saturated to the N-bit element's unsigned integer range 0 to (2^N)-1. This instruction is unpredicated.

The immediate is an unsigned value in the range 0 to 255, and for element widths of 16 bits or higher it may also be a positive multiple of 256 in the range 256 to 65280.

The immediate is encoded in 8 bits with an optional left shift by 8. The preferred disassembly when the shift option is specified is "#<uimm8>, LSL #8". However an assembler and disassembler may also allow use of the shifted 16-bit value unless the immediate is 0 and the shift amount is 8, which must be unambiguously described as "#0, LSL #8".

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

constant integer da = UInt(Zda);
constant integer shift = (2 * esize) - UInt(tsize:imm3);
```

Assembler Symbols

<Zda> Is the name of the third source and destination scalable vector register, encoded in the "Zda" field.

<T> Is the size specifier, encoded in “tszh:tszl”:

tszh	tszl	<T>
00	00	RESERVED
00	01	B
00	1x	H
01	xx	S
1x	xx	D

<Zn> Is the name of the first source scalable vector register, encoded in the "Zn" field.

<const> Is the immediate shift amount, in the range 1 to number of bits per element, encoded in "tszh:tszl:imm3".

Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant bits(VL) operand1 = Z[n, VL];
constant bits(VL) operand2 = Z[da, VL];
bits(VL) result;

for e = 0 to elements-1
    constant integer element = (UInt(Elem[operand1, e, esize]) + (1 << (shift - 1))) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

Z[da, VL] = result;
```

Operational information

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

USDOT (indexed)

Unsigned by signed integer indexed dot product

The unsigned by signed integer indexed dot product instruction computes the dot product of a group of four unsigned 8-bit integer values held in each 32-bit element of the first source vector multiplied by a group of four signed 8-bit integer values in an indexed 32-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit element of the destination vector.

The groups within the second source vector are specified using an immediate index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3. This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

SVE

(FEAT_I8MM)

USDOT (vectors)

Unsigned by signed integer dot product

The unsigned by signed integer dot product instruction computes the dot product of a group of four unsigned 8-bit integer values held in each 32-bit element of the first source vector multiplied by a group of four signed 8-bit integer values in the corresponding 32-bit element of the second source vector, and then destructively adds the widened dot product to the corresponding 32-bit element of the destination vector.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

USMMLA

Unsigned by signed integer matrix multiply-accumulate

The unsigned by signed integer matrix multiply-accumulate instruction multiplies the 2×8 matrix of unsigned 8-bit integer values held in each 128-bit segment of the first source vector by the 8×2 matrix of signed 8-bit integer values in the corresponding segment of the second source vector. The resulting 2×2 widened 32-bit integer matrix product is then destructively added to the 32-bit integer matrix accumulator held in the corresponding segment of the addend and destination vector. This is equivalent to performing an 8-way dot product per destination element.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.I8MM indicates whether this instruction is implemented.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

UXTB, UXTH, UXTW

Unsigned byte / halfword / word extend (predicated)

Zero-extend the least-significant sub-element of each active element of the source vector, and place the results in the corresponding elements of the destination vector. Inactive elements in the destination vector register remain unmodified or are set to zero, depending on whether merging or zeroing predication is selected.

It has encodings from 6 classes: Byte, merging , Byte, zeroing , Halfword, merging , Halfword, zeroing , Word, merging and Word, zeroing

Byte, merging

Assembler Symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<T> For the "Byte, merging" and "Byte, zeroing" variants: is the size specifier, encoded in “size”:

size	<T>
00	RESERVED
01	H
10	S
11	D

For the "Halfword, merging" and "Halfword, zeroing" variants: is the size specifier, encoded in “size<0>”:

size<0>	<T>
0	S
1	D

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn> Is the name of the source scalable vector register, encoded in the "Zn" field.

Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
constant bits(PL) mask = P[g, PL];
constant bits(VL) operand = if AnyActiveElement(mask, esize) then Z[n, VL] else Zeros(VL);
bits(VL) result = if merging then Z[d, VL] else Zeros(VL);

for e = 0 to elements-1
    if ActivePredicateElement(mask, e, esize) then
        constant bits(esize) element = Elem[operand, e, esize];
        Elem[result, e, esize] = Extend(element<s_esize-1:0>, esize, unsigned);

Z[d, VL] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
    - The values of the NZCV flags.

The merging variant of this instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and the merging variant of this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` can be predicated or unpredicated.
- A predicated `MOVPRFX` must use the same governing predicate register as the merging variant this instruction.
- A predicated `MOVPRFX` must use the larger of the destination element size and first source element size in the preferred disassembly of the merging variant of this instruction.
- The `MOVPRFX` must specify the same destination register as the merging variant of this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of the merging variant of this instruction.

UZP1, UZP2 (vectors)

Concatenate even or odd elements from two vectors

Concatenate adjacent even or odd-numbered elements from the first and second source vectors and place in elements of the destination vector. This instruction is unpredicated.

Note: UZP1 is equivalent to truncating and packing each element from two source vectors into a single destination vector with elements of half the size.

The 128-bit element variant requires that the Effective SVE vector length is at least 256 bits. ID_AA64ZFR0_EL1.F64MM indicates whether the 128-bit element variant is implemented. The 128-bit element variant is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 4 classes: Even , Even (quadwords) , Odd and Odd (quadwords)

Even

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

WHILEGE (predicate as counter)

While decrementing signed scalar greater than or equal to scalar (predicate-as-counter)

Generate a predicate for a group of two or four vectors that starting from the highest numbered element of the group is true while the decrementing value of the first, signed scalar operand is greater than or equal to the second scalar operand and false thereafter down to the lowest numbered element of the group.

If the second scalar operand is equal to the minimum signed integer value then a condition which includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is decremented by one for each destination predicate element, irrespective of the predicate result element size.

The predicate result is placed in the predicate destination register using the predicate-as-counter encoding. Sets the First (N), None (Z), !Last (C) condition flags based on the predicate result, and the V flag to zero.

WHILEGT (predicate)

While decrementing signed scalar greater than scalar

Generate a predicate that starting from the highest numbered element is true while the decrementing value of the first, signed scalar operand is greater than the second scalar operand and false thereafter down to the lowest numbered element.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is decremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The predicate result is placed in the predicate destination register. Sets the First (N), None (Z), !Last (C) condition flags based on the predicate result, and the V flag to zero.

WHILELE (predicate pair)

While incrementing signed scalar less than or equal to scalar (pair of predicates)

Generate a pair of predicates that starting from the lowest numbered element of the pair is true while the incrementing value of the first, signed scalar operand is less than or equal to the second scalar operand and false thereafter up to the highest numbered element of the pair.

If the second scalar operand is equal to the maximum signed integer value then a condition which includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is incremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The lower-numbered elements are placed in the first predicate destination register, and the higher-numbered elements in the second predicate destination register. Sets the First (N), None (Z), !Last (C) condition flags based on the predicate result, and the V flag to zero.

WHILELS (predicate)

While incrementing unsigned scalar lower or same as scalar

Generate a predicate that starting from the lowest numbered element is true while the incrementing value of the first, unsigned scalar operand is lower or same as the second scalar operand and false thereafter up to the highest numbered element.

If the second scalar operand is equal to the maximum unsigned integer value then a condition which includes an equality test can never fail and the result will be an all-true predicate.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is incremented by one for each destination predicate element, irrespective of the predicate result element size. The first general-purpose source register is not itself updated.

The predicate result is placed in the predicate destination register. Sets the First (N), None (Z), !Last (C) condition flags based on the predicate result, and the V flag to zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

WHILELT (predicate as counter)

While incrementing signed scalar less than scalar (predicate-as-counter)

Generate a predicate for a group of two or four vectors that starting from the lowest numbered element of the group is true while the incrementing value of the first, signed scalar operand is less than the second scalar operand and false thereafter up to the highest numbered element of the group.

The full width of the scalar operands is significant for the purposes of comparison, and the full width first operand is incremented by one for each destination predicate element, irrespective of the predicate result element size.

The predicate result is placed in the predicate destination register using the predicate-as-counter encoding. Sets the First (N), None (Z), !Last (C) condition flags based on the predicate result, and the V flag to zero.

WHILERW

While free of read-after-write conflicts

This instruction checks two addresses for a conflict or overlap between address ranges of the form [addr,addr+VL÷8), where VL is the accessible vector length in bits, that could result in a loop-carried dependency through memory due to the use of these addresses by contiguous load and store instructions within the same iteration of a loop. Generate a predicate whose elements are true while the addresses cannot conflict within the same iteration, and false thereafter. Sets the First (N), None (Z), !Last (C) condition flags based on the predicate result, and the V flag to zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

WRFFR

Write the first-fault register

Read the source predicate register and place in the first-fault register (FFR). This instruction is intended to restore a saved FFR and is not recommended for general use by applications.

This instruction requires that the source predicate contains a monotonic predicate value, in which starting from bit 0 there are zero or more 1 bits, followed only by 0 bits in any remaining bit positions. If the source is not a monotonic predicate value, then the resulting value in the FFR will be UNPREDICTABLE. It is not possible to generate a non-monotonic value in FFR when using `SETFFR` followed by first-fault or non-fault loads.

This instruction is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if tsize == '0000' then EndOfDecode(Decode_UNDEF);
constant integer esize = 8 << HighestSetBit(tsize);
constant integer m = UInt(Zm);
constant integer dn = UInt(Zdn);
constant integer rot = (2 * esize) - UInt(tsize:imm3);
```

Assembler Symbols

<Zdn> Is the name of the first source and destination scalable vector register, encoded in the "Zdn" field.

<T> Is the size specifier, encoded in “tszh:tszl”:

tszh	tszl	<T>
00	00	RESERVED
00	01	B
00	1x	H
01	xx	S
1x	xx	D

<Zm> Is the name of the second source scalable vector register, encoded in the "Zm" field.

<const> Is the immediate shift amount, in the range 1 to number of bits per element, encoded in "tszh:tszl:imm3".

Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant bits(VL) operand1 = Z[dn, VL];
constant bits(VL) operand2 = Z[m, VL];
bits(VL) result;

for e = 0 to elements-1
    constant bits(esize) element1 = Elem[operand1, e, esize];
    constant bits(esize) element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = ROR(element1 EOR element2, rot);
Z[dn, VL] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

This instruction might be immediately preceded in program order by a `MOVPRFX` instruction. The `MOVPRFX` must conform to all of the following requirements, otherwise the behavior of the `MOVPRFX` and this instruction is CONSTRAINED UNPREDICTABLE:

- The `MOVPRFX` must be unpredicated.
- The `MOVPRFX` must specify the same destination register as this instruction.
- The destination register must not refer to architectural register state referenced by any other source operand register of this instruction.

```
if !IsFeatureImplemented(FEAT_SVE) && !IsFeatureImplemented(FEAT_SME) then
    EndOfDecode(Decode_UNDEF);
constant integer esize = 8 << UInt(size);
constant integer n = UInt(Pn);
constant integer m = UInt(Pm);
constant integer d = UInt(Pd);
constant integer part = 0;
```

Assembler Symbols

<Pd> Is the name of the destination scalable predicate register, encoded in the "Pd" field.

<T> Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Pn> Is the name of the first source scalable predicate register, encoded in the "Pn" field.

<Pm> Is the name of the second source scalable predicate register, encoded in the "Pm" field.

Operation

```
CheckSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer pairs = VL DIV (esize * 2);
constant bits(PL) operand1 = P[n, PL];
constant bits(PL) operand2 = P[m, PL];
bits(PL) result;

constant integer base = part * pairs;
for p = 0 to pairs-1
    Elem[result, 2*p+0, esize DIV 8] = Elem[operand1, base+p, esize DIV 8];
    Elem[result, 2*p+1, esize DIV 8] = Elem[operand2, base+p, esize DIV 8];

