Release Information

For information on the change history and known issues for this release, see the **Release Notes** in the **A64 ISA XML for A-profile architecture (2024-09)**.

Proprietary Notice

This document is protected by copyright and other related rights and the use or implementation of the information contained in this document may be protected by one or more patents or pending patent applications. No part of this document may be reproduced in any form by any means without the express prior written permission of Arm Limited ("Arm"). **No license, express or implied, by estoppel or otherwise to any intellectual property rights is granted by this document unless specifically stated.**

Your access to the information in this document is conditional upon your acceptance that you will not use or permit others to use the information for the purposes of determining whether the subject matter of this document infringes any third party patents.

The content of this document is informational only. Any solutions presented herein are subject to changing conditions, information, scope, and data. This document was produced using reasonable efforts based on information available as of the date of issue of this document. The scope of information in this document may exceed that which Arm is required to provide, and such additional information is merely intended to further assist the recipient and does not represent Arm's view of the scope of its obligations. You acknowledge and agree that you possess the necessary expertise in system security and functional safety and that you shall be solely responsible for compliance with all legal, regulatory, safety and security related requirements concerning your products, notwithstanding any information or support that may be provided by Arm herein. In addition, you are responsible for any applications which are used in conjunction with any Arm technology described in this document, and to minimize risks, adequate design and operating safeguards should be provided for by you.

This document may include technical inaccuracies or typographical errors. THIS DOCUMENT IS PROVIDED "AS IS". ARM PROVIDES NO REPRESENTATIONS AND NO WARRANTIES, EXPRESS, IMPLIED OR STATUTORY, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY, SATISFACTORY QUALITY, NON-INFRINGEMENT OR FITNESS FOR A PARTICULAR PURPOSE WITH RESPECT TO THE DOCUMENT. For the avoidance of doubt, Arm makes no representation with respect to, and has undertaken no analysis to identify or understand the scope and content of, patents, copyrights, trade secrets, or other rights.

TO THE EXTENT NOT PROHIBITED BY LAW, IN NO EVENT WILL ARM BE LIABLE FOR ANY DAMAGES, INCLUDING WITHOUT LIMITATION ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, PUNITIVE, OR CONSEQUENTIAL DAMAGES, HOWEVER CAUSED AND REGARDLESS OF THE THEORY OF LIABILITY, ARISING OUT OF ANY USE OF THIS DOCUMENT, EVEN IF ARM HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Reference by Arm to any third party's products or services within this document is not an express or implied approval or endorsement of the use thereof.

This document consists solely of commercial items. You shall be responsible for ensuring that any use, duplication or disclosure of this document complies fully with any relevant export laws and regulations to assure that this document or any portion thereof is not exported, directly or indirectly, in violation of such export laws. Use of the word "partner" in reference to Arm's customers is not intended to create or refer to any partnership relationship with any other company. Arm may make changes to this document at any time and without notice.

This document may be translated into other languages for convenience, and you agree that if there is any conflict between the English version of this document and any translation, the terms of the English version of the Agreement shall prevail.

The validity, construction and performance of this License shall be governed by English Law.

Confidentiality Status

Product Status

The information relating to the 2024 Extensions is at Alpha quality. Alpha quality means that most major features of the specification are described in this release, but some features and details might be missing.

The information relating to the rest of the A-profile Architecture is at Beta quality. Beta quality means that all major features of the specification are described, but some details might be missing.

Progressive Terminology Commitment

Previous issues of this document included terms that can be offensive. We have replaced these terms. If you find offensive terms in this document, please contact `terms@arm.com`.

Feedback on this document

If you have any comments or queries about this document, create a ticket at `https://support.developer.arm.com`.

As part of the ticket, include:

- The title, *Arm® A64 Instruction Set for A-profile architecture*.
- The number, DDI 0602.
- The section name to which your comments refer.
- The page number(s) to which your comments refer.
- The rule identifier(s) to which your comments refer if applicable.
- A concise explanation of your comments.

Arm also welcomes general suggestions for additions and improvements.

A64 -- Base Instructions (alphabetic order)

ABS: Absolute value.

ADC: Add with carry.

ADCS: Add with carry, setting flags.

ADD (extended register): Add extended and scaled register.

ADD (immediate): Add immediate value.

ADD (shifted register): Add optionally-shifted register.

ADDG: Add with tag.

ADDPT: Add checked pointer.

ADDS (extended register): Add extended and scaled register, setting flags.

ADDS (immediate): Add immediate value, setting flags.

ADDS (shifted register): Add optionally-shifted register, setting flags.

ADR: Form PC-relative address.

ADRP: Form PC-relative address to 4KB page.

AND (immediate): Bitwise AND (immediate).

AND (shifted register): Bitwise AND (shifted register).

ANDS (immediate): Bitwise AND (immediate), setting flags.

ANDS (shifted register): Bitwise AND (shifted register), setting flags.

APAS: Associate physical address space: an alias of SYS.

ASR (immediate): Arithmetic shift right (immediate): an alias of SBFM.

ASR (register): Arithmetic shift right (register): an alias of ASRV.

ASRV: Arithmetic shift right variable.

AT: Address translate: an alias of SYS.

AUTDA, AUTDZA: Authenticate data address, using key A.

AUTDB, AUTDZB: Authenticate data address, using key B.

AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA: Authenticate instruction address, using key A.

AUTIA171615: Authenticate instruction address, using key A.

AUTIASPPC: Authenticate return address using key A, using an immediate offset.

AUTIASPPCR: Authenticate return address using key A, using a register.

AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB: Authenticate instruction address, using key B.

AUTIB171615: Authenticate instruction address, using key B.

AUTIBSPPC: Authenticate return address using key B, using an immediate offset.

AUTIBSPPCR: Authenticate return address using key B, using a register.

AXFLAG: Convert floating-point condition flags from Arm to external format.

B: Branch.

B.cond: Branch conditionally.

BC.cond: Branch consistent conditionally.

BFC: Bitfield clear: an alias of BFM.

BFI: Bitfield insert: an alias of BFM.

BFM: Bitfield move.

BFXIL: Bitfield extract and insert at low end: an alias of BFM.

BIC (shifted register): Bitwise bit clear (shifted register).

BICS (shifted register): Bitwise bit clear (shifted register), setting flags.

BL: Branch with link.

BLR: Branch with link to register.

BLRAA, BLRAAZ, BLRAB, BLRABZ: Branch with link to register, with pointer authentication.

BR: Branch to register.

BRAA, BRAAZ, BRAB, BRABZ: Branch to register, with pointer authentication.

BRB: Branch record buffer: an alias of SYS.

BRK: Breakpoint instruction.

BTI: Branch target identification.

CAS, CASA, CASAL, CASL: Compare and swap word or doubleword in memory.

CASB, CASAB, CASALB, CASLB: Compare and swap byte in memory.

CASH, CASAH, CASALH, CASLH: Compare and swap halfword in memory.

CASP, CASPA, CASPAL, CASPL: Compare and swap pair of words or doublewords in memory.

CASPT, CASPAT, CASPALT, CASPLT: Compare and swap pair unprivileged.

CAST, CASAT, CASALT, CASLT: Compare and swap unprivileged.

CB<cc> (immediate): Compare register with immediate and branch.

CB<cc> (register): Compare registers and branch.

CBB<cc>: Compare bytes and branch.

CBBLE: Compare signed less than or equal bytes and branch: an alias of CBB<cc>.

CBBLO: Compare unsigned lower than bytes and branch: an alias of CBB<cc>.

CBBLS: Compare unsigned lower than or equal bytes and branch: an alias of CBB<cc>.

CBBLT: Compare signed less than bytes and branch: an alias of CBB<cc>.

CBGE (immediate): Compare signed greater than or equal immediate and branch: an alias of CB<cc> (immediate).

CBH<cc>: Compare halfwords and branch.

CBHLE: Compare signed less than or equal halfwords and branch: an alias of CBH<cc>.

CBHLO: Compare unsigned lower than halfwords and branch: an alias of CBH<cc>.

CBHLS: Compare unsigned lower than or equal halfwords and branch: an alias of CBH<cc>.

CBHLT: Compare signed less than halfwords and branch: an alias of CBH<cc>.

CBHS (immediate): Compare unsigned greater than or equal immediate and branch: an alias of CB<cc> (immediate).

CBLE (immediate): Compare signed less than or equal immediate and branch: an alias of CB<cc> (immediate).

CBLE (register): Compare signed less than or equal register and branch: an alias of CB<cc> (register).

CBLO (register): Compare unsigned lower than register and branch: an alias of CB<cc> (register).

CBLS (immediate): Compare unsigned lower than or equal immediate and branch: an alias of CB<cc> (immediate).

CBLS (register): Compare unsigned lower than or equal register and branch: an alias of CB<cc> (register).

CBLT (register): Compare signed less than register and branch: an alias of CB<cc> (register).

CBNZ: Compare and branch on nonzero.

CBZ: Compare and branch on zero.

CCMN (immediate): Conditional compare negative (immediate).

CCMN (register): Conditional compare negative (register).

CCMP (immediate): Conditional compare (immediate).

CCMP (register): Conditional compare (register).

CFINV: Invert carry flag.

CFP: Control flow prediction restriction by context: an alias of SYS.

CHKFEAT: Check feature status.

CINC: Conditional increment: an alias of CSINC.

CINV: Conditional invert: an alias of CSINV.

CLRBHB: Clear branch history.

CLREX: Clear exclusive.

CLS: Count leading sign bits.

CLZ: Count leading zeros.

CMN (extended register): Compare negative (extended register): an alias of ADDS (extended register).

CMN (immediate): Compare negative (immediate): an alias of ADDS (immediate).

CMN (shifted register): Compare negative (shifted register): an alias of ADDS (shifted register).

CMP (extended register): Compare (extended register): an alias of SUBS (extended register).

CMP (immediate): Compare (immediate): an alias of SUBS (immediate).

CMP (shifted register): Compare (shifted register): an alias of SUBS (shifted register).

CMPP: Compare with tag: an alias of SUBPS.

CNEG: Conditional negate: an alias of CSNEG.

CNT: Count bits.

COSP: Clear other speculative prediction restriction by context: an alias of SYS.

CPP: Cache prefetch prediction restriction by context: an alias of SYS.

CPYFP, CPYFM, CPYFE: Memory copy forward-only.

CPYFPN, CPYFMN, CPYFEN: Memory copy forward-only, reads and writes non-temporal.

CPYFPRN, CPYFMRN, CPYFERN: Memory copy forward-only, reads non-temporal.

CPYFPRT, CPYFMRT, CPYFERT: Memory copy forward-only, reads unprivileged.

CPYFPRTN, CPYFMRTN, CPYFERTN: Memory copy forward-only, reads unprivileged, reads and writes non-temporal.

CPYFPRTRN, CPYFMRTRN, CPYFERTRN: Memory copy forward-only, reads unprivileged and non-temporal.

CPYFPRTWN, CPYFMRTWN, CPYFERTWN: Memory copy forward-only, reads unprivileged, writes non-temporal.

CPYFPT, CPYFMT, CPYFET: Memory copy forward-only, reads and writes unprivileged.

CPYFPTN, CPYFMTN, CPYFETN: Memory copy forward-only, reads and writes unprivileged and non-temporal.

CPYFPTRN, CPYFMTRN, CPYFETRN: Memory copy forward-only, reads and writes unprivileged, reads non-temporal.

CPYFPTWN, CPYFMTWN, CPYFETWN: Memory copy forward-only, reads and writes unprivileged, writes non-temporal.

CPYFPWN, CPYFMWN, CPYFEWN: Memory copy forward-only, writes non-temporal.

CPYFPWT, CPYFMWT, CPYFEWT: Memory copy forward-only, writes unprivileged.

CPYFPWTN, CPYFMWTN, CPYFEWTN: Memory copy forward-only, writes unprivileged, reads and writes non-temporal.

CPYFPWTRN, CPYFMWTRN, CPYFEWTRN: Memory copy forward-only, writes unprivileged, reads non-temporal.

CPYFPWTWN, CPYFMWTWN, CPYFEWTWN: Memory copy forward-only, writes unprivileged and non-temporal.

CPYP, CPYM, CPYE: Memory copy.

CPYPN, CPYMN, CPYEN: Memory copy, reads and writes non-temporal.

CPYPRN, CPYMRN, CPYERN: Memory copy, reads non-temporal.

CPYPRT, CPYMRT, CPYERT: Memory copy, reads unprivileged.

CPYPRTN, CPYMRTN, CPYERTN: Memory copy, reads unprivileged, reads and writes non-temporal.

CPYPRTRN, CPYMRTRN, CPYERTRN: Memory copy, reads unprivileged and non-temporal.

CPYPRTWN, CPYMRTWN, CPYERTWN: Memory copy, reads unprivileged, writes non-temporal.

CPYPT, CPYMT, CPYET: Memory copy, reads and writes unprivileged.

CPYPTN, CPYMTN, CPYETN: Memory copy, reads and writes unprivileged and non-temporal.

CPYPTRN, CPYMTRN, CPYETRN: Memory copy, reads and writes unprivileged, reads non-temporal.

CPYPTWN, CPYMTWN, CPYETWN: Memory copy, reads and writes unprivileged, writes non-temporal.

CPYPWN, CPYMWN, CPYEWN: Memory copy, writes non-temporal.

CPYPWT, CPYMWT, CPYEWT: Memory copy, writes unprivileged.

CPYPWTN, CPYMWTN, CPYEWTN: Memory copy, writes unprivileged, reads and writes non-temporal.

CPYPWTRN, CPYMWTRN, CPYEWTRN: Memory copy, writes unprivileged, reads non-temporal.

CPYPWTWN, CPYMWTWN, CPYEWTWN: Memory copy, writes unprivileged and non-temporal.

CRC32B, CRC32H, CRC32W, CRC32X: CRC32 checksum.

CRC32CB, CRC32CH, CRC32CW, CRC32CX: CRC32C checksum.

CSDB: Consumption of speculative data barrier.

CSEL: Conditional select.

CSET: Conditional set: an alias of CSINC.

CSETM: Conditional set mask: an alias of CSINV.

CSINC: Conditional select increment.

CSINV: Conditional select invert.

CSNEG: Conditional select negation.

CTZ: Count trailing zeros.

DC: Data cache operation: an alias of SYS.

DCPS1: Debug change PE state to EL1.

DCPS2: Debug change PE state to EL2.

DCPS3: Debug change PE state to EL3.

DGH: Data gathering hint.

DMB: Data memory barrier.

DRPS: Debug restore PE state.

DSB: Data synchronization barrier.

DVP: Data value prediction restriction by context: an alias of SYS.

EON (shifted register): Bitwise exclusive-OR NOT (shifted register).

EOR (immediate): Bitwise exclusive-OR (immediate).

EOR (shifted register): Bitwise exclusive-OR (shifted register).

ERET: Exception return.

ERETAA, ERETAB: Exception return, with pointer authentication.

ESB: Error synchronization barrier.

EXTR: Extract register.

GCSB: Guarded Control Stack barrier.

GCSPOPCX: Guarded Control Stack pop and compare exception return record: an alias of SYS.

GCSPOPM: Guarded Control Stack pop: an alias of SYSL.

GCSPOPX: Guarded Control Stack pop exception return record: an alias of SYS.

GCSPUSHM: Guarded Control Stack push: an alias of SYS.

GCSPUSHX: Guarded Control Stack push exception return record: an alias of SYS.

GCSSS1: Guarded Control Stack switch stack 1: an alias of SYS.

GCSSS2: Guarded Control Stack switch stack 2: an alias of SYSL.

GCSSTR: Guarded Control Stack store register.

GCSSTTR: Guarded Control Stack store register (unprivileged).

GMI: Tag mask insert.

HINT: Hint instruction.

HLT: Halt instruction.

HVC: Hypervisor call.

IC: Instruction cache operation: an alias of SYS.

IRG: Insert random tag.

ISB: Instruction synchronization barrier.

LD64B: Single-copy atomic 64-byte Load.

LDADD, LDADDA, LDADDAL, LDADDL: Atomic add on word or doubleword in memory.

LDADDB, LDADDAB, LDADDALB, LDADDLB: Atomic add on byte in memory.

LDADDH, LDADDAH, LDADDALH, LDADDLH: Atomic add on halfword in memory.

LDAPR: Load-acquire RCpc register.

LDAPRB: Load-acquire RCpc register byte.

LDAPRH: Load-acquire RCpc register halfword.

LDAPUR: Load-acquire RCpc register (unscaled).

LDAPURB: Load-acquire RCpc register byte (unscaled).

LDAPURH: Load-acquire RCpc register halfword (unscaled).

LDAPURSB: Load-acquire RCpc register signed byte (unscaled).

LDAPURSH: Load-acquire RCpc register signed halfword (unscaled).

LDAPURSW: Load-acquire RCpc register signed word (unscaled).

LDAR: Load-acquire register.

LDARB: Load-acquire register byte.

LDARH: Load-acquire register halfword.

LDATXR: Load-acquire unprivileged exclusive register.

LDAXP: Load-acquire exclusive pair of registers.

LDAXR: Load-acquire exclusive register.

LDAXRB: Load-acquire exclusive register byte.

LDAXRH: Load-acquire exclusive register halfword.

LDCLR, LDCLRA, LDCLRAL, LDCLRL: Atomic bit clear on word or doubleword in memory.

LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB: Atomic bit clear on byte in memory.

LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH: Atomic bit clear on halfword in memory.

LDCLRP, LDCLRPA, LDCLRPAL, LDCLRPL: Atomic bit clear on quadword in memory.

LDEOR, LDEORA, LDEORAL, LDEORL: Atomic exclusive-OR on word or doubleword in memory.

LDEORB, LDEORAB, LDEORALB, LDEORLB: Atomic exclusive-OR on byte in memory.

LDEORH, LDEORAH, LDEORALH, LDEORLH: Atomic exclusive-OR on halfword in memory.

LDG: Load Allocation Tag.

LDGM: Load tag multiple.

LDIAPP: Load-Acquire RCpc ordered pair of registers.

LDLAR: Load LOAcquire register.

LDLARB: Load LOAcquire register byte.

LDLARH: Load LOAcquire register halfword.

LDNP: Load pair of registers, with non-temporal hint.

LDP: Load pair of registers.

LDPSW: Load pair of registers signed word.

LDR (immediate): Load register (immediate).

LDR (literal): Load register (literal).

LDR (register): Load register (register).

LDRAA, LDRAB: Load register, with pointer authentication.

LDRB (immediate): Load register byte (immediate).

LDRB (register): Load register byte (register).

LDRH (immediate): Load register halfword (immediate).

LDRH (register): Load register halfword (register).

LDRSB (immediate): Load register signed byte (immediate).

LDRSB (register): Load register signed byte (register).

LDRSH (immediate): Load register signed halfword (immediate).

LDRSH (register): Load register signed halfword (register).

LDRSW (immediate): Load register signed word (immediate).

LDRSW (literal): Load register signed word (literal).

LDRSW (register): Load register signed word (register).

LDSET, LDSETA, LDSETAL, LDSETL: Atomic bit set on word or doubleword in memory.

LDSETB, LDSETAB, LDSETALB, LDSETLB: Atomic bit set on byte in memory.

LDSETH, LDSETAH, LDSETALH, LDSETLH: Atomic bit set on halfword in memory.

LDSETP, LDSETPA, LDSETPAL, LDSETPL: Atomic bit set on quadword in memory.

LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL: Atomic signed maximum on word or doubleword in memory.

LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB: Atomic signed maximum on byte in memory.

LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH: Atomic signed maximum on halfword in memory.

LDSMIN, LDSMINA, LDSMINAL, LDSMINL: Atomic signed minimum on word or doubleword in memory.

LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB: Atomic signed minimum on byte in memory.

LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH: Atomic signed minimum on halfword in memory.

LDTADD, LDTADDA, LDTADDAL, LDTADDL: Atomic add unprivileged.

LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL: Atomic bit clear unprivileged.

LDTNP: Load unprivileged pair of registers, with non-temporal hint.

LDTP: Load unprivileged pair of registers.

LDTR: Load register (unprivileged).

LDTRB: Load register byte (unprivileged).

LDTRH: Load register halfword (unprivileged).

LDTRSB: Load register signed byte (unprivileged).

LDTRSH: Load register signed halfword (unprivileged).

LDTRSW: Load register signed word (unprivileged).

LDTSET, LDTSETA, LDTSETAL, LDTSETL: Atomic bit set unprivileged.

LDTXR: Load unprivileged exclusive register.

LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL: Atomic unsigned maximum on word or doubleword in memory.

LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB: Atomic unsigned maximum on byte in memory.

LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH: Atomic unsigned maximum on halfword in memory.

LDUMIN, LDUMINA, LDUMINAL, LDUMINL: Atomic unsigned minimum on word or doubleword in memory.

LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB: Atomic unsigned minimum on byte in memory.

LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH: Atomic unsigned minimum on halfword in memory.

LDUR: Load register (unscaled).

LDURB: Load register byte (unscaled).

LDURH: Load register halfword (unscaled).

LDURSB: Load register signed byte (unscaled).

LDURSH: Load register signed halfword (unscaled).

LDURSW: Load register signed word (unscaled).

LDXP: Load exclusive pair of registers.

LDXR: Load exclusive register.

LDXRB: Load exclusive register byte.

LDXRH: Load exclusive register halfword.

LSL (immediate): Logical shift left (immediate): an alias of UBFM.

LSL (register): Logical shift left (register): an alias of LSLV.

LSLV: Logical shift left variable.

LSR (immediate): Logical shift right (immediate): an alias of UBFM.

LSR (register): Logical shift right (register): an alias of LSRV.

LSRV: Logical shift right variable.

MADD: Multiply-add.

MADDPT: Multiply-add checked pointer.

MNEG: Multiply-negate: an alias of MSUB.

MOV (bitmask immediate): Move bitmask immediate value: an alias of ORR (immediate).

MOV (inverted wide immediate): Move inverted wide immediate value: an alias of MOVN.

MOV (register): Move register value: an alias of ORR (shifted register).

MOV (to/from SP): Move register value to or from SP: an alias of ADD (immediate).

MOV (wide immediate): Move wide immediate value: an alias of MOVZ.

MOVK: Move wide with keep.

MOVN: Move wide with NOT.

MOVZ: Move wide with zero.

MRRS: Move System register to two adjacent general-purpose registers.

MRS: Move System register to general-purpose register.

MSR (immediate): Move immediate value to special register.

MSR (register): Move general-purpose register to System register.

MSRR: Move two adjacent general-purpose registers to System register.

MSUB: Multiply-subtract.

MSUBPT: Multiply-subtract checked pointer.

MUL: Multiply: an alias of MADD.

MVN: Bitwise NOT: an alias of ORN (shifted register).

NEG (shifted register): Negate (shifted register): an alias of SUB (shifted register).

NEGS: Negate, setting flags: an alias of SUBS (shifted register).

NGC: Negate with carry: an alias of SBC.

NGCS: Negate with carry, setting flags: an alias of SBCS.

NOP: No operation.

ORN (shifted register): Bitwise OR NOT (shifted register).

ORR (immediate): Bitwise OR (immediate).

ORR (shifted register): Bitwise OR (shifted register).

PACDA, PACDZA: Pointer Authentication Code for data address, using key A.

PACDB, PACDZB: Pointer Authentication Code for data address, using key B.

PACGA: Pointer Authentication Code, using generic key.

PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA: Pointer Authentication Code for instruction address, using key A.

PACIA171615: Pointer Authentication Code for instruction address, using key A.

PACIASPPC: Pointer Authentication Code for return address, using key A.

PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB: Pointer Authentication Code for instruction address, using key B.

PACIB171615: Pointer Authentication Code for instruction address, using key B.

PACIBSPPC: Pointer Authentication Code for return address, using key B.

PACM: Pointer authentication modifier.

PACNBIASPPC: Pointer Authentication Code for return address, using key A, not a branch target.

PACNBIBSPPC: Pointer Authentication Code for return address, using key B, not a branch target.

PRFM (immediate): Prefetch memory (immediate).

PRFM (literal): Prefetch memory (literal).

PRFM (register): Prefetch memory (register).

PRFUM: Prefetch memory (unscaled offset).

PSB: Profiling synchronization barrier.

PSSBB: Physical speculative store bypass barrier: an alias of DSB.

RBIT: Reverse bits.

RCWCAS, RCWCASA, RCWCASAL, RCWCASL: Read check write compare and swap doubleword in memory.

RCWCASP, RCWCASPA, RCWCASPAL, RCWCASPL: Read check write compare and swap quadword in memory.

RCWCLR, RCWCLRA, RCWCLRAL, RCWCLRL: Read check write atomic bit clear on doubleword in memory.

RCWCLRP, RCWCLRPA, RCWCLRPAL, RCWCLRPL: Read check write atomic bit clear on quadword in memory.

RCWSCAS, RCWSCASA, RCWSCASAL, RCWSCASL: Read check write software compare and swap doubleword in memory.

RCWSCASP, RCWSCASPA, RCWSCASPAL, RCWSCASPL: Read check write software compare and swap quadword in memory.

RCWSCLR, RCWSCLRA, RCWSCLRAL, RCWSCLRL: Read check write software atomic bit clear on doubleword in memory.

RCWSCLRP, RCWSCLRPA, RCWSCLRPAL, RCWSCLRPL: Read check write software atomic bit clear on quadword in memory.

RCWSET, RCWSETA, RCWSETAL, RCWSETL: Read check write atomic bit set on doubleword in memory.

RCWSETP, RCWSETPA, RCWSETPAL, RCWSETPL: Read check write atomic bit set on quadword in memory.

RCWSSET, RCWSSETA, RCWSSETAL, RCWSSETL: Read check write software atomic bit set on doubleword in memory.

RCWSSETP, RCWSSETPA, RCWSSETPAL, RCWSSETPL: Read check write software atomic bit set on quadword in memory.

RCWSSWP, RCWSSWPA, RCWSSWPAL, RCWSSWPL: Read check write software swap doubleword in memory.

RCWSSWPP, RCWSSWPPA, RCWSSWPPAL, RCWSSWPPL: Read check write software swap quadword in memory.

RCWSWP, RCWSWPA, RCWSWPAL, RCWSWPL: Read check write swap doubleword in memory.

RCWSWPP, RCWSWPPA, RCWSWPPAL, RCWSWPPL: Read check write swap quadword in memory.

RET: Return from subroutine.

RETAA, RETAB: Return from subroutine, with pointer authentication.

RETAASPPC, RETABSPPC: Return from subroutine, with enhanced pointer authentication return using an immediate offset.

RETAASPPCR, RETABSPPCR: Return from subroutine, with enhanced pointer authentication return using a register.

REV: Reverse bytes.

REV16: Reverse bytes in 16-bit halfwords.

REV32: Reverse bytes in 32-bit words.

REV64: Reverse bytes: an alias of REV.

RMIF: Rotate, mask insert flags.

ROR (immediate): Rotate right (immediate): an alias of EXTR.

ROR (register): Rotate right (register): an alias of RORV.

RORV: Rotate right variable.

RPRFM: Range prefetch memory.

SB: Speculation barrier.

SBC: Subtract with carry.

SBCS: Subtract with carry, setting flags.

SBFIZ: Signed bitfield insert in zeros: an alias of SBFM.

SBFM: Signed bitfield move.

SBFX: Signed bitfield extract: an alias of SBFM.

SDIV: Signed divide.

SETF8, SETF16: Evaluation of 8-bit or 16-bit flag values.

SETGP, SETGM, SETGE: Memory set with tag setting.

SETGPN, SETGMN, SETGEN: Memory set with tag setting, non-temporal.

SETGPT, SETGMT, SETGET: Memory set with tag setting, unprivileged.

SETGPTN, SETGMTN, SETGETN: Memory set with tag setting, unprivileged and non-temporal.

SETP, SETM, SETE: Memory set.

SETPN, SETMN, SETEN: Memory set, non-temporal.

SETPT, SETMT, SETET: Memory set, unprivileged.

SETPTN, SETMTN, SETETN: Memory set, unprivileged and non-temporal.

SEV: Send event.

SEVL: Send event local.

SMADDL: Signed multiply-add long.

SMAX (immediate): Signed maximum (immediate).

SMAX (register): Signed maximum (register).

SMC: Secure monitor call.

SMIN (immediate): Signed minimum (immediate).

SMIN (register): Signed minimum (register).

SMNEGL: Signed multiply-negate long: an alias of SMSUBL.

SMSTART: Enables access to Streaming SVE mode and SME architectural state: an alias of MSR (immediate).

SMSTOP: Disables access to Streaming SVE mode and SME architectural state: an alias of MSR (immediate).

SMSUBL: Signed multiply-subtract long.

SMULH: Signed multiply high.

SMULL: Signed multiply long: an alias of SMADDL.

SSBB: Speculative store bypass barrier: an alias of DSB.

ST2G: Store Allocation Tags.

ST64B: Single-copy atomic 64-byte store without status result.

ST64BV: Single-copy atomic 64-byte store with status result.

ST64BV0: Single-copy atomic 64-byte EL0 store with status result.

STADD, STADDL: Atomic add on word or doubleword in memory, without return: an alias of LDADD, LDADDA, LDADDAL, LDADDL.

STADDB, STADDLB: Atomic add on byte in memory, without return: an alias of LDADDB, LDADDAB, LDADDALB, LDADDLB.

STADDH, STADDLH: Atomic add on halfword in memory, without return: an alias of LDADDH, LDADDAH, LDADDALH, LDADDLH.

STCLR, STCLRL: Atomic bit clear on word or doubleword in memory, without return: an alias of LDCLR, LDCLRA, LDCLRAL, LDCLRL.

STCLRB, STCLRLB: Atomic bit clear on byte in memory, without return: an alias of LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB.

STCLRH, STCLRLH: Atomic bit clear on halfword in memory, without return: an alias of LDCLRH, LDCLRAH, LDCLRALH, LDCLRLH.

STEOR, STEORL: Atomic exclusive-OR on word or doubleword in memory, without return: an alias of LDEOR, LDEORA, LDEORAL, LDEORL.

STEORB, STEORLB: Atomic exclusive-OR on byte in memory, without return: an alias of LDEORB, LDEORAB, LDEORALB, LDEORLB.

STEORH, STEORLH: Atomic exclusive-OR on halfword in memory, without return: an alias of LDEORH, LDEORAH, LDEORALH, LDEORLH.

STG: Store Allocation Tag.

STGM: Store Allocation Tag multiple.

STGP: Store Allocation Tag and pair of registers.

STILP: Store-release ordered pair of registers.

STLLR: Store LORelease register.

STLLRB: Store LORelease register byte.

STLLRH: Store LORelease register halfword.

STLR: Store-release register.

STLRB: Store-release register byte.

STLRH: Store-release register halfword.

STLTXR: Store-release unprivileged exclusive register.

STLUR: Store-release register (unscaled).

STLURB: Store-release register byte (unscaled).

STLURH: Store-release register halfword (unscaled).

STLXP: Store-release exclusive pair of registers.

STLXR: Store-release exclusive register.

STLXRB: Store-release exclusive register byte.

STLXRH: Store-release exclusive register halfword.

STNP: Store pair of registers, with non-temporal hint.

STP: Store pair of registers.

STR (immediate): Store register (immediate).

STR (register): Store register (register).

STRB (immediate): Store register byte (immediate).

STRB (register): Store register byte (register).

STRH (immediate): Store register halfword (immediate).

STRH (register): Store register halfword (register).

STSET, STSETL: Atomic bit set on word or doubleword in memory, without return: an alias of LDSET, LDSETA, LDSETAL, LDSETL.

STSETB, STSETLB: Atomic bit set on byte in memory, without return: an alias of LDSETB, LDSETAB, LDSETALB, LDSETLB.

STSETH, STSETLH: Atomic bit set on halfword in memory, without return: an alias of LDSETH, LDSETAH, LDSETALH, LDSETLH.

STSHH: Store shared hint.

STSMAX, STSMAXL: Atomic signed maximum on word or doubleword in memory, without return: an alias of LDSMAX, LDSMAXA, LDSMAXAL, LDSMAXL.

STSMAXB, STSMAXLB: Atomic signed maximum on byte in memory, without return: an alias of LDSMAXB, LDSMAXAB, LDSMAXALB, LDSMAXLB.

STSMAXH, STSMAXLH: Atomic signed maximum on halfword in memory, without return: an alias of LDSMAXH, LDSMAXAH, LDSMAXALH, LDSMAXLH.

STSMIN, STSMINL: Atomic signed minimum on word or doubleword in memory, without return: an alias of LDSMIN, LDSMINA, LDSMINAL, LDSMINL.

STSMINB, STSMINLB: Atomic signed minimum on byte in memory, without return: an alias of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.

STSMINH, STSMINLH: Atomic signed minimum on halfword in memory, without return: an alias of LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH.

STTADD, STTADDL: Atomic add unprivileged, without return: an alias of LDTADD, LDTADDA, LDTADDAL, LDTADDL.

STTCLR, STTCLRL: Atomic bit clear unprivileged, without return: an alias of LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL.

STTNP: Store unprivileged pair of registers, with non-temporal hint.

STTP: Store unprivileged pair of registers.

STTR: Store register (unprivileged).

STTRB: Store register byte (unprivileged).

STTRH: Store register halfword (unprivileged).

STTSET, STTSETL: Atomic bit set unprivileged, without return: an alias of LDTSET, LDTSETA, LDTSETAL, LDTSETL.

STTXR: Store unprivileged exclusive register.

STUMAX, STUMAXL: Atomic unsigned maximum on word or doubleword in memory, without return: an alias of LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL.

STUMAXB, STUMAXLB: Atomic unsigned maximum on byte in memory, without return: an alias of LDUMAXB, LDUMAXAB, LDUMAXALB, LDUMAXLB.

STUMAXH, STUMAXLH: Atomic unsigned maximum on halfword in memory, without return: an alias of LDUMAXH, LDUMAXAH, LDUMAXALH, LDUMAXLH.

STUMIN, STUMINL: Atomic unsigned minimum on word or doubleword in memory, without return: an alias of LDUMIN, LDUMINA, LDUMINAL, LDUMINL.

STUMINB, STUMINLB: Atomic unsigned minimum on byte in memory, without return: an alias of LDUMINB, LDUMINAB, LDUMINALB, LDUMINLB.

STUMINH, STUMINLH: Atomic unsigned minimum on halfword in memory, without return: an alias of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH.

STUR: Store register (unscaled).

STURB: Store register byte (unscaled).

STURH: Store register halfword (unscaled).

STXP: Store exclusive pair of registers.

STXR: Store exclusive register.

STXRB: Store exclusive register byte.

STXRH: Store exclusive register halfword.

STZ2G: Store Allocation Tags, zeroing.

STZG: Store Allocation Tag, zeroing.

STZGM: Store Allocation Tag and zero multiple.

SUB (extended register): Subtract extended and scaled register.

SUB (immediate): Subtract immediate value.

SUB (shifted register): Subtract optionally-shifted register.

SUBG: Subtract with tag.

SUBP: Subtract pointer.

SUBPS: Subtract pointer, setting flags.

SUBPT: Subtract checked pointer.

SUBS (extended register): Subtract extended and scaled register, setting flags.

SUBS (immediate): Subtract immediate value, setting flags.

SUBS (shifted register): Subtract optionally-shifted register, setting flags.

SVC: Supervisor call.

SWP, SWPA, SWPAL, SWPL: Swap word or doubleword in memory.

SWPB, SWPAB, SWPALB, SWPLB: Swap byte in memory.

SWPH, SWPAH, SWPALH, SWPLH: Swap halfword in memory.

SWPP, SWPPA, SWPPAL, SWPPL: Swap quadword in memory.

SWPT, SWPTA, SWPTAL, SWPTL: Swap unprivileged.

SXTB: Signed extend byte: an alias of SBFM.

SXTH: Sign extend halfword: an alias of SBFM.

SXTW: Sign extend word: an alias of SBFM.

SYS: System instruction.

SYSL: System instruction with result.

SYSP: 128-bit system instruction.

TBNZ: Test bit and branch if nonzero.

TBZ: Test bit and branch if zero.

TCANCEL: Cancel current transaction.

TCOMMIT: Commit current transaction.

TLBI: TLB invalidate operation: an alias of SYS.

TLBIP: TLB invalidate pair operation: an alias of SYSP.

TRCIT: Trace instrumentation: an alias of SYS.

TSB: Trace synchronization barrier.

TST (immediate): Test bits (immediate): an alias of ANDS (immediate).

TST (shifted register): Test (shifted register): an alias of ANDS (shifted register).

TSTART: Start transaction.

TTEST: Test transaction state.

UBFIZ: Unsigned bitfield insert in zeros: an alias of UBFM.

UBFM: Unsigned bitfield move.

UBFX: Unsigned bitfield extract: an alias of UBFM.

UDF: Permanently undefined.

UDIV: Unsigned divide.

UMADDL: Unsigned multiply-add long.

UMAX (immediate): Unsigned maximum (immediate).

UMAX (register): Unsigned maximum (register).

UMIN (immediate): Unsigned minimum (immediate).

UMIN (register): Unsigned minimum (register).

UMNEGL: Unsigned multiply-negate long: an alias of UMSUBL.

UMSUBL: Unsigned multiply-subtract long.

UMULH: Unsigned multiply high.

UMULL: Unsigned multiply long: an alias of UMADDL.

UXTB: Unsigned extend byte: an alias of UBFM.

UXTH: Unsigned extend halfword: an alias of UBFM.

WFE: Wait for event.

WFET: Wait for event with timeout.

WFI: Wait for interrupt.

WFIT: Wait for interrupt with timeout.

XAFLAG: Convert floating-point condition flags from external format to Arm format.

XPACD, XPACI, XPACLRI: Strip Pointer Authentication Code.

YIELD: Yield.

ADD (extended register)

Add extended and scaled register

This instruction adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15 14 13	12 11 10	9 8 7 6 5	4 3 2 1 0
sf	0	0	0	1	0	1	1	0	0	1	Rm	option	imm3	Rn	Rd
	op	S						opt							

32-bit (sf == 0)

```
ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit (sf == 1)

```
ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer shift = UInt(imm3);
constant integer datasize = 32 << UInt(sf);
constant ExtendType extend_type = DecodeRegExtend(option);
```

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[]<datasize-1:0> else X[n, datasize];
constant bits(datasize) operand2 = ExtendReg(m, extend_type, shift, datasize);
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, '0');

if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

ADD (immediate)

Add immediate value

This instruction adds a register value and an optionally-shifted immediate value, and writes the result to the destination register.

This instruction is used by the alias MOV (to/from SP).

31	30	29	28	27	26	25	24	23	22	21 … 10	9 … 5	4 … 0
sf	0	0	1	0	0	0	1	0	sh	imm12	Rn	Rd
	op	S										

32-bit (sf == 0)

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit (sf == 1)

```
ADD <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);

constant bits(24) imm = if sh == '0' then Zeros(12):imm12 else imm12:Zeros(12);
```

Assembler Symbols

<Wd|WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Wn|WSP>	Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm>	Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift>	Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	LSL #0
1	LSL #12

<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
MOV (to/from SP)	`sh == '0' && imm12 == '000000000000' && (Rd == '11111' || Rn == '11111')`

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[]<datasize-1:0> else X[n, datasize];
constant bits(datasize) operand2 = ZeroExtend(imm, datasize);
bits(datasize) result;
(result, -) = AddWithCarry(operand1, operand2, '0');

if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

ADD (shifted register)

Add optionally-shifted register

This instruction adds a register value and an optionally-shifted register value, and writes the result to the destination register.

31	30	29	28	27	26	25	24	23 22	21	20 19 18 17 16	15 14 13 12 11 10	9 8 7 6 5	4 3 2 1 0
sf	0	0	0	1	0	1	1	shift	0	Rm	imm6	Rn	Rd
	op	S											

32-bit (sf == 0)

```
ADD <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit (sf == 1)

```
ADD <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
if shift == '11' then EndOfDecode(Decode_UNDEF);
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, '0');

X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

ADDG

Add with tag

This instruction adds an immediate value scaled by the Tag Granule to the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

Integer
(FEAT_MTE)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if !IsFeatureImplemented(FEAT_MTE) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant bits(4) tag_offset = imm4;
constant bits(64) offset = LSL(ZeroExtend(imm6, 64), LOG2_TAG_GRANULE);
```

Assembler Symbols

<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<uimm6>	Is an unsigned immediate, a multiple of 16 in the range 0 to 1008, encoded in the "imm6" field.
<uimm4>	Is an unsigned immediate, in the range 0 to 15, encoded in the "imm4" field.

Operation

```
constant bits(64) operand1 = if n == 31 then SP[] else X[n, 64];
constant bits(4) start_tag = AArch64.AllocationTagFromAddress(operand1);
constant bits(16) exclude = GCR_EL1.Exclude;
bits(64) result;
bits(4) rtag;

if AArch64.AllocationTagAccessIsEnabled(PSTATE.EL) then
    rtag = AArch64.ChooseNonExcludedTag(start_tag, tag_offset, exclude);
else
    rtag = '0000';

(result, -) = AddWithCarry(operand1, offset, '0');

result = AArch64.AddressWithAllocationTag(result, rtag);

if d == 31 then
    SP[] = result;
else
    X[d, 64] = result;
```

ADDPT

Add checked pointer

This instruction adds a base address register value and an optionally-shifted register value, and writes the result to the destination register. The optionally-shifted register value is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ADDS (extended register)

Add extended and scaled register, setting flags

This instruction adds a register value and a sign or zero-extended register value, followed by an optional left shift amount, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMN (extended register).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	0	1	0	1	0	1	1	0	0	1	Rm					option			imm3			Rn					Rd				
	op	S						opt																							

32-bit (sf == 0)

```
ADDS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit (sf == 1)

```
ADDS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer shift = UInt(imm3);
constant integer datasize = 32 << UInt(sf);
constant ExtendType extend_type = DecodeRegExtend(option);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn|WSP>	Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount>	Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<R>	Is a width specifier, encoded in “option”:

option	<R>
`00x`	`W`
`010`	`W`
`x11`	`X`
`10x`	`W`
`110`	`W`

<m>	Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CMN (extended register)	`Rd == '11111'`

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[]<datasize-1:0> else X[n, datasize];
constant bits(datasize) operand2 = ExtendReg(m, extend_type, shift, datasize);
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '0');

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

ANDS (shifted register)

Bitwise AND (shifted register), setting flags

This instruction performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This instruction is used by the alias TST (shifted register).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	1	1	0	1	0	1	0	shift		0	Rm					imm6						Rn					Rd				
	opc									N																					

32-bit (sf == 0)

```
ANDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit (sf == 1)

```
ANDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
TST (shifted register)	`Rd == '11111'`

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

constant bits(datasize) result = operand1 AND operand2;
X[d, datasize] = result;
PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

APAS

Associate physical address space

This instruction associates a physical address space with a memory-mapped location that is protected by a memory-side physical address space filter.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, encoded in the "immr" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, encoded in the "immr" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

ASR (register)

Arithmetic shift right (register)

This instruction shifts a register value right by a variable number of bits, shifting in copies of its sign bit, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of ASRV. This means:

- The encodings in this description are named to match the encodings of ASRV.
- The description of ASRV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

AUTIA, AUTIA1716, AUTIASP, AUTIAZ, AUTIZA

Authenticate instruction address, using key A

This instruction authenticates an instruction address, using a modifier and key A.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The address is:

- In the general-purpose register that is specified by <Xd> for `AUTIA` and `AUTIZA`.
- In X17, for `AUTIA1716`.
- In X30, for `AUTIASP` and `AUTIAZ`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for `AUTIA`.
- The value zero, for `AUTIZA` and `AUTIAZ`.
- In X16, for `AUTIA1716`.
- In SP, for `AUTIASP`.

If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then `AUTIA1716` and `AUTIASP` include a second modifier that is:

- In X15, for `AUTIA1716`.
- In X16, for `AUTIASP`.

It has encodings from 2 classes: Integer and System

AUTIASPPC

Authenticate return address using key A, using an immediate offset

This instruction authenticates an instruction address, using two modifiers and key A.
If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.
The address is in X30.
The first modifier is in SP.
The second modifier is the address of a program label.

```

AUTIB, AUTIB1716, AUTIBSP, AUTIBZ, AUTIZB

Authenticate instruction address, using key B

This instruction authenticates an instruction address, using a modifier and key B.

If the authentication passes, the upper bits of the address are restored to enable subsequent use of the address. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The address is:

- In the general-purpose register that is specified by <Xd> for `AUTIB` and `AUTIZB`.
- In X17, for `AUTIB1716`.
- In X30, for `AUTIBSP` and `AUTIBZ`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for `AUTIB`.
- The value zero, for `AUTIZB` and `AUTIBZ`.
- In X16, for `AUTIB1716`.
- In SP, for `AUTIBSP`.

If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then `AUTIB1716` and `AUTIBSP` include a second modifier that is:

- In X15, for `AUTIB1716`.
- In X16, for `AUTIBSP`.

It has encodings from 2 classes: Integer and System

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

BFI

Bitfield insert

This instruction copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

BFM

Bitfield move

This instruction is usually accessed via one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the other bits of the destination register remain unchanged.

This instruction is used by the aliases BFC, BFI, and BFXIL.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<immr>	For the "32-bit" variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the "64-bit" variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
<imms>	For the "32-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the "64-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Is preferred when
BFC	`Rn == '11111' && UInt(imms) < UInt(immr)`
BFI	`Rn != '11111' && UInt(imms) < UInt(immr)`
BFXIL	`UInt(imms) >= UInt(immr)`

Operation

```
constant bits(datasize) dst = X[d, datasize];
constant bits(datasize) src = X[n, datasize];

// Perform bitfield move on low bits
constant bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, r) AND wmask);

// Combine extension bits and result bits
X[d, datasize] = (dst AND NOT(tmask)) OR (bot AND tmask);
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

BFXIL

Bitfield extract and insert at low end

This instruction copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, leaving the other destination bits unchanged.

This is an alias of BFM. This means:

- The encodings in this description are named to match the encodings of BFM.
- The description of BFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	opc																														

32-bit (sf == 0 && N == 0)

```
BFXIL <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

64-bit (sf == 1 && N == 1)

```
BFXIL <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
BFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of BFM gives the operational pseudocode for this instruction.

Operational information

BLRAA, BLRAAZ, BLRAB, BLRABZ

Branch with link to register, with pointer authentication

This instruction authenticates the address in the general-purpose register that is specified by <Xn>, using a modifier and the specified key, and calls a subroutine at the authenticated address, setting register X30 to PC+4.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xm|SP>, for `BLRAA` and `BLRAB`.
- The value zero, for `BLRAAZ` and `BLRABZ`.

Key A is used for `BLRAA` and `BLRAAZ`. Key B is used for `BLRAB` and `BLRABZ`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The authenticated address is not written back to the general-purpose register.

Integer

BRK

Breakpoint instruction

This instruction generates a Breakpoint Instruction exception. The PE records the exception in *ESR_ELx*, using the EC value 0x3C, and captures the value of the immediate argument in *ESR_ELx*.ISS.

Within a guarded memory region, while *PSTATE*.BTYPE != 0b00, a `BRK` instruction will not generate a Branch Target exception and will generate a Breakpoint Instruction exception as normal. For more information, see *PSTATE.BTYPE*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	0	1	0	0	0	0	1	imm16																0	0	0	0	0
									opc																			op2		LL	

BRK #<imm>

```
constant bits(16) comment = imm16;
if IsFeatureImplemented(FEAT_BTI) then
    SetBTypeCompatible(TRUE);
```

Assembler Symbols

<imm>	Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
AArch64.SoftwareBreakpoint(comment);
```

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

BTI

Branch target identification

This instruction is used to guard against the execution of instructions that are not the intended target of a branch.

Outside of a guarded memory region, a `BTI` instruction executes as a `NOP`. Within a guarded memory region, while *PSTATE*.BTYPE != 0b00, a `BTI` instruction compatible with the current value of PSTATE.BTYPE will not generate a Branch Target Exception and will allow execution of subsequent instructions within the memory region. For more information, see *PSTATE.BTYPE*.

The operand <targets> passed to a `BTI` instruction determines the values of *PSTATE*.BTYPE that the `BTI` instruction is compatible with.

System

CAS, CASA, CASAL, CASL

Compare and swap word or doubleword in memory

This instruction reads a 32-bit word or 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- `CASA` and `CASAL` load from memory with acquire semantics.
- `CASL` and `CASAL` store to memory with release semantics.
- `CAS` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, or <Xs>, is restored to the value held in the register before the instruction was executed.

For a `CAS` or `CASA` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent `CAS`, `CASA`, `CASAL`, or `CASL` access to the specified location is likely to occur in the near future. The memory system can respond by taking actions that are expected to enable the subsequent `CAS`, `CASA`, `CASAL`, or `CASL` access to succeed when it does occur.

A code sequence starting with a `CAS` or `CASA` instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent `CAS`, `CASA`, `CASAL`, or `CASL` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first `CAS` or `CASA` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CAS` or `CASA` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the `CAS` or `CASA` either fails its compare or writes the same value back to memory.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

CASH, CASAH, CASALH, CASLH

Compare and swap halfword in memory

This instruction reads a 16-bit halfword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- `CASAH` and `CASALH` load from memory with acquire semantics.
- `CASLH` and `CASALH` store to memory with release semantics.
- `CASH` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Ws>, is restored to the values held in the register before the instruction was executed.

For a `CASH` or `CASAH` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` access to the specified location is likely to occur in the near future. The memory system can respond by taking actions that are expected to enable the subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` access to succeed when it does occur.

A code sequence starting with a `CASH` or `CASAH` instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent `CASH`, `CASAH`, `CASALH`, or `CASLH` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first `CASH` or `CASAH` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CASH` or `CASAH` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the `CASH` or `CASAH` either fails its compare or writes the same value back to memory.

CASP, CASPA, CASPAL, CASPL

Compare and swap pair of words or doublewords in memory

This instruction reads a pair of 32-bit words or 64-bit doublewords from memory, and compares them against the values held in the first pair of registers. If the comparison is equal, the values in the second pair of registers are written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the writes are performed, the reads and writes occur atomically such that no other modification of the memory location can take place between the reads and writes.

- `CASPA` and `CASPAL` load from memory with acquire semantics.
- `CASPL` and `CASPAL` store to memory with release semantics.
- `CASP` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the registers which are compared and loaded, that is <Ws> and <W(s+1)>, or <Xs> and <X(s+1)>, are restored to the values held in the registers before the instruction was executed.

For a `CASP` or `CASPA` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` access to the specified location is likely to occur in the near future. The memory system can respond by taking actions that are expected to enable the subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` access to succeed when it does occur.

A code sequence starting with a `CASP` or `CASPA` instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent `CASP`, `CASPA`, `CASPAL`, or `CASPL` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first `CASP` or `CASPA` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CASP` or `CASPA` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the `CASP` or `CASPA` either fails its compare or writes the same value back to memory.

CASPT, CASPAT, CASPALT, CASPLT

Compare and swap pair unprivileged

This instruction reads a pair of 64-bit doublewords from memory, and compares them against the values held in the first pair of registers. If the comparison is equal, the values in the second pair of registers are written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the writes are performed, the reads and writes occur atomically such that no other modification of the memory location can take place between the reads and writes.

- `CASPAT` and `CASPALT` load from memory with acquire semantics.
- `CASPLT` and `CASPALT` store to memory with release semantics.
- `CASPT` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the registers which are compared and loaded, that is <Xs> and <X(s+1)>, are restored to the values held in the registers before the instruction was executed.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For a `CASPT` or `CASPAT` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` access to the specified location is likely to occur in the near future. The memory system can respond by taking actions that are expected to enable the subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` access to succeed when it does occur.

A code sequence starting with a `CASPT` or `CASPAT` instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent `CASPT`, `CASPAT`, `CASPALT`, or `CASPLT` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first `CASPT` or `CASPAT` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CASPT` or `CASPAT` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the `CASPT` or `CASPAT` either fails its compare or writes the same value back to memory.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

CAST, CASAT, CASALT, CASLT

Compare and swap unprivileged

This instruction reads a 64-bit doubleword from memory, and compares it against the value held in a first register. If the comparison is equal, the value in a second register is written to memory. If the comparison is not equal, the architecture permits writing the value read from the location to memory. If the write is performed, the read and write occur atomically such that no other modification of the memory location can take place between the read and write.

- `CASAT` and `CASALT` load from memory with acquire semantics.
- `CASLT` and `CASALT` store to memory with release semantics.
- `CAST` has neither acquire nor release semantics.

The architecture permits that the data read clears any exclusive monitors associated with that location, even if the compare subsequently fails.

If the instruction generates a synchronous Data Abort, the register which is compared and loaded, that is <Xs>, is restored to the value held in the register before the instruction was executed.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For a `CAST` or `CASAT` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, this signals to the memory system that an additional subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` access to the specified location is likely to occur in the near future. The memory system can respond by taking actions that are expected to enable the subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` access to succeed when it does occur.

A code sequence starting with a `CAST` or `CASAT` instruction for which <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, and ending with a subsequent `CAST`, `CASAT`, `CASALT`, or `CASLT` to the same location, exhibits the following properties for best performance when the location may be accessed concurrently, on one or more other PEs:

- The sequence does not contain any direct system register writes, address translation instructions, cache or TLB maintenance operations, exception producing instructions, exception returns, or `ISB` barriers.
- The execution of the sequence includes 32 or fewer instructions.
- The value provided in <Ws> or <Xs> of the first `CAST` or `CASAT` is a value likely to result in the comparison failing. A failing comparison result may lead to better performance due to the hardware not performing a write to memory.

Note

For a `CAST` or `CASAT` instruction, when <Ws> or <Xs> specifies the same register as <Wt> or <Xt>, the value in memory is not modified, because the `CAST` or `CASAT` either fails its compare or writes the same value back to memory.

CBBLE

Compare signed less than or equal bytes and branch

This instruction compares the signed byte values in two registers, and conditionally branches to a label at a PC-relative offset if the second value is less than or equal to the first. It provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.

This is a pseudo-instruction of CBB<cc>. This means:

- The encodings in this description are named to match the encodings of CBB<cc>.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CBB<cc> gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range -1024 to 1020, is encoded as "imm9" times 4.

Operation

The description of CBB<cc> gives the operational pseudocode for this instruction.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

CBBLS

Compare unsigned lower than or equal bytes and branch

This instruction compares the unsigned byte values in two registers, and conditionally branches to a label at a PC-relative offset if the second value is lower than or equal to the first. It provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.

This is a pseudo-instruction of CBB<cc>. This means:

- The encodings in this description are named to match the encodings of CBB<cc>.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CBB<cc> gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the "Rt" field.
<imms1>	Is a signed immediate, in the range -1 to 62, encoded as "imm6" minus 1.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range -1024 to 1020, is encoded as "imm9" times 4.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the "Rt" field.

Operation

The description of CB<cc> (immediate) gives the operational pseudocode for this instruction.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

CBLS (register)

Compare unsigned lower than or equal register and branch

This instruction compares the unsigned values in two registers, and conditionally branches to a label at a PC-relative offset if the second value is lower than or equal to the first. It provides a hint that this is not a subroutine call or return. This instruction does not affect the condition flags.

This is a pseudo-instruction of CB<cc> (register). This means:

- The encodings in this description are named to match the encodings of CB<cc> (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of CB<cc> (register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

CFP

Control flow prediction restriction by context

This instruction prevents control flow predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Control flow predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.
For more information, see CFP RCTX, Control Flow Prediction Restriction by Context.

This is an alias of SYS. This means:

1001	HI	Maps to <cond> LS.
1010	LT	Maps to <cond> GE.
1011	GE	Maps to <cond> LT.
1100	LE	Maps to <cond> GT.
1101	GT	Maps to <cond> LE.

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

Operation

The description of CSINC gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

CINV

Conditional invert

This instruction returns, in the destination register, the bitwise inversion of the value of the source register if the condition is TRUE, and otherwise returns the value of the source register.

This is an alias of CSINV. This means:

- The encodings in this description are named to match the encodings of CSINV.
- The description of CSINV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15 14 13 12	11	10	9 8 7 6 5	4 3 2 1 0

CLRBHB

Clear branch history

This instruction clears the branch history for the current context to the extent that branch history information created before the `CLRBHB` instruction cannot be used by code before the `CLRBHB` instruction to exploitatively control the execution of any indirect branches in code in the current context that appear in program order after the instruction.

System

(FEAT_CLRBHB)

CMN (extended register)

Compare negative (extended register)

This instruction adds a register value and a sign or zero-extended register value, followed by an optional left shift amount. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (extended register). This means:

- The encodings in this description are named to match the encodings of ADDS (extended register).
- The description of ADDS (extended register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	0	1	0	1	0	1	1	0	0	1	Rm					option			imm3			Rn					1	1	1	1	1
	op	S						opt																			Rd				

32-bit (sf == 0)

`CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}`

is equivalent to

`ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}`

and is always the preferred disassembly.

64-bit (sf == 1)

`CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}`

is equivalent to

`ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}`

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP>	Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<extend>	For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Operation

The description of ADDS (extended register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

CMN (immediate)

Compare negative (immediate)

This instruction adds a register value and an optionally-shifted immediate value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (immediate). This means:

- The encodings in this description are named to match the encodings of ADDS (immediate).
- The description of ADDS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	op	S																									Rd				

32-bit (sf == 0)