P[d, PL] = result;
```

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

ZIP1, ZIP2 (vectors)

Interleave elements from two half vectors

Interleave alternating elements from the lowest or highest halves of the first and second source vectors and place in elements of the destination vector. This instruction is unpredicated.

The 128-bit element variant requires that the Effective SVE vector length is at least 256 bits. ID_AA64ZFR0_EL1.F64MM indicates whether the 128-bit element variant is implemented. The 128-bit element variant is illegal when executed in Streaming SVE mode, unless FEAT_SME_FA64 is implemented and enabled.

It has encodings from 4 classes: High halves , High halves (quadwords) , Low halves and Low halves (quadwords)

High halves

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

A64 -- SME Instructions (alphabetic order)

ADD (array accumulators): Add multi-vector to ZA array vector accumulators.

ADD (array results, multiple and single vector): Add replicated single vector to multi-vector with ZA array vector results.

ADD (array results, multiple vectors): Add multi-vector to multi-vector with ZA array vector results.

ADD (to vector): Add replicated single vector to multi-vector with multi-vector result.

ADDHA: Add horizontally vector elements to ZA tile.

ADDSPL: Add multiple of Streaming SVE predicate register size to scalar register.

ADDSVL: Add multiple of Streaming SVE vector register size to scalar register.

ADDVA: Add vertically vector elements to ZA tile.

BF1CVT, BF2CVT: Multi-vector floating-point convert from 8-bit floating-point to BFloat16 (in-order).

BF1CVTL, BF2CVTL: Multi-vector floating-point convert from 8-bit floating-point to deinterleaved BFloat16.

BFADD: BFloat16 floating-point add multi-vector to ZA array vector accumulators.

BFCLAMP: Multi-vector BFloat16 floating-point clamp to minimum/maximum number.

BFCVT: Multi-vector floating-point convert from single-precision to packed BFloat16 format.

BFCVT: Multi-vector floating-point convert from BFloat16 to packed 8-bit floating-point format.

BFCVTN: Multi-vector floating-point convert from single-precision to interleaved BFloat16 format.

BFDOT (multiple and indexed vector): Multi-vector BFloat16 floating-point dot-product by indexed element.

BFDOT (multiple and single vector): Multi-vector BFloat16 floating-point dot-product by vector.

BFDOT (multiple vectors): Multi-vector BFloat16 floating-point dot-product.

BFMAX (multiple and single vector): Multi-vector BFloat16 floating-point maximum by vector.

BFMAX (multiple vectors): Multi-vector BFloat16 floating-point maximum.

BFMAXNM (multiple and single vector): Multi-vector BFloat16 floating-point maximum number by vector.

BFMAXNM (multiple vectors): Multi-vector BFloat16 floating-point maximum number.

BFMIN (multiple and single vector): Multi-vector BFloat16 floating-point minimum by vector.

BFMIN (multiple vectors): Multi-vector BFloat16 floating-point minimum.

BFMINNM (multiple and single vector): Multi-vector BFloat16 floating-point minimum number by vector.

BFMINNM (multiple vectors): Multi-vector BFloat16 floating-point minimum number.

BFMLA (multiple and indexed vector): Multi-vector BFloat16 floating-point fused multiply-add by indexed element.

BFMLA (multiple and single vector): Multi-vector BFloat16 floating-point fused multiply-add by vector.

BFMLA (multiple vectors): Multi-vector BFloat16 floating-point fused multiply-add.

BFMLAL (multiple and indexed vector): Multi-vector BFloat16 floating-point multiply-add long by indexed element.

BFMLAL (multiple and single vector): Multi-vector BFloat16 floating-point multiply-add long by vector.

BFMLAL (multiple vectors): Multi-vector BFloat16 floating-point multiply-add long.

BFMLS (multiple and indexed vector): Multi-vector BFloat16 floating-point fused multiply-subtract by indexed element.

BFMLS (multiple and single vector): Multi-vector BFloat16 floating-point fused multiply-subtract by vector.

BFMLS (multiple vectors): Multi-vector BFloat16 floating-point fused multiply-subtract.

BFMLSL (multiple and indexed vector): Multi-vector BFloat16 floating-point multiply-subtract long by indexed element.

BFMLSL (multiple and single vector): Multi-vector BFloat16 floating-point multiply-subtract long by vector.

BFMLSL (multiple vectors): Multi-vector BFloat16 floating-point multiply-subtract long.

BFMOP4A (non-widening): BFloat16 quarter-tile outer products, accumulating.

BFMOP4A (widening): BFloat16 quarter-tile sums of two outer products, accumulating.

BFMOP4S (non-widening): BFloat16 quarter-tile outer products, subtracting.

BFMOP4S (widening): BFloat16 quarter-tile sums of two outer products, subtracting.

BFMOPA (non-widening): BFloat16 floating-point outer product and accumulate.

BFMOPA (widening): BFloat16 sum of outer products and accumulate.

BFMOPS (non-widening): BFloat16 floating-point outer product and subtract.

BFMOPS (widening): BFloat16 sum of outer products and subtract.

BFMUL (multiple and single vector): Multi-vector BFloat16 floating-point multiply by vector.

BFMUL (multiple vectors): Multi-vector BFloat16 floating-point multiply.

BFSCALE (multiple and single vector): Multi-vector BFloat16 adjust exponent by vector.

BFSCALE (multiple vectors): Multi-vector BFloat16 adjust exponent.

BFSUB: BFloat16 floating-point subtract multi-vector from ZA array vector accumulators.

BFTMOPA (non-widening): BFloat16 sparse outer product, accumulating.

BFTMOPA (widening): BFloat16 sparse sum of two outer products, accumulating.

BFVDOT: Multi-vector BFloat16 floating-point vertical dot-product by indexed element.

BMOPA: Bitwise exclusive NOR population count outer product and accumulate.

BMOPS: Bitwise exclusive NOR population count outer product and subtract.

F1CVT, F2CVT: Multi-vector floating-point convert from 8-bit floating-point to half-precision (in-order).

F1CVTL, F2CVTL: Multi-vector floating-point convert from 8-bit floating-point to deinterleaved half-precision.

FADD: Floating-point add multi-vector to ZA array vector accumulators.

FAMAX: Multi-vector floating-point absolute maximum.

FAMIN: Multi-vector floating-point absolute minimum.

FCLAMP: Multi-vector floating-point clamp to minimum/maximum number.

FCVT (narrowing, FP16 to FP8): Multi-vector floating-point convert from half-precision to packed 8-bit floating-point format.

FCVT (narrowing, FP32 to FP16): Multi-vector floating-point convert from single-precision to packed half-precision.

FCVT (narrowing, FP32 to FP8): Multi-vector floating-point convert from single-precision to packed 8-bit floating-point format.

FCVT (widening): Multi-vector floating-point convert from half-precision to single-precision (in-order).

FCVTL: Multi-vector floating-point convert from half-precision to deinterleaved single-precision.

FCVTN (FP32 to FP16): Multi-vector floating-point convert from single-precision to interleaved half-precision.

FCVTN (FP32 to FP8): Multi-vector floating-point convert from single-precision to interleaved 8-bit floating-point format.

FCVTZS: Multi-vector floating-point convert to signed integer, rounding toward zero.

FCVTZU: Multi-vector floating-point convert to unsigned integer, rounding toward zero.

FDOT (2-way, multiple and indexed vector, FP16 to FP32): Multi-vector half-precision floating-point dot-product by indexed element.

FDOT (2-way, multiple and indexed vector, FP8 to FP16): Multi-vector 8-bit floating-point dot-product by indexed element to half-precision.

FDOT (2-way, multiple and single vector, FP16 to FP32): Multi-vector half-precision floating-point dot-product by vector.

FDOT (2-way, multiple and single vector, FP8 to FP16): Multi-vector 8-bit floating-point dot-product by vector to half-precision.

FDOT (2-way, multiple vectors, FP16 to FP32): Multi-vector half-precision floating-point dot-product.

FDOT (2-way, multiple vectors, FP8 to FP16): Multi-vector 8-bit floating-point dot-product to half-precision.

FDOT (4-way, multiple and indexed vector): Multi-vector 8-bit floating-point dot-product by indexed element to single-precision.

FDOT (4-way, multiple and single vector): Multi-vector 8-bit floating-point dot-product by vector to single-precision.

FDOT (4-way, multiple vectors): Multi-vector 8-bit floating-point dot-product to single-precision.

FMAX (multiple and single vector): Multi-vector floating-point maximum by vector.

FMAX (multiple vectors): Multi-vector floating-point maximum.

FMAXNM (multiple and single vector): Multi-vector floating-point maximum number by vector.

FMAXNM (multiple vectors): Multi-vector floating-point maximum number.

FMIN (multiple and single vector): Multi-vector floating-point minimum by vector.

FMIN (multiple vectors): Multi-vector floating-point minimum.

FMINNM (multiple and single vector): Multi-vector floating-point minimum number by vector.

FMINNM (multiple vectors): Multi-vector floating-point minimum number.

FMLA (multiple and indexed vector): Multi-vector floating-point fused multiply-add by indexed element.

FMLA (multiple and single vector): Multi-vector floating-point fused multiply-add by vector.

FMLA (multiple vectors): Multi-vector floating-point fused multiply-add.

FMLAL (multiple and indexed vector, FP16 to FP32): Multi-vector floating-point multiply-add long by indexed element.

FMLAL (multiple and indexed vector, FP8 to FP16): Multi-vector 8-bit floating-point multiply-add long by indexed element to half-precision.

FMLAL (multiple and single vector, FP16 to FP32): Multi-vector floating-point multiply-add long by vector.

FMLAL (multiple and single vector, FP8 to FP16): Multi-vector 8-bit floating-point multiply-add long by vector to half-precision.

FMLAL (multiple vectors, FP16 to FP32): Multi-vector floating-point multiply-add long.

FMLAL (multiple vectors, FP8 to FP16): Multi-vector 8-bit floating-point multiply-add long to half-precision.

FMLALL (multiple and indexed vector): Multi-vector 8-bit floating-point multiply-add long-long by indexed element to single-precision.

FMLALL (multiple and single vector): Multi-vector 8-bit floating-point multiply-add long-long by vector to single-precision.

FMLALL (multiple vectors): Multi-vector 8-bit floating-point multiply-add long-long to single-precision.

FMLS (multiple and indexed vector): Multi-vector floating-point fused multiply-subtract by indexed element.

FMLS (multiple and single vector): Multi-vector floating-point fused multiply-subtract by vector.

FMLS (multiple vectors): Multi-vector floating-point fused multiply-subtract.

FMLSL (multiple and indexed vector): Multi-vector floating-point multiply-subtract long by indexed element.

FMLSL (multiple and single vector): Multi-vector floating-point multiply-subtract long by vector.

FMLSL (multiple vectors): Multi-vector floating-point multiply-subtract long.

FMOP4A (non-widening): Floating-point quarter-tile outer products, accumulating.

FMOP4A (widening, 2-way, FP16 to FP32): Half-precision quarter-tile sums of two outer products, accumulating.

FMOP4A (widening, 2-way, FP8 to FP16): 8-bit floating-point quarter-tile sums of two outer products, accumulating.

FMOP4A (widening, 4-way): 8-bit floating-point quarter-tile sums of four outer products, accumulating.

FMOP4S (non-widening): Floating-point quarter-tile outer products, subtracting.

FMOP4S (widening): Half-precision quarter-tile sums of two outer products, subtracting.

FMOPA (non-widening): Floating-point outer product and accumulate.

FMOPA (widening, 2-way, FP16 to FP32): Half-precision floating-point sum of outer products and accumulate.

FMOPA (widening, 2-way, FP8 to FP16): 8-bit floating-point sum of outer products and accumulate.

FMOPA (widening, 4-way): 8-bit floating-point sum of outer products and accumulate.

FMOPS (non-widening): Floating-point outer product and subtract.

FMOPS (widening): Half-precision floating-point sum of outer products and subtract.

FMUL (multiple and single vector): Multi-vector floating-point multiply by vector.

FMUL (multiple vectors): Multi-vector floating-point multiply.

FRINTA: Multi-vector floating-point round to integral value, to nearest with ties away from zero.

FRINTM: Multi-vector floating-point round to integral value, toward minus Infinity.

FRINTN: Multi-vector floating-point round to integral value, to nearest with ties to even.

FRINTP: Multi-vector floating-point round to integral value, toward plus Infinity.

FSCALE (multiple and single vector): Multi-vector floating-point adjust exponent by vector.

FSCALE (multiple vectors): Multi-vector floating-point adjust exponent.

FSUB: Floating-point subtract multi-vector from ZA array vector accumulators.

FTMOPA (non-widening): Floating-point sparse outer product, accumulating.

FTMOPA (widening, 2-way, FP16 to FP32): Half-precision sparse sum of two outer products, accumulating.

FTMOPA (widening, 2-way, FP8 to FP16): 8-bit floating-point sparse sum of two outer products, accumulating.

FTMOPA (widening, 4-way): 8-bit floating-point sparse sum of four outer products, accumulating.

FVDOT (FP16 to FP32): Multi-vector half-precision floating-point vertical dot-product by indexed element.

FVDOT (FP8 to FP16): Multi-vector 8-bit floating-point vertical dot-product by indexed element to half-precision.

FVDOTB: Multi-vector 8-bit floating-point vertical dot-product by indexed element to single-precision (bottom).

FVDOTT: Multi-vector 8-bit floating-point vertical dot-product by indexed element to single-precision (top).

LD1B (scalar plus immediate, strided registers): Contiguous load of bytes to multiple strided vectors (immediate index).

LD1B (scalar plus scalar, strided registers): Contiguous load of bytes to multiple strided vectors (scalar index).

LD1B (scalar plus scalar, tile slice): Contiguous load of bytes to 8-bit element ZA tile slice.

LD1D (scalar plus immediate, strided registers): Contiguous load of doublewords to multiple strided vectors (immediate index).

LD1D (scalar plus scalar, strided registers): Contiguous load of doublewords to multiple strided vectors (scalar index).

LD1D (scalar plus scalar, tile slice): Contiguous load of doublewords to 64-bit element ZA tile slice.

LD1H (scalar plus immediate, strided registers): Contiguous load of halfwords to multiple strided vectors (immediate index).

LD1H (scalar plus scalar, strided registers): Contiguous load of halfwords to multiple strided vectors (scalar index).

LD1H (scalar plus scalar, tile slice): Contiguous load of halfwords to 16-bit element ZA tile slice.

LD1Q: Contiguous load of quadwords to 128-bit element ZA tile slice.

LD1W (scalar plus immediate, strided registers): Contiguous load of words to multiple strided vectors (immediate index).

LD1W (scalar plus scalar, strided registers): Contiguous load of words to multiple strided vectors (scalar index).

LD1W (scalar plus scalar, tile slice): Contiguous load of words to 32-bit element ZA tile slice.

LDNT1B (scalar plus immediate, strided registers): Contiguous load non-temporal of bytes to multiple strided vectors (immediate index).

LDNT1B (scalar plus scalar, strided registers): Contiguous load non-temporal of bytes to multiple strided vectors (scalar index).

LDNT1D (scalar plus immediate, strided registers): Contiguous load non-temporal of doublewords to multiple strided vectors (immediate index).

LDNT1D (scalar plus scalar, strided registers): Contiguous load non-temporal of doublewords to multiple strided vectors (scalar index).

LDNT1H (scalar plus immediate, strided registers): Contiguous load non-temporal of halfwords to multiple strided vectors (immediate index).

LDNT1H (scalar plus scalar, strided registers): Contiguous load non-temporal of halfwords to multiple strided vectors (scalar index).

LDNT1W (scalar plus immediate, strided registers): Contiguous load non-temporal of words to multiple strided vectors (immediate index).

LDNT1W (scalar plus scalar, strided registers): Contiguous load non-temporal of words to multiple strided vectors (scalar index).

LDR (array vector): Load ZA array vector.

LDR (table): Load ZT0 register.

LUTI2 (four registers): Lookup table read with 2-bit indexes.

LUTI2 (single): Lookup table read with 2-bit indexes.

LUTI2 (two registers): Lookup table read with 2-bit indexes.

LUTI4 (four registers, 16-bit & 32-bit): Lookup table read with 4-bit indexes.

LUTI4 (four registers, 8-bit): Lookup table read with 4-bit indexes and 8-bit elements.

LUTI4 (single): Lookup table read with 4-bit indexes.

LUTI4 (two registers): Lookup table read with 4-bit indexes.

MOV (array to vector, four registers): Move four ZA single-vector groups to four vector registers: an alias of MOVA (array to vector, four registers).

MOV (array to vector, two registers): Move two ZA single-vector groups to two vector registers: an alias of MOVA (array to vector, two registers).

MOV (tile to vector, four registers): Move four ZA tile slices to four vector registers: an alias of MOVA (tile to vector, four registers).

MOV (tile to vector, single): Move ZA tile slice to vector register: an alias of MOVA (tile to vector, single).

MOV (tile to vector, two registers): Move two ZA tile slices to two vector registers: an alias of MOVA (tile to vector, two registers).

MOV (vector to array, four registers): Move four vector registers to four ZA single-vector groups: an alias of MOVA (vector to array, four registers).

MOV (vector to array, two registers): Move two vector registers to two ZA single-vector groups: an alias of MOVA (vector to array, two registers).

MOV (vector to tile, four registers): Move four vector registers to four ZA tile slices: an alias of MOVA (vector to tile, four registers).

MOV (vector to tile, single): Move vector register to ZA tile slice: an alias of MOVA (vector to tile, single).

MOV (vector to tile, two registers): Move two vector registers to two ZA tile slices: an alias of MOVA (vector to tile, two registers).

MOVA (array to vector, four registers): Move four ZA single-vector groups to four vector registers.

MOVA (array to vector, two registers): Move two ZA single-vector groups to two vector registers.

MOVA (tile to vector, four registers): Move four ZA tile slices to four vector registers.

MOVA (tile to vector, single): Move ZA tile slice to vector register.

MOVA (tile to vector, two registers): Move two ZA tile slices to two vector registers.

MOVA (vector to array, four registers): Move four vector registers to four ZA single-vector groups.

MOVA (vector to array, two registers): Move two vector registers to two ZA single-vector groups.

MOVA (vector to tile, four registers): Move four vector registers to four ZA tile slices.

MOVA (vector to tile, single): Move vector register to ZA tile slice.

MOVA (vector to tile, two registers): Move two vector registers to two ZA tile slices.

MOVAZ (array to vector, four registers): Move and zero four ZA single-vector groups to vector registers.

MOVAZ (array to vector, two registers): Move and zero two ZA single-vector groups to vector registers.

MOVAZ (tile to vector, four registers): Move and zero four ZA tile slices to vector registers.

MOVAZ (tile to vector, single): Move and zero ZA tile slice to vector register.

MOVAZ (tile to vector, two registers): Move and zero two ZA tile slices to vector registers.

MOVT (scalar to table): Move 8 bytes from general-purpose register to ZT0.

MOVT (table to scalar): Move 8 bytes from ZT0 to general-purpose register.

MOVT (vector to table): Move vector register to ZT0.

RDSVL: Read multiple of Streaming SVE vector register size to scalar register.

SCLAMP: Multi-vector signed clamp to minimum/maximum vector.

SCVTF: Multi-vector signed integer convert to floating-point.

SDOT (2-way, multiple and indexed vector): Multi-vector signed integer dot-product by indexed element.

SDOT (2-way, multiple and single vector): Multi-vector signed integer dot-product by vector.

SDOT (2-way, multiple vectors): Multi-vector signed integer dot-product.

SDOT (4-way, multiple and indexed vector): Multi-vector signed integer dot-product by indexed element.

SDOT (4-way, multiple and single vector): Multi-vector signed integer dot-product by vector.

SDOT (4-way, multiple vectors): Multi-vector signed integer dot-product.

SEL: Multi-vector conditionally select elements from two vectors.

SMAX (multiple and single vector): Multi-vector signed maximum by vector.

SMAX (multiple vectors): Multi-vector signed maximum.

SMIN (multiple and single vector): Multi-vector signed minimum by vector.

SMIN (multiple vectors): Multi-vector signed minimum.

SMLAL (multiple and indexed vector): Multi-vector signed integer multiply-add long by indexed element.

SMLAL (multiple and single vector): Multi-vector signed integer multiply-add long by vector.

SMLAL (multiple vectors): Multi-vector signed integer multiply-add long.

SMLALL (multiple and indexed vector): Multi-vector signed integer multiply-add long-long by indexed element.

SMLALL (multiple and single vector): Multi-vector signed integer multiply-add long-long by vector.

SMLALL (multiple vectors): Multi-vector signed integer multiply-add long-long.

SMLSL (multiple and indexed vector): Multi-vector signed integer multiply-subtract long by indexed element.

SMLSL (multiple and single vector): Multi-vector signed integer multiply-subtract long by vector.

SMLSL (multiple vectors): Multi-vector signed integer multiply-subtract long.

SMLSLL (multiple and indexed vector): Multi-vector signed integer multiply-subtract long-long by indexed element.

SMLSLL (multiple and single vector): Multi-vector signed integer multiply-subtract long-long by vector.

SMLSLL (multiple vectors): Multi-vector signed integer multiply-subtract long-long.

SMOP4A (2-way): Signed integer quarter-tile sums of two outer products, accumulating.

SMOP4A (4-way): Signed integer quarter-tile sums of four outer products, accumulating.

SMOP4S (2-way): Signed integer quarter-tile sums of two outer products, subtracting.

SMOP4S (4-way): Signed integer quarter-tile sums of four outer products, subtracting.

SMOPA (2-way): Signed integer sum of outer products and accumulate.

SMOPA (4-way): Signed integer sum of outer products and accumulate.

SMOPS (2-way): Signed integer sum of outer products and subtract.

SMOPS (4-way): Signed integer sum of outer products and subtract.

SQCVT (four registers): Multi-vector signed saturating extract narrow.

SQCVT (two registers): Multi-vector signed saturating extract narrow.

SQCVTN: Multi-vector signed saturating extract narrow and interleave.

SQCVTU (four registers): Multi-vector signed saturating unsigned extract narrow.

SQCVTU (two registers): Multi-vector signed saturating unsigned extract narrow.

SQCVTUN: Multi-vector signed saturating unsigned extract narrow and interleave.

SQDMULH (multiple and single vector): Multi-vector signed saturating doubling multiply high by vector.

SQDMULH (multiple vectors): Multi-vector signed saturating doubling multiply high.

SQRSHR (four registers): Multi-vector signed saturating rounding shift right narrow by immediate.

SQRSHR (two registers): Multi-vector signed saturating rounding shift right narrow by immediate.

SQRSHRN: Multi-vector signed saturating rounding shift right narrow by immediate and interleave.

SQRSHRU (four registers): Multi-vector signed saturating rounding shift right unsigned narrow by immediate.

SQRSHRU (two registers): Multi-vector signed saturating rounding shift right unsigned narrow by immediate.

SQRSHRUN: Multi-vector signed saturating rounding shift right unsigned narrow by immediate and interleave.

SRSHL (multiple and single vector): Multi-vector signed rounding shift left by vector.

SRSHL (multiple vectors): Multi-vector signed rounding shift left.

ST1B (scalar plus immediate, strided registers): Contiguous store of bytes from multiple strided vectors (immediate index).

ST1B (scalar plus scalar, strided registers): Contiguous store of bytes from multiple strided vectors (scalar index).

ST1B (scalar plus scalar, tile slice): Contiguous store of bytes from 8-bit element ZA tile slice.

ST1D (scalar plus immediate, strided registers): Contiguous store of doublewords from multiple strided vectors (immediate index).

ST1D (scalar plus scalar, strided registers): Contiguous store of doublewords from multiple strided vectors (scalar index).

ST1D (scalar plus scalar, tile slice): Contiguous store of doublewords from 64-bit element ZA tile slice.

ST1H (scalar plus immediate, strided registers): Contiguous store of halfwords from multiple strided vectors (immediate index).

ST1H (scalar plus scalar, strided registers): Contiguous store of halfwords from multiple strided vectors (scalar index).

ST1H (scalar plus scalar, tile slice): Contiguous store of halfwords from 16-bit element ZA tile slice.

ST1Q: Contiguous store of quadwords from 128-bit element ZA tile slice.

ST1W (scalar plus immediate, strided registers): Contiguous store of words from multiple strided vectors (immediate index).

ST1W (scalar plus scalar, strided registers): Contiguous store of words from multiple strided vectors (scalar index).

ST1W (scalar plus scalar, tile slice): Contiguous store of words from 32-bit element ZA tile slice.

STMOPA (2-way): Signed integer sparse sum of two outer products, accumulating.

STMOPA (4-way): Signed integer sparse sum of four outer products, accumulating.

STNT1B (scalar plus immediate, strided registers): Contiguous store non-temporal of bytes from multiple strided vectors (immediate index).

STNT1B (scalar plus scalar, strided registers): Contiguous store non-temporal of bytes from multiple strided vectors (scalar index).

STNT1D (scalar plus immediate, strided registers): Contiguous store non-temporal of doublewords from multiple strided vectors (immediate index).

STNT1D (scalar plus scalar, strided registers): Contiguous store non-temporal of doublewords from multiple strided vectors (scalar index).

STNT1H (scalar plus immediate, strided registers): Contiguous store non-temporal of halfwords from multiple strided vectors (immediate index).

STNT1H (scalar plus scalar, strided registers): Contiguous store non-temporal of halfwords from multiple strided vectors (scalar index).

STNT1W (scalar plus immediate, strided registers): Contiguous store non-temporal of words from multiple strided vectors (immediate index).

STNT1W (scalar plus scalar, strided registers): Contiguous store non-temporal of words from multiple strided vectors (scalar index).

STR (array vector): Store ZA array vector.

STR (table): Store ZT0 register.

SUB (array accumulators): Subtract multi-vector from ZA array vector accumulators.

SUB (array results, multiple and single vector): Subtract replicated single vector from multi-vector with ZA array vector results.

SUB (array results, multiple vectors): Subtract multi-vector from multi-vector with ZA array vector results.

SUDOT (multiple and indexed vector): Multi-vector signed by unsigned integer dot-product by indexed elements.

SUDOT (multiple and single vector): Multi-vector signed by unsigned integer dot-product by vector.

SUMLALL (multiple and indexed vector): Multi-vector signed by unsigned integer multiply-add long-long by indexed element.

SUMLALL (multiple and single vector): Multi-vector signed by unsigned integer multiply-add long-long by vector.

SUMOP4A: Signed by unsigned integer quarter-tile sums of four outer products, accumulating.

SUMOP4S: Signed by unsigned integer quarter-tile sums of four outer products, subtracting.

SUMOPA: Signed by unsigned integer sum of outer products and accumulate.

SUMOPS: Signed by unsigned integer sum of outer products and subtract.

SUNPK: Unpack and sign-extend multi-vector elements.

SUTMOPA: Signed by unsigned integer sparse sum of four outer products, accumulating.

SUVDOT: Multi-vector signed by unsigned integer vertical dot-product by indexed element.

SVDOT (2-way): Multi-vector signed integer vertical dot-product by indexed element.

SVDOT (4-way): Multi-vector signed integer vertical dot-product by indexed element.

UCLAMP: Multi-vector unsigned clamp to minimum/maximum vector.

UCVTF: Multi-vector unsigned integer convert to floating-point.

UDOT (2-way, multiple and indexed vector): Multi-vector unsigned integer dot-product by indexed element.

UDOT (2-way, multiple and single vector): Multi-vector unsigned integer dot-product by vector.

UDOT (2-way, multiple vectors): Multi-vector unsigned integer dot-product.

UDOT (4-way, multiple and indexed vector): Multi-vector unsigned integer dot-product by indexed element.

UDOT (4-way, multiple and single vector): Multi-vector unsigned integer dot-product by vector.

UDOT (4-way, multiple vectors): Multi-vector unsigned integer dot-product.

UMAX (multiple and single vector): Multi-vector unsigned maximum by vector.

UMAX (multiple vectors): Multi-vector unsigned maximum.

UMIN (multiple and single vector): Multi-vector unsigned minimum by vector.

UMIN (multiple vectors): Multi-vector unsigned minimum.

UMLAL (multiple and indexed vector): Multi-vector unsigned integer multiply-add long by indexed element.

UMLAL (multiple and single vector): Multi-vector unsigned integer multiply-add long by vector.

UMLAL (multiple vectors): Multi-vector unsigned integer multiply-add long.

UMLALL (multiple and indexed vector): Multi-vector unsigned integer multiply-add long-long by indexed element.

UMLALL (multiple and single vector): Multi-vector unsigned integer multiply-add long-long by vector.

UMLALL (multiple vectors): Multi-vector unsigned integer multiply-add long-long.

UMLSL (multiple and indexed vector): Multi-vector unsigned integer multiply-subtract long by indexed element.

UMLSL (multiple and single vector): Multi-vector unsigned integer multiply-subtract long by vector.

UMLSL (multiple vectors): Multi-vector unsigned integer multiply-subtract long.

UMLSLL (multiple and indexed vector): Multi-vector unsigned integer multiply-subtract long-long by indexed element.

UMLSLL (multiple and single vector): Multi-vector unsigned integer multiply-subtract long-long by vector.

UMLSLL (multiple vectors): Multi-vector unsigned integer multiply-subtract long-long.

UMOP4A (2-way): Unsigned integer quarter-tile sums of two outer products, accumulating.

UMOP4A (4-way): Unsigned integer quarter-tile sums of four outer products, accumulating.

UMOP4S (2-way): Unsigned integer quarter-tile sums of two outer products, subtracting.

UMOP4S (4-way): Unsigned integer quarter-tile sums of four outer products, subtracting.

UMOPA (2-way): Unsigned integer sum of outer products and accumulate.

UMOPA (4-way): Unsigned integer sum of outer products and accumulate.

UMOPS (2-way): Unsigned integer sum of outer products and subtract.

UMOPS (4-way): Unsigned integer sum of outer products and subtract.

UQCVT (four registers): Multi-vector unsigned saturating extract narrow.

UQCVT (two registers): Multi-vector unsigned saturating extract narrow.

UQCVTN: Multi-vector unsigned saturating extract narrow and interleave.

UQRSHR (four registers): Multi-vector unsigned saturating rounding shift right narrow by immediate.

UQRSHR (two registers): Multi-vector unsigned saturating rounding shift right narrow by immediate.

UQRSHRN: Multi-vector unsigned saturating rounding shift right narrow by immediate and interleave.

URSHL (multiple and single vector): Multi-vector unsigned rounding shift left by vector.

URSHL (multiple vectors): Multi-vector unsigned rounding shift left.

USDOT (multiple and indexed vector): Multi-vector unsigned by signed integer dot-product by indexed element.

USDOT (multiple and single vector): Multi-vector unsigned by signed integer dot-product by vector.

USDOT (multiple vectors): Multi-vector unsigned by signed integer dot-product.

USMLALL (multiple and indexed vector): Multi-vector unsigned by signed integer multiply-add long-long by indexed element.

USMLALL (multiple and single vector): Multi-vector unsigned by signed integer multiply-add long-long by vector.

USMLALL (multiple vectors): Multi-vector unsigned by signed integer multiply-add long-long.

USMOP4A: Unsigned by signed integer quarter-tile sums of four outer products, accumulating.

USMOP4S: Unsigned by signed integer quarter-tile sums of four outer products, subtracting.

USMOPA: Unsigned by signed integer sum of outer products and accumulate.

USMOPS: Unsigned by signed integer sum of outer products and subtract.

USTMOPA: Unsigned by signed integer sparse sum of four outer products, accumulating.

USVDOT: Multi-vector unsigned by signed integer vertical dot-product by indexed element.

UTMOPA (2-way): Unsigned integer sparse sum of two outer products, accumulating.

UTMOPA (4-way): Unsigned integer sparse sum of four outer products, accumulating.

UUNPK: Unpack and zero-extend multi-vector elements.

UVDOT (2-way): Multi-vector unsigned integer vertical dot-product by indexed element.

UVDOT (4-way): Multi-vector unsigned integer vertical dot-product by indexed element.

UZP (four registers): Concatenate elements from four vectors.

UZP (two registers): Concatenate elements from two vectors.

ZERO (double-vector): Zero ZA double-vector groups.

ZERO (quad-vector): Zero ZA quad-vector groups.

ZERO (single-vector): Zero ZA single-vector groups.

ZERO (table): Zero ZT0.

ZERO (tiles): Zero a list of 64-bit element ZA tiles.

ZIP (four registers): Interleave elements from four vectors.

ZIP (two registers): Interleave elements from two vectors.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

ADD (array accumulators)

Add multi-vector to ZA array vector accumulators

Destructively add all elements of the two or four source vectors to the corresponding elements of the ZA single-vector groups.
The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.
The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.
This instruction is unpredicated.
ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.
It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

Assembler Symbols

<T> Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv> Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.

<offs> Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.

<Zm1> For the "Two ZA single-vectors" variant: is the name of the first scalable vector register of the source multi-vector group, encoded as "Zm" times 2.

For the "Four ZA single-vectors" variant: is the name of the first scalable vector register of the source multi-vector group, encoded as "Zm" times 4.

<Zm2>	Is the name of the second scalable vector register of the source multi-vector group, encoded as "Zm" times 2 plus 1.
<Zm4>	Is the name of the fourth scalable vector register of the source multi-vector group, encoded as "Zm" times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV nreg;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;

for r = 0 to nreg-1
    constant bits(VL) operand1 = ZAvector[vec, VL];
    constant bits(VL) operand2 = Z[m+r, VL];
    for e = 0 to elements-1
        constant bits(esize) element1 = Elem[operand1, e, esize];
        constant bits(esize) element2 = Elem[operand2, e, esize];
        Elem[result, e, esize] = element1 + element2;
    ZAvector[vec, VL] = result;
    vec = vec + vstride;
```

Operational information

```

Assembler Symbols

<T> Is the size specifier, encoded in “sz”:

sz	<T>
0	S
1	D

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs>	Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.

<Zn1>	For the "Two ZA single-vectors" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2. For the "Four ZA single-vectors" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.
<Zn2>	Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
<Zm1>	For the "Two ZA single-vectors" variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 2. For the "Four ZA single-vectors" variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 4.
<Zm2>	Is the name of the second scalable vector register of the second source multi-vector group, encoded as "Zm" times 2 plus 1.
<Zn4>	Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.
<Zm4>	Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV nreg;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;

for r = 0 to nreg-1
    constant bits(VL) operand1 = Z[n+r, VL];
    constant bits(VL) operand2 = Z[m+r, VL];
    for e = 0 to elements-1
        constant bits(esize) element1 = Elem[operand1, e, esize];
        constant bits(esize) element2 = Elem[operand2, e, esize];
        Elem[result, e, esize] = element1 + element2;
    ZAvector[vec, VL] = result;
    vec = vec + vstride;
```

ADDHA

Add horizontally vector elements to ZA tile

Add each element of the source vector to the corresponding active element of each horizontal slice of a ZA tile. The tile elements are predicated by a pair of governing predicates. An element of a horizontal slice is considered active if its corresponding element in the second governing predicate is TRUE and the element corresponding to its horizontal slice number in the first governing predicate is TRUE. Inactive elements in the destination tile remain unmodified.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

BFADD

BFloat16 floating-point add multi-vector to ZA array vector accumulators

Destructively add all elements of the two or four source vectors to the corresponding BFloat16 elements of the ZA single-vector groups.
The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.
The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.
This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.
This instruction is unpredicated.
ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.
It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

BFCLAMP

Multi-vector BFloat16 floating-point clamp to minimum/maximum number

Clamp each BFloat16 element in the two or four destination vectors to between the BFloat16 minimum value in the corresponding element of the first source vector and the BFloat16 maximum value in the corresponding element of the second source vector and destructively place the clamped results in the corresponding elements of the two or four destination vectors.

Regardless of the value of FPCR.AH, the behavior is as follows for each minimum number and maximum number operation:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is Default NaN.

This instruction follows SME2 non-widening BFloat16 numerical behaviors corresponding to instructions that place their results in two or four SVE Z vectors.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

BFDOT (multiple and indexed vector)

Multi-vector BFloat16 floating-point dot-product by indexed element

The instruction computes the dot product of a pair of BF16 values held in the corresponding 32-bit elements of the two or four first source vectors and the indexed 32-bit element of the second source vector. The single-precision dot product results are destructively added to the corresponding single-precision elements of the ZA single-vector groups.

The BF16 pairs within the second source vector are specified using an immediate index which selects the same BF16 pair position within each 128-bit vector segment. The element index range is from 0 to 3.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

BFDOT (multiple vectors)

Multi-vector BFloat16 floating-point dot-product

The instruction computes the dot product of a pair of BF16 values held in the corresponding 32-bit elements of the two or four first and second source vectors. The single-precision dot product results are destructively added to the corresponding single-precision elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

BFMAX (multiple and single vector)

Multi-vector BFloat16 floating-point maximum by vector

Determine the maximum of BFloat16 elements of the second source vector and the corresponding BFloat16 elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction follows SME2 non-widening BFloat16 numerical behaviors corresponding to instructions that place their results in two or four SVE Z vectors.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

BFMIN (multiple and single vector)

Multi-vector BFloat16 floating-point minimum by vector

Determine the minimum of BFloat16 elements of the second source vector and the corresponding BFloat16 elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction follows SME2 non-widening BFloat16 numerical behaviors corresponding to instructions that place their results in two or four SVE Z vectors.

This instruction is unpredicated.

ID_AA64ZFR0_EL1.B16B16 indicates whether this instruction is implemented.

BFMLA (multiple and indexed vector)

Multi-vector BFloat16 floating-point fused multiply-add by indexed element

Multiply the indexed element of the second source vector by the corresponding BFloat16 floating-point elements of the two or four first source vectors and destructively add without intermediate rounding to the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

BFMLA (multiple and single vector)

Multi-vector BFloat16 floating-point fused multiply-add by vector

Multiply the corresponding BFloat16 floating-point elements of the two or four first source vector with corresponding elements of the second source vector and destructively add without intermediate rounding to the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

BFMLAL (multiple and indexed vector)

Multi-vector BFloat16 floating-point multiply-add long by indexed element

This BFloat16 floating-point multiply-add long instruction widens all 16-bit BFloat16 elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively adds these values without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The BF16 elements within the second source vector are specified using a 3-bit immediate index which selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

BFMLS (multiple and indexed vector)

Multi-vector BFloat16 floating-point fused multiply-subtract by indexed element

Multiply the indexed element of the second source vector by the corresponding BFloat16 floating-point elements of the two or four first source vectors and destructively subtract without intermediate rounding from the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

BFMLSL (multiple and indexed vector)

Multi-vector BFloat16 floating-point multiply-subtract long by indexed element

This BFloat16 floating-point multiply-subtract long instruction widens all 16-bit BFloat16 elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively subtracts these values without intermediate rounding from the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The BF16 elements within the second source vector are specified using a 3-bit immediate index which selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

BFMLSL (multiple and single vector)

Multi-vector BFloat16 floating-point multiply-subtract long by vector

This BFloat16 floating-point multiply-subtract long instruction widens all 16-bit BFloat16 elements in the one, two, or four first source vectors and the second source vector to single-precision format, then multiplies the corresponding elements and destructively subtracts these values without intermediate rounding from the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

One ZA double-vector

BFMOP4A (non-widening)

BFloat16 quarter-tile outer products, accumulating

This instruction generates four independent quarter-tile BFloat16 outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 16-bit element ZA tile.

Each of the quarter-tile outer products is generated by multiplying the $SVL_H \div 2 \times 1$ sub-matrix of BFloat16 values held in the half-vectors of the first source vectors by the $1 \times SVL_H \div 2$ sub-matrix of BFloat16 values held in the half-vectors of the second source vectors.

The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ BFloat16 outer products are destructively added to the destination ZA tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

Single and multiple vectors

BFMOP4A (widening)

BFloat16 quarter-tile sums of two outer products, accumulating

This instruction generates four independent quarter-tile BFloat16 sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the SVL_S÷2 × 2 sub-matrix of BFloat16 values held in the half-vectors of the first source vectors by the 2 × SVL_S÷2 sub-matrix of BFloat16 values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 2 elements of each row of a SVL_S÷2 × 2 sub-matrix. Similarly, each 32-bit container of the second source vectors holds 2 elements of each column of a 2 × SVL_S÷2 sub-matrix.

The instruction widens the sub-matrices of BFloat16 values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of BFloat16 values in the second source vectors to single-precision values. The resulting quarter-tile SVL_S÷2 × SVL_S÷2 single-precision sums of outer products are then destructively added to the single-precision destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction follows SME BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

BFMOP4S (non-widening)

BFloat16 quarter-tile outer products, subtracting

This instruction generates four independent quarter-tile BFloat16 outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 16-bit element ZA tile.

Each of the quarter-tile outer products is generated by multiplying the $SVL_H \div 2 \times 1$ sub-matrix of BFloat16 values held in the half-vectors of the first source vectors by the $1 \times SVL_H \div 2$ sub-matrix of BFloat16 values held in the half-vectors of the second source vectors.

The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ BFloat16 outer products are destructively subtracted from the destination ZA tile. This is equivalent to performing a single multiply-subtract from each of the destination tile elements.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

BFMOP4S (widening)

BFloat16 quarter-tile sums of two outer products, subtracting

This instruction generates four independent quarter-tile BFloat16 sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_{S} \div 2 \times 2$ sub-matrix of BFloat16 values held in the half-vectors of the first source vectors by the $2 \times SVL_{S} \div 2$ sub-matrix of BFloat16 values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 2 elements of each row of a $SVL_{S} \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_{S} \div 2$ sub-matrix.

The instruction widens the sub-matrices of BFloat16 values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of BFloat16 values in the second source vectors to single-precision values. The resulting quarter-tile $SVL_{S} \div 2 \times SVL_{S} \div 2$ single-precision sums of outer products are then destructively subtracted from the single-precision destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

This instruction follows SME BFloat16 numerical behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

BFMOPA (non-widening)

BFloat16 floating-point outer product and accumulate

This instruction works with a 16-bit element ZA tile.

These instructions generate an outer product of the first source vector and the second source vector. The first source is SVL_H×1 vector and the second source is 1×SVL_H vector.

Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is Inactive the corresponding destination tile element remains unmodified.

The resulting outer product, SVL_H×SVL_H, is then destructively added to the destination tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

BFMOPA (widening)

BFloat16 sum of outer products and accumulate

The BFloat16 floating-point sum of outer products and accumulate instruction works with a 32-bit element ZA tile.

This instruction multiplies the $SVL_S \times 2$ sub-matrix of BFloat16 values held in the first source vector by the $2 \times SVL_S$ sub-matrix of BFloat16 values in the second source vector.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting $SVL_S \times SVL_S$ single-precision floating-point sum of outer products is then destructively added to the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a $SVL_S \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a $2 \times SVL_S$ sub-matrix.

This instruction follows SME BFloat16 numerical behaviors.

BFMOPS (non-widening)

BFloat16 floating-point outer product and subtract

This instruction works with a 16-bit element ZA tile.

These instructions generate an outer product of the first source vector and the second source vector. The first source is $\text{SVL}_\text{H}\times 1$ vector and the second source is $1\times\text{SVL}_\text{H}$ vector.

Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is Inactive the corresponding destination tile element remains unmodified.

The resulting outer product, $\text{SVL}_\text{H}\times\text{SVL}_\text{H}$, is then destructively subtracted from the destination tile. This is equivalent to performing a single multiply-subtract from each of the destination tile elements.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

BFMOPS (widening)

BFloat16 sum of outer products and subtract

The BFloat16 floating-point sum of outer products and subtract instruction works with a 32-bit element ZA tile.

This instruction multiplies the SVL$_S$×2 sub-matrix of BFloat16 values held in the first source vector by the 2×SVL$_S$ sub-matrix of BFloat16 values in the second source vector.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting SVL$_S$×SVL$_S$ single-precision floating-point sum of outer products is then destructively subtracted from the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVL$_S$×2 sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVL$_S$ sub-matrix.

This instruction follows SME BFloat16 numerical behaviors.

BFSUB

BFloat16 floating-point subtract multi-vector from ZA array vector accumulators

Destructively subtract all elements of the two or four source vectors from the corresponding BFloat16 elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.B16B16 indicates whether this instruction is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

BFTMOPA (non-widening)

BFloat16 sparse outer product, accumulating

This instruction generates BFloat16 outer product by multiplying the 1-in-2 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the destination ZA tile elements.

The outer product is generated by multiplying the selected 1-in-2 BFloat16 value from each overlapping 16-bit containers of the two $\text{SVL}_\text{H}\times 1$ sub-matrices in the first source vectors by the BFloat16 value from the corresponding 16-bit container of the compressed $1\times\text{SVL}_\text{H}$ sub-matrix in the second source vector.

The 1-in-2 BFloat16 value in the first source vectors is selected by 2-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the result. If both bits of the 2-bit control corresponding to the elements of the first source vectors are 1, only the element corresponding to the least significant bit is selected.

The instruction multiplies the selected elements of sub-matrices of BFloat16 values held in the first source vectors by the corresponding elements of sub-matrix of BFloat16 values in the second source vector. The resulting BFloat16 $\text{SVL}_\text{H}\times\text{SVL}_\text{H}$ outer product is then destructively added to the BFloat16 destination tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME2 ZA-targeting non-widening BFloat16 numerical behaviors.

This instruction is unpredicated.

BFTMOPA (widening)

BFloat16 sparse sum of two outer products, accumulating

This instruction generates BFloat16 sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 BFloat16 values from each overlapping 32-bit containers of the two $SVL_S \times 2$ sub-matrices in the first source vectors by the two BFloat16 values from the corresponding 32-bit container of the $2 \times SVL_S$ sub-matrix in the second source vector. The two selected elements from each overlapping 32-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two $SVL_S \times 2$ sub-matrices. Each 32-bit container of the second source vector holds 2 elements of columns of a compressed $2 \times SVL_S$ sub-matrix.

The 2-in-4 BFloat16 values from overlapping 32-bit containers of the first source vectors are selected by 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 32-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The instruction widens the selected elements of sub-matrices of BFloat16 values held in the first source vectors to single-precision values and multiplies them by the corresponding widened elements of sub-matrix of BFloat16 values in the second source vector to single-precision values. The resulting $SVL_S \times SVL_S$ single-precision sum of outer products is then destructively added to the single-precision destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction follows SME BFloat16 numerical behaviors.

This instruction is unpredicated.

BFVDOT

Multi-vector BFloat16 floating-point vertical dot-product by indexed element

The instruction computes the sum-of-products of each vertical pair of BFloat16 values in the corresponding elements of the two first source vectors with the pair of BFloat16 values in the indexed 32-bit group of the corresponding 128-bit segment of the second source vector. The single-precision sum-of-products are destructively added to the corresponding single-precision elements of the two ZA single-vector groups.

The BF16 pairs within the second source vector are specified using an immediate index which selects the same BF16 pair position within each 128-bit vector segment. The element index range is from 0 to 3.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The vector group symbol VGx2 indicates that the ZA operand consists of two ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME2 ZA-targeting BFloat16 numerical behaviors.

This instruction is unpredicated.

BMOPA

Bitwise exclusive NOR population count outer product and accumulate

This instruction works with 32-bit element ZA tile. This instruction generates an outer product of the first source SVL_S×1 vector and the second source 1×SVL_S vector. Each outer product element is obtained as population count of the bitwise XNOR result of the corresponding 32-bit elements of the first source vector and the second source vector. Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is inactive the corresponding destination tile element remains unmodified. The resulting SVL_S×SVL_S product is then destructively added to the destination tile.

This instruction works with 32-bit element ZA tile. This instruction generates an outer product of the first source $SVL_{S}\times 1$ vector and the second source $1\times SVL_{S}$ vector. Each outer product element is obtained as population count of the bitwise XNOR result of the corresponding 32-bit elements of the first source vector and the second source vector. Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is inactive the corresponding destination tile element remains unmodified. The resulting $SVL_{S}\times SVL_{S}$ product is then destructively subtracted from the destination tile.

FADD

Floating-point add multi-vector to ZA array vector accumulators

Destructively add all elements of the two or four source vectors to the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors , Two ZA single-vectors of half precision elements , Four ZA single-vectors and Four ZA single-vectors of half precision elements

FAMAX

Multi-vector floating-point absolute maximum

Determine the maximum absolute value from floating-point elements of the two or four second source vectors and the corresponding floating-point elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

The behavior is as follows:

- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is the Default NaN.
- Denormalized inputs and results are never flushed to zero, as if FPCR.{FZ16, FZ, FIZ} are all 0.
- Denormalized inputs never generate an Input Denormal floating-point exception.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

FCLAMP

Multi-vector floating-point clamp to minimum/maximum number

Clamp each floating-point element in the two or four destination vectors to between the floating-point minimum value in the corresponding element of the first source vector and the floating-point maximum value in the corresponding element of the second source vector and destructively place the clamped results in the corresponding elements of the two or four destination vectors.