```
CMN <Wn|WSP>, #<imm>{, <shift>}
```

is equivalent to

```
ADDS WZR, <Wn|WSP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

64-bit (sf == 1)

```
CMN <Xn|SP>, #<imm>{, <shift>}
```

is equivalent to

```
ADDS XZR, <Xn|SP>, #<imm>{, <shift>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP>	Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.
<imm>	Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.
<shift>	Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	`LSL #0`
1	`LSL #12`

<Xn|SP>	Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of ADDS (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

CMN (shifted register)

Compare negative (shifted register)

This instruction adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ADDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ADDS (shifted register).
- The description of ADDS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

32-bit (sf == 0)

```
CMN <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit (sf == 1)

```
CMN <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of ADDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

CMP (extended register)

Compare (extended register)

This instruction subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (extended register). This means:

- The encodings in this description are named to match the encodings of SUBS (extended register).
- The description of SUBS (extended register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

32-bit (sf == 0)

```
CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

is equivalent to

```
SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

64-bit (sf == 1)

```
CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

is equivalent to

```
SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP>	Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
`000`	`UXTB`
`001`	`UXTH`
`010`	`UXTW`
`011`	`LSL|UXTX`
`100`	`SXTB`
`101`	`SXTH`
`110`	`SXTW`
`111`	`SXTX`

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
`00x`	`W`
`010`	`W`
`x11`	`X`
`10x`	`W`
`110`	`W`

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Operation

The description of SUBS (extended register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

CMP (immediate)

Compare (immediate)

This instruction subtracts an optionally-shifted immediate value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (immediate). This means:

- The encodings in this description are named to match the encodings of SUBS (immediate).
- The description of SUBS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	op	S																									Rd				

32-bit (sf == 0)

`CMP <Wn|WSP>, #<imm>{, <shift>}`

is equivalent to

`SUBS WZR, <Wn|WSP>, #<imm>{, <shift>}`

and is always the preferred disassembly.

64-bit (sf == 1)

`CMP <Xn|SP>, #<imm>{, <shift>}`

is equivalent to

`SUBS XZR, <Xn|SP>, #<imm>{, <shift>}`

and is always the preferred disassembly.

Assembler Symbols

<Wn|WSP> Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

<imm> Is an unsigned immediate, in the range 0 to 4095, encoded in the "imm12" field.

<shift> Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in “sh”:

sh	<shift>
0	`LSL #0`
1	`LSL #12`

<Xn|SP> Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the "Rn" field.

Operation

The description of SUBS (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

CMP (shifted register)

Compare (shifted register)

This instruction subtracts an optionally-shifted register value from a register value. It updates the condition flags based on the result, and discards the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23 22	21	20 19 18 17 16	15 14 13 12 11 10	9 8 7 6 5	4	3	2	1	0

	op	S											Rd				

32-bit (sf == 0)

```
CMP <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS WZR, <Wn>, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit (sf == 1)

```
CMP <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS XZR, <Xn>, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

COSP

Clear other speculative prediction restriction by context

This instruction prevents predictions, other than Cache prefetch, Control flow, and Data Value predictions, that predict execution addresses based on information gathered from earlier execution within a particular execution context. Predictions, other than Cache prefetch, Control flow, and Data Value predictions, determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot exploitatively control any speculative access occurring after the instruction is complete and synchronized.

This is an alias of SYS. This means:

CPYFP, CPYFM, CPYFE

Memory copy forward-only

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFP, then CPYFM, and then CPYFE.

CPYFP performs some preconditioning of the arguments suitable for using the CPYFM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFM performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFE performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFP, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFP, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFE, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFE, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

CPYFPN, CPYFMN, CPYFEN

Memory copy forward-only, reads and writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPN, then CPYFMN, and then CPYFEN.

CPYFPN performs some preconditioning of the arguments suitable for using the CPYFMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

CPYFPRN, CPYFMRN, CPYFERN

Memory copy forward-only, reads non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRN, then CPYFMRN, and then CPYFERN.

CPYFPRN performs some preconditioning of the arguments suitable for using the CPYFMRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFERN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

CPYFPRT, CPYFMRT, CPYFERT

Memory copy forward-only, reads unprivileged

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRT, then CPYFMRT, and then CPYFERT.

CPYFPRT performs some preconditioning of the arguments suitable for using the CPYFMRT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFERT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPRTN, CPYFMRTN, CPYFERTN

Memory copy forward-only, reads unprivileged, reads and writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTN, then CPYFMRTN, and then CPYFERTN.

CPYFPRTN performs some preconditioning of the arguments suitable for using the CPYFMRTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERTN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPRTRN, CPYFMRTRN, CPYFERTRN

Memory copy forward-only, reads unprivileged and non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTRN, then CPYFMRTRN, and then CPYFERTRN.

CPYFPRTRN performs some preconditioning of the arguments suitable for using the CPYFMRTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERTRN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRTRN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRTRN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTRN option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPRTWN, CPYFMRTWN, CPYFERTWN

Memory copy forward-only, reads unprivileged, writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPRTWN, then CPYFMRTWN, and then CPYFERTWN.

CPYFPRTWN performs some preconditioning of the arguments suitable for using the CPYFMRTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMRTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFERTWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPRTWN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPRTWN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMRTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMRTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFERTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFERTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPT, CPYFMT, CPYFET

Memory copy forward-only, reads and writes unprivileged

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPT, then CPYFMT, and then CPYFET.

CPYFPT performs some preconditioning of the arguments suitable for using the CPYFMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFET performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFET, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFET, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPTN, CPYFMTN, CPYFETN

Memory copy forward-only, reads and writes unprivileged and non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTN, then CPYFMTN, and then CPYFETN.

CPYFPTN performs some preconditioning of the arguments suitable for using the CPYFMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFETN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPTRN, CPYFMTRN, CPYFETRN

Memory copy forward-only, reads and writes unprivileged, reads non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTRN, then CPYFMTRN, and then CPYFETRN.

CPYFPTRN performs some preconditioning of the arguments suitable for using the CPYFMTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFETRN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPTRN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPTRN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFETRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFETRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPTWN, CPYFMTWN, CPYFETWN

Memory copy forward-only, reads and writes unprivileged, writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPTWN, then CPYFMTWN, and then CPYFETWN.

CPYFPTWN performs some preconditioning of the arguments suitable for using the CPYFMTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFETWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPTWN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPTWN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFETWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFETWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPWN, CPYFMWN, CPYFEWN

Memory copy forward-only, writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWN, then CPYFMWN, and then CPYFEWN.

CPYFPWN performs some preconditioning of the arguments suitable for using the CPYFMWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

CPYFPWT, CPYFMWT, CPYFEWT

Memory copy forward-only, writes unprivileged

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWT, then CPYFMWT, and then CPYFEWT.

CPYFPWT performs some preconditioning of the arguments suitable for using the CPYFMWT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPWTN, CPYFMWTN, CPYFEWTN

Memory copy forward-only, writes unprivileged, reads and writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTN, then CPYFMWTN, and then CPYFEWTN.

CPYFPWTN performs some preconditioning of the arguments suitable for using the CPYFMWTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWTN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPWTRN, CPYFMWTRN, CPYFEWTRN

Memory copy forward-only, writes unprivileged, reads non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTRN, then CPYFMWTRN, and then CPYFEWTRN.

CPYFPWTRN performs some preconditioning of the arguments suitable for using the CPYFMWTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWTRN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWTRN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWTRN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYFPWTWN, CPYFMWTWN, CPYFEWTWN

Memory copy forward-only, writes unprivileged and non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYFPWTWN, then CPYFMWTWN, and then CPYFEWTWN.

CPYFPWTWN performs some preconditioning of the arguments suitable for using the CPYFMWTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFMWTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYFEWTWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

The memory copy performed by these instructions is in the forward direction only, so the instructions are suitable for a memory copy only where there is no overlap between the source and destination locations, or where the source address is greater than the destination address.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYFPWTWN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + saturated Xn.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of CPYFPWTWN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For CPYFMWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.

For CPYFMWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

For CPYFEWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number and holds -1* the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from -Xn.
- Xd holds the lowest address that the copy is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For CPYFEWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be copied in the memory copy in total.
- Xs holds the lowest address that the copy is copied from.
- Xd holds the lowest address that the copy is copied to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xs is written back with the lowest address that has not been copied from.
  - the value of Xd is written back with the lowest address that has not been copied to.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYP, CPYM, CPYE

Memory copy

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYP, then CPYM, and then CPYE.

CPYP performs some preconditioning of the arguments suitable for using the CPYM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYM performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYE performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYP, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYP, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYP, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is copied to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.

    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYE, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is made to.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYE, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from.
    - Xd holds the highest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.

CPYPN, CPYMN, CPYEN

Memory copy, reads and writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPN, then CPYMN, and then CPYEN.

CPYPN performs some preconditioning of the arguments suitable for using the CPYMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
    - Xs holds the original Xs + saturated Xn.
    - Xd holds the original Xd + saturated Xn.
    - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
    - Xs and Xd are unchanged.
    - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
    - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
    - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
    - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
    - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
    - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
    - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
    - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
    - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

```

CPYPRN, CPYMRN, CPYERN

Memory copy, reads non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRN, then CPYMRN, and then CPYERN.

CPYPRN performs some preconditioning of the arguments suitable for using the CPYMRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
    - Xs holds the original Xs + saturated Xn.
    - Xd holds the original Xd + saturated Xn.
    - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
    - Xs and Xd are unchanged.
    - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
    - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
    - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
    - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
    - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
    - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
    - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
    - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
    - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.

        - Xd holds the lowest address that the copy is copied to.
        - At the end of the instruction:
            - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
            - the value of Xs is written back with the lowest address that has not been copied from.
            - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYERN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

```

CPYPRT, CPYMRT, CPYERT

Memory copy, reads unprivileged

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRT, then CPYMRT, and then CPYERT.

CPYPRT performs some preconditioning of the arguments suitable for using the CPYMRT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRT, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRT, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRT, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMRT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYERT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

```

CPYPRTN, CPYMRTN, CPYERTN

Memory copy, reads unprivileged, reads and writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTN, then CPYMRTN, and then CPYERTN.

CPYPRTN performs some preconditioning of the arguments suitable for using the CPYMRTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERTN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRTN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRTN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRTN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMRTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYERTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.

CPYPRTRN, CPYMRTRN, CPYERTRN

Memory copy, reads unprivileged and non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTRN, then CPYMRTRN, and then CPYERTRN.

CPYPRTRN performs some preconditioning of the arguments suitable for using the CPYMRTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERTRN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRTRN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRTRN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRTRN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMRTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with 0.

For CPYERTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

```

CPYPRTWN, CPYMRTWN, CPYERTWN

Memory copy, reads unprivileged, writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPRTWN, then CPYMRTWN, and then CPYERTWN.

CPYPRTWN performs some preconditioning of the arguments suitable for using the CPYMRTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMRTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYERTWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPRTWN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPRTWN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPRTWN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMRTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMRTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYERTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYERTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory Read effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Read effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYPT, CPYMT, CPYET

Memory copy, reads and writes unprivileged

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPT, then CPYMT, and then CPYET.

CPYPT performs some preconditioning of the arguments suitable for using the CPYMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYET performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPT, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPT, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPT, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYET, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYET, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

```

CPYPTN, CPYMTN, CPYETN

Memory copy, reads and writes unprivileged and non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTN, then CPYMTN, and then CPYETN.

CPYPTN performs some preconditioning of the arguments suitable for using the CPYMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPTN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPTN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPTN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.

CPYPTRN, CPYMTRN, CPYETRN

Memory copy, reads and writes unprivileged, reads non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTRN, then CPYMTRN, and then CPYETRN.

CPYPTRN performs some preconditioning of the arguments suitable for using the CPYMTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETRN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPTRN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPTRN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPTRN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYETRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYETRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

```

CPYPTWN, CPYMTWN, CPYETWN

Memory copy, reads and writes unprivileged, writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPTWN, then CPYMTWN, and then CPYETWN.

CPYPTWN performs some preconditioning of the arguments suitable for using the CPYMTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYETWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPTWN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPTWN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPTWN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYETWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYETWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CPYPWN, CPYMWN, CPYEWN

Memory copy, writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWN, then CPYMWN, and then CPYEWN.

CPYPWN performs some preconditioning of the arguments suitable for using the CPYMWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with 0.

For CPYEWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.
  - Xd holds the lowest address that the copy is copied to.
  - At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the lowest address that has not been copied from.
    - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
  - Xs holds the highest address that the copy is copied from +1.
  - Xd holds the highest address that the copy is copied to +1.
  - At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xs is written back with the highest address that has not been copied from +1.
    - the value of Xd is written back with the highest address that has not been copied to +1.

CPYPWT, CPYMWT, CPYEWT

Memory copy, writes unprivileged

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWT, then CPYMWT, and then CPYEWT.

CPYPWT performs some preconditioning of the arguments suitable for using the CPYMWT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWT performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWT performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWT, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWT, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWT, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYEWT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.

CPYPWTN, CPYMWTN, CPYEWTN

Memory copy, writes unprivileged, reads and writes non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTN, then CPYMWTN, and then CPYEWTN.

CPYPWTN performs some preconditioning of the arguments suitable for using the CPYMWTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWTN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWTN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWTN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWTN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWTN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYEWTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Assembler Symbols

<Xd>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the destination address and is updated by the instruction, encoded in the "Rd" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the destination address, encoded in the "Rd" field.
<Xs>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the source address and is updated by the instruction, encoded in the "Rs" field. For the "Epilogue" and "Main" variants: is the 64-bit name of the general-purpose register that holds an encoding of the source address, encoded in the "Rs" field.
<Xn>	For the "Prologue" variant: is the 64-bit name of the general-purpose register that holds the number of bytes to be transferred and is updated by the instruction to encode the remaining size and destination, encoded in the "Rn" field. For the "Main" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred, encoded in the "Rn" field. For the "Epilogue" variant: is the 64-bit name of the general-purpose register that holds an encoding of the number of bytes to be transferred and is set to zero at the end of the instruction, encoded in the "Rn" field.

CPYPWTRN, CPYMWTRN, CPYEWTRN

Memory copy, writes unprivileged, reads non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTRN, then CPYMWTRN, and then CPYEWTRN.

CPYPWTRN performs some preconditioning of the arguments suitable for using the CPYMWTRN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWTRN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWTRN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWTRN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWTRN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWTRN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWTRN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYEWTRN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

```

CPYPWTWN, CPYMWTWN, CPYEWTWN

Memory copy, writes unprivileged and non-temporal

These instructions perform a memory copy. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: CPYPWTWN, then CPYMWTWN, and then CPYEWTWN.

CPYPWTWN performs some preconditioning of the arguments suitable for using the CPYMWTWN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYMWTWN performs an IMPLEMENTATION DEFINED amount of the memory copy. CPYEWTWN performs the last part of the memory copy.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory copy allows some optimization of the size that can be performed.

For CPYPWTWN, the following saturation logic is applied:

If Xn<63:55> != 000000000, the copy size Xn is saturated to 0x007FFFFFFFFFFFFF.

After that saturation logic is applied, the direction of the memory copy is based on the following algorithm:

If (Xs > Xd) && (Xd + saturated Xn) > Xs, then direction = forward

Elsif (Xs < Xd) && (Xs + saturated Xn) > Xd, then direction = backward

Else direction = IMPLEMENTATION DEFINED choice between forward and backward.

The architecture supports two algorithms for the memory copy: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of CPYPWTWN, option A (which results in encoding PSTATE.C = 0):

- PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the forward direction, then:
  - Xs holds the original Xs + saturated Xn.
  - Xd holds the original Xd + saturated Xn.
  - Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes copied.
- If the copy is in the backward direction, then:
  - Xs and Xd are unchanged.
  - Xn holds the saturated value of Xn - an IMPLEMENTATION DEFINED number of bytes copied.

After execution of CPYPWTWN, option B (which results in encoding PSTATE.C = 1):

- If the copy is in the forward direction, then:
  - Xs holds the original Xs + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {0,0,0}.
- If the copy is in the backward direction, then:
  - Xs holds the original Xs + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xd holds the original Xd + saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes copied.
  - PSTATE.{N,Z,V} are set to {1,0,0}.

For CPYMWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
  - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the lowest address that the copy is copied from -Xn.
  - Xd holds the lowest address that the copy is made to -Xn.
  - At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be copied in the memory copy in total.
- If the copy is in the backward direction (Xn is a positive number), then:
  - Xn holds the number of bytes remaining to be copied in the memory copy in total.
  - Xs holds the highest address that the copy is copied from -Xn+1.
  - Xd holds the highest address that the copy is copied to -Xn+1.
  - At the end of the instruction, the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.

For CPYMWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
  - Xs holds the lowest address that the copy is copied from.

    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with the number of bytes remaining to be copied in the memory copy in total.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

For CPYEWTWN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- If the copy is in the forward direction (Xn is a negative number), then:
    - Xn holds -1* the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the lowest address that the copy is copied from -Xn.
    - Xd holds the lowest address that the copy is made to -Xn.
    - At the end of the instruction, the value of Xn is written back with 0.
- If the copy is in the backward direction (Xn is a positive number), then:
    - Xn holds the number of bytes remaining to be copied in the memory copy in total.
    - Xs holds the highest address that the copy is copied from -Xn+1.
    - Xd holds the highest address that the copy is copied to -Xn+1.
    - At the end of the instruction, the value of Xn is written back with 0.

For CPYEWTWN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes to be copied in the memory copy in total.
- If the copy is in the forward direction (PSTATE.N == 0), then:
    - Xs holds the lowest address that the copy is copied from.
    - Xd holds the lowest address that the copy is copied to.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the lowest address that has not been copied from.
        - the value of Xd is written back with the lowest address that has not been copied to.
- If the copy is in the backward direction (PSTATE.N == 1), then:
    - Xs holds the highest address that the copy is copied from +1.
    - Xd holds the highest address that the copy is copied to +1.
    - At the end of the instruction:
        - the value of Xn is written back with 0.
        - the value of Xs is written back with the highest address that has not been copied from +1.
        - the value of Xd is written back with the highest address that has not been copied to +1.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

CRC32B, CRC32H, CRC32W, CRC32X

CRC32 checksum

This instruction performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.
In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC32C checksum

This instruction performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, 32, or 64 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note

ID_AA64ISAR0_EL1.CRC32 indicates whether this instruction is supported.

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<cond>	Is one of the standard conditions, encoded in the standard way, and encoded in “cond”:

cond	<cond>
0000	EQ
0001	NE
0010	CS
0011	CC
0100	MI
0101	PL
0110	VS
0111	VC
1000	HI
1001	LS
1010	GE
1011	LT
1100	GT
1101	LE
1110	AL
1111	NV

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CINC	`Rm != '11111' && Rn != '11111' && !(cond IN {'111x'}) && Rn == Rm`

Alias	Is preferred when
CSET	`Rm == '11111' && Rn == '11111' && !(cond IN {'111x'})`

Operation

```
bits(datasize) result;
if ConditionHolds(condition) then
    result = X[n, datasize];
else
    result = X[m, datasize] + 1;

X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

CSINV

Conditional select invert

This instruction returns, in the destination register, the value of the first source register if the condition is TRUE, and otherwise returns the bitwise inversion value of the second source register.

This instruction is used by the aliases CINV, and CSETM.

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15 14 13 12	11	10	9 8 7 6 5	4 3 2 1 0

<Xt> Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

DCPS1

Debug change PE state to EL1

This instruction, when executed in Debug state:

- If executed at EL0, changes the current Exception level and SP to EL1 using SP_EL1.
- Otherwise, if executed at ELx, selects *SP_ELx*.

The target exception level of a DCPS1 instruction is:

- EL1 if the instruction is executed at EL0.
- Otherwise, the Exception level at which the instruction is executed.

When the target Exception level of a DCPS1 instruction is ELx, on executing this instruction:

- *ELR_ELx* becomes UNKNOWN.
- *SPSR_ELx* becomes UNKNOWN.
- *ESR_ELx* becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to *SCTLR_ELx*.EE.

This instruction is UNDEFINED at EL0 in Non-secure state if EL2 is implemented and HCR_EL2.TGE == 1.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see *DCPS*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
DCPS1 {#<imm>}
```

```
// Empty.
```

Assembler Symbols

<imm>	Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
if !Halted() then UNDEFINED;
DCPSInstruction(EL1);
```

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

DCPS2

Debug change PE state to EL2

This instruction, when executed in Debug state:

- If executed at EL0 or EL1, changes the current Exception level and SP to EL2 using SP_EL2.
- Otherwise, if executed at ELx, selects *SP_ELx*.

The target exception level of a DCPS2 instruction is:

- EL2 if the instruction is executed at an exception level that is not EL3.
- EL3 if the instruction is executed at EL3.

When the target Exception level of a DCPS2 instruction is ELx, on executing this instruction:

- *ELR_ELx* becomes UNKNOWN.
- *SPSR_ELx* becomes UNKNOWN.
- *ESR_ELx* becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to *SCTLR_ELx*.EE.

This instruction is UNDEFINED at the following exception levels:

- All exception levels if EL2 is not implemented.
- At EL0 and EL1 if EL2 is disabled in the current Security state.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see *DCPS*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler Symbols

<imm>	Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the "imm16" field.

Operation

```
if !Halted() then UNDEFINED;
DCPSInstruction(EL2);
```

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

DCPS3

Debug change PE state to EL3

This instruction, when executed in Debug state:

- If executed at EL3, selects SP_EL3.
- Otherwise, changes the current Exception level and SP to EL3 using SP_EL3.

The target exception level of a DCPS3 instruction is EL3.

On executing a DCPS3 instruction:

- ELR_EL3 becomes UNKNOWN.
- SPSR_EL3 becomes UNKNOWN.
- ESR_EL3 becomes UNKNOWN.
- DLR_EL0 and DSPSR_EL0 become UNKNOWN.
- The endianness is set according to SCTLR_EL3.EE.

This instruction is UNDEFINED at all exception levels if either:

- *EDSCR*.SDD == 1.
- EL3 is not implemented.

This instruction is always UNDEFINED in Non-debug state.

For more information on the operation of the DCPS<n> instructions, see *DCPS*.

    when '10' types = MBReqTypes_Writes;
    when '11' types = MBReqTypes_All;
```

Assembler Symbols

<option> Specifies the limitation on the barrier operation. Values are:

SY

Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST

Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD

Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH

Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST

Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

ISHLD

Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

NSH

Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST

Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD

Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.

OSH
Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST
Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD
Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of "CRm" that are not listed are reserved and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see *Data Memory Barrier (DMB)* or see *Data Synchronization Barrier (DSB)*.

CRm	<option>
`xx00`	`RESERVED`
`0001`	`OSHLD`
`0010`	`OSHST`
`0011`	`OSH`
`0101`	`NSHLD`
`0110`	`NSHST`
`0111`	`NSH`
`1001`	`ISHLD`
`1010`	`ISHST`
`1011`	`ISH`
`1101`	`LD`
`1110`	`ST`
`1111`	`SY`

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Operation

```
DataMemoryBarrier(domain, types);
```

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

DRPS

Debug restore PE state

This instruction restores *PSTATE* from the SPSR.
The SPSR is checked for the current Exception level for an illegal return event. See *Illegal return events from AArch64 state*.
This instruction is UNDEFINED at EL0.
This instruction is UNDEFINED in Non-debug state.
For more information on the operation of `DRPS`, see *DRPS*.

DSB

Data synchronization barrier

This instruction is a memory barrier that ensures the completion of memory accesses, see *Data Synchronization Barrier*.
This instruction is used by the aliases PSSBB, and SSBB.
It has encodings from 2 classes: Memory barrier and Memory nXS barrier

Memory barrier

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler Symbols

<option> For the "Memory barrier" variant: specifies the limitation on the barrier operation. Values are:

SY
Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as CRm = 0b1111.

ST
Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1110.

LD
Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1101.

ISH
Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b1011.

ISHST
Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b1010.

ISHLD
Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b1001.

NSH
Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as CRm = 0b0111.

NSHST
Non-shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0110.

NSHLD
Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0101.

OSH
Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as CRm = 0b0011.

OSHST
Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as CRm = 0b0010.

OSHLD
Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as CRm = 0b0001.

All other encodings of "CRm" that are not listed, other than the values 0b0000 and 0b0100, are reserved and can be encoded using the #<imm> syntax. All unsupported and reserved options must execute as a full system barrier operation, but software must not rely on this behavior. For more information on whether an access is before or after a barrier instruction, see *Data Memory Barrier (DMB)* or see *Data Synchronization Barrier (DSB)*.

Note

The value 0b0000 is used to encode SSBB and the value 0b0100 is used to encode PSSBB.

CRm	<option>
`0001`	`OSHLD`
`0010`	`OSHST`
`0011`	`OSH`
`0101`	`NSHLD`
`0110`	`NSHST`
`0111`	`NSH`
`1000`	`RESERVED`
`1001`	`ISHLD`
`1010`	`ISHST`
`1011`	`ISH`
`1100`	`RESERVED`
`1101`	`LD`
`1110`	`ST`
`1111`	`SY`

For the "Memory nXS barrier" variant: specifies the limitation on the barrier operation. Values are:

SY

Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. This option is referred to as the full system barrier. Encoded as imm2 = 0b11.

ISH

Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as imm2 = 0b10.

NSH

Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as imm2 = 0b01.

OSH

Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as imm2 = 0b00.

imm2	<option>
`00`	`OSH`
`01`	`NSH`
`10`	`ISH`
`11`	`SY`

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "CRm" field.

Alias Conditions

Alias	Is preferred when
PSSBB	`CRm == '0100'`
SSBB	`CRm == '0000'`

Operation

```
case alias of
    when DSBAlias_SSBB
        SpeculativeStoreBypassBarrierToVA();
    when DSBAlias_PSSBB
        SpeculativeStoreBypassBarrierToPA();
    when DSBAlias_DSB
        if IsFeatureImplemented(FEAT_TME) && TSTATE.depth > 0 then
            FailTransaction(TMFailure_ERR, FALSE);
        if !nXS && IsFeatureImplemented(FEAT_XS) then
            nXS = PSTATE.EL IN {EL0, EL1} && IsHCRXEL2Enabled() && HCRX_EL2.FnXS == '1';
        DataSynchronizationBarrier(domain, types, nXS);
    otherwise
        Unreachable();
```

DVP

Data value prediction restriction by context

This instruction prevents data value predictions that predict execution addresses based on information gathered from earlier execution within a particular execution context. Data value predictions determined by the actions of code in the target execution context or contexts appearing in program order before the instruction cannot be used to exploitatively control speculative execution occurring after the instruction is complete and synchronized.
For more information, see DVP RCTX, Data Value Prediction Restriction by Context.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_SPECRES)

	opc								N				

32-bit (sf == 0)

```
EON <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit (sf == 1)

```
EON <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

X[d, datasize] = operand1 EOR NOT(operand2);
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.

    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

ERET

Exception return

This instruction restores *PSTATE* from the SPSR, and branches to the address held in the ELR.
The SPSR is checked for the current Exception level for an illegal return event. See *Illegal return events from AArch64 state*.
`ERET` is UNDEFINED at EL0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ERETAA, ERETAB

Exception return, with pointer authentication

This instruction authenticates the address in ELR, using SP as the modifier and the specified key, restores *PSTATE* from the SPSR for the current Exception level, and branches to the authenticated address.

Key A is used for `ERETAA`. Key B is used for `ERETAB`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The authenticated address is not written back to ELR.

The SPSR is checked for the current Exception level for an illegal return event. See *Illegal return events from AArch64 state*.

`ERETAA` and `ERETAB` are UNDEFINED at EL0.

ESB

Error synchronization barrier

This instruction is an error synchronization event that might also update DISR_EL1 and VDISR_EL2.
This instruction can be used at all Exception levels and in Debug state.
In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. For more information, see *RAS PE architecture* and *RAS System architecture*.
If *FEAT_RAS* is not implemented, this instruction executes as a `NOP`.