Regardless of the value of FPCR.AH, the behavior is as follows for each minimum number and maximum number operation:

- Negative zero compares less than positive zero.
- If one value is numeric and the other is a quiet NaN, the result is the numeric value.
- When FPCR.DN is 0, if either value is a signaling NaN or if both values are NaNs, the result is a quiet NaN.
- When FPCR.DN is 1, if either value is a signaling NaN or if both values are NaNs, the result is Default NaN.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

Two registers

(FEAT_SME2)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FCVTZU

Multi-vector floating-point convert to unsigned integer, rounding toward zero

Convert to the unsigned 32-bit integer nearer to zero from single-precision, each element of the two or four source vectors, and place the results in the corresponding elements of the two or four destination vectors.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

FDOT (2-way, multiple and indexed vector, FP16 to FP32)

Multi-vector half-precision floating-point dot-product by indexed element

The instruction computes the fused sum-of-products of a pair of half-precision floating-point values held in the corresponding 32-bit elements of the two or four first source vectors and the indexed 32-bit element of the second source vector, without intermediate rounding. The single-precision sum-of-products are destructively added to the corresponding single-precision elements of the ZA single-vector groups.

The half-precision floating-point pairs within the second source vector are specified using an immediate index which selects the same pair position within each 128-bit vector segment. The element index range is from 0 to 3.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

FDOT (2-way, multiple and indexed vector, FP8 to FP16)

Multi-vector 8-bit floating-point dot-product by indexed element to half-precision

The instruction computes the fused sum-of-products of a group of two 8-bit floating-point values held in the corresponding 16-bit elements of the two or four first source vectors and the indexed 16-bit element of the second source vector. The half-precision sum-of-products are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$, before being destructively added without intermediate rounding to the corresponding half-precision elements of the ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

The 8-bit floating-point pairs within the second source vector are specified using an immediate index which selects the same pair position within each 128-bit vector segment.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

FDOT (2-way, multiple vectors, FP16 to FP32)

Multi-vector half-precision floating-point dot-product

The instruction computes the fused sum-of-products of a pair of half-precision floating-point values held in the corresponding 32-bit elements of the two or four first and second source vectors, without intermediate rounding. The single-precision sum-of-products are destructively added to the corresponding single-precision elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

FDOT (4-way, multiple and indexed vector)

Multi-vector 8-bit floating-point dot-product by indexed element to single-precision

The instruction computes the fused sum-of-products of a group of four 8-bit floating-point values held in the corresponding 32-bit elements of the two or four first source vectors and the indexed 32-bit element of the second source vector. The single-precision sum-of-products are scaled by $2^{-UInt(FPMR.LSCALE)}$, before being destructively added without intermediate rounding to the corresponding single-precision elements of the ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

The 8-bit floating-point groups within the second source vector are specified using an immediate index which selects the same group position within each 128-bit vector segment.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

FDOT (4-way, multiple vectors)

Multi-vector 8-bit floating-point dot-product to single-precision

The instruction computes the fused sum-of-products of a group of four 8-bit floating-point values held in the corresponding 32-bit elements of the two or four first and second source vectors. The single-precision sum-of-products are scaled by $2^{-\text{UInt(FPMR.LSCALE)}}$, before being destructively added without intermediate rounding to the corresponding single-precision elements of the ZA single-vector groups. The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

constant integer v = UInt('010':Rv);
constant integer n = UInt(Zn:'00');
constant integer m = UInt(Zm:'00');
constant integer offset = UInt(off3);
constant integer nreg = 4;
```

Assembler Symbols

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs>	Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.
<Zn1>	For the "Two ZA single-vectors" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2. For the "Four ZA single-vectors" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.
<Zn2>	Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
<Zm1>	For the "Two ZA single-vectors" variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 2.

For the "Four ZA single-vectors" variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 4.

<Zm2>	Is the name of the second scalable vector register of the second source multi-vector group, encoded as "Zm" times 2 plus 1.
<Zn4>	Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.
<Zm4>	Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.

Operation

```
CheckFPMREnabled();
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV 32;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV nreg;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;

for r = 0 to nreg-1
    constant bits(VL) operand1 = Z[n+r, VL];
    constant bits(VL) operand2 = Z[m+r, VL];
    constant bits(VL) operand3 = ZAvector[vec, VL];
    for e = 0 to elements-1
        constant bits(32) op1 = Elem[operand1, e, 32];
        constant bits(32) op2 = Elem[operand2, e, 32];
        bits(32) sum = Elem[operand3, e, 32];
        sum = FP8DotAddFP(sum, op1, op2, FPCR, FPMR);
        Elem[result, e, 32] = sum;
    ZAvector[vec, VL] = result;
    vec = vec + vstride;

FMAX (multiple and single vector)

Multi-vector floating-point maximum by vector

Determine the maximum of floating-point elements of the second source vector and the corresponding floating-point elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

FMIN (multiple vectors)

Multi-vector floating-point minimum

Determine the minimum of floating-point elements of the two or four second source vectors and the corresponding floating-point elements of the two or four first source vectors and destructively place the results in the corresponding elements of the two or four first source vectors.

When FPCR.AH is 0, the behavior is as follows:

- Negative zero compares less than positive zero.
- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is Default NaN.

When FPCR.AH is 1, the behavior is as follows:

- If both elements are zeros, regardless of the sign of either zero, the result is the second element.
- If either element is a NaN, regardless of the value of FPCR.DN, the result is the second element.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

FMLA (multiple and indexed vector)

Multi-vector floating-point fused multiply-add by indexed element

Multiply the indexed element of the second source vector by the corresponding floating-point elements of the two or four first source vectors and destructively add without intermediate rounding to the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 2 bits depending on the size of the element.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 6 classes: Two ZA single-vectors of half precision elements , Two ZA single-vectors of single precision elements , Two ZA single-vectors of double precision elements , Four ZA single-vectors of half precision elements , Four ZA single-vectors of single precision elements and Four ZA single-vectors of double precision elements

FMLA (multiple vectors)

Multi-vector floating-point fused multiply-add

Multiply the corresponding floating-point elements of the two or four first and second source vectors and destructively add without intermediate rounding to the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors , Two ZA single-vectors of half precision elements , Four ZA single-vectors and Four ZA single-vectors of half precision elements

FMLAL (multiple and indexed vector, FP16 to FP32)

Multi-vector floating-point multiply-add long by indexed element

This half-precision floating-point multiply-add long instruction widens all 16-bit half-precision elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively adds these values without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The half-precision elements within the second source vector are specified using a 3-bit immediate index which selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

```

FMLAL (multiple and indexed vector, FP8 to FP16)

Multi-vector 8-bit floating-point multiply-add long by indexed element to half-precision

This 8-bit floating-point multiply-add long instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the indexed element of the second source vector to half-precision format and multiplies the corresponding elements. The intermediate products are scaled by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$ before being destructively added without intermediate rounding to the overlapping 16-bit half-precision elements of the ZA double-vector groups.

The 8-bit floating-point elements within the second source vector are specified using a 4-bit immediate index which selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs1>	For the "One ZA double-vector" variant: is the first vector select offset, encoded as "off3" field times 2. For the "Four ZA double-vectors" and "Two ZA double-vectors" variants: is the first vector select offset, encoded as "off2" field times 2.
<offs2>	For the "One ZA double-vector" variant: is the second vector select offset, encoded as "off3" field times 2 plus 1. For the "Four ZA double-vectors" and "Two ZA double-vectors" variants: is the second vector select offset, encoded as "off2" field times 2 plus 1.
<Zn>	Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zm>	Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.
<index>	For the "One ZA double-vector" variant: is the element index, in the range 0 to 15, encoded in the "i4A:i4B:i4C" fields. For the "Four ZA double-vectors" and "Two ZA double-vectors" variants: is the element index, in the range 0 to 15, encoded in the "i4h:i4l" fields.
<Zn1>	For the "Two ZA double-vectors" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2. For the "Four ZA double-vectors" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.
<Zn2>	Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
<Zn4>	Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.

Operation

```
CheckFPMREnabled();
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV 16;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV nreg;
constant integer eltspersegment = 128 DIV 16;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;
vec = vec - (vec MOD 2);

for r = 0 to nreg-1

                                              FPCR, FPMR);
        ZAvector[vec + i, VL] = result;
    vec = vec + vstride;
```

FMLAL (multiple and single vector, FP16 to FP32)

Multi-vector floating-point multiply-add long by vector

This half-precision floating-point multiply-add long instruction widens all 16-bit half-precision elements in the one, two, or four first source vectors and the second source vector to single-precision format, then multiplies the corresponding elements and destructively adds these values without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

One ZA double-vector

FMLALL (multiple and indexed vector)

Multi-vector 8-bit floating-point multiply-add long-long by indexed element to single-precision

This 8-bit floating-point multiply-add long long instruction widens all 8-bit floating-point elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format and multiplies the corresponding elements. The intermediate products are scaled by $2^{-\text{UInt(FPMR.LSCALE)}}$ before being destructively added without intermediate rounding to the overlapping 32-bit single-precision elements of the ZA quad-vector groups.

The 8-bit floating-point elements within the second source vector are specified using a 4-bit immediate index which selects the same element position within each 128-bit vector segment.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA quad-vector , Two ZA quad-vectors and Four ZA quad-vectors

One ZA quad-vector

FMLS (multiple and indexed vector)

Multi-vector floating-point fused multiply-subtract by indexed element

Multiply the indexed element of the second source vector by the corresponding floating-point elements of the two or four first source vectors and destructively subtract without intermediate rounding from the corresponding elements of the ZA single-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 1 to 2 bits depending on the size of the element.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 6 classes: Two ZA single-vectors of half precision elements , Two ZA single-vectors of single precision elements , Two ZA single-vectors of double precision elements , Four ZA single-vectors of half precision elements , Four ZA single-vectors of single precision elements and Four ZA single-vectors of double precision elements

Assembler Symbols

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs>	Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.
<Zn1>	For the "Two ZA single-vectors of double precision elements", "Two ZA single-vectors of half precision elements", and "Two ZA single-vectors of single precision elements" variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2. For the "Four ZA single-vectors of double precision elements", "Four ZA single-vectors of half precision elements", and "Four ZA single-vectors of single precision elements" variants: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.
<Zn2>	Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
<Zm>	Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.
<index>	For the "Four ZA single-vectors of half precision elements" and "Two ZA single-vectors of half precision elements" variants: is the element index, in the range 0 to 7, encoded in the "i3h:i3l" fields. For the "Four ZA single-vectors of single precision elements" and "Two ZA single-vectors of single precision elements" variants: is the element index, in the range 0 to 3, encoded in the "i2" field. For the "Four ZA single-vectors of double precision elements" and "Two ZA single-vectors of double precision elements" variants: is the element index, in the range 0 to 1, encoded in the "i1" field.
<Zn4>	Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;

constant integer eltspersegment = 128 DIV esize;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;

for r = 0 to nreg-1
    constant bits(VL) op1 = Z[n+r, VL];
    constant bits(VL) op2 = Z[m, VL];
    constant bits(VL) op3 = ZAvector[vec, VL];
    for e = 0 to elements-1
        constant bits(esize) elem1 = FPNeg(Elem[op1, e, esize], FPCR);
        constant integer segmentbase = e - (e MOD eltspersegment);
        constant integer s = segmentbase + index;
        constant bits(esize) elem2 = Elem[op2, s, esize];
        constant bits(esize) elem3 = Elem[op3, e, esize];
        Elem[result, e, esize] = FPMulAdd_ZA(elem3, elem1, elem2, FPCR);
    ZAvector[vec, VL] = result;
    vec = vec + vstride;
```

FMLS (multiple and single vector)

Multi-vector floating-point fused multiply-subtract by vector

Multiply the corresponding floating-point elements of the two or four first source vector with corresponding elements of the second source vector and destructively subtract without intermediate rounding from the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors , Two ZA single-vectors of half precision elements , Four ZA single-vectors and Four ZA single-vectors of half precision elements

FMLSL (multiple and indexed vector)

Multi-vector floating-point multiply-subtract long by indexed element

This half-precision floating-point multiply-subtract long instruction widens all 16-bit half-precision elements in the one, two, or four first source vectors and the indexed element of the second source vector to single-precision format, then multiplies the corresponding elements and destructively subtracts these values without intermediate rounding from the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The half-precision elements within the second source vector are specified using a 3-bit immediate index which selects the same element position within each 128-bit vector segment.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs1>	For the "One ZA double-vector" variant: is the first vector select offset, encoded as "off3" field times 2. For the "Four ZA double-vectors" and "Two ZA double-vectors" variants: is the first vector select offset, encoded as "off2" field times 2.
<offs2>	For the "One ZA double-vector" variant: is the second vector select offset, encoded as "off3" field times 2 plus 1. For the "Four ZA double-vectors" and "Two ZA double-vectors" variants: is the second vector select offset, encoded as "off2" field times 2 plus 1.
<Zn>	Is the name of the first source scalable vector register, encoded in the "Zn" field.
<Zm>	Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.
<index>	Is the element index, in the range 0 to 7, encoded in the "i3h:i3l" fields.
<Zn1>	For the "Two ZA double-vectors" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2. For the "Four ZA double-vectors" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.
<Zn2>	Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
<Zn4>	Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV 32;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV nreg;
constant integer eltspersegment = 128 DIV 32;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;
vec = vec - (vec MOD 2);

for r = 0 to nreg-1
    constant bits(VL) op1 = Z[n+r, VL];
    constant bits(VL) op2 = Z[m, VL];
    for i = 0 to 1
        constant bits(VL) op3 = ZAvector[vec + i, VL];
        for e = 0 to elements-1
            constant integer segmentbase = e - (e MOD eltspersegment);
            constant integer s = 2 * segmentbase + index;
            constant bits(16) elem1 = FPNeg(Elem[op1, 2 * e + i, 16], FPCR);
            constant bits(16) elem2 = Elem[op2, s, 16];
            constant bits(32) elem3 = Elem[op3, e, 32];
            Elem[result, e, 32] = FPMulAddH_ZA(elem3, elem1, elem2,
                                               FPCR);
        ZAvector[vec + i, VL] = result;
    vec = vec + vstride;
```

FMLSL (multiple and single vector)

Multi-vector floating-point multiply-subtract long by vector

This half-precision floating-point multiply-subtract long instruction widens all 16-bit half-precision elements in the one, two, or four first source vectors and the second source vector to single-precision format, then multiplies the corresponding elements and destructively subtracts these values without intermediate rounding from the overlapping 32-bit single-precision elements of the ZA double-vector groups.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

One ZA double-vector

FMOP4A (non-widening)

Floating-point quarter-tile outer products, accumulating

This instruction generates four independent quarter-tile floating-point outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 16-bit, 32-bit, or 64-bit element ZA tile.

In case of the half-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_H÷2 × 1$ sub-matrix of half-precision values held in the half-vectors of the first source vectors by the $1 × SVL_H÷2$ sub-matrix of half-precision values held in the half-vectors of the second source vectors. In case of the single-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_S÷2 × 1$ sub-matrix of single-precision values held in the half-vectors of the first source vectors by the $1 × SVL_S÷2$ sub-matrix of single-precision values held in the half-vectors of the second source vectors. In case of the double-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_D÷2 × 1$ sub-matrix of double-precision values held in the half-vectors of the first source vectors by the $1 × SVL_D÷2$ sub-matrix of double-precision values held in the half-vectors of the second source vectors.

The resulting quarter-tile $SVL_H÷2 × SVL_H÷2$ half-precision outer products in case of the half-precision variant, $SVL_S÷2 × SVL_S÷2$ single-precision outer products in case of the single-precision variant, or $SVL_D÷2 × SVL_D÷2$ double-precision outer products in case of the double-precision variant are destructively added to the destination ZA tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 12 classes: Half-precision, single and multiple vectors , Half-precision, single vectors , Half-precision, multiple and single vectors , Half-precision, multiple vectors , Single-precision, single and multiple vectors , Single-precision, single vectors , Single-precision, multiple and single vectors , Single-precision, multiple vectors , Double-precision, single and multiple vectors , Double-precision, single vectors , Double-precision, multiple and single vectors and Double-precision, multiple vectors

FMOP4A (widening, 2-way, FP16 to FP32)

Half-precision quarter-tile sums of two outer products, accumulating

This instruction generates four independent quarter-tile half-precision sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of half-precision values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of half-precision values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix.

The instruction widens the sub-matrices of half-precision values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of half-precision values in the second source vectors to single-precision values. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ single-precision sums of outer products are then destructively added to the single-precision destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

FMOP4A (widening, 2-way, FP8 to FP16)

8-bit floating-point quarter-tile sums of two outer products, accumulating

This instruction generates four independent quarter-tile 8-bit floating-point sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 16-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_H \div 2 \times 2$ sub-matrix of 8-bit floating-point values held in the half-vectors of the first source vectors by the $2 \times SVL_H \div 2$ sub-matrix of 8-bit floating-point values held in the half-vectors of the second source vectors. Each 16-bit container of the first source vectors holds 2 elements of each row of a $SVL_H \div 2 \times 2$ sub-matrix. Similarly, each 16-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_H \div 2$ sub-matrix.

This instruction widens the sub-matrices of 8-bit floating-point values held in the first source vectors to half-precision floating-point values and multiplies them by the corresponding widened sub-matrices of 8-bit floating-point values in the second source vectors to half-precision floating-point values. The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ half-precision sums of outer products are scaled by $2^{-UInt(FPMR.LSCALE[3:0])}$, before being destructively added to the half-precision floating-point destination tile. This is equivalent to performing a downscaled 2-way dot product and accumulate to each of the destination tile elements.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

FMOP4A (widening, 4-way)

8-bit floating-point quarter-tile sums of four outer products, accumulating

This instruction generates four independent quarter-tile 8-bit floating-point sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit floating-point values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit floating-point values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

This instruction widens the sub-matrices of 8-bit floating-point values held in the first source vectors to single-precision floating-point values and multiplies them by the corresponding widened sub-matrices of 8-bit floating-point values in the second source vectors to single-precision floating-point values. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ single-precision sums of outer products are scaled by $2^{-UInt(FPMR.LSCALE)}$, before being destructively added to the single-precision floating-point destination tile. This is equivalent to performing a downscaled 4-way dot product and accumulate to each of the destination tile elements.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

FMOP4S (non-widening)

Floating-point quarter-tile outer products, subtracting

This instruction generates four independent quarter-tile floating-point outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 16-bit, 32-bit, or 64-bit element ZA tile.

In case of the half-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_H \div 2 \times 1$ sub-matrix of half-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_H \div 2$ sub-matrix of half-precision values held in the half-vectors of the second source vectors. In case of the single-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_S \div 2 \times 1$ sub-matrix of single-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_S \div 2$ sub-matrix of single-precision values held in the half-vectors of the second source vectors. In case of the double-precision variant, each of the quarter-tile outer products is generated by multiplying the $SVL_D \div 2 \times 1$ sub-matrix of double-precision values held in the half-vectors of the first source vectors by the $1 \times SVL_D \div 2$ sub-matrix of double-precision values held in the half-vectors of the second source vectors.

The resulting quarter-tile $SVL_H \div 2 \times SVL_H \div 2$ half-precision outer products in case of the half-precision variant, $SVL_S \div 2 \times SVL_S \div 2$ single-precision outer products in case of the single-precision variant, or $SVL_D \div 2 \times SVL_D \div 2$ double-precision outer products in case of the double-precision variant are destructively subtracted from the destination ZA tile. This is equivalent to performing a single multiply-subtract from each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

FMOP4S (widening)

Half-precision quarter-tile sums of two outer products, subtracting

This instruction generates four independent quarter-tile half-precision sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of half-precision values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of half-precision values held in the half-vectors of the second source vectors. Each 32-bit container of the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the second source vectors holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix.

The instruction widens the sub-matrices of half-precision values held in the first source vectors to single-precision values and multiplies them by the corresponding widened sub-matrices of half-precision values in the second source vectors to single-precision values. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ single-precision sums of outer products are then destructively subtracted from the single-precision destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

FMOPA (non-widening)

Floating-point outer product and accumulate

The half-precision variant works with a 16-bit element ZA tile.

The single-precision variant works with a 32-bit element ZA tile.

The double-precision variant works with a 64-bit element ZA tile.

These instructions generate an outer product of the first source vector and the second source vector. In case of the half-precision variant, the first source is $SVL_H \times 1$ vector and the second source is $1 \times SVL_H$ vector. In case of the single-precision variant, the first source is $SVL_S \times 1$ vector and the second source is $1 \times SVL_S$ vector. In case of the double-precision variant, the first source is $SVL_D \times 1$ vector and the second source is $1 \times SVL_D$ vector.

Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is Inactive the corresponding destination tile element remains unmodified.

The resulting outer product, $SVL_H \times SVL_H$ in case of half-precision variant, $SVL_S \times SVL_S$ in case of single-precision variant or $SVL_D \times SVL_D$ in case of double-precision variant, is then destructively added to the destination tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 3 classes: Half-precision , Single-precision and Double-precision

FMOPA (widening, 2-way, FP16 to FP32)

Half-precision floating-point sum of outer products and accumulate

The half-precision floating-point sum of outer products and accumulate instruction works with a 32-bit element ZA tile.

This instruction widens the SVL_{S}×2 sub-matrix of half-precision floating-point values held in the first source vector to single-precision floating-point values and multiplies it by the widened 2×SVL_{S} sub-matrix of half-precision floating-point values in the second source vector to single-precision floating-point values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting SVL_{S}×SVL_{S} single-precision floating-point sum of outer products is then destructively added to the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVL_{S}×2 sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVL_{S} sub-matrix.

This instruction follows SME ZA-targeting floating-point behaviors.

FMOPA (widening, 2-way, FP8 to FP16)

8-bit floating-point sum of outer products and accumulate

The 8-bit floating-point sum of outer products and accumulate instruction works with a 16-bit element ZA tile.

This instruction widens the $SVL_H \times 2$ sub-matrix of 8-bit floating-point values held in the first source vector to half-precision floating-point values and multiplies it by the widened $2 \times SVL_H$ sub-matrix of 8-bit floating-point values in the second source vector to half-precision floating-point values.

Each source vector is independently predicated by a corresponding governing predicate. When a 8-bit source element is Inactive it is treated as having the value +0.0, but if both groups of source vector elements that correspond to a 16-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting $SVL_H \times SVL_H$ half-precision floating-point sum of outer products are scaled by $2^{-UInt(FPMR.LSCALE[3:0])}$, before being destructively added to the half-precision floating-point destination tile. This is equivalent to performing a downscaled 2-way dot product and accumulate to each of the destination tile elements.

Each 16-bit container of the first source vector holds 2 consecutive column elements of each row of a $SVL_H \times 2$ sub-matrix. Similarly, each 16-bit container of the second source vector holds 2 consecutive row elements of each column of a $2 \times SVL_H$ sub-matrix.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

FMOPA (widening, 4-way)

8-bit floating-point sum of outer products and accumulate

The 8-bit floating-point sum of outer products and accumulate instruction works with a 32-bit element ZA tile.

This instruction widens the $\text{SVL}_S \times 4$ sub-matrix of 8-bit floating-point values held in the first source vector to single-precision floating-point values and multiplies it by the widened $4 \times \text{SVL}_S$ sub-matrix of 8-bit floating-point values in the second source vector to single-precision floating-point values.

Each source vector is independently predicated by a corresponding governing predicate. When a 8-bit source element is Inactive it is treated as having the value +0.0, but if both groups of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting $\text{SVL}_S \times \text{SVL}_S$ single-precision floating-point sum of outer products are scaled by $2^{-\text{UInt(FPMR.LSCALE)}}$, before being destructively added to the single-precision floating-point destination tile. This is equivalent to performing a downscaled 4-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $\text{SVL}_S \times 4$ sub-matrix. Similarly, each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4 \times \text{SVL}_S$ sub-matrix.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

FMOPS (non-widening)

Floating-point outer product and subtract

The half-precision variant works with a 16-bit element ZA tile.

The single-precision variant works with a 32-bit element ZA tile.

The double-precision variant works with a 64-bit element ZA tile.

These instructions generate an outer product of the first source vector and the second source vector. In case of the half-precision variant, the first source is SVL$_H$×1 vector and the second source is 1×SVL$_H$ vector. In case of the single-precision variant, the first source is SVL$_S$×1 vector and the second source is 1×SVL$_S$ vector. In case of the double-precision variant, the first source is SVL$_D$×1 vector and the second source is 1×SVL$_D$ vector.

Each source vector is independently predicated by a corresponding governing predicate. When either source vector element is Inactive the corresponding destination tile element remains unmodified.

The resulting outer product, SVL$_H$×SVL$_H$ in case of half-precision variant, SVL$_S$×SVL$_S$ in case of single-precision variant or SVL$_D$×SVL$_D$ in case of double-precision variant, is then destructively subtracted from the destination tile. This is equivalent to performing a single multiply-subtract from each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 3 classes: Half-precision , Single-precision and Double-precision

FMOPS (widening)

Half-precision floating-point sum of outer products and subtract

The half-precision floating-point sum of outer products and subtract instruction works with a 32-bit element ZA tile.

This instruction widens the $\text{SVL}_\text{S}\times2$ sub-matrix of half-precision floating-point values held in the first source vector to single-precision floating-point values and multiplies it by the widened $2\times\text{SVL}_\text{S}$ sub-matrix of half-precision floating-point values in the second source vector to single-precision floating-point values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is Inactive it is treated as having the value +0.0, but if both pairs of source vector elements that correspond to a 32-bit destination element contain Inactive elements, then the destination element remains unmodified.

The resulting $\text{SVL}_\text{S}\times\text{SVL}_\text{S}$ single-precision floating-point sum of outer products is then destructively subtracted from the single-precision floating-point destination tile. This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a $\text{SVL}_\text{S}\times2$ sub-matrix. Similarly, each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a $2\times\text{SVL}_\text{S}$ sub-matrix.

This instruction follows SME ZA-targeting floating-point behaviors.

FRINTA

Multi-vector floating-point round to integral value, to nearest with ties away from zero

Round to the nearest integral floating-point value, with ties rounding away from zero, each element of the two or four source vectors, and place the results in the corresponding elements of the two or four destination vectors.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

FSUB

Floating-point subtract multi-vector from ZA array vector accumulators

Destructively subtract all elements of the two or four source vectors from the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.F64F64 indicates whether the double-precision variant is implemented, and ID_AA64SMFR0_EL1.F16F16 indicates whether the half-precision variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors , Two ZA single-vectors of half precision elements , Four ZA single-vectors and Four ZA single-vectors of half precision elements

FTMOPA (non-widening)

Floating-point sparse outer product, accumulating

This instruction generates floating-point outer product by multiplying the 1-in-2 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the destination ZA tile elements.

In case of the half-precision variant, the outer product is generated by multiplying the selected 1-in-2 half-precision value from each overlapping 16-bit containers of the two SVL_H×1 sub-matrices in the first source vectors by the half-precision value from the corresponding 16-bit container of the compressed 1×SVL_H sub-matrix in the second source vector. In case of the single-precision variant, the outer product is generated by multiplying the selected 1-in-2 single-precision value from each overlapping 32-bit containers of the two SVL_S×1 sub-matrices in the first source vectors by the single-precision value from the corresponding 32-bit container of the compressed 1×SVL_S sub-matrix in the second source vector.

The 1-in-2 floating-point value in the first source vectors is selected by 2-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the result. If both bits of the 2-bit control corresponding to the elements of the first source vectors are 1, only the element corresponding to the least significant bit is selected.

The instruction multiplies the selected elements of sub-matrices of floating-point values held in the first source vectors by the corresponding elements of sub-matrix of floating-point values in the second source vector. The resulting outer product, SVL_H×SVL_H in case of the half-precision variant or SVL_S×SVL_S in case of the single-precision variant, is then destructively added to the destination tile. This is equivalent to performing a single multiply-accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

It has encodings from 2 classes: Half-precision and Single-precision

Half-precision

FTMOPA (widening, 2-way, FP16 to FP32)

Half-precision sparse sum of two outer products, accumulating

This instruction generates half-precision sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 half-precision values from each overlapping 32-bit containers of the two $SVL_S\times 2$ sub-matrices in the first source vectors by the two half-precision values from the corresponding 32-bit container of the $2\times SVL_S$ sub-matrix in the second source vector. The two selected elements from each overlapping 32-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two $SVL_S\times 2$ sub-matrices. Each 32-bit container of the second source vector holds 2 elements of columns of a compressed $2\times SVL_S$ sub-matrix.

The 2-in-4 half-precision values from overlapping 32-bit containers of the first source vectors are selected by 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 32-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The instruction widens the selected elements of sub-matrices of half-precision values held in the first source vectors to single-precision values and multiplies them by the corresponding widened elements of sub-matrix of half-precision values in the second source vector to single-precision values. The resulting $SVL_S\times SVL_S$ single-precision sum of outer products is then destructively added to the single-precision destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

FTMOPA (widening, 2-way, FP8 to FP16)

8-bit floating-point sparse sum of two outer products, accumulating

This instruction generates 8-bit floating-point sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 16-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 8-bit floating-point values from each overlapping 16-bit containers of the two $SVL_H \times 2$ sub-matrices in the first source vectors by the two 8-bit floating point values from the corresponding 16-bit container of the $2 \times SVL_H$ sub-matrix in the second source vector. The two selected elements from each overlapping 16-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two $SVL_H \times 2$ sub-matrices. Each 16-bit container of the second source vector holds 2 elements of columns of a compressed $2 \times SVL_H$ sub-matrix.

The 2-in-4 8-bit floating values from overlapping 16-bit containers of the first source vectors are selected by 4-bit control in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 16-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The instruction widens the selected elements of sub-matrices of 8-bit floating-point values held in the first source vectors to half-precision values and multiplies them by the corresponding widened elements of sub-matrix of 8-bit floating-point values in the second source vector to half-precision values. The resulting $SVL_H \times SVL_H$ half-precision sum of outer products is scaled by $2^{-UInt(FPMR.LSCALE[3:0])}$, before being destructively added to the half-precision destination tile. This is equivalent to performing a downscaled 2-way dot product and accumulate to each of the destination tile elements.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

FTMOPA (widening, 4-way)

8-bit floating-point sparse sum of four outer products, accumulating

This instruction generates 8-bit floating-point sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit floating-point values from each overlapping 32-bit containers of the two SVL_S×4 sub-matrices in the first source vectors by the four 8-bit floating-point values from the corresponding 32-bit container of the 4×SVL_S sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two SVL_S×4 sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed 4×SVL_S sub-matrix.

The two sets of 2-in-4 8-bit floating values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The instruction widens the selected elements of sub-matrices of 8-bit floating-point values held in the first source vectors to single-precision values and multiplies them by the corresponding widened elements of sub-matrix of 8-bit floating-point values in the second source vector to single-precision values. The resulting SVL_S×SVL_S single-precision sum of outer products is scaled by $2^{-\text{UInt(FPMR.LSCALE)}}$, before being destructively added to the single-precision destination tile. This is equivalent to performing a downscaled 4-way dot product and accumulate to each of the destination tile elements.

The 8-bit floating-point encoding format for the elements of the first source vector and the second source vector is selected by FPMR.F8S1 and FPMR.F8S2 respectively.

This instruction is unpredicated.

FVDOT (FP16 to FP32)

Multi-vector half-precision floating-point vertical dot-product by indexed element

The instruction computes the fused sum-of-products of each vertical pair of half-precision floating-point values in the corresponding elements of the two first source vectors with the pair of half-precision floating-point values in the indexed 32-bit group of the corresponding 128-bit segment of the second source vector, without intermediate rounding. The single-precision sum-of-products are destructively added to the corresponding single-precision elements of the two ZA single-vector groups.

The half-precision floating-point pairs within the second source vector are specified using an immediate index which selects the same pair position within each 128-bit vector segment. The element index range is from 0 to 3.

The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.

The vector group symbol VGx2 indicates that the ZA operand consists of two ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction follows SME ZA-targeting floating-point behaviors.

This instruction is unpredicated.

LD1B (scalar plus immediate, strided registers)

Contiguous load of bytes to multiple strided vectors (immediate index)

Contiguous load of unsigned bytes to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: Two registers and Four registers

Two registers

Assembler Symbols

<Zt1>	For the "Two registers" variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 to be transferred, encoded as "T:'0':Zt". For the "Four registers" variant: is the name of the first scalable vector register Z0-Z3 or Z16-Z19 to be transferred, encoded as "T:'00':Zt".
<Zt2>	For the "Two registers" variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 to be transferred, encoded as "T:'1':Zt". For the "Four registers" variant: is the name of the second scalable vector register Z4-Z7 or Z20-Z23 to be transferred, encoded as "T:'01':Zt".
<PNg>	Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>	For the "Two registers" variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the "imm4" field. For the "Four registers" variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.
<Zt3>	Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".
<Zt4>	Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".

LD1B (scalar plus scalar, strided registers)

Contiguous load of bytes to multiple strided vectors (scalar index)

Contiguous load of unsigned bytes to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: Two registers and Four registers

Two registers

LD1B (scalar plus scalar, tile slice)

Contiguous load of bytes to 8-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 8-bit elements in a vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

LD1H (scalar plus immediate, strided registers)

Contiguous load of halfwords to multiple strided vectors (immediate index)

Contiguous load of unsigned halfwords to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: Two registers and Four registers

LD1H (scalar plus scalar, tile slice)

Contiguous load of halfwords to 16-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 16-bit elements in a vector. The immediate offset is in the range 0 to 7. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 2 and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

LD1W (scalar plus scalar, strided registers)

Contiguous load of words to multiple strided vectors (scalar index)

Contiguous load of unsigned words to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

It has encodings from 2 classes: Two registers and Four registers

LD1W (scalar plus scalar, tile slice)

Contiguous load of words to 32-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 32-bit elements in a vector. The immediate offset is in the range 0 to 3. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 4 and added to the base address. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

LDNT1D (scalar plus scalar, strided registers)

Contiguous load non-temporal of doublewords to multiple strided vectors (scalar index)

Contiguous load non-temporal of doublewords to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

LDNT1W (scalar plus scalar, strided registers)

Contiguous load non-temporal of words to multiple strided vectors (scalar index)

Contiguous load non-temporal of words to elements of two or four strided vector registers from the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated. Inactive elements will not cause a read from Device memory or signal a fault, and are set to zero in the destination vector.

A non-temporal load is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

Two registers

LDR (array vector)

Load ZA array vector

The ZA array vector is selected by the sum of the vector select register and immediate offset, modulo the number of bytes in a Streaming SVE vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base, plus the same optional immediate offset multiplied by the current vector length in bytes. This instruction is unpredicated.

The load is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

<Zd1>	For the "Consecutive" variant: is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 2. For the "Strided" variant: is the name of the first scalable vector register Z0-Z7 or Z16-Z23 of the destination multi-vector group, encoded as "D:'0':Zd".
<T>	For the "Consecutive" variant: is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	RESERVED

For the "Strided" variant: is the size specifier, encoded in “size<0>”:

size<0>	<T>
0	B
1	H

<Zd2>	For the "Consecutive" variant: is the name of the second scalable vector register of the destination multi-vector group, encoded as "Zd" times 2 plus 1. For the "Strided" variant: is the name of the second scalable vector register Z8-Z15 or Z24-Z31 of the destination multi-vector group, encoded as "D:'1':Zd".
<Zn>	Is the name of the source scalable vector register, encoded in the "Zn" field.
<index>	Is the vector segment index, in the range 0 to 7, encoded in the "i3" field.

Operation

```
CheckStreamingSVEEnabled();
CheckSMEZT0Enabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant integer segments = esize DIV (isize * nreg);
constant integer segment = imm MOD segments;
constant bits(VL) indexes = Z[n, VL];
integer dst = d;
constant bits(512) table = ZT0[512];

for r = 0 to nreg-1
    constant integer base = (segment * nreg + r) * elements;
    bits(VL) result;
    for e = 0 to elements-1
        constant integer index = UInt(Elem[indexes, base+e, isize]);
        Elem[result, e, esize] = Elem[table, index, 32]<esize-1:0>;
    Z[dst, VL] = result;
    dst = dst + dstride;
```

LUTI4 (four registers, 16-bit & 32-bit)

Lookup table read with 4-bit indexes

Copy 16-bit or 32-bit elements from ZT0 to four destination vectors using packed 4-bit indices from a segment of the source vector register. A segment corresponds to a portion of the source vector that is consumed in order to fill the destination vector. The segment is selected by the vector segment index modulo the total number of segments.

This instruction is unpredicated.

It has encodings from 2 classes: Consecutive and Strided

MOV (array to vector, four registers)

Move four ZA single-vector groups to four vector registers

The instruction operates on four ZA single-vector groups.
The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.
The vector group symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.
The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The vector group symbol is preferred for disassembly, but optional in assembler source code.
This instruction is unpredicated.

This is an alias of MOVA (array to vector, four registers). This means:

- The encodings in this description are named to match the encodings of MOVA (array to vector, four registers).
- The description of MOVA (array to vector, four registers) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	Rv		0	1	1	0	0	off3			Zd			0	0