System
(FEAT_RAS)

Alias Conditions

Alias	Is preferred when
ROR (immediate)	`Rn == Rm`

Operation

```
bits(datasize) result;
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
constant bits(2*datasize) concat = operand1:operand2;

result = concat<(lsb+datasize)-1:lsb>;

X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

GCSB

Guarded Control Stack barrier

This instruction generates a GCSB effect.
If *FEAT_GCS* is not implemented, this instruction executes as a `NOP`.

System
(FEAT_GCS)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

																				CRm				op2							

`GCSB DSYNC`

```
if !IsFeatureImplemented(FEAT_GCS) then EndOfDecode(Decode_NOP);
```

Operation

```
GCSSynchronizationBarrier();
```

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

GCSPOPCX

Guarded Control Stack pop and compare exception return record

This instruction loads an exception return record from the location indicated by the current Guarded control stack pointer register, compares the loaded values with the current ELR_ELx, SPSR_ELx, and LR, and increments the pointer by the size of a Guarded Control Stack exception return record.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_GCS)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

										L			op1			CRn				CRm				op2							

`GCSPOPCX`

is equivalent to

`SYS #0, C7, C7, #5{, <Xt>}`

and is always the preferred disassembly.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

GCSPOPM

Guarded Control Stack pop

This instruction loads the 64-bit doubleword that is pointed to by the current Guarded Control Stack pointer, writes it to the destination register, and increments the current Guarded Control Stack pointer register by the size of a Guarded Control Stack procedure return record.

This is an alias of SYSL. This means:

- The encodings in this description are named to match the encodings of SYSL.
- The description of SYSL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

GCSSS1

Guarded Control Stack switch stack 1

This instruction validates that the stack being switched to contains a Valid cap entry, stores an In-progress cap entry to the stack that is being switched to, and sets the current Guarded control stack pointer to the stack that is being switched to.

If the instruction generates a synchronous Data Abort exception, Watchpoint exception, GPC exception, or GCS Data Check exception, the value of *GCSPR_ELx* for the current Exception level is restored to the value held in the register before the instruction was executed.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

`SYS #3, C7, C7, #2, <Xt>`

and is always the preferred disassembly.

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

GCSSS2

Guarded Control Stack switch stack 2

This instruction validates that the most recent entry of the Guarded Control Stack being switched to contains an In-progress cap entry, stores a Valid cap entry to the Guarded Control Stack that is being switched from, and sets Xt to the Guarded Control Stack pointer that is being switched from.

This is an alias of SYSL. This means:

- The encodings in this description are named to match the encodings of SYSL.
- The description of SYSL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System
(FEAT_GCS)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

																		opc													

GCSSTR <Xt>, [<Xn|SP>]

```
if !IsFeatureImplemented(FEAT_GCS) then EndOfDecode(Decode_UNDEF);
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
bits(64) address;

constant bits(2) effective_el = PSTATE.EL;

if effective_el == PSTATE.EL then
    CheckGCSSTREnabled();

constant boolean privileged = effective_el != EL0;
constant AccessDescriptor accdesc = CreateAccDescGCS(MemOp_STORE, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

Mem[address, 8, accdesc] = X[t, 64];
```

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

GCSSTTR

Guarded Control Stack store register (unprivileged)

This instruction stores a doubleword from a register to memory. The address that is used for the store is calculated from a base register.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1 and the *Effective value* of HCR_EL2.{NV, NV1} is not {1, 1}.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

HINT

Hint instruction

This instruction is for the instruction set space that is reserved for architectural hint instructions.

Some encodings described here are not allocated in this revision of the architecture, and behave as NOPs. These encodings might be allocated to other hint functionality in future revisions of the architecture and therefore must not be used by software.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

<imm>	Is a 7-bit unsigned immediate, in the range 0 to 127, encoded in the "CRm:op2" field. The encodings that are allocated to architectural hint functionality are described in the 'Hints' table in the 'Index by Encoding'.

Note

For allocated encodings of "CRm:op2":

- A disassembler will disassemble the allocated instruction, rather than the `HINT` instruction.
- An assembler may support assembly of allocated encodings using `HINT` with the corresponding <imm> value, but it is not required to do so.

Operation

```
case op of
    when SystemHintOp_YIELD
        Hint_Yield();

HLT

Halt instruction

This instruction can generate a Halt Instruction debug event, which causes entry into Debug state.
Within a guarded memory region, while *PSTATE*.BTYPE != 0b00, an `HLT` instruction that would cause entry into Debug state will not generate a Branch Target exception and will cause entry into Debug state as normal. For more information, see *PSTATE.BTYPE*.

HVC

Hypervisor call

This instruction causes an exception to EL2. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The `HVC` instruction is UNDEFINED:

- When EL3 is implemented and SCR_EL3.HCE is set to 0.
- When EL3 is not implemented and HCR_EL2.HCD is set to 1.
- When EL2 is not implemented.
- At EL1 if EL2 is not enabled in the current Security state.
- At EL0.

On executing an `HVC` instruction, the PE records the exception as a Hypervisor Call exception in *ESR_ELx*, using the EC value 0x16, and the value of the immediate argument.

IC

Instruction cache operation

For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions*.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	0	1	0	1	0	0	0	0	1	op1			0	1	1	1	CRm				op2			Rt				
										L						CRn															

`IC <ic_op>{, <Xt>}`

is equivalent to

`SYS #<op1>, C7, <Cm>, #<op2>{, <Xt>}`

and is the preferred disassembly when `SysOp(op1, '0111', CRm, op2) == Sys_IC`.

Assembler Symbols

<ic_op> Is an IC operation name, as listed for the IC system instruction pages, encoded in “op1:CRm:op2”:

op1	CRm	op2	<ic_op>
000	0001	000	IALLUIS
000	0101	000	IALLU
011	0101	001	IVAU

<Xt> Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.

Operation

The description of SYS gives the operational pseudocode for this instruction.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

IRG

Insert random tag

This instruction inserts a random Logical Address Tag into the address in the first source register, and writes the result to the destination register. Any tags specified in the optional second source register or in GCR_EL1.Exclude are excluded from the selection of the random Logical Address Tag.

LD64B

Single-copy atomic 64-byte Load

This instruction derives an address from a base register value, loads eight 64-bit doublewords from a memory location, and writes them to consecutive registers. The load starts at register Xt, with the data being read as X(t+7):X(t+6):X(t+5):X(t+4):X(t+3):X(t+2):X(t+1):Xt = Data<511:0>. The data is loaded atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `LD64B` also supports `ST64B`. For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

LDAPR

Load-acquire RCpc register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from the derived address in memory, and writes it to a register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 2 classes: Post-index and No offset

Post-index

LDAPRB

Load-acquire RCpc register byte

This instruction derives an address from a base register value, loads a byte from the derived address in memory, zero-extends it and writes it to a register.

The instruction has memory ordering semantics as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, except that:

- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

This difference in memory ordering is not described in the pseudocode.

For information about addressing modes, see *Load/Store addressing modes*.

LDAR

Load-acquire register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.

Note

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

LDARB

Load-acquire register byte

This instruction derives an address from a base register value, loads a byte from memory, zero-extends it and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.

Note

For this instruction, if the destination is WZR/XZR, it is impossible for software to observe the presence of the acquire semantic other than its effect on the arrival at endpoints.

LDATXR

Load-acquire unprivileged exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `LDATXR` is equivalent to `LDXR`.

For information about addressing modes, see *Load/Store addressing modes*.

LDAXP

Load-acquire exclusive pair of registers

This instruction derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. The instruction also has memory ordering semantics, as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.

LDCLR, LDCLRA, LDCLRAL, LDCLRL

Atomic bit clear on word or doubleword in memory

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDCLRA` and `LDCLRAL` load from memory with acquire semantics.
- `LDCLRL` and `LDCLRAL` store to memory with release semantics.
- `LDCLR` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This instruction is used by the alias STCLR, STCLRL.

LDCLRB, LDCLRAB, LDCLRALB, LDCLRLB

Atomic bit clear on byte in memory

This instruction atomically loads an 8-bit byte from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDCLRAB` and `LDCLRALB` load from memory with acquire semantics.
- `LDCLRLB` and `LDCLRALB` store to memory with release semantics.
- `LDCLRB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This instruction is used by the alias STCLRB, STCLRLB.

LDGM

Load tag multiple

This instruction reads a naturally aligned block of N Allocation Tags, where the size of N is identified in GMID_EL1.BS, and writes the Allocation Tag read from address A to the destination register at 4*A<7:4>+3:4*A<7:4>. Bits of the destination register not written with an Allocation Tag are set to 0.

This instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

LDIAPP

Load-Acquire RCpc ordered pair of registers

This instruction calculates an address from a base register value and an optional offset, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The instruction also has memory ordering semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, except that:

- The Memory effects associated with Xt1/Wt1 are Ordered-before the Memory effects associated with Xt2/Wt2.
- There is no ordering requirement, separate from the requirements of a Load-AcquirePC or a Store-Release, created by having a Store-Release followed by a Load-AcquirePC instruction.
- The reading of a value written by a Store-Release by a Load-AcquirePC instruction by the same observer does not make the write of the Store-Release globally observed.

For information about addressing modes, see *Load/Store addressing modes*.

LDPSW

Load pair of registers signed word

This instruction calculates an address from a base register value and an immediate offset, loads two 32-bit words from memory, sign-extends them, and writes them to two registers. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LDR (immediate)

Load register (immediate)

This instruction loads a word or doubleword from memory and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*. The Unsigned offset variant scales the immediate offset value by the size of the value accessed before adding it to the base register value.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

LDRAA, LDRAB

Load register, with pointer authentication

This instruction authenticates an address from a base register using a modifier of zero and the specified key, adds an immediate offset to the authenticated address, and loads a 64-bit doubleword from memory at this resulting address into a register.

Key A is used for `LDRAA`. Key B is used for `LDRAB`.

If the authentication passes, the PE behaves the same as for an `LDR` instruction. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The authenticated address is not written back to the base register, unless the pre-indexed variant of the instruction is used. In this case, the address that is written back to the base register does not include the pointer authentication code.

For information about addressing modes, see *Load/Store addressing modes*.

LDRB (immediate)

Load register byte (immediate)

This instruction loads a byte from memory, zero-extends it, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	0	0	0	0	1	0	imm9									0	1	Rn					Rt				
size					VR			opc																							

LDRB <Wt>, [<Xn|SP>], #<simm>

```
boolean wback = TRUE;
constant boolean postindex = TRUE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	0	0	0	0	1	0	imm9									1	1	Rn					Rt				
size					VR			opc																							

LDRB <Wt>, [<Xn|SP>, #<simm>]!

```
boolean wback = TRUE;
constant boolean postindex = FALSE;
constant bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	0	0	1	0	1	imm12												Rn					Rt				
size					VR			opc																							

LDRB <Wt>, [<Xn|SP>{, #<pimm>}]

```
boolean wback = FALSE;
constant boolean postindex = FALSE;
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 0);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *LDRH (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = wback || n != 31;

Constraint c;
boolean wb_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPLD);
    assert c IN {Constraint_WBSUPPRESS, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_WBSUPPRESS wback = FALSE;        // Writeback is suppressed
        when Constraint_UNKNOWN    wb_unknown = TRUE;    // Writeback is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                     tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

constant bits(8) data = Mem[address, 1, accdesc];
X[t, 32] = ZeroExtend(data, 32);

if wback then
    if wb_unknown then
        address = bits(64) UNKNOWN;
    elsif postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[] = address;
    else
        X[n, 64] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRB (register)

Load register byte (register)

This instruction calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15 14 13	12	11	10	9 8 7 6 5	4 3 2 1 0
0	0	1	1	1	0	0	0	0	1	1	Rm	option	S	1	0	Rn	Rt
size					VR			opc									

Extended register (option != 011)

```
LDRB <Wt>, [<Xn|SP>, (<Wm>|<Xm>), <extend> {<amount>}]
```

Shifted register (option == 011)

```
LDRB <Wt>, [<Xn|SP>, <Xm>{, LSL <amount>}]
```

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = 0;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm>	When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm>	When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.
<extend>	Is the index extend specifier, encoded in “option”:

option	<extend>
010	UXTW
110	SXTW
111	SXTX

<amount>	Is the index shift amount, it must be #0, encoded in "S" as 0 if omitted, or as 1 if present.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = TRUE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,
                                                     tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

constant bits(8) data = Mem[address, 1, accdesc];
X[t, 32] = ZeroExtend(data, 32);
```

Operational information

LDRH (register)

Load register halfword (register)

This instruction calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it, and writes it to a register. For information about addressing modes, see *Load/Store addressing modes*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	0	0	0	1	1	Rm					option			S	1	0	Rn					Rt				
size					VR			opc																							

LDRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);          // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm>	When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm>	When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#1

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = TRUE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,

LDRSH (immediate)

Load register signed halfword (immediate)

This instruction loads a halfword from memory, sign-extends it to 32 bits or 64 bits, and writes the result to a register. The address that is used for the load is calculated from a base register and an immediate offset. For information about addressing modes, see *Load/Store addressing modes*.

It has encodings from 3 classes: Post-index , Pre-index and Unsigned offset

Post-index

LDRSH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

64-bit (opc == 10)

```
LDRSH <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);              // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm>	When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm>	When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#1

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer regsize = 64 >> UInt(opc<0>);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = TRUE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_LOAD, nontemporal, privileged,

LDSET, LDSETA, LDSETAL, LDSETL

Atomic bit set on word or doubleword in memory

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDSETA` and `LDSETAL` load from memory with acquire semantics.
- `LDSETL` and `LDSETAL` store to memory with release semantics.
- `LDSET` has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This instruction is used by the alias STSET, STSETL.

LDSETH, LDSETAH, LDSETALH, LDSETLH

Atomic bit set on halfword in memory

This instruction atomically loads a 16-bit halfword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDSETAH` and `LDSETALH` load from memory with acquire semantics.
- `LDSETLH` and `LDSETALH` store to memory with release semantics.
- `LDSETH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This instruction is used by the alias STSETH, STSETLH.

LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB

Atomic signed minimum on byte in memory

This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDSMINAB` and `LDSMINALB` load from memory with acquire semantics.
- `LDSMINLB` and `LDSMINALB` store to memory with release semantics.
- `LDSMINB` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This instruction is used by the alias STSMINB, STSMINLB.

LDSMINH, LDSMINAH, LDSMINALH, LDSMINLH

Atomic signed minimum on halfword in memory

This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `LDSMINAH` and `LDSMINALH` load from memory with acquire semantics.
- `LDSMINLH` and `LDSMINALH` store to memory with release semantics.
- `LDSMINH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This instruction is used by the alias STSMINH, STSMINLH.

LDTADD, LDTADDA, LDTADDAL, LDTADDL

Atomic add unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR, or XZR, `LDTADDA` and `LDTADDAL` load from memory with acquire semantics.
- `LDTADDL` and `LDTADDAL` store to memory with release semantics.
- `LDTADD` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

This instruction is used by the alias STTADD, STTADDL.

LDTCLR, LDTCLRA, LDTCLRAL, LDTCLRL

Atomic bit clear unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR, or XZR, `LDTCLRA` and `LDTCLRAL` load from memory with acquire semantics.
- `LDTCLRL` and `LDTCLRAL` store to memory with release semantics.
- `LDTCLR` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

This instruction is used by the alias STTCLR, STTCLRL.

LDTR

Load register (unprivileged)

This instruction loads a word or doubleword from memory, and writes it to a register. The address that is used for the load is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.

LDTSET, LDTSETA, LDTSETAL, LDTSETL

Atomic bit set unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR, or XZR, `LDTSETA` and `LDTSETAL` load from memory with acquire semantics.
- `LDTSETL` and `LDTSETAL` store to memory with release semantics.
- `LDTSET` has neither acquire nor release semantics.

For more information about memory ordering semantics see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

This instruction is used by the alias STTSET, STTSETL.

LDTXR

Load unprivileged exclusive register

This instruction derives an address from a base register value, loads a 32-bit word or a 64-bit doubleword from memory, and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `LDTXR` is equivalent to `LDXR`.

For information about addressing modes, see *Load/Store addressing modes*.

LDUMAX, LDUMAXA, LDUMAXAL, LDUMAXL

Atomic unsigned maximum on word or doubleword in memory

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, compares it against the value held in a register, and stores the larger value back to memory, treating the values as unsigned numbers. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `LDUMAXA` and `LDUMAXAL` load from memory with acquire semantics.
- `LDUMAXL` and `LDUMAXAL` store to memory with release semantics.
- `LDUMAX` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This instruction is used by the alias STUMAX, STUMAXL.

LDXP

Load exclusive pair of registers

This instruction derives an address from a base register value, loads two 32-bit words or two 64-bit doublewords from memory, and writes them to two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. For information about addressing modes, see *Load/Store addressing modes*.

LDXRH

Load exclusive register halfword

This instruction derives an address from a base register value, loads a halfword from memory, zero-extends it and writes it to a register. The memory access is atomic. The PE marks the physical address being accessed as an exclusive access. This exclusive access mark is checked by Store Exclusive instructions. See *Synchronization and semaphores*. For information about addressing modes, see *Load/Store addressing modes*.

LSL (immediate)

Logical shift left (immediate)

This instruction shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21 20 19 18 17 16	15 14 13 12 11 10	9 8 7 6 5	4 3 2 1 0
sf	1	0	1	0	0	1	1	0	N	immr	imms	Rn	Rd
	opc												

32-bit (sf == 0 && N == 0 && imms != 011111)

```
LSL <Wd>, <Wn>, #<shift>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #(-<shift> MOD 32), #(31-<shift>)
```

and is the preferred disassembly when `UInt(imms) + 1 == UInt(immr)`.

64-bit (sf == 1 && N == 1 && imms != 111111)

```
LSL <Xd>, <Xn>, #<shift>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #(-<shift> MOD 64), #(63-<shift>)
```

and is the preferred disassembly when `UInt(imms) + 1 == UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<shift>	For the "32-bit" variant: is the shift amount, in the range 0 to 31. For the "64-bit" variant: is the shift amount, in the range 0 to 63.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

LSL (register)

Logical shift left (register)

This instruction shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is left-shifted.

This is an alias of LSLV. This means:

- The encodings in this description are named to match the encodings of LSLV.
- The description of LSLV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

The description of LSLV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

LSLV

Logical shift left variable

This instruction shifts a register value left by a variable number of bits, shifting in zeros, and writes the result to the destination register. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is left-shifted.

This instruction is used by the alias LSL (register).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(op2);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
constant bits(datasize) operand2 = X[m, datasize];

X[d, datasize] = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

LSR (immediate)

Logical shift right (immediate)

This instruction shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MADDPT

Multiply-add checked pointer

This instruction multiplies two register values, adds a third register value, and writes the result to the destination register. The intermediate product is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

If the intermediate product cannot be correctly represented as a 64-bit two's complement value, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)

```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

64-bit (sf == 1)

```
MOV <Xd|SP>, #<imm>
```

is equivalent to

```
ORR <Xd|SP>, XZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

Assembler Symbols

<Wd|WSP>	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.
<imm>	For the "32-bit" variant: is the bitmask immediate, encoded in "imms:immr", but excluding values which could be encoded by MOVZ or MOVN. For the "64-bit" variant: is the bitmask immediate, encoded in "N:imms:immr", but excluding values which could be encoded by MOVZ or MOVN.
<Xd|SP>	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

Operation

The description of ORR (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MOVK

Move wide with keep

This instruction moves an optionally-shifted 16-bit immediate value into a register, keeping other bits unchanged.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	1	1	1	0	0	1	0	1	hw		imm16																Rd				
	opc																														

32-bit (sf == 0 && hw == 0x)

```
MOVK <Wd>, #<imm>{, LSL #<shift>}
```

64-bit (sf == 1)

```
MOVK <Xd>, #<imm>{, LSL #<shift>}
```

```
if sf == '0' && hw<1> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer datasize = 32 << UInt(sf);
constant bits(16) imm = imm16;
constant integer pos = UInt(hw:'0000');
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift>	For the "32-bit" variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the "64-bit" variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

```
bits(datasize) result = X[d, datasize];
result<pos+15:pos> = imm;
X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

MOVN

Move wide with NOT

This instruction moves the inverse of an optionally-shifted 16-bit immediate value to a register.

This instruction is used by the alias MOV (inverted wide immediate).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

```
if sf == '0' && hw<1> == '1' then EndOfDecode(Decode_UNDEF);

constant integer d = UInt(Rd);
constant integer datasize = 32 << UInt(sf);
constant bits(16) imm = imm16;
constant integer pos = UInt(hw:'0000');
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.
<shift>	For the "32-bit" variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the "hw" field as <shift>/16. For the "64-bit" variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the "hw" field as <shift>/16.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Alias Conditions

Alias	Of variant	Is preferred when
MOV (inverted wide immediate)	32-bit	`!(IsZero(imm16) && hw != '00') && !IsOnes(imm16)`
MOV (inverted wide immediate)	64-bit	`!(IsZero(imm16) && hw != '00')`

Operation

```
bits(datasize) result = Zeros(datasize);
result<pos+15:pos> = imm;
X[d, datasize] = NOT(result);
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MOVZ

Move wide with zero

This instruction moves an optionally-shifted 16-bit immediate value to a register.
This instruction is used by the alias MOV (wide immediate).

31	30	29	28	27	26	25	24	23	22 21	20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5	4 3 2 1 0

MSR (immediate)

Move immediate value to special register

This instruction moves an immediate value to selected bits of the PSTATE. For more information, see *Process state, PSTATE*.

The bits that can be written by this instruction are:

- PSTATE.D, PSTATE.A, PSTATE.I, PSTATE.F, and PSTATE.SP.
- If *FEAT_SSBS* is implemented, PSTATE.SSBS.
- If *FEAT_PAN* is implemented, PSTATE.PAN.
- If *FEAT_UAO* is implemented, PSTATE.UAO.
- If *FEAT_DIT* is implemented, PSTATE.DIT.
- If *FEAT_MTE* is implemented, PSTATE.TCO.
- If *FEAT_NMI* is implemented, PSTATE.ALLINT.
- If *FEAT_SME* is implemented, PSTATE.SM and PSTATE.ZA.
- If FEAT_EBEP is implemented, PSTATE.PM.

This instruction is used by the aliases SMSTART, and SMSTOP.

MSR (register)

Move general-purpose register to System register

This instruction allows the PE to write an AArch64 System register from a general-purpose register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18 17 16	15 14 13 12	11 10 9 8	7 6 5	4 3 2 1 0
1	1	0	1	0	1	0	1	0	0	0	1	o0	op1	CRn	CRm	op2	Rt
										L							

```
MSR (<systemreg>|S<op0>_<op1>_<Cn>_<Cm>_<op2>), <Xt>
```

```
constant integer t        = UInt(Rt);
constant integer sys_L    = UInt(L);
constant integer sys_op0 = 2 + UInt(o0);
constant integer sys_op1 = UInt(op1);
constant integer sys_op2 = UInt(op2);
constant integer sys_crn = UInt(CRn);
constant integer sys_crm = UInt(CRm);
```

Assembler Symbols

<systemreg>	Is a System register name, encoded in "o0:op1:CRn:CRm:op2". The System register names are defined in *'AArch64 System Registers' in the System Register XML*.
<op0>	Is an unsigned immediate, encoded in “o0”:

o0	<op0>
0	2
1	3

<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt>	Is the 64-bit name of the general-purpose source register, encoded in the "Rt" field.

Operation

```
AArch64.CheckSystemAccess(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, sys_L);
AArch64.SysRegWrite(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

MSUB

Multiply-subtract

This instruction multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register. This instruction is used by the alias MNEG.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	0	0	1	1	0	1	1	0	0	0	Rm					1	Ra					Rn					Rd				
	op54							op31								o0															

32-bit (sf == 0)

```
MSUB <Wd>, <Wn>, <Wm>, <Wa>
```

64-bit (sf == 1)

```
MSUB <Xd>, <Xn>, <Xm>, <Xa>
```

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Wa>	Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
MNEG	`Ra == '11111'`

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
constant bits(datasize) operand3 = X[a, datasize];

constant integer result = UInt(operand3) - (UInt(operand1) * UInt(operand2));

X[d, datasize] = result<datasize-1:0>;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

MSUBPT

Multiply-subtract checked pointer

This instruction multiplies two register values, subtracts the product from a third register value, and writes the result to the destination register. The intermediate product is treated as the offset.

If the operation would have generated a result where the most significant 8 bits of the result register differ from the most significant 8 bits of the base register, then the result is modified such that it is likely to be non-canonical when used as an address.

If the intermediate product cannot be correctly represented as a 64-bit two's complement value, then the result is modified such that it is likely to be non-canonical when used as an address.

Integer

(FEAT_CPA)

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15	14 13 12 11 10	9 8 7 6 5	4 3 2 1 0

sf	op54							op31				o0			

MSUBPT <Xd>, <Xn>, <Xm>, <Xa>

```
if !IsFeatureImplemented(FEAT_CPA) then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```
constant bits(64) operand1 = X[n, 64];
constant bits(64) operand2 = X[m, 64];
constant bits(64) operand3 = X[a, 64];

bits(64) result;

constant integer product = SInt(operand1) * SInt(operand2);

// Signed and unsigned twos complement arithmetic are equivalent if only a
// fixed number of bits are considered.
result = operand3 - product<63:0>;

constant boolean overflow = (product != SInt(product<63:0>));
result = PointerMultiplyAddCheck(result, operand3, overflow);

X[d, 64] = result;
```

MUL

Multiply

This instruction multiplies two register values and writes the result to the destination register.

This is an alias of MADD. This means:

- The encodings in this description are named to match the encodings of MADD.
- The description of MADD gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	0	0	1	1	0	1	1	0	0	0	Rm					0	1	1	1	1	1	Rn					Rd				
	op54							op31								o0	Ra														

32-bit (sf == 0)

`MUL <Wd>, <Wn>, <Wm>`

is equivalent to

`MADD <Wd>, <Wn>, <Wm>, WZR`

and is always the preferred disassembly.

64-bit (sf == 1)

`MUL <Xd>, <Xn>, <Xm>`

is equivalent to

`MADD <Xd>, <Xn>, <Xm>, XZR`

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

The description of MADD gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MVN

Bitwise NOT

This instruction writes the bitwise inverse of a register value to the destination register.

This is an alias of ORN (shifted register). This means:

- The encodings in this description are named to match the encodings of ORN (shifted register).
- The description of ORN (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	opc									N												Rn									

32-bit (sf == 0)

```
MVN <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit (sf == 1)

```
MVN <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wm>	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xm>	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of ORN (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

	op	S										Rn					

32-bit (sf == 0)

```
NEG <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUB <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

64-bit (sf == 1)

```
NEG <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUB <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wm>	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xm>	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SUB (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

NEGS

Negate, setting flags

This instruction negates an optionally-shifted register value, and writes the result to the destination register. It updates the condition flags based on the result.

This is an alias of SUBS (shifted register). This means:

- The encodings in this description are named to match the encodings of SUBS (shifted register).
- The description of SUBS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	1	1	0	1	0	1	1	shift		0	Rm					imm6						1	1	1	1	1	!= 11111				
	op	S																				Rn					Rd				

32-bit (sf == 0)

`NEGS <Wd>, <Wm>{, <shift> #<amount>}`

is equivalent to

`SUBS <Wd>, WZR, <Wm>{, <shift> #<amount>}`

and is always the preferred disassembly.

64-bit (sf == 1)

`NEGS <Xd>, <Xm>{, <shift> #<amount>}`

is equivalent to

`SUBS <Xd>, XZR, <Xm>{, <shift> #<amount>}`

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wm>	Is the 32-bit name of the general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	RESERVED

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xm>	Is the 64-bit name of the general-purpose source register, encoded in the "Rm" field.

Operation

The description of SUBS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

NGC

Negate with carry

This instruction negates the sum of a register value and the value of NOT (Carry flag), and writes the result to the destination register.