```
MOV { <Zd1>.D-<Zd4>.D }, ZA.D[<Wv>, <offs>{, VGx4}]
```

is equivalent to

```
MOVA { <Zd1>.D-<Zd4>.D }, ZA.D[<Wv>, <offs>{, VGx4}]
```

and is always the preferred disassembly.

Assembler Symbols

<Zd1>	Is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 4.
<Zd4>	Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.
<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs>	Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.

Operation

The description of MOVA (array to vector, four registers) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

MOV (array to vector, two registers)

Move two ZA single-vector groups to two vector registers

The instruction operates on two ZA single-vector groups.
The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.
The vector group symbol VGx2 indicates that the instruction operates on two ZA single-vector groups.
The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The vector group symbol is preferred for disassembly, but optional in assembler source code.
This instruction is unpredicated.

This is an alias of MOVA (array to vector, two registers). This means:

- The encodings in this description are named to match the encodings of MOVA (array to vector, two registers).
- The description of MOVA (array to vector, two registers) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

MOV (tile to vector, four registers)

Move four ZA tile slices to four vector registers

The instruction operates on four consecutive horizontal or vertical slices within a named ZA tile of the specified element size. The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 4 in the range 0 to the number of elements in a 128-bit vector segment minus 4. This instruction is unpredicated.

This is an alias of MOVA (tile to vector, four registers). This means:

- The encodings in this description are named to match the encodings of MOVA (tile to vector, four registers).
- The description of MOVA (tile to vector, four registers) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 4 classes: 8-bit , 16-bit , 32-bit and 64-bit

8-bit

Assembler Symbols

<Zd1>	Is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 4.
<Zd4>	Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.
<HV>	Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>	Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
<offs1>	For the "8-bit" variant: is the first slice index offset, encoded as "off2" field times 4. For the "16-bit" variant: is the first slice index offset, encoded as "o1" field times 4. For the "32-bit" and "64-bit" variants: is the first slice index offset, with implicit value 0.
<offs4>	For the "8-bit" variant: is the fourth slice index offset, encoded as "off2" field times 4 plus 3. For the "16-bit" variant: is the fourth slice index offset, encoded as "o1" field times 4 plus 3. For the "32-bit" and "64-bit" variants: is the fourth slice index offset, with implicit value 3.
<ZAn>	For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field. For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field. For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.

Operation

The description of MOVA (tile to vector, four registers) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MOV (tile to vector, single)

Move ZA tile slice to vector register

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination vector remain unmodified.

This is an alias of MOVA (tile to vector, single). This means:

- The encodings in this description are named to match the encodings of MOVA (tile to vector, single).
- The description of MOVA (tile to vector, single) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 5 classes: 8-bit , 16-bit , 32-bit , 64-bit and 128-bit

8-bit

and is always the preferred disassembly.

Assembler Symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<HV> Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<offs> For the "8-bit" variant: is the slice index offset, in the range 0 to 15, encoded in the "off4" field.

For the "16-bit" variant: is the slice index offset, in the range 0 to 7, encoded in the "off3" field.

For the "32-bit" variant: is the slice index offset, in the range 0 to 3, encoded in the "off2" field.

For the "64-bit" variant: is the slice index offset, in the range 0 to 1, encoded in the "o1" field.

For the "128-bit" variant: is the slice index offset, with implicit value 0.

<ZAn> For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field.

For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field.

For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.

For the "128-bit" variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the "ZAn" field.

Operation

The description of MOVA (tile to vector, single) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
    - The values of the NZCV flags.

Operation

The description of MOVA (tile to vector, two registers) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MOV (vector to array, four registers)

Move four vector registers to four ZA single-vector groups

The instruction operates on four ZA single-vector groups.
The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.
The vector group symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.
The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands.
The vector group symbol is preferred for disassembly, but optional in assembler source code.
This instruction is unpredicated.

This is an alias of MOVA (vector to array, four registers). This means:

- The encodings in this description are named to match the encodings of MOVA (vector to array, four registers).
- The description of MOVA (vector to array, four registers) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

<HV> Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<offs1> For the "8-bit" variant: is the first slice index offset, encoded as "off2" field times 4.

For the "16-bit" variant: is the first slice index offset, encoded as "o1" field times 4.

For the "32-bit" and "64-bit" variants: is the first slice index offset, with implicit value 0.

<offs4> For the "8-bit" variant: is the fourth slice index offset, encoded as "off2" field times 4 plus 3.

For the "16-bit" variant: is the fourth slice index offset, encoded as "o1" field times 4 plus 3.

For the "32-bit" and "64-bit" variants: is the fourth slice index offset, with implicit value 3.

<Zn1> Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 4.

<Zn4> Is the name of the fourth scalable vector register of the source multi-vector group, encoded as "Zn" times 4 plus 3.

<ZAd> For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAd" field.

For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAd" field.

For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAd" field.

Operation

The description of MOVA (vector to tile, four registers) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MOV (vector to tile, single)

Move vector register to ZA tile slice

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.
Inactive elements in the destination slice remain unmodified.

This is an alias of MOVA (vector to tile, single). This means:

- The encodings in this description are named to match the encodings of MOVA (vector to tile, single).
- The description of MOVA (vector to tile, single) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from 5 classes: 8-bit , 16-bit , 32-bit , 64-bit and 128-bit

8-bit

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

and is always the preferred disassembly.

Assembler Symbols

<HV>

Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>

Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<offs>

For the "8-bit" variant: is the slice index offset, in the range 0 to 15, encoded in the "off4" field.

For the "16-bit" variant: is the slice index offset, in the range 0 to 7, encoded in the "off3" field.

For the "32-bit" variant: is the slice index offset, in the range 0 to 3, encoded in the "off2" field.

For the "64-bit" variant: is the slice index offset, in the range 0 to 1, encoded in the "o1" field.

For the "128-bit" variant: is the slice index offset, with implicit value 0.

<Pg>

Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Zn>

Is the name of the source scalable vector register, encoded in the "Zn" field.

<ZAd>

For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAd" field.

For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAd" field.

For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAd" field.

For the "128-bit" variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the "ZAd" field.

Operation

The description of MOVA (vector to tile, single) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
    - The values of the NZCV flags.

and is always the preferred disassembly.

Assembler Symbols

<HV>	Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>	Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
<offs1>	For the "8-bit" variant: is the first slice index offset, encoded as "off3" field times 2. For the "16-bit" variant: is the first slice index offset, encoded as "off2" field times 2. For the "32-bit" variant: is the first slice index offset, encoded as "o1" field times 2. For the "64-bit" variant: is the first slice index offset, with implicit value 0.
<offs2>	For the "8-bit" variant: is the second slice index offset, encoded as "off3" field times 2 plus 1. For the "16-bit" variant: is the second slice index offset, encoded as "off2" field times 2 plus 1. For the "32-bit" variant: is the second slice index offset, encoded as "o1" field times 2 plus 1. For the "64-bit" variant: is the second slice index offset, with implicit value 1.
<Zn1>	Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 2.
<Zn2>	Is the name of the second scalable vector register of the source multi-vector group, encoded as "Zn" times 2 plus 1.
<ZAd>	For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAd" field. For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAd" field. For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAd" field.

Operation

The description of MOVA (vector to tile, two registers) gives the operational pseudocode for this instruction.

Operational information

If FEAT_SVE2 is implemented or FEAT_SME is implemented, then if PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

MOVA (array to vector, four registers)

Move four ZA single-vector groups to four vector registers

The instruction operates on four ZA single-vector groups.
The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.
The vector group symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.
The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The vector group symbol is preferred for disassembly, but optional in assembler source code.
This instruction is unpredicated.
This instruction is used by the alias MOV (array to vector, four registers).

SME2
(FEAT_SME2)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
MOVA { <Zd1>.D-<Zd4>.D }, ZA.D[<Wv>, <offs>{, VGx4}]
```

```
if !IsFeatureImplemented(FEAT_SME2) then EndOfDecode(Decode_UNDEF);
constant integer v = UInt('010':Rv);
constant integer offset = UInt(off3);
constant integer d = UInt(Zd:'00');
constant integer nreg = 4;
```

Assembler Symbols

<Zd1>	Is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 4.
<Zd4>	Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.
<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs>	Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV nreg;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;

for r = 0 to nreg-1
    constant bits(VL) result = ZAvector[vec, VL];
    Z[d + r, VL] = result;
    vec = vec + vstride;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MOVA (array to vector, two registers)

Move two ZA single-vector groups to two vector registers

The instruction operates on two ZA single-vector groups.
The single-vector group within each half of the ZA array is selected by the sum of the vector select register and offset, modulo half the number of ZA array vectors.
The vector group symbol VGx2 indicates that the instruction operates on two ZA single-vector groups.
The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The vector group symbol is preferred for disassembly, but optional in assembler source code.
This instruction is unpredicated.
This instruction is used by the alias MOV (array to vector, two registers).

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs>	Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV nreg;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;

for r = 0 to nreg-1
    constant bits(VL) result = ZAvector[vec, VL];
    Z[d + r, VL] = result;
    vec = vec + vstride;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

MOVA (tile to vector, four registers)

Move four ZA tile slices to four vector registers

The instruction operates on four consecutive horizontal or vertical slices within a named ZA tile of the specified element size. The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 4 in the range 0 to the number of elements in a 128-bit vector segment minus 4.

This instruction is unpredicated.

This instruction is used by the alias MOV (tile to vector, four registers).

It has encodings from 4 classes: 8-bit , 16-bit , 32-bit and 64-bit

constant integer n = UInt(ZAn);
constant integer offset = 0;
constant boolean vertical = V == '1';
```

Assembler Symbols

<Zd1>	Is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 4.
<Zd4>	Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.
<HV>	Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>	Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
<offs1>	For the "8-bit" variant: is the first slice index offset, encoded as "off2" field times 4. For the "16-bit" variant: is the first slice index offset, encoded as "o1" field times 4. For the "32-bit" and "64-bit" variants: is the first slice index offset, with implicit value 0.
<offs4>	For the "8-bit" variant: is the fourth slice index offset, encoded as "off2" field times 4 plus 3. For the "16-bit" variant: is the fourth slice index offset, encoded as "o1" field times 4 plus 3. For the "32-bit" and "64-bit" variants: is the fourth slice index offset, with implicit value 3.
<ZAn>	For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field. For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field. For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
if nreg == 4 && esize == 64 && VL < 256 then EndOfDecode(Decode_UNDEF);
constant integer slices = VL DIV esize;
constant bits(32) index = X[s, 32];
constant integer slice = ((UInt(index) - (UInt(index) MOD nreg)) + offset) MOD slices;

for r = 0 to nreg-1
    constant bits(VL) result = ZAslice[n, esize, vertical, slice + r, VL];
    Z[d + r, VL] = result;
```

MOVA (tile to vector, single)

Move ZA tile slice to vector register

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination vector remain unmodified.

This instruction is used by the alias MOV (tile to vector, single).

It has encodings from 5 classes: 8-bit , 16-bit , 32-bit , 64-bit and 128-bit

8-bit

MOVA (vector to array, four registers)

Move four vector registers to four ZA single-vector groups

The instruction operates on four ZA single-vector groups.

The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.

The vector group symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

This instruction is used by the alias MOV (vector to array, four registers).

Assembler Symbols

<HV> Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<offs1> For the "8-bit" variant: is the first slice index offset, encoded as "off2" field times 4.

For the "16-bit" variant: is the first slice index offset, encoded as "o1" field times 4.

For the "32-bit" and "64-bit" variants: is the first slice index offset, with implicit value 0.

<offs4> For the "8-bit" variant: is the fourth slice index offset, encoded as "off2" field times 4 plus 3.

For the "16-bit" variant: is the fourth slice index offset, encoded as "o1" field times 4 plus 3.

For the "32-bit" and "64-bit" variants: is the fourth slice index offset, with implicit value 3.

<Zn1> Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 4.

<Zn4> Is the name of the fourth scalable vector register of the source multi-vector group, encoded as "Zn" times 4 plus 3.

<ZAd> For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAd" field.

For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAd" field.

For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAd" field.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
if nreg == 4 && esize == 64 && VL < 256 then EndOfDecode(Decode_UNDEF);
constant integer slices = VL DIV esize;
constant bits(32) index = X[s, 32];
constant integer slice = ((UInt(index) - (UInt(index) MOD nreg)) + offset) MOD slices;

for r = 0 to nreg-1
    constant bits(VL) result = Z[n + r, VL];
    ZAslice[d, esize, vertical, slice + r, VL] = result;
```

Operational information

MOVA (vector to tile, single)

Move vector register to ZA tile slice

The instruction operates on individual horizontal or vertical slices within a named ZA tile of the specified element size. The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

Inactive elements in the destination slice remain unmodified.

This instruction is used by the alias MOV (vector to tile, single).

It has encodings from 5 classes: 8-bit , 16-bit , 32-bit , 64-bit and 128-bit

8-bit

MOVAZ (array to vector, four registers)

Move and zero four ZA single-vector groups to vector registers

The instruction operates on four ZA single-vector groups. The ZA single-vector groups are zeroed after moving their contents to the destination vectors.

The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.

The vector group symbol VGx4 indicates that the instruction operates on four ZA single-vector groups.

The preferred disassembly syntax uses a 64-bit element size, but an assembler should accept any element size if it is used consistently for all operands. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

Assembler Symbols

<Zd1>	Is the name of the first scalable vector register of the destination multi-vector group, encoded as "Zd" times 4.
<Zd4>	Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.
<HV>	Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws>	Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.
<offs1>	For the "8-bit" variant: is the first slice index offset, encoded as "off2" field times 4.
	For the "16-bit" variant: is the first slice index offset, encoded as "o1" field times 4.
	For the "32-bit" and "64-bit" variants: is the first slice index offset, with implicit value 0.
<offs4>	For the "8-bit" variant: is the fourth slice index offset, encoded as "off2" field times 4 plus 3.
	For the "16-bit" variant: is the fourth slice index offset, encoded as "o1" field times 4 plus 3.
	For the "32-bit" and "64-bit" variants: is the fourth slice index offset, with implicit value 3.
<ZAn>	For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field.
	For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field.
	For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.

Operation

MOVAZ (tile to vector, single)

Move and zero ZA tile slice to vector register

The instruction operates on a horizontal or vertical slice within a named ZA tile of the specified element size. The tile slice is zeroed after moving its contents to the destination vector.

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is in the range 0 to the number of elements in a 128-bit vector segment minus 1.

This instruction is unpredicated.

It has encodings from 5 classes: 8-bit , 16-bit , 32-bit , 64-bit and 128-bit

Assembler Symbols

<Zd> Is the name of the destination scalable vector register, encoded in the "Zd" field.

<HV> Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<offs> For the "8-bit" variant: is the slice index offset, in the range 0 to 15, encoded in the "off4" field.

For the "16-bit" variant: is the slice index offset, in the range 0 to 7, encoded in the "off3" field.

For the "32-bit" variant: is the slice index offset, in the range 0 to 3, encoded in the "off2" field.

For the "64-bit" variant: is the slice index offset, in the range 0 to 1, encoded in the "o1" field.

For the "128-bit" variant: is the slice index offset, with implicit value 0.

<ZAn> For the "16-bit" variant: is the name of the ZA tile ZA0-ZA1 to be accessed, encoded in the "ZAn" field.

For the "32-bit" variant: is the name of the ZA tile ZA0-ZA3 to be accessed, encoded in the "ZAn" field.

For the "64-bit" variant: is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAn" field.

For the "128-bit" variant: is the name of the ZA tile ZA0-ZA15 to be accessed, encoded in the "ZAn" field.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer dim = VL DIV esize;
constant bits(32) index = X[s, 32];
constant integer  slice = (UInt(index) + offset) MOD dim;
constant bits(VL) operand = ZAslice[n, esize, vertical, slice, VL];
ZAslice[n, esize, vertical, slice, VL] = Zeros(VL);
Z[d, VL] = operand;
```

MOVAZ (tile to vector, two registers)

Move and zero two ZA tile slices to vector registers

The instruction operates on two consecutive horizontal or vertical slices within a named ZA tile of the specified element size. The tile slices are zeroed after moving their contents to the destination vectors.

The consecutive slice numbers within the tile are selected starting from the sum of the slice index register and immediate offset, modulo the number of such elements in a vector. The immediate offset is a multiple of 2 in the range 0 to the number of elements in a 128-bit vector segment minus 2.

This instruction is unpredicated.

It has encodings from 4 classes: 8-bit , 16-bit , 32-bit and 64-bit

Assembler Symbols

<offs>	Is the vector length offset, in the range 0 to 3, defaulting to 0 when omitted, encoded in the "off2" field.
<Zt>	Is the name of the scalable vector register to be transferred, encoded in the "Zt" field.

Operation

```
CheckStreamingSVEEnabled();
CheckSMEZT0Enabled();
constant integer VL = CurrentVL;
constant integer tsize = if VL <= 512 then VL else 512;
constant integer offset = imm MOD (512 DIV tsize);
bits(512) result = if imm == 0 then Zeros(512) else ZT0[512];

Elem[result, offset, tsize] = Z[t, VL]<tsize-1:0>;
ZT0[512] = result;
```

Operational information

- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

RDSVL

Read multiple of Streaming SVE vector register size to scalar register

Multiply the Streaming SVE vector register size in bytes by an immediate in the range -32 to 31 and place the result in the 64-bit destination general-purpose register.
This instruction does not require the PE to be in Streaming SVE mode.

SDOT (2-way, multiple and indexed vector)

Multi-vector signed integer dot-product by indexed element

The signed integer dot product instruction computes the dot product of two signed 16-bit integer values held in each 32-bit element of the two or four first source vectors and two signed 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

SDOT (4-way, multiple and indexed vector)

Multi-vector signed integer dot-product by indexed element

The signed integer dot product instruction computes the dot product of four signed 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four signed 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors of 32-bit elements , Two ZA single-vectors of 64-bit elements , Four ZA single-vectors of 32-bit elements and Four ZA single-vectors of 64-bit elements

For the "Two registers" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 2.

For the "Four registers" variant: is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.

<Zn2>	Is the name of the second scalable vector register of the first source multi-vector group, encoded as "Zn" times 2 plus 1.
<Zm1>	For the "Two registers" variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 2. For the "Four registers" variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 4.
<Zm2>	Is the name of the second scalable vector register of the second source multi-vector group, encoded as "Zm" times 2 plus 1.
<Zd4>	Is the name of the fourth scalable vector register of the destination multi-vector group, encoded as "Zd" times 4 plus 3.
<Zn4>	Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.
<Zm4>	Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
array [0..3] of bits(VL) results;
constant bits(PL) pred = P[g, PL];
constant bits(PL * nreg) mask = CounterToPredicate(pred<15:0>, PL * nreg);

for r = 0 to nreg-1
    constant bits(VL) operand1 = Z[n+r, VL];
    constant bits(VL) operand2 = Z[m+r, VL];
    for e = 0 to elements-1
        if ActivePredicateElement(mask, r * elements + e, esize) then
            Elem[results[r], e, esize] = Elem[operand1, e, esize];
        else
            Elem[results[r], e, esize] = Elem[operand2, e, esize];

for r = 0 to nreg-1
    Z[d+r, VL] = results[r];
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its operand registers when its governing predicate register contains the same value for each execution.
    - The values of the NZCV flags.

SMLAL (multiple and indexed vector)

Multi-vector signed integer multiply-add long by indexed element

This signed integer multiply-add long instruction multiplies each signed 16-bit element in the one, two, or four first source vectors with each signed 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

SMLAL (multiple and single vector)

Multi-vector signed integer multiply-add long by vector

This signed integer multiply-add long instruction multiplies each signed 16-bit element in the one, two, or four first source vectors with each signed 16-bit element in the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

One ZA double-vector

SMLALL (multiple and indexed vector)

Multi-vector signed integer multiply-add long-long by indexed element

This signed integer multiply-add long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: One ZA quad-vector of 32-bit elements , One ZA quad-vector of 64-bit elements , Two ZA quad-vectors of 32-bit elements , Two ZA quad-vectors of 64-bit elements , Four ZA quad-vectors of 32-bit elements and Four ZA quad-vectors of 64-bit elements

SMLALL (multiple and single vector)

Multi-vector signed integer multiply-add long-long by vector

This signed integer multiply-add long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit element in the second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 3 classes: One ZA quad-vector , Two ZA quad-vectors and Four ZA quad-vectors

SMLSL (multiple and indexed vector)

Multi-vector signed integer multiply-subtract long by indexed element

This signed integer multiply-subtract long instruction multiplies each signed 16-bit element in the one, two, or four first source vectors with each signed 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

SMLSL (multiple vectors)

Multi-vector signed integer multiply-subtract long

This signed integer multiply-subtract long instruction multiplies each signed 16-bit element in the two or four first source vectors with each signed 16-bit element in the two or four second source vectors, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The double-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA double-vectors and Four ZA double-vectors

SMLSLL (multiple and indexed vector)

Multi-vector signed integer multiply-subtract long-long by indexed element

This signed integer multiply-subtract long-long instruction multiplies each signed 8-bit or 16-bit element in the one, two, or four first source vectors with each signed 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: One ZA quad-vector of 32-bit elements , One ZA quad-vector of 64-bit elements , Two ZA quad-vectors of 32-bit elements , Two ZA quad-vectors of 64-bit elements , Four ZA quad-vectors of 32-bit elements and Four ZA quad-vectors of 64-bit elements

SMLSLL (multiple vectors)

Multi-vector signed integer multiply-subtract long-long

This signed integer multiply-subtract long-long instruction multiplies each signed 8-bit or 16-bit element in the two or four first source vectors with each signed 8-bit or 16-bit element in the one, two, or four second source vectors, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The quad-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: Two ZA quad-vectors and Four ZA quad-vectors

Two ZA quad-vectors

SMOP4A (2-way)

Signed integer quarter-tile sums of two outer products, accumulating

This instruction generates four independent quarter-tile signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_\text{S}\div 2 \times 2$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $2 \times \text{SVL}_\text{S}\div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 2 elements of each row of a $\text{SVL}_\text{S}\div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 2 elements of each column of a $2 \times \text{SVL}_\text{S}\div 2$ sub-matrix. The resulting quarter-tile $\text{SVL}_\text{S}\div 2 \times \text{SVL}_\text{S}\div 2$ widened 32-bit integer sums of outer products are then destructively added to the 32-bit integer destination tile.

This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

Single and multiple vectors

SMOP4A (4-way)

Signed integer quarter-tile sums of four outer products, accumulating

This instruction generates four independent quarter-tile signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_{\text{S}}\div 2 \times 4$ sub-matrix of 8-bit signed values held in the half-vectors of the first source vectors by the $4 \times \text{SVL}_{\text{S}}\div 2$ sub-matrix of 8-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\text{SVL}_{\text{S}}\div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \text{SVL}_{\text{S}}\div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_{\text{D}}\div 2 \times 4$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $4 \times \text{SVL}_{\text{D}}\div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\text{SVL}_{\text{D}}\div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \text{SVL}_{\text{D}}\div 2$ sub-matrix.

The resulting quarter-tile $\text{SVL}_{\text{S}}\div 2 \times \text{SVL}_{\text{S}}\div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $\text{SVL}_{\text{D}}\div 2 \times \text{SVL}_{\text{D}}\div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively added to the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors , 32-bit, single vectors , 32-bit, multiple and single vectors , 32-bit, multiple vectors , 64-bit, single and multiple vectors , 64-bit, single vectors , 64-bit, multiple and single vectors and 64-bit, multiple vectors

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

SMOP4S (2-way)

Signed integer quarter-tile sums of two outer products, subtracting

This instruction generates four independent quarter-tile signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the SVL$_S$÷2 × 2 sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the 2 × SVL$_S$÷2 sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 2 elements of each row of a SVL$_S$÷2 × 2 sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 2 elements of each column of a 2 × SVL$_S$÷2 sub-matrix. The resulting quarter-tile SVL$_S$÷2 × SVL$_S$÷2 widened 32-bit integer sums of outer products are then destructively subtracted from the 32-bit integer destination tile.

This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

SMOP4S (4-way)

Signed integer quarter-tile sums of four outer products, subtracting

This instruction generates four independent quarter-tile signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\mathrm{SVL}_\mathrm{S}\div 2 \times 4$ sub-matrix of 8-bit signed values held in the half-vectors of the first source vectors by the $4 \times \mathrm{SVL}_\mathrm{S}\div 2$ sub-matrix of 8-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\mathrm{SVL}_\mathrm{S}\div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \mathrm{SVL}_\mathrm{S}\div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\mathrm{SVL}_\mathrm{D}\div 2 \times 4$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $4 \times \mathrm{SVL}_\mathrm{D}\div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\mathrm{SVL}_\mathrm{D}\div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \mathrm{SVL}_\mathrm{D}\div 2$ sub-matrix.

The resulting quarter-tile $\mathrm{SVL}_\mathrm{S}\div 2 \times \mathrm{SVL}_\mathrm{S}\div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $\mathrm{SVL}_\mathrm{D}\div 2 \times \mathrm{SVL}_\mathrm{D}\div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively subtracted from the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors , 32-bit, single vectors , 32-bit, multiple and single vectors , 32-bit, multiple vectors , 64-bit, single and multiple vectors , 64-bit, single vectors , 64-bit, multiple and single vectors and 64-bit, multiple vectors

SMOPA (2-way)

Signed integer sum of outer products and accumulate

This instruction works with a 32-bit element ZA tile.

The signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds SVL_S×2 sub-matrix of signed 16-bit integer values, and the second source holds 2×SVL_S sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting SVL_S×SVL_S widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a SVL_S×2 sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a 2×SVL_S sub-matrix.

SMOPA (4-way)

Signed integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVL_S×4 sub-matrix of signed 8-bit integer values, and the second source holds 4×SVL_S sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVL_D×4 sub-matrix of signed 16-bit integer values, and the second source holds 4×SVL_D sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVL_S×SVL_S widened 32-bit integer or SVL_D×SVL_D widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_S×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_S sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_D×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_D sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

SMOPS (4-way)

Signed integer sum of outer products and subtract

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVL_S×4 sub-matrix of signed 8-bit integer values, and the second source holds 4×SVL_S sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVL_D×4 sub-matrix of signed 16-bit integer values, and the second source holds 4×SVL_D sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVL_S×SVL_S widened 32-bit integer or SVL_D×SVL_D widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_S×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_S sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_D×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_D sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

01	B
1x	H

<Zn1> Is the name of the first scalable vector register of the source multi-vector group, encoded as "Zn" times 4.

<Tb> Is the size specifier, encoded in “tsize”:

tsize	<Tb>
00	RESERVED
01	S
1x	D

<Zn4> Is the name of the fourth scalable vector register of the source multi-vector group, encoded as "Zn" times 4 plus 3.

<const> Is the immediate shift amount, in the range 1 to number of bits per source element, encoded in "tsize:imm5".

Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV (4 * esize);
bits(VL) result;

for r = 0 to 3
    constant bits(VL) operand = Z[n+r, VL];
    for e = 0 to elements-1
        constant bits(4 * esize) element = Elem[operand, e, 4 * esize];
        constant integer res = (SInt(element) + (1 << (shift-1))) >> shift;
        Elem[result, r*elements + e, esize] = SignedSat(res, esize);

Z[d, VL] = result;
```

SQRSHR (two registers)

Multi-vector signed saturating rounding shift right narrow by immediate

Shift right by an immediate value, the signed integer value in each element of the two source vectors and place the rounded results in the half-width destination elements. Each result element is saturated to the half-width N-bit element's signed integer range $-2^{(N-1)}$ to $(2^{(N-1)})-1$. The immediate shift amount is an unsigned value in the range 1 to 16.
This instruction is unpredicated.

ST1B (scalar plus scalar, strided registers)

Contiguous store of bytes from multiple strided vectors (scalar index)

Contiguous store of bytes from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements are not written to memory.

It has encodings from 2 classes: Two registers and Four registers

Two registers

ST1B (scalar plus scalar, tile slice)

Contiguous store of bytes from 8-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 8-bit elements in a vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is added to the base address. Inactive elements are not written to memory.

Assembler Symbols

<ZAt> Is the name of the ZA tile ZA0-ZA7 to be accessed, encoded in the "ZAt" field.

<HV> Is the horizontal or vertical slice indicator, encoded in “V”:

V	<HV>
0	H
1	V

<Ws> Is the 32-bit name of the slice index register W12-W15, encoded in the "Rs" field.

<offs> Is the slice index offset, in the range 0 to 1, encoded in the "o1" field.

<Pg> Is the name of the governing scalable predicate register P0-P7, encoded in the "Pg" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<Xm> Is the optional 64-bit name of the general-purpose offset register, defaulting to XZR, encoded in the "Rm" field.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer dim = VL DIV esize;
bits(64) base;
bits(64) addr;
constant bits(PL) mask = P[g, PL];
bits(64) moffs = X[m, 64];
constant bits(32) index = X[s, 32];
constant integer  slice = (UInt(index) + offset) MOD dim;
bits(VL) src;
constant integer mbytes = esize DIV 8;
constant boolean contiguous = TRUE;
constant boolean nontemporal = FALSE;
constant boolean tagchecked = TRUE;
constant AccessDescriptor accdesc = CreateAccDescSME(MemOp_STORE, nontemporal, contiguous,
                                                      tagchecked);

if n == 31 then
    if (AnyActiveElement(mask, esize) ||
          ConstrainUnpredictableBool(Unpredictable_CHECKSPNONEACTIVE)) then
        CheckSPAlignment();
    base = SP[];
else
    base = X[n, 64];

src = ZAslice[t, esize, vertical, slice, VL];
for e = 0 to dim-1
    addr = AddressAdd(base, UInt(moffs) * mbytes, accdesc);
    if ActivePredicateElement(mask, e, esize) then
        Mem[addr, mbytes, accdesc] = Elem[src, e, esize];
    moffs = moffs + 1;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored when its governing predicate register contains the same value for each execution.

ST1H (scalar plus scalar, tile slice)

Contiguous store of halfwords from 16-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 16-bit elements in a vector. The immediate offset is in the range 0 to 7. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 2 and added to the base address. Inactive elements are not written to memory.

ST1W (scalar plus scalar, strided registers)

Contiguous store of words from multiple strided vectors (scalar index)

Contiguous store of words from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements are not written to memory.

It has encodings from 2 classes: Two registers and Four registers

Two registers

ST1W (scalar plus scalar, tile slice)

Contiguous store of words from 32-bit element ZA tile slice

The slice number within the tile is selected by the sum of the slice index register and immediate offset, modulo the number of 32-bit elements in a vector. The immediate offset is in the range 0 to 3. The memory address is generated by a 64-bit scalar base and an optional 64-bit scalar offset which is multiplied by 4 and added to the base address. Inactive elements are not written to memory.

STMOPA (2-way)

Signed integer sparse sum of two outer products, accumulating

This instruction generates signed integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 16-bit signed values from each overlapping 32-bit containers of the two SVL_S×2 sub-matrices in the first source vectors by the two 16-bit signed values from the corresponding 32-bit container of the 2×SVL_S sub-matrix in the second source vector. The two selected elements from each overlapping 32-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two SVL_S×2 sub-matrices. Each 32-bit container of the second source vector holds 2 elements of columns of a compressed 2×SVL_S sub-matrix.

The 2-in-4 16-bit signed values from overlapping 32-bit containers of the first source vectors are selected by 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 32-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting SVL_S×SVL_S widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

STMOPA (4-way)

Signed integer sparse sum of four outer products, accumulating

This instruction generates signed integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit signed values from each overlapping 32-bit containers of the two SVL_S×4 sub-matrices in the first source vectors by the four 8-bit signed values from the corresponding 32-bit container of the 4×SVL_S sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two SVL_S×4 sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed 4×SVL_S sub-matrix.

The two sets of 2-in-4 8-bit signed values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting SVL_S×SVL_S widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

<PNg>	Is the name of the governing scalable predicate register PN8-PN15, with predicate-as-counter encoding, encoded in the "PNg" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

<imm>	For the "Two registers" variant: is the optional signed immediate vector offset, a multiple of 2 in the range -16 to 14, defaulting to 0, encoded in the "imm4" field. For the "Four registers" variant: is the optional signed immediate vector offset, a multiple of 4 in the range -32 to 28, defaulting to 0, encoded in the "imm4" field.
<Zt3>	Is the name of the third scalable vector register Z8-Z11 or Z24-Z27 to be transferred, encoded as "T:'10':Zt".
<Zt4>	Is the name of the fourth scalable vector register Z12-Z15 or Z28-Z31 to be transferred, encoded as "T:'11':Zt".

Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer PL = VL DIV 8;
constant integer elements = VL DIV esize;
constant integer mbytes = esize DIV 8;
bits(64) base;
bits(64) addr;
bits(VL) src;
constant bits(PL) pred = P[g, PL];
constant bits(PL * nreg) mask = CounterToPredicate(pred<15:0>, PL * nreg);
constant boolean contiguous = TRUE;
constant boolean nontemporal = TRUE;
integer transfer = t;
constant boolean tagchecked = n != 31;
constant AccessDescriptor accdesc = CreateAccDescSVE(MemOp_STORE, nontemporal, contiguous,
                                                     tagchecked);

if !AnyActiveElement(mask, esize) then
    if n == 31 && ConstrainUnpredictableBool(Unpredictable_CHECKSPNONEACTIVE) then
        CheckSPAlignment();
else
    if n == 31 then CheckSPAlignment();

base = if n == 31 then SP[] else X[n, 64];
addr = AddressAdd(base, offset * nreg * elements * mbytes, accdesc);

for r = 0 to nreg-1
    src = Z[transfer, VL];
    for e = 0 to elements-1
        if ActivePredicateElement(mask, r * elements + e, esize) then
            Mem[addr, mbytes, accdesc] = Elem[src, e, esize];
        addr = AddressIncrement(addr, mbytes, accdesc);
    transfer = transfer + tstride;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored when its governing predicate register contains the same value for each execution.

STNT1B (scalar plus scalar, strided registers)

Contiguous store non-temporal of bytes from multiple strided vectors (scalar index)

Contiguous store non-temporal of bytes from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and scalar index which is added to the base address. After each element access the index value is incremented, but the index register is not updated.

Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

STNT1W (scalar plus immediate, strided registers)

Contiguous store non-temporal of words from multiple strided vectors (immediate index)

Contiguous store non-temporal of words from elements of two or four strided vector registers to the memory address generated by a 64-bit scalar base and immediate index which is multiplied by the vector's in-memory size, irrespective of predication, and added to the base address.

Inactive elements are not written to memory.

A non-temporal store is a hint to the system that this data is unlikely to be referenced again soon.

It has encodings from 2 classes: Two registers and Four registers

STR (array vector)

Store ZA array vector

The ZA array vector is selected by the sum of the vector select register and immediate offset, modulo the number of bytes in a Streaming SVE vector. The immediate offset is in the range 0 to 15. The memory address is generated by a 64-bit scalar base, plus the same optional immediate offset multiplied by the current vector length in bytes. This instruction is unpredicated.

The store is performed as contiguous byte accesses, with no endian conversion and no guarantee of single-copy atomicity larger than a byte. However, if alignment is checked, then the base register must be aligned to 16 bytes.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

SUB (array accumulators)

Subtract multi-vector from ZA array vector accumulators

Destructively subtract all elements of the two or four source vectors from the corresponding elements of the ZA single-vector groups.
The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.
The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.
This instruction is unpredicated.
ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.
It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

SUB (array results, multiple and single vector)

Subtract replicated single vector from multi-vector with ZA array vector results

Subtract all corresponding elements of the second source vector from the two or four first source vectors and place the results in the corresponding elements of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 64-bit integer variant is implemented.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

SUDOT (multiple and indexed vector)

Multi-vector signed by unsigned integer dot-product by indexed elements

The signed by unsigned integer dot product instruction computes the dot product of four signed 8-bit integer values held in each 32-bit element of the two or four first source vectors and four unsigned 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

SUMLALL (multiple and indexed vector)

Multi-vector signed by unsigned integer multiply-add long-long by indexed element

This signed by unsigned integer multiply-add long-long instruction multiplies each signed 8-bit element in the one, two, or four first source vectors with each unsigned 8-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The element index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 4 bits.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA quad-vector , Two ZA quad-vectors and Four ZA quad-vectors

SUMLALL (multiple and single vector)

Multi-vector signed by unsigned integer multiply-add long-long by vector

This signed by unsigned integer multiply-add long-long instruction multiplies each signed 8-bit element in the two or four first source vectors with each unsigned 8-bit element in the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The quad-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA quad-vectors and Four ZA quad-vectors

Two ZA quad-vectors

SUMOP4A

Signed by unsigned integer quarter-tile sums of four outer products, accumulating

This instruction generates four independent quarter-tile signed by unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_{S}\div 2 \times 4$ sub-matrix of 8-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_{S}\div 2$ sub-matrix of 8-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_{S}\div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_{S}\div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_{D}\div 2 \times 4$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $4 \times SVL_{D}\div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_{D}\div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_{D}\div 2$ sub-matrix.

The resulting quarter-tile $SVL_{S}\div 2 \times SVL_{S}\div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_{D}\div 2 \times SVL_{D}\div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively added to the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors , 32-bit, single vectors , 32-bit, multiple and single vectors , 32-bit, multiple vectors , 64-bit, single and multiple vectors , 64-bit, single vectors , 64-bit, multiple and single vectors and 64-bit, multiple vectors

SUMOP4S

Signed by unsigned integer quarter-tile sums of four outer products, subtracting

This instruction generates four independent quarter-tile signed by unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_S \div 2 \times 4$ sub-matrix of 8-bit signed values held in the half-vectors of the first source vectors by the $4 \times \text{SVL}_S \div 2$ sub-matrix of 8-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\text{SVL}_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \text{SVL}_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_D \div 2 \times 4$ sub-matrix of 16-bit signed values held in the half-vectors of the first source vectors by the $4 \times \text{SVL}_D \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\text{SVL}_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \text{SVL}_D \div 2$ sub-matrix.

The resulting quarter-tile $\text{SVL}_S \div 2 \times \text{SVL}_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $\text{SVL}_D \div 2 \times \text{SVL}_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively subtracted from the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors , 32-bit, single vectors , 32-bit, multiple and single vectors , 32-bit, multiple vectors , 64-bit, single and multiple vectors , 64-bit, single vectors , 64-bit, multiple and single vectors and 64-bit, multiple vectors

```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

SUMOPA

Signed by unsigned integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The signed by unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVL_S×4 sub-matrix of signed 8-bit integer values, and the second source holds 4×SVL_S sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVL_D×4 sub-matrix of signed 16-bit integer values, and the second source holds 4×SVL_D sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVL_S×SVL_S widened 32-bit integer or SVL_D×SVL_D widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_S×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_S sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_D×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_D sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

SUTMOPA

Signed by unsigned integer sparse sum of four outer products, accumulating

This instruction generates signed by unsigned integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit signed values from each overlapping 32-bit containers of the two SVL$_S$×4 sub-matrices in the first source vectors by the four 8-bit unsigned values from the corresponding 32-bit container of the 4×SVL$_S$ sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two SVL$_S$×4 sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed 4×SVL$_S$ sub-matrix.

The two sets of 2-in-4 8-bit signed values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting SVL$_S$×SVL$_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

SUVDOT

Multi-vector signed by unsigned integer vertical dot-product by indexed element

The signed by unsigned integer vertical dot product instruction computes the vertical dot product of the corresponding signed 8-bit elements from the four first source vectors and four unsigned 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.

The vector group symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

UCVTF

Multi-vector unsigned integer convert to floating-point

Convert to single-precision from unsigned 32-bit integer, each element of the two or four source vectors, and place the results in the corresponding elements of the two or four destination vectors.

This instruction follows SME2 floating-point numerical behaviors corresponding to instructions that place their results in one or more SVE Z vectors.

This instruction is unpredicated.

It has encodings from 2 classes: Two registers and Four registers

UDOT (2-way, multiple and indexed vector)

Multi-vector unsigned integer dot-product by indexed element

The unsigned integer dot product instruction computes the dot product of two unsigned 16-bit integer values held in each 32-bit element of the two or four first source vectors and two unsigned 16-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

UDOT (4-way, multiple and indexed vector)

Multi-vector unsigned integer dot-product by indexed element

The unsigned integer dot product instruction computes the dot product of four unsigned 8-bit or 16-bit integer values held in each 32-bit or 64-bit element of the two or four first source vectors and four unsigned 8-bit or 16-bit integer values in the corresponding indexed 32-bit or 64-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit or 64-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to one less than the number of groups per 128-bit segment, encoded in 1 to 2 bits depending on the size of the group.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 4 classes: Two ZA single-vectors of 32-bit elements , Two ZA single-vectors of 64-bit elements , Four ZA single-vectors of 32-bit elements and Four ZA single-vectors of 64-bit elements

Assembler Symbols

<Zdn1> For the "Two registers" variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 2.

For the "Four registers" variant: is the name of the first scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 4.

<T> Is the size specifier, encoded in “size”:

size	<T>
00	B
01	H
10	S
11	D

<Zdn2> Is the name of the second scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 2 plus 1.

<Zm1> For the "Two registers" variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 2.

For the "Four registers" variant: is the name of the first scalable vector register of the second source multi-vector group, encoded as "Zm" times 4.

<Zm2>	Is the name of the second scalable vector register of the second source multi-vector group, encoded as "Zm" times 2 plus 1.
<Zdn4>	Is the name of the fourth scalable vector register of the destination and first source multi-vector group, encoded as "Zdn" times 4 plus 3.
<Zm4>	Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.

Operation

```
CheckStreamingSVEEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
array [0..3] of bits(VL) results;

for r = 0 to nreg-1
    constant bits(VL) operand1 = Z[dn+r, VL];
    constant bits(VL) operand2 = Z[m+r, VL];
    for e = 0 to elements-1
        constant integer element1 = Int(Elem[operand1, e, esize], unsigned);
        constant integer element2 = Int(Elem[operand2, e, esize], unsigned);
        constant integer res = Max(element1, element2);
        Elem[results[r], e, esize] = res<esize-1:0>;

for r = 0 to nreg-1
    Z[dn+r, VL] = results[r];
```

Operational information

UMLAL (multiple and indexed vector)

Multi-vector unsigned integer multiply-add long by indexed element

This unsigned integer multiply-add long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

One ZA double-vector

UMLAL (multiple vectors)

Multi-vector unsigned integer multiply-add long

This unsigned integer multiply-add long instruction multiplies each unsigned 16-bit element in the two or four first source vectors with each unsigned 16-bit element in the two or four second source vectors, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA double-vector groups.