This is an alias of SBC. This means:

- The encodings in this description are named to match the encodings of SBC.
- The description of SBC gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The description of SBCS gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

NOP

No operation

This instruction does nothing, other than advance the value of the program counter by 4. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a `NOP` instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, `NOP` instructions are not suitable for timing loops.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
ORN <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
if sf == '0' && imm6<5> == '1' then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(shift);
constant integer shift_amount = UInt(imm6);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<shift>	Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>	For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field. For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
MVN	`Rn == '11111'`

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount, datasize);

X[d, datasize] = operand1 OR NOT(operand2);
```

Operational information

PACIA, PACIA1716, PACIASP, PACIAZ, PACIZA

Pointer Authentication Code for instruction address, using key A

This instruction computes and inserts a Pointer Authentication Code for an instruction address, using a modifier and key A.

The address is:

- In the general-purpose register that is specified by <Xd> for `PACIA` and `PACIZA`.
- In X17, for `PACIA1716`.
- In X30, for `PACIASP` and `PACIAZ`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for `PACIA`.
- The value zero, for `PACIZA` and `PACIAZ`.
- In X16, for `PACIA1716`.
- In SP, for `PACIASP`.

If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then `PACIA1716` and `PACIASP` include a second modifier that is:

- In X15, for `PACIA1716`.
- The value of PC, for `PACIASP`.

A `PACIASP` instruction has an implicit `BTI` instruction. The implicit `BTI` instruction of a `PACIASP` instruction is always compatible with *PSTATE*.BTYPE == 0b01 and *PSTATE*.BTYPE == 0b10. Controls in *SCTLR_ELx* configure whether the implicit `BTI` instruction of a `PACIASP` instruction is compatible with *PSTATE*.BTYPE == 0b11. For more information, see *PSTATE.BTYPE*.

It has encodings from 2 classes: Integer and System

PACIASPPC

Pointer Authentication Code for return address, using key A

This instruction computes and inserts a Pointer Authentication Code for an instruction address, using two modifiers and key A.
The address is in X30.
The first modifier is in SP.
The second modifier is the value of PC.
A `PACIASPPC` instruction has an implicit `BTI` instruction. The implicit `BTI` instruction of a `PACIASPPC` instruction is always compatible with *PSTATE*.BTYPE == 0b01 and *PSTATE*.BTYPE == 0b10. Controls in *SCTLR_ELx* configure whether the implicit `BTI` instruction of a `PACIASPPC` instruction is compatible with *PSTATE*.BTYPE == 0b11. For more information, see *PSTATE.BTYPE*.

```

PACIB, PACIB1716, PACIBSP, PACIBZ, PACIZB

Pointer Authentication Code for instruction address, using key B

This instruction computes and inserts a Pointer Authentication Code for an instruction address, using a modifier and key B.

The address is:

- In the general-purpose register that is specified by <Xd> for `PACIB` and `PACIZB`.
- In X17, for `PACIB1716`.
- In X30, for `PACIBSP` and `PACIBZ`.

The modifier is:

- In the general-purpose register or stack pointer that is specified by <Xn|SP> for `PACIB`.
- The value zero, for `PACIZB` and `PACIBZ`.
- In X16, for `PACIB1716`.
- In SP, for `PACIBSP`.

If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then `PACIB1716` and `PACIBSP` include a second modifier that is:

- In X15, for `PACIB1716`.
- The value of PC, for `PACIBSP`.

A `PACIBSP` instruction has an implicit `BTI` instruction. The implicit `BTI` instruction of a `PACIBSP` instruction is always compatible with *PSTATE*.BTYPE == 0b01 and *PSTATE*.BTYPE == 0b10. Controls in *SCTLR_ELx* configure whether the implicit `BTI` instruction of a `PACIBSP` instruction is compatible with *PSTATE*.BTYPE == 0b11. For more information, see *PSTATE.BTYPE*.

It has encodings from 2 classes: Integer and System

PRFM (immediate)

Prefetch memory (immediate)

This instruction signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of a `PRFM` instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory*.

For information about addressing modes, see *Load/Store addressing modes*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

```
constant bits(64) offset = LSL(ZeroExtend(imm12, 64), 3);
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = FALSE;
```

Assembler Symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:

PLD
Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.

PLI
Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

PST
Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

IR
When FEAT_PCDPHINT is implemented, intent to read on update, encoded in the "Rt<4:3>" field as 0b11.

<target> is one of:

L1
Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.

L2
Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.

L3
Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

SLC
When FEAT_PRFMSLC is implemented, system level cache, encoded in the "Rt<2:1>" field as 0b11.

If "Rt<4:3>" is 0b11 (IR), <target> is omitted.

<policy> is one of:

KEEP
Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.

STRM
Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

If "Rt<4:3>" is 0b11 (IR), <policy> is omitted.

If "Rt<4:3>" is 0b11 (IR), "Rt<2:0>" is 0b000.

For more information on these prefetch operations, see *Prefetch memory*.

For other encodings of the "Rt" field, use <imm5>.

PRFM (register)

Prefetch memory (register)

This instruction signals the memory system that data memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into one or more caches.

The effect of a `PRFM` instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory*.

For information about addressing modes, see *Load/Store addressing modes*.

Assembler Symbols

<prfop> Is the prefetch operation, defined as <type><target><policy>.

<type> is one of:

PLD

Prefetch for load, encoded in the "Rt<4:3>" field as 0b00.

PLI

Preload instructions, encoded in the "Rt<4:3>" field as 0b01.

PST

Prefetch for store, encoded in the "Rt<4:3>" field as 0b10.

<target> is one of:

L1

Level 1 cache, encoded in the "Rt<2:1>" field as 0b00.

L2

Level 2 cache, encoded in the "Rt<2:1>" field as 0b01.

L3

Level 3 cache, encoded in the "Rt<2:1>" field as 0b10.

SLC

When FEAT_PRFMSLC is implemented, system level cache, encoded in the "Rt<2:1>" field as 0b11.

<policy> is one of:

KEEP

Retained or temporal prefetch, allocated in the cache normally. Encoded in the "Rt<0>" field as 0.

STRM

Streaming or non-temporal prefetch, for data that is used only once. Encoded in the "Rt<0>" field as 1.

For more information on these prefetch operations, see *Prefetch memory*.

For other encodings of the "Rt" field, use <imm5>.

PSB

Profiling synchronization barrier

This instruction is a barrier that ensures that all existing profiling data for the current PE has been formatted, and profiling buffer addresses have been translated such that all writes to the profiling buffer have been initiated. A following `DSB` instruction completes when the writes to the profiling buffer have completed.

If *FEAT_SPE* is not implemented, this instruction executes as a `NOP`.

System
(FEAT_SPE)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PSSBB

Physical speculative store bypass barrier

This instruction is a memory barrier that prevents speculative loads from bypassing earlier stores to the same physical address under certain conditions. For more information and details of the semantics, see *Physical Speculative Store Bypass Barrier (PSSBB)*.

This is an alias of DSB. This means:

- The encodings in this description are named to match the encodings of DSB.
- The description of DSB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	0	1	0	1	0	0	0	0	0	0	1	1	0	0	1	1	0	1	0	0	1	0	0	1	1	1	1	1
																				CRm					opc		Rt				

`PSSBB`

is equivalent to

`DSB #4`

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

RBIT

Reverse bits

This instruction reverses the bit order in a register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	1	0	1	1	0	1	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	Rn					Rd				
		S									opcode2					opcode															

32-bit (sf == 0)

```
RBIT <Wd>, <Wn>
```

64-bit (sf == 1)

```
RBIT <Xd>, <Xn>
```

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer datasize = 32 << UInt(sf);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

```
constant bits(datasize) operand = X[n, datasize];
bits(datasize) result;

for i = 0 to datasize-1
    result<(datasize-1)-i> = operand<i>;

X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

RCWCAS, RCWCASA, RCWCASAL, RCWCASL

Read check write compare and swap doubleword in memory

This instruction reads a 64-bit doubleword from memory, and compares it against the value held in a register. If the comparison is equal, the value in a second register is conditionally written to memory. Storing back to memory is conditional on RCW Checks. If the compare fails or the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the update of memory.

- `RCWCASA` and `RCWCASAL` load from memory with acquire semantics.
- `RCWCASL` and `RCWCASAL` store to memory with release semantics.
- `RCWCAS` has neither acquire nor release semantics.

Integer
(FEAT_THE)

RCWCASP, RCWCASPA, RCWCASPAL, RCWCASPL

Read check write compare and swap quadword in memory

This instruction reads a 128-bit quadword from memory, and compares it against the value held in a pair of registers. If the comparison is equal, the value in a second pair of registers is conditionally written to memory. Storing back to memory is conditional on RCW Checks. If the compare fails or the RCW Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the update of memory.

- `RCWCASPA` and `RCWCASPAL` load from memory with acquire semantics.
- `RCWCASPL` and `RCWCASPAL` store to memory with release semantics.
- `RCWCASP` has neither acquire nor release semantics.

RCWCLR, RCWCLRA, RCWCLRAL, RCWCLRL

Read check write atomic bit clear on doubleword in memory

This instruction atomically loads a 64-bit doubleword from memory, performs a bitwise AND with the complement of the value held in a register on it, and conditionally stores the result back to memory. Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the destination register. This instruction updates the condition flags based on the result of the update of memory.

- `RCWCLRA` and `RCWCLRAL` load from memory with acquire semantics.
- `RCWCLRL` and `RCWCLRAL` store to memory with release semantics.
- `RCWCLR` has neither acquire nor release semantics.

RCWSCAS, RCWSCASA, RCWSCASAL, RCWSCASL

Read check write software compare and swap doubleword in memory

This instruction reads a 64-bit doubleword from memory, and compares it against the value held in a register. If the comparison is equal, the value in a second register is conditionally written to memory. Storing back to memory is conditional on RCW Checks and RCWS Checks. If the compare fails, the RCW Checks fail, or the RCWS Checks fail, the architecture permits writing the value read from the location to memory. If the write is performed, the read and the write occur atomically such that no other modification of the memory location can take place between the read and the write. This instruction updates the condition flags based on the result of the update of memory.

- `RCWSCASA` and `RCWSCASAL` load from memory with acquire semantics.
- `RCWSCASL` and `RCWSCASAL` store to memory with release semantics.
- `RCWSCAS` has neither acquire nor release semantics.

RCWSET, RCWSETA, RCWSETAL, RCWSETL

Read check write atomic bit set on doubleword in memory

This instruction atomically loads a 64-bit doubleword from memory, performs a bitwise OR with the complement of the value held in a register on it, and conditionally stores the result back to memory. Storing of the result back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the destination register. This instruction updates the condition flags based on the result of the update of memory.

- `RCWSETA` and `RCWSETAL` load from memory with acquire semantics.
- `RCWSETL` and `RCWSETAL` store to memory with release semantics.
- `RCWSET` has neither acquire nor release semantics.

RCWSWP, RCWSWPA, RCWSWPAL, RCWSWPL

Read check write swap doubleword in memory

This instruction atomically loads a 64-bit doubleword from a memory location, and conditionally stores the value held in a register back to the same memory location. Storing back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the destination register. This instruction updates the condition flags based on the result of the update of memory.

- `RCWSWPA` and `RCWSWPAL` load from memory with acquire semantics.
- `RCWSWPL` and `RCWSWPAL` store to memory with release semantics.
- `RCWSWP` has neither acquire nor release semantics.

RCWSWPP, RCWSWPPA, RCWSWPPAL, RCWSWPPL

Read check write swap quadword in memory

This instruction atomically loads a 128-bit quadword from a memory location, and conditionally stores the value held in a pair of registers back to the same memory location. Storing back to memory is conditional on RCW Checks. The value initially loaded from memory is returned in the same pair of registers. This instruction updates the condition flags based on the result of the update of memory.

- `RCWSWPPA` and `RCWSWPPAL` load from memory with acquire semantics.
- `RCWSWPPL` and `RCWSWPPAL` store to memory with release semantics.
- `RCWSWPP` has neither acquire nor release semantics.

RETAA, RETAB

Return from subroutine, with pointer authentication

This instruction authenticates the address that is held in LR, using SP as the modifier and the specified key, and branches to the authenticated address, with a hint that this instruction is a subroutine return.

Key A is used for `RETAA`. Key B is used for `RETAB`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The authenticated address is not written back to LR.

If *FEAT_PAuth_LR* is implemented and PSTATE.PACM is 1, then `RETAA` and `RETAB` include a second modifier that is in X16.

Integer

RETAASPPC, RETABSPPC

Return from subroutine, with enhanced pointer authentication return using an immediate offset

This instruction authenticates the address that is held in LR, using SP as the first modifier, the specified immediate subtracted from PC as the second modifier, and the specified key, and branches to the authenticated address, with a hint that this instruction is a subroutine return.

Key A is used for `RETAASPPC`. Key B is used for `RETABSPPC`.

If the authentication passes, the PE continues execution at the target of the branch. For information on behavior if the authentication fails, see *Faulting on pointer authentication*.

The authenticated address is not written back to LR.

REV64

Reverse bytes

This instruction reverses the byte order in a 64-bit general-purpose register.

When assembling for Armv8.2, an assembler must support this pseudo-instruction. It is OPTIONAL whether an assembler supports this pseudo-instruction when assembling for an architecture earlier than Armv8.2.

This is a pseudo-instruction of REV. This means:

- The encodings in this description are named to match the encodings of REV.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of REV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of REV gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

RMIF

Rotate, mask insert flags

This instruction performs a rotation right of a value held in a general-purpose register by an immediate value, and then inserts a selection of the bottom four bits of the result of the rotation into the PSTATE flags, under the control of a second immediate mask.

Integer

(FEAT_FlagM)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ROR (immediate)

Rotate right (immediate)

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

This is an alias of EXTR. This means:

- The encodings in this description are named to match the encodings of EXTR.
- The description of EXTR gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	0	0	1	0	0	1	1	1	N	0	Rm					imms						Rn					Rd				
	op21									o0																					

32-bit (sf == 0 && N == 0 && imms == 0xxxxx)

```
ROR <Wd>, <Ws>, #<shift>
```

is equivalent to

```
EXTR <Wd>, <Ws>, <Ws>, #<shift>
```

and is the preferred disassembly when `Rn == Rm`.

64-bit (sf == 1 && N == 1)

```
ROR <Xd>, <Xs>, #<shift>
```

is equivalent to

```
EXTR <Xd>, <Xs>, <Xs>, #<shift>
```

and is the preferred disassembly when `Rn == Rm`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Ws>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.
<shift>	For the "32-bit" variant: is the amount by which to rotate, in the range 0 to 31, encoded in the "imms" field. For the "64-bit" variant: is the amount by which to rotate, in the range 0 to 63, encoded in the "imms" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xs>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" and "Rm" fields.

Operation

The description of EXTR gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

ROR (register)

Rotate right (register)

This instruction provides the value of the contents of a register rotated by a variable number of bits. The bits that are rotated off the right end are inserted into the vacated bit positions on the left. The value of the second source register modulo the register size in bits gives the number of bits by which the first source register is right-shifted.

This is an alias of RORV. This means:

- The encodings in this description are named to match the encodings of RORV.
- The description of RORV gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 32 << UInt(sf);
constant ShiftType shift_type = DecodeShift(op2);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the "Rm" field.

Operation

```
constant bits(datasize) operand2 = X[m, datasize];

X[d, datasize] = ShiftReg(n, shift_type, UInt(operand2) MOD datasize, datasize);
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

RPRFM

Range prefetch memory

This instruction signals the memory system that data memory accesses from a specified range of addresses are likely to occur in the near future. The instruction may also signal the memory system about the likelihood of data reuse of the specified range of addresses. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as prefetching locations within the specified address ranges into one or more caches. The memory system may also exploit the data reuse hints to decide whether to retain the data in other caches upon eviction from the innermost caches or to discard it.

The effect of an `RPRFM` instruction is IMPLEMENTATION DEFINED. For more information, see *Prefetch memory*.

An `RPRFM` instruction specifies the type of accesses and range of addresses using the following parameters:

- 'Type', in the <rprfop> operand opcode bits, specifies whether the prefetched data will be accessed by load or store instructions.
- 'Policy', in the <rprfop> operand opcode bits, specifies whether the data is likely to be reused or if it is a streaming, non-temporal prefetch. If a streaming prefetch is specified, then the 'ReuseDistance' parameter is ignored.
- 'BaseAddress', in the 64-bit base register, holds the initial block address for the accesses.
- 'ReuseDistance', in the metadata register bits[63:60], indicates the maximum number of bytes to be accessed by this PE before executing the next `RPRFM` instruction that specifies the same range. This includes the total number of bytes inside and outside of the range that will be accessed by the same PE. This parameter can be used to influence cache eviction and replacement policies, in order to retain the data in the most optimal levels of the memory hierarchy after each access. If software cannot easily determine the amount of other memory that will be accessed, these bits can be set to zero to indicate that 'ReuseDistance' is not known. Otherwise, these four bits encode decreasing powers of two in the range 512MiB (0b0001) to 32KiB (0b1111).
- 'Stride', in the metadata register bits[59:38], is a signed, two's complement integer encoding of the number of bytes to advance the block address after 'Length' bytes have been accessed, in the range -2MiB to +2MiB-1B. A negative value indicates that the block address is advanced in a descending direction.
- 'Count', in the metadata register bits[37:22], is an unsigned integer encoding of the number of blocks of data to be accessed minus 1, representing the range 1 to 65536 blocks. If 'Count' is 0, then the 'Stride' parameter is ignored and only a single block of contiguous bytes from 'BaseAddress' to ('BaseAddress' + 'Length' - 1) is described.
- 'Length', in the metadata register bits[21:0], is a signed, two's complement integer encoding of the number of contiguous bytes to be accessed starting from the current block address, without changing the block address, in the range -2MiB to +2MiB-1B. A negative value indicates that the bytes are accessed in a descending direction.

Note

Software is expected to honor the parameters it provides to the `RPRFM` instruction, and the same PE should access all locations in the range, in the direction specified by the sign of the 'Length' and 'Stride' parameters. A range prefetch is considered active on a PE until all locations in the range have been accessed by the PE. A range prefetch might also be inactivated by the PE prior to completion, for example due to a software context switch or lack of hardware resources.

Software should not specify overlapping addresses in multiple active ranges. If a range is expected to be accessed by both load and store instructions (read-modify-write), then a single range with a 'Type' parameter of PST (prefetch for store) should be specified.

Integer

(FEAT_RPRFM)

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15	14	13	12	11	10	9 8 7 6 5	4	3	2	1	0

size					VR			opc				option							Rt				

RPRFM (<rprfop>|#<imm6>), <Xm>, [<Xn|SP>]

```
if !IsFeatureImplemented(FEAT_RPRFM) then EndOfDecode(Decode_NOP);
constant bits(6) operation = option<2>:option<0>:S:Rt<2:0>;
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
```

Assembler Symbols

<rprfop> Is the range prefetch operation, defined as <type><policy>.

<type> is one of:

PLD

Prefetch for load, encoded in the "Rt<0>" field as 0.

PST

Prefetch for store, encoded in the "Rt<0>" field as 1.

<policy> is one of:

KEEP

Retained or temporal prefetch, for data that is expected to be kept in caches to be accessed more than once, encoded in the "option<2>:option<0>:S:Rt<2:1>" fields as 0b00000.

STRM

Streaming or non-temporal prefetch, for data that is expected to be accessed once and not reused, encoded in the "option<2>:option<0>:S:Rt<2:1>" fields as 0b00010.

For other encodings of the "option<2>:option<0>:S:Rt<2:0>" fields, use <imm6>.

option	S	Rt	<rprfop>
010	0	11000	PLDKEEP
010	0	11001	PSTKEEP
010	0	11100	PLDSTRM
010	0	11101	PSTSTRM

<imm6>	Is the range prefetch operation encoding as an immediate, in the range 0 to 63, encoded in "option<2>:option<0>:S:Rt<2:0>". This syntax is only for encodings that are not representable using <rprfop>.
<Xm>	Is the 64-bit name of the general-purpose register that holds an encoding of the metadata, encoded in the "Rm" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

```
constant bits(64) address  = if n == 31 then SP[] else X[n, 64];
constant bits(64) metadata = X[m, 64];
constant integer stride = SInt(metadata<59:38>);
constant integer count  = UInt(metadata<37:22>) + 1;
constant integer length = SInt(metadata<21:0>);
integer reuse;

if metadata<63:60> == '0000' then
    reuse = -1; // Not known
else
    reuse = 32768 << (15 - UInt(metadata<63:60>));

Hint_RangePrefetch(address, length, stride, count, reuse, operation);
```

	opc																														

32-bit (sf == 0 && N == 0)

```
SBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit (sf == 1 && N == 1)

```
SBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.

  - The values of the NZCV flags.

SBFM

Signed bitfield move

This instruction is usually accessed via one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the destination bits below the bitfield are set to zero, and the bits above the bitfield are set to a copy of the most significant bit of the bitfield.

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<immr>	For the "32-bit" variant: is the right rotate amount, in the range 0 to 31, encoded in the "immr" field. For the "64-bit" variant: is the right rotate amount, in the range 0 to 63, encoded in the "immr" field.
<imms>	For the "32-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the "imms" field. For the "64-bit" variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the "imms" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Alias Conditions

Alias	Of variant	Is preferred when
ASR (immediate)	32-bit	`imms == '011111'`
ASR (immediate)	64-bit	`imms == '111111'`
SBFIZ		`UInt(imms) < UInt(immr)`
SBFX		`BFXPreferred(sf, opc<1>, imms, immr)`
SXTB		`immr == '000000' && imms == '000111'`

Alias	Of variant	Is preferred when
SXTH		`immr == '000000' && imms == '001111'`
SXTW		`immr == '000000' && imms == '011111'`

Operation

```
constant bits(datasize) src = X[n, datasize];

// Perform bitfield move on low bits
constant bits(datasize) bot = ROR(src, r) AND wmask;

constant bits(datasize) top = Replicate(src<s>, datasize);

// Combine extension bits and result bits
X[d, datasize] = (top AND NOT(tmask)) OR (bot AND tmask);
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

SBFX

Signed bitfield extract

This instruction copies a bitfield of <width> bits starting from bit position <lsb> in the source register to the least significant bits of the destination register, and sets destination bits above the bitfield to a copy of the most significant bit of the bitfield.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

SETF8, SETF16

Evaluation of 8-bit or 16-bit flag values

This instruction sets the PSTATE.NZV flags based on the value in the specified general-purpose register. `SETF8` treats the value as an 8-bit value. `SETF16` treats the value as a 16-bit value.
The PSTATE.C flag is not affected by these instructions.

SETGP, SETGM, SETGE

Memory set with tag setting

These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGP, then SETGM, and then SETGE.

SETGP performs some preconditioning of the arguments suitable for using the SETGM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGM performs an IMPLEMENTATION DEFINED amount of the memory set. SETGE performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGP, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGP, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETGE, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGE, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

SETGPN, SETGMN, SETGEN

Memory set with tag setting, non-temporal

These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPN, then SETGMN, and then SETGEN.

SETGPN performs some preconditioning of the arguments suitable for using the SETGMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGMN performs an IMPLEMENTATION DEFINED amount of the memory set. SETGEN performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGPN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGPN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETGEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

```

SETGPT, SETGMT, SETGET

Memory set with tag setting, unprivileged

These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPT, then SETGMT, and then SETGET.

SETGPT performs some preconditioning of the arguments suitable for using the SETGMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGMT performs an IMPLEMENTATION DEFINED amount of the memory set. SETGET performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGPT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGPT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETGET, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGET, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

SETGPTN, SETGMTN, SETGETN

Memory set with tag setting, unprivileged and non-temporal

These instructions perform a memory set using the value in the bottom byte of the source register and store an Allocation Tag to memory for each Tag Granule written. The Allocation Tag is calculated from the Logical Address Tag in the register which holds the first address that the set is made to. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETGPTN, then SETGMTN, and then SETGETN.

SETGPTN performs some preconditioning of the arguments suitable for using the SETGMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETGMTN performs an IMPLEMENTATION DEFINED amount of the memory set. SETGETN performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETGPTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETGPTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFF0.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETGMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* number of bytes remaining to be set in the memory set in total.

For SETGMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
    - the value of Xd is written back with the lowest address that has not been set.

For SETGETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETGETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xd is written back with the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

SETP, SETM, SETE

Memory set

These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETP, then SETM, and then SETE.

SETP performs some preconditioning of the arguments suitable for using the SETM instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETM performs an IMPLEMENTATION DEFINED amount of the memory set. SETE performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETP, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETP, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETM, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETM, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
    - the value of Xd is written back with the lowest address that has not been set.

For SETE, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETE, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xd is written back with the lowest address that has not been set.

SETPN, SETMN, SETEN

Memory set, non-temporal

These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPN, then SETMN, and then SETEN.

SETPN performs some preconditioning of the arguments suitable for using the SETMN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETMN performs an IMPLEMENTATION DEFINED amount of the memory set. SETEN performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETPN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETMN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETMN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
    - the value of Xd is written back with the lowest address that has not been set.

For SETEN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETEN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xd is written back with the lowest address that has not been set.

SETPT, SETMT, SETET

Memory set, unprivileged

These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPT, then SETMT, and then SETET.

SETPT performs some preconditioning of the arguments suitable for using the SETMT instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETMT performs an IMPLEMENTATION DEFINED amount of the memory set. SETET performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPT, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETPT, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETMT, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETMT, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
  - the value of Xd is written back with the lowest address that has not been set.

For SETET, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETET, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
  - the value of Xn is written back with 0.
  - the value of Xd is written back with the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

SETPTN, SETMTN, SETETN

Memory set, unprivileged and non-temporal

These instructions perform a memory set using the value in the bottom byte of the source register. The prologue, main, and epilogue instructions are expected to be run in succession and to appear consecutively in memory: SETPTN, then SETMTN, and then SETETN.

SETPTN performs some preconditioning of the arguments suitable for using the SETMTN instruction, and performs an IMPLEMENTATION DEFINED amount of the memory set. SETMTN performs an IMPLEMENTATION DEFINED amount of the memory set. SETETN performs the last part of the memory set.

Note

The inclusion of IMPLEMENTATION DEFINED amounts of memory set allows some optimization of the size that can be performed.

The architecture supports two algorithms for the memory set: option A and option B. Which algorithm is used is IMPLEMENTATION DEFINED.

Note

Portable software should not assume that the choice of algorithm is constant.

After execution of SETPTN, option A (which results in encoding PSTATE.C = 0):

- If Xn<63> == 1, the set size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + saturated Xn.
- Xn holds -1* saturated Xn + an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

After execution of SETPTN, option B (which results in encoding PSTATE.C = 1):

- If Xn<63> == 1, the copy size is saturated to 0x7FFFFFFFFFFFFFFF.
- Xd holds the original Xd + an IMPLEMENTATION DEFINED number of bytes set.
- Xn holds the saturated Xn - an IMPLEMENTATION DEFINED number of bytes set.
- PSTATE.{N,Z,V} are set to {0,0,0}.

For SETMTN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with -1* the number of bytes remaining to be set in the memory set in total.

For SETMTN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
    - the value of Xn is written back with the number of bytes remaining to be set in the memory set in total.
    - the value of Xd is written back with the lowest address that has not been set.

For SETETN, option A (encoded by PSTATE.C = 0), the format of the arguments is:

- Xn is treated as a signed 64-bit number.
- Xn holds -1* the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to -Xn.
- At the end of the instruction, the value of Xn is written back with 0.

For SETETN, option B (encoded by PSTATE.C = 1), the format of the arguments is:

- Xn holds the number of bytes remaining to be set in the memory set in total.
- Xd holds the lowest address that the set is made to.
- At the end of the instruction:
    - the value of Xn is written back with 0.
    - the value of Xd is written back with the lowest address that has not been set.

Explicit Memory Write effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory Write effects operate with the restrictions determined by the Exception level at which the instruction is executed.

SMADDL <Xd>, <Wn>, <Wm>, <Xa>
```

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
SMULL	`Ra == '11111'`

Operation

```
constant bits(32) operand1 = X[n, 32];
constant bits(32) operand2 = X[m, 32];
constant bits(64) operand3 = X[a, 64];

constant integer result = SInt(operand3) + (SInt(operand1) * SInt(operand2));

X[d, 64] = result<63:0>;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

SMC

Secure monitor call

This instruction causes an exception to EL3.

`SMC` is available only for software executing at EL1 or higher. It is UNDEFINED in EL0.

If the values of HCR_EL2.TSC and SCR_EL3.SMD are both 0, execution of an `SMC` instruction at EL1 or higher generates a Secure Monitor Call exception, recording it in *ESR_ELx*, using the EC value 0x17, that is taken to EL3.

If the value of HCR_EL2.TSC is 1 and EL2 is enabled in the current Security state, execution of an `SMC` instruction at EL1 generates an exception that is taken to EL2, regardless of the value of SCR_EL3.SMD.

If the value of HCR_EL2.TSC is 0 and the value of SCR_EL3.SMD is 1, the SMC instruction is UNDEFINED.

`SSBB`

is equivalent to

`DSB #0`

and is always the preferred disassembly.

Operation

The description of DSB gives the operational pseudocode for this instruction.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

ST2G

Store Allocation Tags

This instruction stores an Allocation Tag to two Tag Granules of memory. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag Granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

Post-index

ST64B

Single-copy atomic 64-byte store without status result

This instruction stores eight 64-bit doublewords from consecutive registers to a memory location. The store starts at register Xt, with the data being formed as Data<511:0> = X(t+7):X(t+6):X(t+5):X(t+4):X(t+3):X(t+2):X(t+1):Xt. The data is stored atomically and is required to be 64-byte aligned.

It is IMPLEMENTATION DEFINED which memory locations support this instruction. A memory location that supports `ST64B` also supports `LD64B`. For more information, including about the memory types accessible and how the accesses are performed, see *Single-copy atomic 64-byte load/store*.

STADD, STADDL

Atomic add on word or doubleword in memory, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, adds the value held in a register to it, and stores the result back to memory.

- `STADD` does not have release semantics.
- `STADDL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDADD, LDADDA, LDADDAL, LDADDL. This means:

- The encodings in this description are named to match the encodings of LDADD, LDADDA, LDADDAL, LDADDL.
- The description of LDADD, LDADDA, LDADDAL, LDADDL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

STEOR, STEORL

Atomic exclusive-OR on word or doubleword in memory, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs an exclusive-OR with the value held in a register on it, and stores the result back to memory.

- `STEOR` does not have release semantics.
- `STEORL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDEOR, LDEORA, LDEORAL, LDEORL. This means:

- The encodings in this description are named to match the encodings of LDEOR, LDEORA, LDEORAL, LDEORL.
- The description of LDEOR, LDEORA, LDEORAL, LDEORL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

STILP

Store-release ordered pair of registers

This instruction calculates an address from a base register value and an optional offset, and stores two 32-bit words or two 64-bit doublewords to the calculated address, from two registers. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. The instruction also has memory ordering semantics, as described in *Load-Acquire, Load-AcquirePC, and Store-Release*, with the additional requirement that:

- When using the pre-index addressing mode, the Memory effects associated with Xt2/Wt2 are Ordered-before the Memory effects associated with Xt1/Wt1.
- For all other addressing modes, the Memory effects associated with Xt1/Wt1 are Ordered-before the Memory effects associated with Xt2/Wt2.

For information about addressing modes, see *Load/Store addressing modes*.

STLTXR

Store-release unprivileged exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `STLTXR` is equivalent to `STXR`.

For information about addressing modes, see *Load/Store addressing modes*.

        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

`STLTXR` has the same CONSTRAINED UNPREDICTABLE behavior as `STLXR`. See *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXR*.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is: **0** If the operation updates memory. **1** If the operation fails to update memory.
<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(elsize) data;

constant integer dbytes = elsize DIV 8;
constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel,
                                                        tagchecked, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(elsize) UNKNOWN;
else
    data = X[t, elsize];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64.ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64.ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STLXP

Store-release exclusive pair of registers

This instruction stores two 32-bit words or two 64-bit doublewords to a memory location if the PE has exclusive access to the memory address, from two registers, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. The instruction also has memory ordering semantics, as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is: **0** If the operation updates memory. **1** If the operation fails to update memory.
<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(datasize) data;

constant integer dbytes = datasize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel,
                                                        tagchecked, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    constant bits(datasize DIV 2) el1 = X[t, datasize DIV 2];
    constant bits(datasize DIV 2) el2 = X[t2, datasize DIV 2];
    data = if BigEndian(accdesc.acctype) then el1:el2 else el2:el1;
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64.ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64.ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STLXR

Store-release exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. The memory access is atomic. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*. For information about addressing modes, see *Load/Store addressing modes*.

        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STLXRH*.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is: **0** If the operation updates memory. **1** If the operation fails to update memory.
<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(16) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel,
                                                         tagchecked, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t, 16];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64.ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64.ExclusiveMonitorsPass(address, 2, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Assembler Symbols

<Wt1>	Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<imm>	For the "32-bit Post-index" and "32-bit Pre-index" variants: is the signed immediate byte offset, a multiple of 4 in the range -256 to 252, encoded in the "imm7" field as <imm>/4. For the "64-bit Post-index" and "64-bit Pre-index" variants: is the signed immediate byte offset, a multiple of 8 in the range -512 to 504, encoded in the "imm7" field as <imm>/8. For the "32-bit Signed offset" variant: is the optional signed immediate byte offset, a multiple of 4 in the range -256 to 252, defaulting to 0 and encoded in the "imm7" field as <imm>/4. For the "64-bit Signed offset" variant: is the optional signed immediate byte offset, a multiple of 8 in the range -512 to 504, defaulting to 0 and encoded in the "imm7" field as <imm>/8.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

STR (register)

Store register (register)

This instruction calculates an address from a base register value and an offset register value, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about addressing modes, see *Load/Store addressing modes*.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

64-bit (size == 11)

```
STR <Xt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]
```

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer scale = UInt(size);
constant integer shift = if S == '1' then scale else 0;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm>	When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm>	When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> For the "32-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#2

For the "64-bit" variant: is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#3

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer datasize = 8 << scale;
constant boolean nontemporal = FALSE;
constant boolean tagchecked = TRUE;

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STRH (immediate)*.

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the "imm9" field.
<pimm>	Is the optional positive immediate byte offset, a multiple of 2 in the range 0 to 8190, defaulting to 0 and encoded in the "imm12" field as <pimm>/2.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = wback || n != 31;

Constraint c;
boolean rt_unknown = FALSE;
if wback && n == t && n != 31 then
    c = ConstrainUnpredictable(Unpredictable_WBOVERLAPST);
    assert c IN {Constraint_NONE, Constraint_UNKNOWN, Constraint_UNDEF, Constraint_NOP};
    case c of
        when Constraint_NONE    rt_unknown = FALSE;    // Value stored is original value
        when Constraint_UNKNOWN rt_unknown = TRUE;     // Value stored is UNKNOWN
        when Constraint_UNDEF   EndOfDecode(Decode_UNDEF);
        when Constraint_NOP     EndOfDecode(Decode_NOP);
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                     tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

if !postindex then
    address = AddressAdd(address, offset, accdesc);

bits(16) data;
if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t, 16];

Mem[address, 2, accdesc] = data;

if wback then
    if postindex then
        address = AddressAdd(address, offset, accdesc);
    if n == 31 then
        SP[] = address;
    else
        X[n, 64] = address;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STRH (register)

Store register halfword (register)

This instruction calculates an address from a base register value and an offset register value, and stores a halfword from a 32-bit register to the calculated address. For information about addressing modes, see *Load/Store addressing modes*.

The instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an offset register value. The offset can be optionally shifted and extended.

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15 14 13	12	11	10	9 8 7 6 5	4 3 2 1 0
0	1	1	1	1	0	0	0	0	0	1	Rm	option	S	1	0	Rn	Rt
size					VR			opc									

STRH <Wt>, [<Xn|SP>, (<Wm>|<Xm>){, <extend> {<amount>}}]

```
if option<1> == '0' then EndOfDecode(Decode_UNDEF);             // sub-word index
constant ExtendType extend_type = DecodeRegExtend(option);
constant integer shift = if S == '1' then 1 else 0;
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Wm>	When option<0> is set to 0, is the 32-bit name of the general-purpose index register, encoded in the "Rm" field.
<Xm>	When option<0> is set to 1, is the 64-bit name of the general-purpose index register, encoded in the "Rm" field.

<extend> Is the index extend/shift specifier, defaulting to LSL, and which must be omitted for the LSL option when <amount> is omitted. encoded in “option”:

option	<extend>
010	UXTW
011	LSL
110	SXTW
111	SXTX

<amount> Is the index shift amount, optional only when <extend> is not LSL. Where it is permitted to be optional, it defaults to #0. It is encoded in “S”:

S	<amount>
0	#0
1	#1

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant boolean nontemporal = FALSE;
constant boolean tagchecked = TRUE;
```

Operation

```
constant bits(64) offset = ExtendReg(m, extend_type, shift, 64);
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                     tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, 2, accdesc] = X[t, 16];
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STSET, STSETL

Atomic bit set on word or doubleword in memory, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STSET` does not have release semantics.
- `STSETL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDSET, LDSETA, LDSETAL, LDSETL. This means:

- The encodings in this description are named to match the encodings of LDSET, LDSETA, LDSETAL, LDSETL.
- The description of LDSET, LDSETA, LDSETAL, LDSETL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

STSHH

Store shared hint

This instruction signals to the memory system that if the next instruction in program order generates an explicit write effect, then it is to a location that one or more other threads of execution will observe, and there is a performance benefit to ensuring that the updated value from the write to that location propagates to those other observers with minimal latency.

The thread of execution on the other observers might be polling the location using load or load-exclusive instructions, or may have executed a `PRFM IR` instruction targeting the location.

System

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

STSMINB, STSMINLB

Atomic signed minimum on byte in memory, without return

This instruction atomically loads an 8-bit byte from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

- `STSMINB` does not have release semantics.
- `STSMINLB` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB. This means:

- The encodings in this description are named to match the encodings of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB.
- The description of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDSMINB, LDSMINAB, LDSMINALB, LDSMINLB gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STSMINH, STSMINLH

Atomic signed minimum on halfword in memory, without return

This instruction atomically loads a 16-bit halfword from memory, compares it against the value held in a register, and stores the smaller value back to memory, treating the values as signed numbers.

- `STSMINH` does not have release semantics.
- `STSMINLH` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

STTNP

Store unprivileged pair of registers, with non-temporal hint

This instruction calculates an address from a base register value and an immediate offset, and stores two 64-bit doublewords to the calculated address, from two registers. For information about addressing modes, see *Load/Store addressing modes*. For information about non-temporal pair instructions, see *Load/Store non-temporal pair*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

STTRH

Store register halfword (unprivileged)

This instruction stores a halfword from a 32-bit register to memory. The address that is used for the store is calculated from a base register and an immediate offset.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

For information about addressing modes, see *Load/Store addressing modes*.

size					VR			opc																							

STTRH <Wt>, [<Xn|SP>{, #<simm>}]

```
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.

Shared Decode

```
constant integer t = UInt(Rt);
constant integer n = UInt(Rn);

constant integer datasize = 16;
constant boolean nontemporal = FALSE;
constant boolean tagchecked = n != 31;
```

Operation

```
bits(64) address;

constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                     tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

STTSET, STTSETL

Atomic bit set unprivileged, without return

This instruction atomically loads a 32-bit word or 64-bit doubleword from memory, performs a bitwise OR with the value held in a register on it, and stores the result back to memory.

- `STTSET` does not have release semantics.
- `STTSETL` stores to memory with release semantics, as described in *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

This is an alias of LDTSET, LDTSETA, LDTSETAL, LDTSETL. This means:

- The encodings in this description are named to match the encodings of LDTSET, LDTSETA, LDTSETAL, LDTSETL.
- The description of LDTSET, LDTSETA, LDTSETAL, LDTSETL gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xs>	Is the 64-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.

Operation

The description of LDTSET, LDTSETA, LDTSETAL, LDTSETL gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

STTXR

Store unprivileged exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

Note

For the purposes of the Exclusives monitors, and the forward progress guarantees for Load-Exclusive and Store-Exclusive loops, `STTXR` is equivalent to `STXR`.

For information about addressing modes, see *Load/Store addressing modes*.

        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

`STTXR` has the same CONSTRAINED UNPREDICTABLE behavior as `STXR`. See *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXR*.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is: **0** If the operation updates memory. **1** If the operation fails to update memory.
<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(elsize) data;

constant integer dbytes = elsize DIV 8;
constant boolean privileged = AArch64.IsUnprivAccessPriv();
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel,
                                                        tagchecked, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(elsize) UNKNOWN;
else
    data = X[t, elsize];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64.ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64.ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

No memory ordering (R == 0)

```
STUMINH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMINH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Release (R == 1)

```
STUMINLH <Ws>, [<Xn|SP>]
```

is equivalent to

```
LDUMINLH <Ws>, WZR, [<Xn|SP>]
```

and is always the preferred disassembly.

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register holding the data value to be operated on with the contents of the memory location, encoded in the "Rs" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Operation

The description of LDUMINH, LDUMINAH, LDUMINALH, LDUMINLH gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

STUR

Store register (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a 32-bit word or a 64-bit doubleword to the calculated address, from a register. For information about addressing modes, see *Load/Store addressing modes*.

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16 15 14 13 12	11	10	9 8 7 6 5	4 3 2 1 0
1	x	1	1	1	0	0	0	0	0	0	imm9	0	0	Rn	Rt
size					VR			opc							

32-bit (size == 10)

```
STUR <Wt>, [<Xn|SP>{, #<simm>}]
```

64-bit (size == 11)

```
STUR <Xt>, [<Xn|SP>{, #<simm>}]
```

```
constant integer scale = UInt(size);
constant bits(64) offset = SignExtend(imm9, 64);
```

Assembler Symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the "imm9" field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

Shared Decode

```
constant integer n = UInt(Rn);
constant integer t = UInt(Rt);
constant integer datasize = 8 << scale;
constant boolean nontemporal = FALSE;
constant boolean tagchecked = n != 31;
```

Operation

```
bits(64) address;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescGPR(MemOp_STORE, nontemporal, privileged,
                                                     tagchecked);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n, 64];

address = AddressAdd(address, offset, accdesc);

Mem[address, datasize DIV 8, accdesc] = X[t, datasize];
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STURB

Store register byte (unscaled)

This instruction calculates an address from a base register value and an immediate offset, and stores a byte to the calculated address, from a 32-bit register. For information about addressing modes, see *Load/Store addressing modes*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

STXP

Store exclusive pair of registers

This instruction stores two 32-bit words or two 64-bit doublewords from two registers to a memory location if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*. For information on single-copy atomicity and alignment requirements, see *Requirements for single-copy atomicity* and *Alignment of data accesses*. If a 64-bit pair Store-Exclusive succeeds, it causes a single-copy atomic update of the 128-bit memory location being updated. For information about addressing modes, see *Load/Store addressing modes*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

        when Constraint_UNKNOWN    rn_unknown = TRUE;    // address is UNKNOWN
        when Constraint_UNDEF      EndOfDecode(Decode_UNDEF);
        when Constraint_NOP        EndOfDecode(Decode_NOP);
```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXP*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0

If the operation updates memory.

1

If the operation fails to update memory.

<Wt1> Is the 32-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.

<Wt2>	Is the 32-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.
<Xt1>	Is the 64-bit name of the first general-purpose register to be transferred, encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second general-purpose register to be transferred, encoded in the "Rt2" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

Accessing an address that is not aligned to the size of the data being accessed causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(datasize) data;

constant integer dbytes = datasize DIV 8;
constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel,
                                                        tagchecked, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(datasize) UNKNOWN;
else
    constant bits(datasize DIV 2) el1 = X[t, datasize DIV 2];
    constant bits(datasize DIV 2) el2 = X[t2, datasize DIV 2];
    data = if BigEndian(accdesc.acctype) then el1:el2 else el2:el1;
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64.ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64.ExclusiveMonitorsPass(address, dbytes, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, dbytes, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STXR

Store exclusive register

This instruction stores a 32-bit word or a 64-bit doubleword from a register to memory if the PE has exclusive access to the memory address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed. See *Synchronization and semaphores*.

For information about addressing modes, see *Load/Store addressing modes*.

```

For information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *STXRB*.

Assembler Symbols

<Ws> Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is:

0

If the operation updates memory.

1

If the operation fails to update memory.

<Wt> Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(8) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel,
                                                        tagchecked, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(8) UNKNOWN;
else
    data = X[t, 8];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64.ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64.ExclusiveMonitorsPass(address, 1, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 1, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

```

Assembler Symbols

<Ws>	Is the 32-bit name of the general-purpose register into which the status result of the store exclusive is written, encoded in the "Rs" field. The value returned is: **0** If the operation updates memory. **1** If the operation fails to update memory.
<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the "Rt" field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Ws> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch64.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
bits(64) address;
bits(16) data;

constant boolean privileged = PSTATE.EL != EL0;
constant AccessDescriptor accdesc = CreateAccDescExLDST(MemOp_STORE, acqrel,
                                                        tagchecked, privileged);

if n == 31 then
    CheckSPAlignment();
    address = SP[];
elsif rn_unknown then
    address = bits(64) UNKNOWN;
else
    address = X[n, 64];

if rt_unknown then
    data = bits(16) UNKNOWN;
else
    data = X[t, 16];
bit status = '1';
// Check whether the Exclusives monitors are set to include the
// physical memory locations corresponding to virtual address
// range [address, address+dbytes-1].
// If AArch64.ExclusiveMonitorsPass() returns FALSE and the memory address,
// if accessed, would generate a synchronous Data Abort exception, it is
// IMPLEMENTATION DEFINED whether the exception is generated.
// It is a limitation of this model that synchronous Data Aborts are never
// generated in this case, as Mem[] is not called.

// If FEAT_SPE is implemented, it is also IMPLEMENTATION DEFINED whether or not the
// physical address packet is output when permitted and when
// AArch64.ExclusiveMonitorPass() returns FALSE for a Store Exclusive instruction.
// This behavior is not reflected here due to the previously stated limitation.
if AArch64.ExclusiveMonitorsPass(address, 2, accdesc) then
    // This atomic write will be rejected if it does not refer
    // to the same physical locations after address translation.
    Mem[address, 2, accdesc] = data;
    status = ExclusiveMonitorsStatus();
X[s, 32] = ZeroExtend(status, 32);
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STZ2G

Store Allocation Tags, zeroing

This instruction stores an Allocation Tag to two Tag Granules of memory, zeroing the associated data locations. The address used for the store is calculated from the base register and an immediate signed offset scaled by the Tag Granule. The Allocation Tag is calculated from the Logical Address Tag in the source register.

This instruction generates an Unchecked access.

It has encodings from 3 classes: Post-index , Pre-index and Signed offset

STZGM

Store Allocation Tag and zero multiple

This instruction writes a naturally aligned block of N Allocation Tags and stores zero to the associated data locations, where the size of N is identified in DCZID_EL0.BS, and the Allocation Tag is taken from the source register bits<3:0>.

This instruction is UNDEFINED at EL0.

This instruction generates an Unchecked access.

Integer

SUB (extended register)

Subtract extended and scaled register

This instruction subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword.

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15 14 13	12 11 10	9 8 7 6 5	4 3 2 1 0
sf	1	0	0	1	0	1	1	0	0	1	Rm	option	imm3	Rn	Rd
	op	S						opt							

32-bit (sf == 0)

```
SUB <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit (sf == 1)

```
SUB <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer shift = UInt(imm3);
constant integer datasize = 32 << UInt(sf);
constant ExtendType extend_type = DecodeRegExtend(option);
```

Assembler Symbols

<Wd|WSP> Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Wn|WSP> Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rd" or "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

<Xd|SP> Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the "Rd" field.

<Xn|SP> Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.

<R> Is a width specifier, encoded in “option”:

option	<R>
00x	W
010	W
x11	X
10x	W
110	W

<m> Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[]<datasize-1:0> else X[n, datasize];
constant bits(datasize) operand2 = NOT(ExtendReg(m, extend_type, shift, datasize));
bits(datasize) result;

(result, -) = AddWithCarry(operand1, operand2, '1');

if d == 31 then
    SP[] = ZeroExtend(result, 64);
else
    X[d, datasize] = result;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

SUBG

Subtract with tag

This instruction subtracts an immediate value scaled by the Tag Granule from the address in the source register, modifies the Logical Address Tag of the address using an immediate value, and writes the result to the destination register. Tags specified in GCR_EL1.Exclude are excluded from the possible outputs when modifying the Logical Address Tag.

SUBS (extended register)

Subtract extended and scaled register, setting flags

This instruction subtracts a sign or zero-extended register value, followed by an optional left shift amount, from a register value, and writes the result to the destination register. The argument that is extended from the <Rm> register can be a byte, halfword, word, or doubleword. It updates the condition flags based on the result.

This instruction is used by the alias CMP (extended register).

31	30	29	28	27	26	25	24	23	22	21	20 19 18 17 16	15 14 13	12 11 10	9 8 7 6 5	4 3 2 1 0
sf	1	1	0	1	0	1	1	0	0	1	Rm	option	imm3	Rn	Rd
	op	S						opt							

32-bit (sf == 0)

```
SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit (sf == 1)

```
SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```
if imm3 IN {'101', '110', '111'} then EndOfDecode(Decode_UNDEF);
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer shift = UInt(imm3);
constant integer datasize = 32 << UInt(sf);
constant ExtendType extend_type = DecodeRegExtend(option);
```

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn|WSP>	Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<extend> For the "32-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	LSL|UXTW
011	UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (WSP) and "option" is '010' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTW when "option" is '010'.

For the "64-bit" variant: is the extension to be applied to the second source operand, encoded in “option”:

option	<extend>
000	UXTB
001	UXTH
010	UXTW
011	LSL|UXTX
100	SXTB
101	SXTH
110	SXTW
111	SXTX

If "Rn" is '11111' (SP) and "option" is '011' then LSL is preferred, but may be omitted when "imm3" is '000'. In all other cases <extend> is required and must be UXTX when "option" is '011'.

<amount>	Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the "imm3" field. It must be absent when <extend> is absent, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn|SP>	Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the "Rn" field.
<R>	Is a width specifier, encoded in “option”:

option	<R>
`00x`	`W`
`010`	`W`
`x11`	`X`
`10x`	`W`
`110`	`W`

<m>	Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the "Rm" field.

Alias Conditions

Alias	Is preferred when
CMP (extended register)	`Rd == '11111'`

Operation

```
constant bits(datasize) operand1 = if n == 31 then SP[]<datasize-1:0> else X[n, datasize];
constant bits(datasize) operand2 = NOT(ExtendReg(m, extend_type, shift, datasize));
bits(datasize) result;
bits(4) nzcv;

(result, nzcv) = AddWithCarry(operand1, operand2, '1');

X[d, datasize] = result;
PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

SWP, SWPA, SWPAL, SWPL

Swap word or doubleword in memory

This instruction atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `SWPA` and `SWPAL` load from memory with acquire semantics.
- `SWPL` and `SWPAL` store to memory with release semantics.
- `SWP` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

SWPH, SWPAH, SWPALH, SWPLH

Swap halfword in memory

This instruction atomically loads a 16-bit halfword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not WZR, `SWPAH` and `SWPALH` load from memory with acquire semantics.
- `SWPLH` and `SWPALH` store to memory with release semantics.
- `SWPH` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

else
    X[t, 64]  = data<63:0>;
    X[t2, 64] = data<127:64>;
```

Operational information

If PSTATE.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

SWPT, SWPTA, SWPTAL, SWPTL

Swap unprivileged

This instruction atomically loads a 32-bit word or 64-bit doubleword from a memory location, and stores the value held in a register back to the same memory location. The value initially loaded from memory is returned in the destination register.

- If the destination register is not one of WZR or XZR, `SWPTA` and `SWPTAL` load from memory with acquire semantics.
- `SWPTL` and `SWPTAL` store to memory with release semantics.
- `SWPT` has neither acquire nor release semantics.

For more information about memory ordering semantics, see *Load-Acquire, Store-Release*.

For information about addressing modes, see *Load/Store addressing modes*.

Explicit Memory effects produced by the instruction behave as if the instruction was executed at EL0 if the *Effective value* of PSTATE.UAO is 0 and either:

- The instruction is executed at EL1.
- The instruction is executed at EL2 when the *Effective value* of HCR_EL2.{E2H, TGE} is {1, 1}.

Otherwise, the Explicit Memory effects operate with the restrictions determined by the Exception level at which the instruction is executed.

SXTB

Signed extend byte

This instruction extracts an 8-bit value from a register, sign-extends it to the size of the register, and writes the result to the destination register.

This is an alias of SBFM. This means:

- The encodings in this description are named to match the encodings of SBFM.
- The description of SBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	0	0	1	0	0	1	1	0	N	0	0	0	0	0	0	0	0	0	1	1	1	Rn					Rd				
	opc									immr						imms															

32-bit (sf == 0 && N == 0)

```
SXTB <Wd>, <Wn>
```

is equivalent to

```
SBFM <Wd>, <Wn>, #0, #7
```

and is always the preferred disassembly.

64-bit (sf == 1 && N == 1)

```
SXTB <Xd>, <Wn>
```

is equivalent to

```
SBFM <Xd>, <Xn>, #0, #7
```

and is always the preferred disassembly.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.

Operation

The description of SBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

constant integer sys_op0 = 1;
constant integer sys_op1 = UInt(op1);
constant integer sys_op2 = UInt(op2);
constant integer sys_crn = UInt(CRn);
constant integer sys_crm = UInt(CRm);
```

Assembler Symbols

<Xt>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rt" field.
<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.

Alias Conditions

Alias	Is preferred when
GCSPOPM	`op1 == '011' && CRn == '0111' && CRm == '0111' && op2 == '001'`
GCSSS2	`op1 == '011' && CRn == '0111' && CRm == '0111' && op2 == '011'`

Operation

```
AArch64.CheckSystemAccess(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, sys_L);
AArch64.SysInstrWithResult(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t);
```

SYSP

128-bit system instruction

128-bit system instruction.
This instruction is used by the alias TLBIP.

System
(FEAT_SYSINSTR128)

31	30	29	28	27	26	25	24	23	22	21	20	19	18 17 16	15 14 13 12	11 10 9 8	7 6 5	4 3 2 1 0
1	1	0	1	0	1	0	1	0	1	0	0	1	op1	CRn	CRm	op2	Rt
										L							

SYSP #<op1>, <Cn>, <Cm>, #<op2>{, <Xt1>, <Xt2>}

```
if !IsFeatureImplemented(FEAT_SYSINSTR128) then EndOfDecode(Decode_UNDEF);
if Rt<0> == '1' && Rt != '11111' then EndOfDecode(Decode_UNDEF);

constant integer t       = UInt(Rt);
constant integer t2      = if t == 31 then 31 else t + 1;
constant integer sys_L   = UInt(L);
constant integer sys_op0 = 1;
constant integer sys_op1 = UInt(op1);
constant integer sys_op2 = UInt(op2);
constant integer sys_crn = UInt(CRn);
constant integer sys_crm = UInt(CRm);
```

Assembler Symbols

<op1>	Is a 3-bit unsigned immediate, in the range 0 to 6, encoded in the "op1" field.
<Cn>	Is a name 'Cn', with 'n' in the range 8 to 9, encoded in the "CRn" field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 7, encoded in the "CRm" field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "op2" field.
<Xt1>	Is the 64-bit name of the first optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second optional general-purpose source register, defaulting to '11111', encoded as "Rt" +1. Defaults to '11111' if "Rt" = '11111'.

Alias Conditions

Alias	Is preferred when
TLBIP	`CRn IN {'100x'} && SysOp128(op1, CRn, CRm, op2) == Sys_TLBIP`

Operation

```
AArch64.CheckSystemAccess(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, sys_L);
AArch64.SysInstr128(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, t, t2);
```

TBNZ

Test bit and branch if nonzero

This instruction compares the value of a bit in a general-purpose register with zero, and conditionally branches to a label at a PC-relative offset if the comparison is not equal. It provides a hint that this is not a subroutine call or return. This instruction does not affect condition flags.

31	30	29	28	27	26	25	24	23 22 21 20 19	18 17 16 15 14 13 12 11 10 9 8 7 6 5	4 3 2 1 0
b5	0	1	1	0	1	1	1	b40	imm14	Rt
							op			

TBNZ <R><t>, #<imm>, <label>

```
constant integer t = UInt(Rt);

constant integer datasize = 32 << UInt(b5);
constant integer bit_pos = UInt(b5:b40);
constant bits(64) offset = SignExtend(imm14:'00', 64);
```

Assembler Symbols

<R>	Is a width specifier, encoded in “b5”:

b5	<R>
0	W
1	X

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t>	Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the "Rt" field.
<imm>	Is the bit number to be tested, in the range 0 to 63, encoded in "b5:b40".
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as "imm14" times 4.

Operation

```
constant bits(datasize) operand = X[t, datasize];
constant boolean branch_conditional = TRUE;
if operand<bit_pos> != '0' then
    BranchTo(PC64 + offset, BranchType_DIR, branch_conditional);
else
    BranchNotTaken(BranchType_DIR, branch_conditional);
```

TCANCEL

Cancel current transaction

This instruction exits Transactional state and discards all state modifications that were performed transactionally. Execution continues at the instruction that follows the TSTART instruction of the outer transaction. The destination register of the TSTART instruction of the outer transaction is written with the immediate operand of TCANCEL.

System

(FEAT_TME)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	0	1	0	0	0	1	1	imm16																0	0	0	0	0
									opc																			op2		LL	

TCANCEL #<imm>

```
if !IsFeatureImplemented(FEAT_TME) then EndOfDecode(Decode_UNDEF);
constant boolean  retry  = (imm16<15> == '1');
constant bits(15) reason = imm16<14:0>;
```

Assembler Symbols

<imm>	Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm16" field.

Operation

```
if !IsTMEEnabled() then UNDEFINED;

if TSTATE.depth > 0 then
    FailTransaction(TMFailure_CNCL, retry, FALSE, reason);
```

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

TCOMMIT

Commit current transaction

This instruction commits the current transaction. If the current transaction is an outer transaction, then Transactional state is exited, and all state modifications performed transactionally are committed to the architectural state. TCOMMIT takes no inputs and returns no value.
Execution of TCOMMIT is UNDEFINED in Non-transactional state.

System
(FEAT_TME)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

TLBI

TLB invalidate operation

For more information, see *op0==0b01, cache maintenance, TLB maintenance, and address translation instructions*.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	0	1	0	1	0	0	0	0	1	op1			1	0	0	x	CRm				op2			Rt				
										L						CRn															

`TLBI <tlbi_op>{, <Xt>}`

is equivalent to

`SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}`

and is the preferred disassembly when `SysOp(op1, CRn, CRm, op2) == Sys_TLBI`.

Assembler Symbols

<tlbi_op>	Is a TLBI operation name, as listed for the TLBI system instruction group, encoded in “op1:CRn:CRm:op2”:

<Xt1>	Is the 64-bit name of the first optional general-purpose source register, defaulting to '11111', encoded in the "Rt" field.
<Xt2>	Is the 64-bit name of the second optional general-purpose source register, defaulting to '11111', encoded as "Rt" +1. Defaults to '11111' if "Rt" = '11111'.

Operation

The description of SYSP gives the operational pseudocode for this instruction.

TRCIT

Trace instrumentation

This instruction generates an instrumentation trace packet that contains the value of the provided register.

This is an alias of SYS. This means:

- The encodings in this description are named to match the encodings of SYS.
- The description of SYS gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

System

(FEAT_ITE)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

TST (immediate)

Test bits (immediate)

This instruction performs a bitwise AND of a register value and an immediate value, and discards the results. It updates the condition flags based on the result.

This is an alias of ANDS (immediate). This means:

- The encodings in this description are named to match the encodings of ANDS (immediate).
- The description of ANDS (immediate) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	1	1	1	0	0	1	0	0	N	immr						imms						Rn					1	1	1	1	1
	opc																										Rd				

32-bit (sf == 0 && N == 0)

```
TST <Wn>, #<imm>
```

is equivalent to

```
ANDS WZR, <Wn>, #<imm>
```

and is always the preferred disassembly.

64-bit (sf == 1)

```
TST <Xn>, #<imm>
```

is equivalent to

```
ANDS XZR, <Xn>, #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<imm>	For the "32-bit" variant: is the bitmask immediate, encoded in "imms:immr". For the "64-bit" variant: is the bitmask immediate, encoded in "N:imms:immr".
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of ANDS (immediate) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

TST (shifted register)

Test (shifted register)

This instruction performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

This is an alias of ANDS (shifted register). This means:

- The encodings in this description are named to match the encodings of ANDS (shifted register).
- The description of ANDS (shifted register) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	1	1	0	1	0	1	0	shift		0	Rm					imm6						Rn					1	1	1	1	1
	opc									N																	Rd				

32-bit (sf == 0)

`TST <Wn>, <Wm>{, <shift> #<amount>}`

is equivalent to

`ANDS WZR, <Wn>, <Wm>{, <shift> #<amount>}`

and is always the preferred disassembly.