The double-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA double-vectors and Four ZA double-vectors

Two ZA double-vectors

UMLALL (multiple and indexed vector)

Multi-vector unsigned integer multiply-add long-long by indexed element

This unsigned integer multiply-add long-long instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors with each unsigned 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: One ZA quad-vector of 32-bit elements , One ZA quad-vector of 64-bit elements , Two ZA quad-vectors of 32-bit elements , Two ZA quad-vectors of 64-bit elements , Four ZA quad-vectors of 32-bit elements and Four ZA quad-vectors of 64-bit elements

UMLALL (multiple vectors)

Multi-vector unsigned integer multiply-add long-long

This unsigned integer multiply-add long-long instruction multiplies each unsigned 8-bit or 16-bit element in the two or four first source vectors with each unsigned 8-bit or 16-bit element in the one, two, or four second source vectors, widens each product to 32-bits or 64-bits and destructively adds these values to the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The quad-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: Two ZA quad-vectors and Four ZA quad-vectors

Two ZA quad-vectors

UMLSL (multiple and indexed vector)

Multi-vector unsigned integer multiply-subtract long by indexed element

This unsigned integer multiply-subtract long instruction multiplies each unsigned 16-bit element in the one, two, or four first source vectors with each unsigned 16-bit indexed element of the second source vector, widens each product to 32-bits and destructively subtracts these values from the corresponding 32-bit elements of the ZA double-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to 7, encoded in 3 bits.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

UMLSLL (multiple and indexed vector)

Multi-vector unsigned integer multiply-subtract long-long by indexed element

This unsigned integer multiply-subtract long-long instruction multiplies each unsigned 8-bit or 16-bit element in the one, two, or four first source vectors with each unsigned 8-bit or 16-bit indexed element of second source vector, widens each product to 32-bits or 64-bits and destructively subtracts these values from the corresponding 32-bit or 64-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 3 to 4 bits depending on the size of the element.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 6 classes: One ZA quad-vector of 32-bit elements , One ZA quad-vector of 64-bit elements , Two ZA quad-vectors of 32-bit elements , Two ZA quad-vectors of 64-bit elements , Four ZA quad-vectors of 32-bit elements and Four ZA quad-vectors of 64-bit elements

<Zm4>	Is the name of the fourth scalable vector register of the second source multi-vector group, encoded as "Zm" times 4 plus 3.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV nreg;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
bits(VL) result;
vec = vec - (vec MOD 4);

for r = 0 to nreg-1
    constant bits(VL) operand1 = Z[n+r, VL];
    constant bits(VL) operand2 = Z[m+r, VL];
    for i = 0 to 3
        constant bits(VL) operand3 = ZAvector[vec + i, VL];
        for e = 0 to elements-1
            constant integer element1 = UInt(Elem[operand1, 4 * e + i, esize DIV 4]);
            constant integer element2 = UInt(Elem[operand2, 4 * e + i, esize DIV 4]);
            constant bits(esize) product = (element1 * element2)<esize-1:0>;
            Elem[result, e, esize] = Elem[operand3, e, esize] - product;
        ZAvector[vec + i, VL] = result;
    vec = vec + vstride;
```

UMOP4A (2-way)

Unsigned integer quarter-tile sums of two outer products, accumulating

This instruction generates four independent quarter-tile unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $2 \times SVL_S \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 2 elements of each row of a $SVL_S \div 2 \times 2$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 2 elements of each column of a $2 \times SVL_S \div 2$ sub-matrix. The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products are then destructively added to the 32-bit integer destination tile.

This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

UMOP4A (4-way)

Unsigned integer quarter-tile sums of four outer products, accumulating

This instruction generates four independent quarter-tile unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_\text{S}\div2 \times 4$ sub-matrix of 8-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times \text{SVL}_\text{S}\div2$ sub-matrix of 8-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\text{SVL}_\text{S}\div2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \text{SVL}_\text{S}\div2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_\text{D}\div2 \times 4$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times \text{SVL}_\text{D}\div2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\text{SVL}_\text{D}\div2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \text{SVL}_\text{D}\div2$ sub-matrix.

The resulting quarter-tile $\text{SVL}_\text{S}\div2 \times \text{SVL}_\text{S}\div2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $\text{SVL}_\text{D}\div2 \times \text{SVL}_\text{D}\div2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively added to the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

UMOP4S (2-way)

Unsigned integer quarter-tile sums of two outer products, subtracting

This instruction generates four independent quarter-tile unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit element ZA tile.

Each of the quarter-tile sums of outer products is generated by multiplying the SVL_{S}÷2 × 2 sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the 2 × SVL_{S}÷2 sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 2 elements of each row of a SVL_{S}÷2 × 2 sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 2 elements of each column of a 2 × SVL_{S}÷2 sub-matrix. The resulting quarter-tile SVL_{S}÷2 × SVL_{S}÷2 widened 32-bit integer sums of outer products are then destructively subtracted from the 32-bit integer destination tile.

This is equivalent to performing a 2-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 4 classes: Single and multiple vectors , Single vectors , Multiple and single vectors and Multiple vectors

UMOP4S (4-way)

Unsigned integer quarter-tile sums of four outer products, subtracting

This instruction generates four independent quarter-tile unsigned integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S \div 2 \times 4$ sub-matrix of 8-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_S \div 2$ sub-matrix of 8-bit unsigned values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D \div 2 \times 4$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times SVL_D \div 2$ sub-matrix of 16-bit unsigned values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times SVL_D \div 2$ sub-matrix.

The resulting quarter-tile $SVL_S \div 2 \times SVL_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D \div 2 \times SVL_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively subtracted from the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

This instruction is unpredicated.

UMOPA (2-way)

Unsigned integer sum of outer products and accumulate

This instruction works with a 32-bit element ZA tile.

The unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. The first source holds $SVL_S \times 2$ sub-matrix of unsigned 16-bit integer values, and the second source holds $2 \times SVL_S$ sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When a 16-bit source element is inactive, it is treated as having the value 0.

The resulting $SVL_S \times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

Each 32-bit container of the first source vector holds 2 consecutive column elements of each row of a $SVL_S \times 2$ sub-matrix, and each 32-bit container of the second source vector holds 2 consecutive row elements of each column of a $2 \times SVL_S$ sub-matrix.

UMOPA (4-way)

Unsigned integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVL_{S}×4 sub-matrix of unsigned 8-bit integer values, and the second source holds 4×SVL_{S} sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVL_{D}×4 sub-matrix of unsigned 16-bit integer values, and the second source holds 4×SVL_{D} sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVL_{S}×SVL_{S} widened 32-bit integer or SVL_{D}×SVL_{D} widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_{S}×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_{S} sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_{D}×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_{D} sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

UMOPS (4-way)

Unsigned integer sum of outer products and subtract

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned integer sum of outer products and subtract instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds $\text{SVL}_\text{S}\times 4$ sub-matrix of unsigned 8-bit integer values, and the second source holds $4\times\text{SVL}_\text{S}$ sub-matrix of unsigned 8-bit integer values. In case of the 16-bit integer variant, the first source holds $\text{SVL}_\text{D}\times 4$ sub-matrix of unsigned 16-bit integer values, and the second source holds $4\times\text{SVL}_\text{D}$ sub-matrix of unsigned 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting $\text{SVL}_\text{S}\times\text{SVL}_\text{S}$ widened 32-bit integer or $\text{SVL}_\text{D}\times\text{SVL}_\text{D}$ widened 64-bit integer sum of outer products is then destructively subtracted from the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a $\text{SVL}_\text{S}\times 4$ sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a $4\times\text{SVL}_\text{S}$ sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a $\text{SVL}_\text{D}\times 4$ sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a $4\times\text{SVL}_\text{D}$ sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

USDOT (multiple and indexed vector)

Multi-vector unsigned by signed integer dot-product by indexed element

The unsigned by signed integer dot product instruction computes the dot product of four unsigned 8-bit integer values held in each 32-bit element of the two or four first source vectors and four signed 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

USDOT (multiple vectors)

Multi-vector unsigned by signed integer dot-product

The unsigned by signed integer dot product instruction computes the dot product of four unsigned 8-bit integer values held in each 32-bit element of the two or four first source vectors and four signed 8-bit integer values in the corresponding 32-bit element of the two or four second source vectors. The widened dot product result is destructively added to corresponding 32-bit element of the ZA single-vector groups.

The single-vector group within each half of or each quarter of the ZA array is selected by the sum of the vector select register and offset , modulo half or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA single-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 2 classes: Two ZA single-vectors and Four ZA single-vectors

Two ZA single-vectors

USMLALL (multiple and indexed vector)

Multi-vector unsigned by signed integer multiply-add long-long by indexed element

This unsigned by signed integer multiply-add long-long instruction multiplies each unsigned 8-bit element in the one, two, or four first source vectors with each signed 8-bit indexed element of the second source vector, widens each product to 32-bits and destructively adds these values to the corresponding 32-bit elements of the ZA quad-vector groups.

The elements within the second source vector are specified using an immediate element index which selects the same element position within each 128-bit vector segment. The element index range is from 0 to one less than the number of elements per 128-bit segment, encoded in 4 bits.

The quad-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA quad-vector groups respectively. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

It has encodings from 3 classes: One ZA quad-vector , Two ZA quad-vectors and Four ZA quad-vectors

USMOP4A

Unsigned by signed integer quarter-tile sums of four outer products, accumulating

This instruction generates four independent quarter-tile unsigned by signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and accumulates the results to the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_S \div 2 \times 4$ sub-matrix of 8-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times \text{SVL}_S \div 2$ sub-matrix of 8-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\text{SVL}_S \div 2 \times 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \text{SVL}_S \div 2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $\text{SVL}_D \div 2 \times 4$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $4 \times \text{SVL}_D \div 2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $\text{SVL}_D \div 2 \times 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 \times \text{SVL}_D \div 2$ sub-matrix.

The resulting quarter-tile $\text{SVL}_S \div 2 \times \text{SVL}_S \div 2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $\text{SVL}_D \div 2 \times \text{SVL}_D \div 2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively added to the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

It has encodings from 8 classes: 32-bit, single and multiple vectors , 32-bit, single vectors , 32-bit, multiple and single vectors , 32-bit, multiple vectors , 64-bit, single and multiple vectors , 64-bit, single vectors , 64-bit, multiple and single vectors and 64-bit, multiple vectors

USMOP4S

Unsigned by signed integer quarter-tile sums of four outer products, subtracting

This instruction generates four independent quarter-tile unsigned by signed integer sums of outer products from the sub-matrices in the half-vectors of the one or two first and second source vectors and subtracts the results from the corresponding elements of a 32-bit or 64-bit element ZA tile.

In case of the 8-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_S÷2 × 4$ sub-matrix of 8-bit unsigned values held in the half-vectors of the first source vectors by the $4 × SVL_S÷2$ sub-matrix of 8-bit signed values held in the half-vectors of the second source vectors. Each 32-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_S÷2 × 4$ sub-matrix. Similarly, each 32-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 × SVL_S÷2$ sub-matrix.

In case of the 16-bit integer variant, each of the quarter-tile sums of outer products is generated by multiplying the $SVL_D÷2 × 4$ sub-matrix of 16-bit unsigned values held in the half-vectors of the first source vectors by the $4 × SVL_D÷2$ sub-matrix of 16-bit signed values held in the half-vectors of the second source vectors. Each 64-bit container of the half-vectors in the first source vectors holds 4 elements of each row of a $SVL_D÷2 × 4$ sub-matrix. Similarly, each 64-bit container of the half-vectors in the second source vector holds 4 elements of each column of a $4 × SVL_D÷2$ sub-matrix.

The resulting quarter-tile $SVL_S÷2 × SVL_S÷2$ widened 32-bit integer sums of outer products in case of the 8-bit integer variant or $SVL_D÷2 × SVL_D÷2$ widened 64-bit integer sums of outer products in case of the 16-bit integer variant are then destructively subtracted from the 32-bit or 64-bit integer destination tile respectively.

This is equivalent to performing a 4-way dot product and subtract from each of the destination tile elements.

USMOPA

Unsigned by signed integer sum of outer products and accumulate

The 8-bit integer variant works with a 32-bit element ZA tile.

The 16-bit integer variant works with a 64-bit element ZA tile.

The unsigned by signed integer sum of outer products and accumulate instructions multiply the sub-matrix in the first source vector by the sub-matrix in the second source vector. In case of the 8-bit integer variant, the first source holds SVL_S×4 sub-matrix of unsigned 8-bit integer values, and the second source holds 4×SVL_S sub-matrix of signed 8-bit integer values. In case of the 16-bit integer variant, the first source holds SVL_D×4 sub-matrix of unsigned 16-bit integer values, and the second source holds 4×SVL_D sub-matrix of signed 16-bit integer values.

Each source vector is independently predicated by a corresponding governing predicate. When an 8-bit source element in case of 8-bit integer variant or a 16-bit source element in case of 16-bit integer variant is Inactive, it is treated as having the value 0.

The resulting SVL_S×SVL_S widened 32-bit integer or SVL_D×SVL_D widened 64-bit integer sum of outer products is then destructively added to the 32-bit integer or 64-bit integer destination tile, respectively for 8-bit integer and 16-bit integer instruction variants. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

In case of the 8-bit integer variant, each 32-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_S×4 sub-matrix, and each 32-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_S sub-matrix. In case of the 16-bit integer variant, each 64-bit container of the first source vector holds 4 consecutive column elements of each row of a SVL_D×4 sub-matrix, and each 64-bit container of the second source vector holds 4 consecutive row elements of each column of a 4×SVL_D sub-matrix.

ID_AA64SMFR0_EL1.I16I64 indicates whether the 16-bit integer variant is implemented.

It has encodings from 2 classes: 32-bit and 64-bit

USTMOPA

Unsigned by signed integer sparse sum of four outer products, accumulating

This instruction generates unsigned by signed integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit unsigned values from each overlapping 32-bit containers of the two SVL_S×4 sub-matrices in the first source vectors by the four 8-bit signed values from the corresponding 32-bit container of the 4×SVL_S sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two SVL_S×4 sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed 4×SVL_S sub-matrix.

The two sets of 2-in-4 8-bit unsigned values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting SVL_S×SVL_S widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

USVDOT

Multi-vector unsigned by signed integer vertical dot-product by indexed element

The unsigned by signed integer vertical dot product instruction computes the vertical dot product of corresponding unsigned 8-bit elements from the four first source vectors and four signed 8-bit integer values in the corresponding indexed 32-bit element of the second source vector. The widened dot product result is destructively added to the corresponding 32-bit element of the ZA single-vector groups.

The groups within the second source vector are specified using an immediate element index which selects the same group position within each 128-bit vector segment. The index range is from 0 to 3, encoded in 2 bits.

The single-vector group within each quarter of the ZA array is selected by the sum of the vector select register and offset, modulo quarter the number of ZA array vectors.

The vector group symbol VGx4 indicates that the ZA operand consists of four ZA single-vector groups. The vector group symbol is preferred for disassembly, but optional in assembler source code.

This instruction is unpredicated.

UTMOPA (2-way)

Unsigned integer sparse sum of two outer products, accumulating

This instruction generates unsigned integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected 2-in-4 16-bit unsigned values from each overlapping 32-bit containers of the two $SVL_S\times2$ sub-matrices in the first source vectors by the two 16-bit unsigned values from the corresponding 32-bit container of the $2\times SVL_S$ sub-matrix in the second source vector. The two selected elements from each overlapping 32-bit containers of the first source vectors correspond to 2-in-4 elements of rows of two $SVL_S\times2$ sub-matrices. Each 32-bit container of the second source vector holds 2 elements of columns of a compressed $2\times SVL_S$ sub-matrix.

The 2-in-4 16-bit unsigned values from overlapping 32-bit containers of the first source vectors are selected by 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to 32-bit containers of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting $SVL_S\times SVL_S$ widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 2-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

UTMOPA (4-way)

Unsigned integer sparse sum of four outer products, accumulating

This instruction generates unsigned integer sum of outer products by multiplying the 2-in-4 selected elements from the dense sub-matrices in the two first source vectors with the corresponding elements of the compressed sparse sub-matrix in the second source vector and accumulates the results to the corresponding elements of a 32-bit element ZA tile.

The sum of outer products is generated by multiplying the selected two sets of 2-in-4 8-bit unsigned values from each overlapping 32-bit containers of the two SVL_S×4 sub-matrices in the first source vectors by the four 8-bit unsigned values from the corresponding 32-bit container of the 4×SVL_S sub-matrix in the second source vector. The four selected elements from the overlapping 32-bit containers of the first source vectors correspond to two sets of 2-in-4 elements of rows of two SVL_S×4 sub-matrices. Each 32-bit container of the second source vector holds 4 elements of columns of a compressed 4×SVL_S sub-matrix.

The two sets of 2-in-4 8-bit unsigned values from overlapping 32-bit containers of the first source vectors are selected by pairs of 4-bit controls in the indexed segment of the control vector register. If the control bit corresponding to an element in the first source vectors is 0, the element is discarded and does not contribute to the sum of products result. If more than two bits of the 4-bit control corresponding to each 32-bit container of the first source vectors are 1, only the elements corresponding to the least two significant bits are selected.

The resulting SVL_S×SVL_S widened 32-bit integer sum of outer products is then destructively added to the 32-bit integer destination tile. This is equivalent to performing a 4-way dot product and accumulate to each of the destination tile elements.

This instruction is unpredicated.

Assembler Symbols

<Wv>	Is the 32-bit name of the vector select register W8-W11, encoded in the "Rv" field.
<offs>	Is the vector select offset, in the range 0 to 7, encoded in the "off3" field.
<Zn1>	Is the name of the first scalable vector register of the first source multi-vector group, encoded as "Zn" times 4.
<Zn4>	Is the name of the fourth scalable vector register of the first source multi-vector group, encoded as "Zn" times 4 plus 3.

<Zm>	Is the name of the second source scalable vector register Z0-Z15, encoded in the "Zm" field.
<index>	For the "32-bit" variant: is the immediate index of a 32-bit group of four 8-bit values within each 128-bit vector segment, in the range 0 to 3, encoded in the "i2" field. For the "64-bit" variant: is the immediate index of a 64-bit group of four 16-bit values within each 128-bit vector segment, in the range 0 to 1, encoded in the "i1" field.

Operation

```
CheckStreamingSVEAndZAEnabled();
constant integer VL = CurrentVL;
constant integer elements = VL DIV esize;
constant integer vectors = VL DIV 8;
constant integer vstride = vectors DIV 4;
constant integer eltspersegment = 128 DIV esize;
constant bits(32) vbase = X[v, 32];
integer vec = (UInt(vbase) + offset) MOD vstride;
constant bits(VL) operand2 = Z[m, VL];

ZERO (double-vector)

Zero ZA double-vector groups

The instruction zeroes one, two, or four ZA double-vector groups.

The double-vector group within all of, each half of, or each quarter of the ZA array is selected by the sum of the vector select register and offset range, modulo all, half, or quarter the number of ZA array vectors.

The vector group symbol, VGx2 or VGx4, indicates that the ZA operand consists of two or four ZA double-vector groups respectively.

It has encodings from 3 classes: One ZA double-vector , Two ZA double-vectors and Four ZA double-vectors

One ZA double-vector

Zero ZT0

Zero all bytes of the ZT0 register.
This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

ZERO (tiles)

Zero a list of 64-bit element ZA tiles

Zeroes all bytes within each of the up to eight listed 64-bit element tiles named ZA0.D to ZA7.D, leaving the other 64-bit element tiles unmodified.

This instruction does not require the PE to be in Streaming SVE mode, and it is expected that this instruction will not experience a significant slowdown due to contention with other PEs that are executing in Streaming SVE mode.

For programmer convenience an assembler must also accept the names of 32-bit, 16-bit, and 8-bit element tiles which are converted into the corresponding set of 64-bit element tiles.

In accordance with the architecturally defined mapping between different element size tiles:

- Zeroing the 8-bit element tile name ZA0.B, or the entire array name ZA, is equivalent to zeroing all eight 64-bit element tiles named ZA0.D to ZA7.D.
- Zeroing the 16-bit element tile name ZA0.H is equivalent to zeroing 64-bit element tiles named ZA0.D, ZA2.D, ZA4.D, and ZA6.D.
- Zeroing the 16-bit element tile name ZA1.H is equivalent to zeroing 64-bit element tiles named ZA1.D, ZA3.D, ZA5.D, and ZA7.D.
- Zeroing the 32-bit element tile name ZA0.S is equivalent to zeroing 64-bit element tiles named ZA0.D and ZA4.D.
- Zeroing the 32-bit element tile name ZA1.S is equivalent to zeroing 64-bit element tiles named ZA1.D and ZA5.D.
- Zeroing the 32-bit element tile name ZA2.S is equivalent to zeroing 64-bit element tiles named ZA2.D and ZA6.D.
- Zeroing the 32-bit element tile name ZA3.S is equivalent to zeroing 64-bit element tiles named ZA3.D and ZA7.D.

The preferred disassembly of this instruction uses the shortest list of tile names that represent the encoded immediate mask.

For example:

- An immediate which encodes 64-bit element tiles ZA0.D, ZA1.D, ZA4.D, and ZA5.D is disassembled as {ZA0.S, ZA1.S}.
- An immediate which encodes 64-bit element tiles ZA0.D, ZA2.D, ZA4.D, and ZA6.D is disassembled as {ZA0.H}.
- An all-ones immediate is disassembled as {ZA}.
- An all-zeros immediate is disassembled as an empty list { }.