64-bit (sf == 1)

`TST <Xn>, <Xm>{, <shift> #<amount>}`

is equivalent to

`ANDS XZR, <Xn>, <Xm>{, <shift> #<amount>}`

and is always the preferred disassembly.

Assembler Symbols

<Wn> Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Wm> Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the optional shift to be applied to the final source, defaulting to LSL and encoded in “shift”:

shift	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "32-bit" variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm6" field.

For the "64-bit" variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the "imm6" field,

<Xn> Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.

<Xm> Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

The description of ANDS (shifted register) gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

TSTART

Start transaction

This instruction starts a new transaction. If the transaction started successfully, the destination register is set to zero. If the transaction failed or was canceled, then all state modifications that were performed transactionally are discarded and the destination register is written with a nonzero value that encodes the cause of the failure.

System

(FEAT_TME)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

UBFIZ

Unsigned bitfield insert in zeros

This instruction copies a bitfield of <width> bits from the least significant bits of the source register to bit position <lsb> of the destination register, setting the destination bits above and below the bitfield to zero.

This is an alias of UBFM. This means:

- The encodings in this description are named to match the encodings of UBFM.
- The description of UBFM gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
sf	1	0	1	0	0	1	1	0	N	immr						imms						Rn					Rd				
	opc																														

32-bit (sf == 0 && N == 0)

```
UBFIZ <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit (sf == 1 && N == 1)

```
UBFIZ <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)
```

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "32-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 31. For the "64-bit" variant: is the bit number of the lsb of the destination bitfield, in the range 0 to 63.
<width>	For the "32-bit" variant: is the width of the bitfield, in the range 1 to 32-<lsb>. For the "64-bit" variant: is the width of the bitfield, in the range 1 to 64-<lsb>.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the "Rn" field.

Operation

The description of UBFM gives the operational pseudocode for this instruction.

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.

- The values of the NZCV flags.

UBFM

Unsigned bitfield move

This instruction is usually accessed via one of its aliases, which are always preferred for disassembly.

If <imms> is greater than or equal to <immr>, this copies a bitfield of (<imms>-<immr>+1) bits starting from bit position <immr> in the source register to the least significant bits of the destination register.

If <imms> is less than <immr>, this copies a bitfield of (<imms>+1) bits from the least significant bits of the source register to bit position (regsize-<immr>) of the destination register, where regsize is the destination register size of 32 or 64 bits.

In both cases, the destination bits below and above the bitfield are set to zero.

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the "Rm" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the "Rn" field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the "Rm" field.

Operation

```
constant bits(datasize) operand1 = X[n, datasize];
constant bits(datasize) operand2 = X[m, datasize];
constant integer result = Min(UInt(operand1), UInt(operand2));
X[d, datasize] = result<datasize-1:0>;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

sf	op54							U								o0															

UMSUBL <Xd>, <Wn>, <Wm>, <Xa>

```
constant integer d = UInt(Rd);
constant integer n = UInt(Rn);
constant integer m = UInt(Rm);
constant integer a = UInt(Ra);
```

Assembler Symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Alias Conditions

Alias	Is preferred when
UMNEGL	`Ra == '11111'`

Operation

```
constant bits(32) operand1 = X[n, 32];
constant bits(32) operand2 = X[m, 32];
constant bits(64) operand3 = X[a, 64];

constant integer result = UInt(operand3) - (UInt(operand1) * UInt(operand2));

X[d, 64] = result<63:0>;
```

Operational information

If PSTATE.DIT is 1:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

WFE

Wait for event

This instruction is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the `SEV` instruction on any PE in the multiprocessor system. For more information, see *Wait For Event mechanism and Send event*.

As described in *Wait For Event mechanism and Send event*, the execution of a `WFE` instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

YIELD

Yield

This instruction is a hint instruction. Software with a multithreading capability can use a `YIELD` instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction, see *The YIELD instruction*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

A64 -- SIMD and Floating-point Instructions (alphabetic order)

ABS: Absolute value (vector).

ADD (vector): Add (vector).

ADDHN, ADDHN2: Add returning high narrow.

ADDP (scalar): Add pair of elements (scalar).

ADDP (vector): Add pairwise (vector).

ADDV: Add across vector.

AESD: AES single round decryption.

AESE: AES single round encryption.

AESIMC: AES inverse mix columns.

AESMC: AES mix columns.

AND (vector): Bitwise AND (vector).

BCAX: Bit clear and exclusive-OR.

BF1CVTL, BF1CVTL2, BF2CVTL, BF2CVTL2: 8-bit floating-point convert to BFloat16 (vector).

BFCVT: Floating-point convert from single-precision to BFloat16 format (scalar).

BFCVTN, BFCVTN2: Floating-point convert from single-precision to BFloat16 format (vector).

BFDOT (by element): BFloat16 floating-point dot product (vector, by element).

BFDOT (vector): BFloat16 floating-point dot product (vector).

BFMLALB, BFMLALT (by element): BFloat16 floating-point widening multiply-add long (by element).

BFMLALB, BFMLALT (vector): BFloat16 floating-point widening multiply-add long (vector).

BFMMLA: BFloat16 floating-point matrix multiply-accumulate into 2x2 matrix.

BIC (vector, immediate): Bitwise bit clear (vector, immediate).

BIC (vector, register): Bitwise bit clear (vector, register).

BIF: Bitwise insert if false.

BIT: Bitwise insert if true.

BSL: Bitwise select.

CLS (vector): Count leading sign bits (vector).

CLZ (vector): Count leading zero bits (vector).

CMEQ (register): Compare bitwise equal (vector).

CMEQ (zero): Compare bitwise equal to zero (vector).

CMGE (register): Compare signed greater than or equal (vector).

CMGE (zero): Compare signed greater than or equal to zero (vector).

CMGT (register): Compare signed greater than (vector).

CMGT (zero): Compare signed greater than zero (vector).

CMHI (register): Compare unsigned higher (vector).

CMHS (register): Compare unsigned higher or same (vector).

CMLE (zero): Compare signed less than or equal to zero (vector).

CMLT (zero): Compare signed less than zero (vector).

CMTST: Compare bitwise test bits nonzero (vector).

CNT: Population count per byte.

DUP (element): Duplicate vector element to vector or scalar.

DUP (general): Duplicate general-purpose register to vector.

EOR (vector): Bitwise exclusive-OR (vector).

EOR3: Three-way exclusive-OR.

EXT: Extract vector from pair of vectors.

F1CVTL, F1CVTL2, F2CVTL, F2CVTL2: 8-bit floating-point convert to half-precision (vector).

FABD: Floating-point absolute difference (vector).

FABS (scalar): Floating-point absolute value (scalar).

FABS (vector): Floating-point absolute value (vector).

FACGE: Floating-point absolute compare greater than or equal (vector).

FACGT: Floating-point absolute compare greater than (vector).

FADD (scalar): Floating-point add (scalar).

FADD (vector): Floating-point add (vector).

FADDP (scalar): Floating-point add pair of elements (scalar).

FADDP (vector): Floating-point add pairwise (vector).

FAMAX: Floating-point absolute maximum.

FAMIN: Floating-point absolute minimum.

FCADD: Floating-point complex add.

FCCMP: Floating-point conditional quiet compare (scalar).

FCCMPE: Floating-point conditional signaling compare (scalar).

FCMEQ (register): Floating-point compare equal (vector).

FCMEQ (zero): Floating-point compare equal to zero (vector).

FCMGE (register): Floating-point compare greater than or equal (vector).

FCMGE (zero): Floating-point compare greater than or equal to zero (vector).

FCMGT (register): Floating-point compare greater than (vector).

FCMGT (zero): Floating-point compare greater than zero (vector).

FCMLA: Floating-point complex multiply accumulate.

FCMLA (by element): Floating-point complex multiply accumulate (by element).

FCMLE (zero): Floating-point compare less than or equal to zero (vector).

FCMLT (zero): Floating-point compare less than zero (vector).

FCMP: Floating-point quiet compare (scalar).

FCMPE: Floating-point signaling compare (scalar).

FCSEL: Floating-point conditional select (scalar).

FCVT: Floating-point convert precision (scalar).

FCVTAS (scalar SIMD&FP): Floating-point convert to signed integer, rounding to nearest with ties to away (scalar SIMD&FP).

FCVTAS (scalar): Floating-point convert to signed integer, rounding to nearest with ties to away (scalar).

FCVTAS (vector): Floating-point convert to signed integer, rounding to nearest with ties to away (vector).

FCVTAU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding to nearest with ties to away (scalar SIMD&FP).

FCVTAU (scalar): Floating-point convert to unsigned integer, rounding to nearest with ties to away (scalar).

FCVTAU (vector): Floating-point convert to unsigned integer, rounding to nearest with ties to away (vector).

FCVTL, FCVTL2: Floating-point convert to higher precision long (vector).

FCVTMS (scalar SIMD&FP): Floating-point convert to signed integer, rounding toward minus infinity (scalar SIMD&FP).

FCVTMS (scalar): Floating-point convert to signed integer, rounding toward minus infinity (scalar).

FCVTMS (vector): Floating-point convert to signed integer, rounding toward minus infinity (vector).

FCVTMU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding toward minus infinity (scalar SIMD&FP).

FCVTMU (scalar): Floating-point convert to unsigned integer, rounding toward minus infinity (scalar).

FCVTMU (vector): Floating-point convert to unsigned integer, rounding toward minus infinity (vector).

FCVTN (half-precision to 8-bit floating-point): Half-precision to 8-bit floating-point convert and narrow (vector).

FCVTN, FCVTN2 (double to single-precision, single to half-precision): Floating-point convert to lower precision narrow (vector).

FCVTN, FCVTN2 (single-precision to 8-bit floating-point): Single-precision to 8-bit floating-point convert and narrow (vector).

FCVTNS (scalar SIMD&FP): Floating-point convert to signed integer, rounding to nearest with ties to even (scalar SIMD&FP).

FCVTNS (scalar): Floating-point convert to signed integer, rounding to nearest with ties to even (scalar).

FCVTNS (vector): Floating-point convert to signed integer, rounding to nearest with ties to even (vector).

FCVTNU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding to nearest with ties to even (scalar SIMD&FP).

FCVTNU (scalar): Floating-point convert to unsigned integer, rounding to nearest with ties to even (scalar).

FCVTNU (vector): Floating-point convert to unsigned integer, rounding to nearest with ties to even (vector).

FCVTPS (scalar SIMD&FP): Floating-point convert to signed integer, rounding toward plus infinity (scalar SIMD&FP).

FCVTPS (scalar): Floating-point convert to signed integer, rounding toward plus infinity (scalar).

FCVTPS (vector): Floating-point convert to signed integer, rounding toward plus infinity (vector).

FCVTPU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding toward plus infinity (scalar SIMD&FP).

FCVTPU (scalar): Floating-point convert to unsigned integer, rounding toward plus infinity (scalar).

FCVTPU (vector): Floating-point convert to unsigned integer, rounding toward plus infinity (vector).

FCVTXN, FCVTXN2: Floating-point convert to lower precision narrow, rounding to odd (vector).

FCVTZS (scalar SIMD&FP): Floating-point convert to signed integer, rounding toward zero (scalar SIMD&FP).

FCVTZS (scalar, fixed-point): Floating-point convert to signed fixed-point, rounding toward zero (scalar).

FCVTZS (scalar, integer): Floating-point convert to signed integer, rounding toward zero (scalar).

FCVTZS (vector, fixed-point): Floating-point convert to signed fixed-point, rounding toward zero (vector).

FCVTZS (vector, integer): Floating-point convert to signed integer, rounding toward zero (vector).

FCVTZU (scalar SIMD&FP): Floating-point convert to unsigned integer, rounding toward zero (scalar SIMD&FP).

FCVTZU (scalar, fixed-point): Floating-point convert to unsigned fixed-point, rounding toward zero (scalar).

FCVTZU (scalar, integer): Floating-point convert to unsigned integer, rounding toward zero (scalar).

FCVTZU (vector, fixed-point): Floating-point convert to unsigned fixed-point, rounding toward zero (vector).

FCVTZU (vector, integer): Floating-point convert to unsigned integer, rounding toward zero (vector).

FDIV (scalar): Floating-point divide (scalar).

FDIV (vector): Floating-point divide (vector).

FDOT (8-bit floating-point to half-precision, by element): 8-bit floating-point dot product to half-precision (vector, by element).

FDOT (8-bit floating-point to half-precision, vector): 8-bit floating-point dot product to half-precision (vector).

FDOT (8-bit floating-point to single-precision, by element): 8-bit floating-point dot product to single-precision (vector, by element).

FDOT (8-bit floating-point to single-precision, vector): 8-bit floating-point dot product to single-precision (vector).

FJCVTZS: Floating-point Javascript convert to signed fixed-point, rounding toward zero.

FMADD: Floating-point fused multiply-add (scalar).

FMAX (scalar): Floating-point maximum (scalar).

FMAX (vector): Floating-point maximum (vector).

FMAXNM (scalar): Floating-point maximum number (scalar).

FMAXNM (vector): Floating-point maximum number (vector).

FMAXNMP (scalar): Floating-point maximum number of pair of elements (scalar).

FMAXNMP (vector): Floating-point maximum number pairwise (vector).

FMAXNMV: Floating-point maximum number across vector.

FMAXP (scalar): Floating-point maximum of pair of elements (scalar).

FMAXP (vector): Floating-point maximum pairwise (vector).

FMAXV: Floating-point maximum across vector.

FMIN (scalar): Floating-point minimum (scalar).

FMIN (vector): Floating-point minimum (vector).

FMINNM (scalar): Floating-point minimum number (scalar).

FMINNM (vector): Floating-point minimum number (vector).

FMINNMP (scalar): Floating-point minimum number of pair of elements (scalar).

FMINNMP (vector): Floating-point minimum number pairwise (vector).

FMINNMV: Floating-point minimum number across vector.

FMINP (scalar): Floating-point minimum of pair of elements (scalar).

FMINP (vector): Floating-point minimum pairwise (vector).

FMINV: Floating-point minimum across vector.

FMLA (by element): Floating-point fused multiply-add to accumulator (by element).

FMLA (vector): Floating-point fused multiply-add to accumulator (vector).

FMLAL, FMLAL2 (by element): Floating-point fused multiply-add long to accumulator (by element).

FMLAL, FMLAL2 (vector): Floating-point fused multiply-add long to accumulator (vector).

FMLALB, FMLALT (by element): 8-bit floating-point multiply-add long to half-precision (vector, by element).

FMLALB, FMLALT (vector): 8-bit floating-point multiply-add long to half-precision (vector).

FMLALLBB, FMLALLBT, FMLALLTB, FMLALLTT (by element): 8-bit floating-point multiply-add long-long to single-precision (vector, by element).

FMLALLBB, FMLALLBT, FMLALLTB, FMLALLTT (vector): 8-bit floating-point multiply-add long-long to single-precision (vector).

FMLS (by element): Floating-point fused multiply-subtract from accumulator (by element).

FMLS (vector): Floating-point fused multiply-subtract from accumulator (vector).

FMLSL, FMLSL2 (by element): Floating-point fused multiply-subtract long from accumulator (by element).

FMLSL, FMLSL2 (vector): Floating-point fused multiply-subtract long from accumulator (vector).

FMMLA (8-bit floating-point to half-precision): 8-bit floating-point matrix multiply-accumulate into 2x2 half-precision matrix.

FMMLA (8-bit floating-point to single-precision): 8-bit floating-point matrix multiply-accumulate into 2x2 single-precision matrix.

FMOV (general): Floating-point move to or from general-purpose register without conversion.

FMOV (register): Floating-point move register without conversion.

FMOV (scalar, immediate): Floating-point move immediate (scalar).

FMOV (vector, immediate): Floating-point move immediate (vector).

FMSUB: Floating-point fused multiply-subtract (scalar).

FMUL (by element): Floating-point multiply (by element).

FMUL (scalar): Floating-point multiply (scalar).

FMUL (vector): Floating-point multiply (vector).

FMULX: Floating-point multiply extended.

FMULX (by element): Floating-point multiply extended (by element).

FNEG (scalar): Floating-point negate (scalar).

FNEG (vector): Floating-point negate (vector).

FNMADD: Floating-point negated fused multiply-add (scalar).

FNMSUB: Floating-point negated fused multiply-subtract (scalar).

FNMUL (scalar): Floating-point multiply-negate (scalar).

FRECPE: Floating-point reciprocal estimate.

FRECPS: Floating-point reciprocal step.

FRECPX: Floating-point reciprocal exponent (scalar).

FRINT32X (scalar): Floating-point round to 32-bit integer, using current rounding mode (scalar).

FRINT32X (vector): Floating-point round to 32-bit integer, using current rounding mode (vector).

FRINT32Z (scalar): Floating-point round to 32-bit integer toward zero (scalar).

FRINT32Z (vector): Floating-point round to 32-bit integer toward zero (vector).

FRINT64X (scalar): Floating-point round to 64-bit integer, using current rounding mode (scalar).

FRINT64X (vector): Floating-point round to 64-bit integer, using current rounding mode (vector).

FRINT64Z (scalar): Floating-point round to 64-bit integer toward zero (scalar).

FRINT64Z (vector): Floating-point round to 64-bit integer toward zero (vector).

FRINTA (scalar): Floating-point round to integral, to nearest with ties to away (scalar).

FRINTA (vector): Floating-point round to integral, to nearest with ties to away (vector).

FRINTI (scalar): Floating-point round to integral, using current rounding mode (scalar).

FRINTI (vector): Floating-point round to integral, using current rounding mode (vector).

FRINTM (scalar): Floating-point round to integral, toward minus infinity (scalar).

FRINTM (vector): Floating-point round to integral, toward minus infinity (vector).

FRINTN (scalar): Floating-point round to integral, to nearest with ties to even (scalar).

FRINTN (vector): Floating-point round to integral, to nearest with ties to even (vector).

FRINTP (scalar): Floating-point round to integral, toward plus infinity (scalar).

FRINTP (vector): Floating-point round to integral, toward plus infinity (vector).

FRINTX (scalar): Floating-point round to integral exact, using current rounding mode (scalar).

FRINTX (vector): Floating-point round to integral exact, using current rounding mode (vector).

FRINTZ (scalar): Floating-point round to integral, toward zero (scalar).

FRINTZ (vector): Floating-point round to integral, toward zero (vector).

FRSQRTE: Floating-point reciprocal square root estimate.

FRSQRTS: Floating-point reciprocal square root step.

FSCALE: Floating-point adjust exponent by vector.

FSQRT (scalar): Floating-point square root (scalar).

FSQRT (vector): Floating-point square root (vector).

FSUB (scalar): Floating-point subtract (scalar).

FSUB (vector): Floating-point subtract (vector).

INS (element): Insert vector element from another vector element.

INS (general): Insert vector element from general-purpose register.

LD1 (multiple structures): Load multiple single-element structures to one, two, three, or four registers.

LD1 (single structure): Load one single-element structure to one lane of one register.

LD1R: Load one single-element structure and replicate to all lanes (of one register).

LD2 (multiple structures): Load multiple 2-element structures to two registers.

LD2 (single structure): Load single 2-element structure to one lane of two registers.

LD2R: Load single 2-element structure and replicate to all lanes of two registers.

LD3 (multiple structures): Load multiple 3-element structures to three registers.

LD3 (single structure): Load single 3-element structure to one lane of three registers.

LD3R: Load single 3-element structure and replicate to all lanes of three registers.

LD4 (multiple structures): Load multiple 4-element structures to four registers.

LD4 (single structure): Load single 4-element structure to one lane of four registers.

LD4R: Load single 4-element structure and replicate to all lanes of four registers.

LDAP1 (SIMD&FP): Load-acquire RCpc one single-element structure to one lane of one register.

LDAPUR (SIMD&FP): Load-acquire RCpc SIMD&FP register (unscaled offset).

LDBFADD, LDBFADDA, LDBFADDAL, LDBFADDL: BFloat16 floating-point add in memory.

LDBFMAX, LDBFMAXA, LDBFMAXAL, LDBFMAXL: BFloat16 floating-point atomic maximum in memory.

LDBFMAXNM, LDBFMAXNMA, LDBFMAXNMAL, LDBFMAXNML: BFloat16 floating-point atomic maximum number in memory.

LDBFMIN, LDBFMINA, LDBFMINAL, LDBFMINL: BFloat16 floating-point atomic minimum in memory.

LDBFMINNM, LDBFMINNMA, LDBFMINNMAL, LDBFMINNML: BFloat16 floating-point atomic minimum number in memory.

LDFADD, LDFADDA, LDFADDAL, LDFADDL: Floating-point atomic add in memory.

LDFMAX, LDFMAXA, LDFMAXAL, LDFMAXL: Floating-point atomic maximum in memory.

LDFMAXNM, LDFMAXNMA, LDFMAXNMAL, LDFMAXNML: Floating-point atomic maximum number in memory.

LDFMIN, LDFMINA, LDFMINAL, LDFMINL: Floating-point atomic minimum in memory.

LDFMINNM, LDFMINNMA, LDFMINNMAL, LDFMINNML: Floating-point atomic minimum number in memory.

LDNP (SIMD&FP): Load pair of SIMD&FP registers, with non-temporal hint.

LDP (SIMD&FP): Load pair of SIMD&FP registers.

LDR (immediate, SIMD&FP): Load SIMD&FP register (immediate offset).

LDR (literal, SIMD&FP): Load SIMD&FP register (PC-relative literal).

LDR (register, SIMD&FP): Load SIMD&FP register (register offset).

LDTNP (SIMD&FP): Load unprivileged pair of SIMD&FP registers, with non-temporal hint.

LDTP (SIMD&FP): Load unprivileged pair of SIMD&FP registers.

LDUR (SIMD&FP): Load SIMD&FP register (unscaled offset).

LUTI2: Lookup table read with 2-bit indices.

LUTI4: Lookup table read with 4-bit indices.

MLA (by element): Multiply-add to accumulator (vector, by element).

MLA (vector): Multiply-add to accumulator (vector).

MLS (by element): Multiply-subtract from accumulator (vector, by element).

MLS (vector): Multiply-subtract from accumulator (vector).

MOV (element): Move vector element to another vector element: an alias of INS (element).

MOV (from general): Move general-purpose register to a vector element: an alias of INS (general).

MOV (scalar): Move vector element to scalar: an alias of DUP (element).

MOV (to general): Move vector element to general-purpose register: an alias of UMOV.

MOV (vector): Move vector: an alias of ORR (vector, register).

MOVI: Move immediate (vector).

MUL (by element): Multiply (vector, by element).

MUL (vector): Multiply (vector).

MVN: Bitwise NOT (vector): an alias of NOT.

MVNI: Move inverted immediate (vector).

NEG (vector): Negate (vector).

NOT: Bitwise NOT (vector).

ORN (vector): Bitwise inclusive OR NOT (vector).

ORR (vector, immediate): Bitwise inclusive OR (vector, immediate).

ORR (vector, register): Bitwise inclusive OR (vector, register).

PMUL: Polynomial multiply.

PMULL, PMULL2: Polynomial multiply long.

RADDHN, RADDHN2: Rounding add returning high narrow.

RAX1: Rotate and exclusive-OR.

RBIT (vector): Reverse bit order (vector).

REV16 (vector): Reverse elements in 16-bit halfwords (vector).

REV32 (vector): Reverse elements in 32-bit words (vector).

REV64: Reverse elements in 64-bit doublewords (vector).

RSHRN, RSHRN2: Rounding shift right narrow (immediate).

RSUBHN, RSUBHN2: Rounding subtract returning high narrow.

SABA: Signed absolute difference and accumulate.

SABAL, SABAL2: Signed absolute difference and accumulate long.

SABD: Signed absolute difference.

SABDL, SABDL2: Signed absolute difference long.

SADALP: Signed add and accumulate long pairwise.

SADDL, SADDL2: Signed add long (vector).

SADDLP: Signed add long pairwise.

SADDLV: Signed add long across vector.

SADDW, SADDW2: Signed add wide.

SCVTF (scalar SIMD&FP): Signed integer convert to floating-point (scalar SIMD&FP).

SCVTF (scalar, fixed-point): Signed fixed-point convert to floating-point (scalar).

SCVTF (scalar, integer): Signed integer convert to floating-point (scalar).

SCVTF (vector, fixed-point): Signed fixed-point convert to floating-point (vector).

SCVTF (vector, integer): Signed integer convert to floating-point (vector).

SDOT (by element): Dot product signed arithmetic (vector, by element).

SDOT (vector): Dot product signed arithmetic (vector).

SHA1C: SHA1 hash update (choose).

SHA1H: SHA1 fixed rotate.

SHA1M: SHA1 hash update (majority).

SHA1P: SHA1 hash update (parity).

SHA1SU0: SHA1 schedule update 0.

SHA1SU1: SHA1 schedule update 1.

SHA256H: SHA256 hash update (part 1).

SHA256H2: SHA256 hash update (part 2).

SHA256SU0: SHA256 schedule update 0.

SHA256SU1: SHA256 schedule update 1.

SHA512H: SHA512 hash update part 1.

SHA512H2: SHA512 hash update part 2.

SHA512SU0: SHA512 schedule update 0.

SHA512SU1: SHA512 schedule update 1.

SHADD: Signed halving add.

SHL: Shift left (immediate).

SHLL, SHLL2: Shift left long (by element size).

SHRN, SHRN2: Shift right narrow (immediate).

SHSUB: Signed halving subtract.

SLI: Shift left and insert (immediate).

SM3PARTW1: SM3PARTW1.

SM3PARTW2: SM3PARTW2.

SM3SS1: SM3SS1.

SM3TT1A: SM3TT1A.

SM3TT1B: SM3TT1B.

SM3TT2A: SM3TT2A.

SM3TT2B: SM3TT2B.

SM4E: SM4 encode.

SM4EKEY: SM4 key.

SMAX: Signed maximum (vector).

SMAXP: Signed maximum pairwise.

SMAXV: Signed maximum across vector.

SMIN: Signed minimum (vector).

SMINP: Signed minimum pairwise.

SMINV: Signed minimum across vector.

SMLAL, SMLAL2 (by element): Signed multiply-add long (vector, by element).

SMLAL, SMLAL2 (vector): Signed multiply-add long (vector).

SMLSL, SMLSL2 (by element): Signed multiply-subtract long (vector, by element).

SMLSL, SMLSL2 (vector): Signed multiply-subtract long (vector).

SMMLA (vector): Signed 8-bit integer matrix multiply-accumulate (vector).

SMOV: Signed move vector element to general-purpose register.

SMULL, SMULL2 (by element): Signed multiply long (vector, by element).

SMULL, SMULL2 (vector): Signed multiply long (vector).

SQABS: Signed saturating absolute value.

SQADD: Signed saturating add.

SQDMLAL, SQDMLAL2 (by element): Signed saturating doubling multiply-add long (by element).

SQDMLAL, SQDMLAL2 (vector): Signed saturating doubling multiply-add long.

SQDMLSL, SQDMLSL2 (by element): Signed saturating doubling multiply-subtract long (by element).

SQDMLSL, SQDMLSL2 (vector): Signed saturating doubling multiply-subtract long.

SQDMULH (by element): Signed saturating doubling multiply returning high half (by element).

SQDMULH (vector): Signed saturating doubling multiply returning high half.

SQDMULL, SQDMULL2 (by element): Signed saturating doubling multiply long (by element).

SQDMULL, SQDMULL2 (vector): Signed saturating doubling multiply long.

SQNEG: Signed saturating negate.

SQRDMLAH (by element): Signed saturating rounding doubling multiply accumulate returning high half (by element).

SQRDMLAH (vector): Signed saturating rounding doubling multiply accumulate returning high half (vector).

SQRDMLSH (by element): Signed saturating rounding doubling multiply subtract returning high half (by element).

SQRDMLSH (vector): Signed saturating rounding doubling multiply subtract returning high half (vector).

SQRDMULH (by element): Signed saturating rounding doubling multiply returning high half (by element).

SQRDMULH (vector): Signed saturating rounding doubling multiply returning high half.

SQRSHL: Signed saturating rounding shift left (register).

SQRSHRN, SQRSHRN2: Signed saturating rounded shift right narrow (immediate).

SQRSHRUN, SQRSHRUN2: Signed saturating rounded shift right unsigned narrow (immediate).

SQSHL (immediate): Signed saturating shift left (immediate).

SQSHL (register): Signed saturating shift left (register).

SQSHLU: Signed saturating shift left unsigned (immediate).

SQSHRN, SQSHRN2: Signed saturating shift right narrow (immediate).

SQSHRUN, SQSHRUN2: Signed saturating shift right unsigned narrow (immediate).

SQSUB: Signed saturating subtract.

SQXTN, SQXTN2: Signed saturating extract narrow.

SQXTUN, SQXTUN2: Signed saturating extract unsigned narrow.

SRHADD: Signed rounding halving add.

SRI: Shift right and insert (immediate).

SRSHL: Signed rounding shift left (register).

SRSHR: Signed rounding shift right (immediate).

SRSRA: Signed rounding shift right and accumulate (immediate).

SSHL: Signed shift left (register).

SSHLL, SSHLL2: Signed shift left long (immediate).

SSHR: Signed shift right (immediate).

SSRA: Signed shift right and accumulate (immediate).

SSUBL, SSUBL2: Signed subtract long.

SSUBW, SSUBW2: Signed subtract wide.

ST1 (multiple structures): Store multiple single-element structures from one, two, three, or four registers.

ST1 (single structure): Store a single-element structure from one lane of one register.

ST2 (multiple structures): Store multiple 2-element structures from two registers.

ST2 (single structure): Store single 2-element structure from one lane of two registers.

ST3 (multiple structures): Store multiple 3-element structures from three registers.

ST3 (single structure): Store single 3-element structure from one lane of three registers.

ST4 (multiple structures): Store multiple 4-element structures from four registers.

ST4 (single structure): Store single 4-element structure from one lane of four registers.

STBFADD, STBFADDL: BFloat16 floating-point atomic add in memory, without return.

STBFMAX, STBFMAXL: BFloat16 floating-point atomic maximum in memory, without return.

STBFMAXNM, STBFMAXNML: BFloat16 floating-point atomic maximum number in memory, without return.

STBFMIN, STBFMINL: BFloat16 floating-point atomic minimum in memory, without return.

STBFMINNM, STBFMINNML: BFloat16 floating-point atomic minimum number in memory, without return.

STFADD, STFADDL: Floating-point atomic add in memory, without return.

STFMAX, STFMAXL: Floating-point atomic maximum in memory, without return.

STFMAXNM, STFMAXNML: Floating-point atomic maximum number in memory, without return.

STFMIN, STFMINL: Floating-point atomic minimum in memory, without return.

STFMINNM, STFMINNML: Floating-point atomic minimum number in memory, without return.

STL1 (SIMD&FP): Store-release a single-element structure from one lane of one register.

STLUR (SIMD&FP): Store-release SIMD&FP register (unscaled offset).

STNP (SIMD&FP): Store pair of SIMD&FP registers, with non-temporal hint.

STP (SIMD&FP): Store pair of SIMD&FP registers.

STR (immediate, SIMD&FP): Store SIMD&FP register (immediate offset).

STR (register, SIMD&FP): Store SIMD&FP register (register offset).

STTNP (SIMD&FP): Store unprivileged pair of SIMD&FP registers, with non-temporal hint.

STTP (SIMD&FP): Store unprivileged pair of SIMD&FP registers.

STUR (SIMD&FP): Store SIMD&FP register (unscaled offset).

SUB (vector): Subtract (vector).

SUBHN, SUBHN2: Subtract returning high narrow.

SUDOT (by element): Dot product with signed and unsigned integers (vector, by element).

SUQADD: Signed saturating accumulate of unsigned value.

SXTL, SXTL2: Signed extend long: an alias of SSHLL, SSHLL2.

TBL: Table vector lookup.

TBX: Table vector lookup extension.

TRN1: Transpose vectors (primary).

TRN2: Transpose vectors (secondary).

UABA: Unsigned absolute difference and accumulate.

UABAL, UABAL2: Unsigned absolute difference and accumulate long.

UABD: Unsigned absolute difference (vector).

UABDL, UABDL2: Unsigned absolute difference long.

UADALP: Unsigned add and accumulate long pairwise.

UADDL, UADDL2: Unsigned add long (vector).

UADDLP: Unsigned add long pairwise.

UADDLV: Unsigned sum long across vector.

UADDW, UADDW2: Unsigned add wide.

UCVTF (scalar SIMD&FP): Unsigned integer convert to floating-point (scalar SIMD&FP).

UCVTF (scalar, fixed-point): Unsigned fixed-point convert to floating-point (scalar).

UCVTF (scalar, integer): Unsigned integer convert to floating-point (scalar).

UCVTF (vector, fixed-point): Unsigned fixed-point convert to floating-point (vector).

UCVTF (vector, integer): Unsigned integer convert to floating-point (vector).

UDOT (by element): Dot product unsigned arithmetic (vector, by element).

UDOT (vector): Dot product unsigned arithmetic (vector).

UHADD: Unsigned halving add.

UHSUB: Unsigned halving subtract.

UMAX: Unsigned maximum (vector).

UMAXP: Unsigned maximum pairwise.

UMAXV: Unsigned maximum across vector.

UMIN: Unsigned minimum (vector).

UMINP: Unsigned minimum pairwise.

UMINV: Unsigned minimum across vector.

UMLAL, UMLAL2 (by element): Unsigned multiply-add long (vector, by element).

UMLAL, UMLAL2 (vector): Unsigned multiply-add long (vector).

UMLSL, UMLSL2 (by element): Unsigned multiply-subtract long (vector, by element).

UMLSL, UMLSL2 (vector): Unsigned multiply-subtract long (vector).

UMMLA (vector): Unsigned 8-bit integer matrix multiply-accumulate (vector).

UMOV: Unsigned move vector element to general-purpose register.

UMULL, UMULL2 (by element): Unsigned multiply long (vector, by element).

UMULL, UMULL2 (vector): Unsigned multiply long (vector).

UQADD: Unsigned saturating add.

UQRSHL: Unsigned saturating rounding shift left (register).

UQRSHRN, UQRSHRN2: Unsigned saturating rounded shift right narrow (immediate).

UQSHL (immediate): Unsigned saturating shift left (immediate).

UQSHL (register): Unsigned saturating shift left (register).

UQSHRN, UQSHRN2: Unsigned saturating shift right narrow (immediate).

UQSUB: Unsigned saturating subtract.

UQXTN, UQXTN2: Unsigned saturating extract narrow.

URECPE: Unsigned reciprocal estimate.

URHADD: Unsigned rounding halving add.

URSHL: Unsigned rounding shift left (register).

URSHR: Unsigned rounding shift right (immediate).

URSQRTE: Unsigned reciprocal square root estimate.

URSRA: Unsigned rounding shift right and accumulate (immediate).

USDOT (by element): Dot product with unsigned and signed integers (vector, by element).

USDOT (vector): Dot product with unsigned and signed integers (vector).

USHL: Unsigned shift left (register).

USHLL, USHLL2: Unsigned shift left long (immediate).

USHR: Unsigned shift right (immediate).

USMMLA (vector): Unsigned and signed 8-bit integer matrix multiply-accumulate (vector).

USQADD: Unsigned saturating accumulate of signed value.

USRA: Unsigned shift right and accumulate (immediate).

USUBL, USUBL2: Unsigned subtract long.

USUBW, USUBW2: Unsigned subtract wide.

UXTL, UXTL2: Unsigned extend long: an alias of USHLL, USHLL2.

UZP1: Unzip vectors (primary).

UZP2: Unzip vectors (secondary).

XAR: Exclusive-OR and rotate.

XTN, XTN2: Extract narrow.

ZIP1: Zip vectors (primary).

ZIP2: Zip vectors (secondary).

ABS

Absolute value (vector)

This instruction calculates the absolute value of each vector element in the source SIMD&FP register, puts the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

ADDHN, ADDHN2

Add returning high narrow

This instruction adds each vector element in the first source SIMD&FP register to the corresponding vector element in the second source SIMD&FP register, places the most significant half of the result into a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register.

The results are truncated. For rounded results, see *RADDHN*.

The `ADDHN` instruction writes the vector to the lower half of the destination register and clears the upper half. The `ADDHN2` instruction writes the vector to the upper half of the destination register without affecting the other bits of the register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers, not all the same type

ADDP (vector)

Add pairwise (vector)

This instruction creates a vector by concatenating the vector elements of the first source SIMD&FP register after the vector elements of the second source SIMD&FP register, reads each pair of adjacent vector elements from the concatenated vector, adds each pair of values together, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

AND (vector)

Bitwise AND (vector)

This instruction performs a bitwise AND between the two source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Three registers of the same type

BCAX

Bit clear and exclusive-OR

This instruction performs a bitwise AND of the 128-bit vector in a source SIMD&FP register and the complement of the vector in another source SIMD&FP register, then performs a bitwise exclusive-OR of the resulting vector and the vector in a third source SIMD&FP register, and writes the result to the destination SIMD&FP register.

BF1CVTL, BF1CVTL2, BF2CVTL, BF2CVTL2

8-bit floating-point convert to BFloat16 (vector)

This instruction converts each 8-bit floating-point element from the lower or upper half of the source vector to BFloat16 while downscaling the value, and places the results in the 16-bit elements of the destination vector. `BF1CVTL` and `BF2CVTL` convert the elements from the lower half of the source vector while scaling the values by $2^{-\text{UInt(FPMR.LSCALE[5:0])}}$ and $2^{-\text{UInt(FPMR.LSCALE2[5:0])}}$, respectively. `BF1CVTL2` and `BF2CVTL2` convert the elements from the upper half of the source vector while scaling the values by $2^{-\text{UInt(FPMR.LSCALE[5:0])}}$ and $2^{-\text{UInt(FPMR.LSCALE2[5:0])}}$, respectively. The 8-bit floating-point encoding format for `BF1CVTL` and `BF1CVTL2` is selected by FPMR.F8S1. The 8-bit floating-point encoding format for `BF2CVTL` and `BF2CVTL2` is selected by FPMR.F8S2.

BFCVTN, BFCVTN2

Floating-point convert from single-precision to BFloat16 format (vector)

This instruction reads each single-precision element in the SIMD&FP source vector, converts each value to BFloat16 format, and writes the results in the lower or upper half of the SIMD&FP destination vector. The result elements are half the width of the source elements.

The `BFCVTN` instruction writes the half-width results to the lower half of the destination vector and clears the upper half to zero. The `BFCVTN2` instruction writes the results to the upper half of the destination vector without affecting the other bits in the register.

Vector single-precision to BFloat16

    Elem[result, e, 16] = FPConvertBF(Elem[operand, e, 32], FPCR);

Vpart[d, part, 64] = result;
```

BFDOT (by element)

BFloat16 floating-point dot product (vector, by element)

This instruction delimits the source vectors into pairs of BFloat16 elements. The BFloat16 pair within the second source vector is specified using an immediate index. The index range is from 0 to 3 inclusive.

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Performs an unfused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are rounded before they are summed, and the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

- Performs a fused sum-of-products of each pair of adjacent BFloat16 elements in the first source vector with the specified pair of elements in the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the single-precision destination element that overlaps with the corresponding pair of BFloat16 elements in the first source vector.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

BFloat16 floating-point matrix multiply-accumulate into 2x2 matrix

If FEAT_EBF16 is not implemented or FPCR.EBF is 0, this instruction:

- Performs two unfused sums-of-products within each two pairs of adjacent BFloat16 elements while multiplying the 2x4 matrix of BFloat16 values in the first source vector with the 4x2 matrix of BFloat16 values in the second source vector. The intermediate single-precision products are rounded before they are summed and the intermediate sum is rounded before accumulation into the 2x2 single-precision matrix in the destination vector. This is equivalent to accumulating two 2-way unfused dot products per destination element.
- Uses the non-IEEE 754 Round-to-Odd rounding mode, which forces bit 0 of an inexact result to 1, and rounds an overflow to an appropriately signed Infinity.
- Flushes denormalized inputs and results to zero, as if FPCR.{FZ, FIZ} is {1, 1}.
- Disables alternative floating point behaviors, as if FPCR.AH is 0.

If FEAT_EBF16 is implemented and FPCR.EBF is 1, then this instruction:

- Performs two fused sums-of-products within each two pairs of adjacent BFloat16 elements while multiplying the 2x4 matrix of BFloat16 values in the first source vector with the 4x2 matrix of BFloat16 values in the second source vector. The intermediate single-precision products are not rounded before they are summed, but the intermediate sum is rounded before accumulation into the 2x2 single-precision matrix in the destination vector. This is equivalent to accumulating two 2-way fused dot products per destination element.
- Follows all other floating-point behaviors that apply to single-precision arithmetic, as governed by FPCR.RMode, FPCR.FZ, FPCR.AH, and FPCR.FIZ.

Irrespective of FEAT_EBF16 and FPCR.EBF, this instruction:

- Does not modify the cumulative FPSR exception bits (IDC, IXC, UFC, OFC, DZC, and IOC).
- Disables trapped floating-point exceptions, as if the FPCR trap enable bits (IDE, IXE, UFE, OFE, DZE, and IOE) are all zero.
- Generates only the default NaN, as if FPCR.DN is 1.

ID_AA64ISAR1_EL1.BF16 indicates whether this instruction is supported.

constant bits(128) op2 = V[m, 128];
constant bits(128) acc = V[d, 128];

V[d, 128] = BFMatMulAdd(acc, op1, op2, FPCR);
```

Operational information

Arm expects that the BFMMLA instruction will deliver a peak BFloat16 multiply throughput that is at least as high as can be achieved using two BFDOT (vector) instructions, with a goal that it should have significantly higher throughput.

BIC (vector, immediate)

Bitwise bit clear (vector, immediate)

This instruction reads each vector element from the destination SIMD&FP register, performs a bitwise AND between each result and the complement of an immediate constant, places the result into a vector, and writes the vector to the destination SIMD&FP register.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

CLS (vector)

Count leading sign bits (vector)

This instruction counts the number of consecutive bits following the most significant bit that are the same as the most significant bit in each vector element in the source SIMD&FP register, places the result into a vector, and writes the vector to the destination SIMD&FP register. The count does not include the most significant bit itself.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

CMGE (register)

Compare signed greater than or equal (vector)

This instruction compares each vector element in the first source SIMD&FP register with the corresponding vector element in the second source SIMD&FP register and if the first signed integer value is greater than or equal to the second signed integer value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

CMLE (zero)

Compare signed less than or equal to zero (vector)

This instruction reads each vector element in the source SIMD&FP register and if the signed integer value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 2 classes: Scalar and Vector

EOR3

Three-way exclusive-OR

This instruction performs a three-way exclusive-OR of the values in the three source SIMD&FP registers, and writes the result to the destination SIMD&FP register.

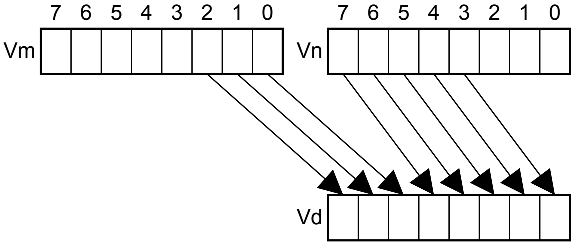
EXT

Extract vector from pair of vectors

This instruction extracts the lowest vector elements from the second source SIMD&FP register and the highest vector elements from the first source SIMD&FP register, concatenates the results into a vector, and writes the vector to the destination SIMD&FP register vector. The index value specifies the lowest vector element to extract from the first source register, and consecutive elements are extracted from the first, then second, source registers until the destination vector is filled.

The following figure shows an example of the operation of EXT doubleword operation for Q = 0 and imm4<2:0> = 3.



Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

F1CVTL, F1CVTL2, F2CVTL, F2CVTL2

8-bit floating-point convert to half-precision (vector)

This instruction converts each 8-bit floating-point element from the lower or upper half of the source vector to half-precision while downscaling the value, and places the results in the 16-bit elements of the destination vector. `F1CVTL` and `F2CVTL` convert the elements from the lower half of the source vector while scaling the values by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$ and $2^{-\text{UInt(FPMR.LSCALE2[3:0])}}$, respectively. `F1CVTL2` and `F2CVTL2` convert the elements from the upper half of the source vector while scaling the values by $2^{-\text{UInt(FPMR.LSCALE[3:0])}}$ and $2^{-\text{UInt(FPMR.LSCALE2[3:0])}}$, respectively. The 8-bit floating-point encoding format for `F1CVTL` and `F1CVTL2` is selected by FPMR.F8S1. The 8-bit floating-point encoding format for `F2CVTL` and `F2CVTL2` is selected by FPMR.F8S2.

FACGE

Floating-point absolute compare greater than or equal (vector)

This instruction compares the absolute value of each floating-point value in the first source SIMD&FP register with the absolute value of the corresponding floating-point value in the second source SIMD&FP register and if the first value is greater than or equal to the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FACGT

Floating-point absolute compare greater than (vector)

This instruction compares the absolute value of each vector element in the first source SIMD&FP register with the absolute value of the corresponding vector element in the second source SIMD&FP register and if the first value is greater than the second value sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision , Scalar single-precision and double-precision , Vector half precision and Vector single-precision and double-precision

FAMAX

Floating-point absolute maximum

This instruction determines the maximum absolute value from floating-point elements of the first source vector and the corresponding floating-point elements of the second source vector, and places the results in the corresponding elements of the destination vector.

The behavior is as follows:

- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is the Default NaN.
- Denormalized inputs and results are never flushed to zero, as if FPCR.{FZ, FZ16, FIZ} is {0, 0, 0}.
- Denormalized inputs never generate an Input Denormal floating-point exception.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FAMIN

Floating-point absolute minimum

This instruction determines the minimum absolute value from floating-point elements of the first source vector and the corresponding floating-point elements of the second source vector, and places the results in the corresponding elements of the destination vector.

The behavior is as follows:

- When FPCR.DN is 0, if either element is a NaN, the result is a quiet NaN.
- When FPCR.DN is 1, if either element is a NaN, the result is the Default NaN.
- Denormalized inputs and results are never flushed to zero, as if FPCR.{FZ, FZ16, FIZ} is {0, 0, 0}.
- Denormalized inputs never generate an Input Denormal floating-point exception.

It has encodings from 2 classes: Half-precision and Single-precision and double-precision

FCADD

Floating-point complex add

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCCMP

Floating-point conditional quiet compare (scalar)

This instruction compares the two SIMD&FP source register values and writes the result to the *PSTATE*.{N, Z, C, V} flags. If the condition does not pass, then the *PSTATE*.{N, Z, C, V} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPEnabled64();

constant bits(datasize) operand1 = V[n, datasize];
constant bits(datasize) operand2 = V[m, datasize];

if ConditionHolds(condition) then
    constant boolean signal_all_nans = FALSE;
    flags = FPCompare(operand1, operand2, signal_all_nans, FPCR);

PSTATE.<N,Z,C,V> = flags;
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.

Internal version only: aarchmrs v2024-09_rel, pseudocode v2024-09_rel ; Build timestamp: 2024-09-26T12:00

FCCMPE

Floating-point conditional signaling compare (scalar)

This instruction compares the two SIMD&FP source register values and writes the result to the *PSTATE*.{N, Z, C, V} flags. If the condition does not pass, then the *PSTATE*.{N, Z, C, V} flags are set to the flag bit specifier.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCMGE (register)

Floating-point compare greater than or equal (vector)

This instruction reads each floating-point value in the first source SIMD&FP register and if the value is greater than or equal to the corresponding floating-point value in the second source SIMD&FP register sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision , Scalar single-precision and double-precision , Vector half precision and Vector single-precision and double-precision

FCMLA

Floating-point complex multiply accumulate

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers and the destination register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

FCMLE (zero)

Floating-point compare less than or equal to zero (vector)

This instruction reads each floating-point value in the source SIMD&FP register and if the value is less than or equal to zero sets every bit of the corresponding vector element in the destination SIMD&FP register to one, otherwise sets every bit of the corresponding vector element in the destination SIMD&FP register to zero.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision , Scalar single-precision and double-precision , Vector half precision and Vector single-precision and double-precision

FCMP

Floating-point quiet compare (scalar)

This instruction compares the two SIMD&FP source register values, or the first SIMD&FP source register value and zero. It writes the result to the *PSTATE*.{N, Z, C, V} flags.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

```

Assembler Symbols

<Hn>	For the "Half-precision" variant: is the 16-bit name of the first SIMD&FP source register, encoded in the "Rn" field. For the "Half-precision, zero" variant: is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<Hm>	Is the 16-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<Sn>	For the "Single-precision" variant: is the 32-bit name of the first SIMD&FP source register, encoded in the "Rn" field. For the "Single-precision, zero" variant: is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Rm" field.
<Dn>	For the "Double-precision" variant: is the 64-bit name of the first SIMD&FP source register, encoded in the "Rn" field. For the "Double-precision, zero" variant: is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "Rm" field.

Operation

```
CheckFPEnabled64();

constant bits(datasize) operand1 = V[n, datasize];
constant bits(datasize) operand2 = if cmp_with_zero then FPZero('0', datasize) else V[m, datasize];

PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the PSTATE condition flags to N=0, Z=0, C=1, and V=1.

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the NZCV condition flags written by this instruction might be significantly delayed.

FCVTAS (scalar SIMD&FP)

Floating-point convert to signed integer, rounding to nearest with ties to away (scalar SIMD&FP)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round to Nearest with Ties to Away rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCVTAS (vector)

Floating-point convert to signed integer, rounding to nearest with ties to away (vector)

This instruction converts each element in a vector from a floating-point value to a signed integer value using the Round to Nearest with Ties to Away rounding mode and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision , Scalar single-precision and double-precision , Vector half precision and Vector single-precision and double-precision

FCVTL, FCVTL2

Floating-point convert to higher precision long (vector)

This instruction reads each element in a vector in the SIMD&FP source register, converts each value to double the precision of the source element using the rounding mode that is determined by the FPCR, and writes each result to the equivalent element of the vector in the SIMD&FP destination register.

Where the operation lengthens a 64-bit vector to a 128-bit vector, the `FCVTL2` variant operates on the elements in the top 64 bits of the source register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCVTMS (scalar)

Floating-point convert to signed integer, rounding toward minus infinity (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round towards Minus Infinity rounding mode, and writes the result to the general-purpose destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCVTN (half-precision to 8-bit floating-point)

Half-precision to 8-bit floating-point convert and narrow (vector)

This instruction converts half-precision elements of the two source vectors to 8-bit floating-point while scaling the values by $2^{SInt(FPMR.NSCALE[4:0])}$, and places the in-order results in the 8-bit elements of the destination vector.
The 8-bit floating-point encoding format is selected by FPMR.F8D.

    Elem[result, 1*elements + e, 8] = FPConvertFP8(Elem[operand2, e, 16], FPCR, FPMR, 8);

V[d, datasize] = result;
```

FCVTN, FCVTN2 (double to single-precision, single to half-precision)

Floating-point convert to lower precision narrow (vector)

This instruction reads each vector element in the SIMD&FP source register, converts each result to half the precision of the source element, writes the final result to a vector, and writes the vector to the lower or upper half of the destination SIMD&FP register. The destination vector elements are half as long as the source vector elements. The rounding mode is determined by the FPCR.

`FCVTN` writes the vector to the lower half of the destination register and clears the upper half. `FCVTN2` writes the vector to the upper half of the destination register without affecting the other bits of the register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCVTN, FCVTN2 (single-precision to 8-bit floating-point)

Single-precision to 8-bit floating-point convert and narrow (vector)

This instruction converts each single-precision element of the two source vectors to 8-bit floating-point while scaling the value by $2^{\text{SInt(FPMR.NSCALE)}}$, and places the in-order results in the 8-bit elements of the lower or upper half of the destination vector. `FCVTN` writes the results to the lower half of the destination vector and clears the upper half. `FCVTN2` writes the results to the upper half of the destination vector without affecting the other bits of the vector.

The 8-bit floating-point encoding format is selected by FPMR.F8D.

Assembler Symbols

<Hd> Is the 16-bit name of the SIMD&FP destination register, encoded in the "Rd" field.

<Hn> Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.

<V> Is a width specifier, encoded in “sz”:

sz	<V>
0	S
1	D

<d> Is the number of the SIMD&FP destination register, encoded in the "Rd" field.

<n> Is the number of the SIMD&FP source register, encoded in the "Rn" field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the "Rd" field.

<T> For the "Vector half precision" variant: is an arrangement specifier, encoded in “Q”:

Q	<T>
0	4H
1	8H

For the "Vector single-precision and double-precision" variant: is an arrangement specifier, encoded in “sz:Q”:

sz	Q	<T>
0	0	2S
0	1	4S
1	0	RESERVED
1	1	2D

<Vn> Is the name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
if elements == 1 && IsFeatureImplemented(FEAT_SME2p2) then
    CheckFPEnabled64();
else
    CheckFPAdvSIMDEnabled64();

constant bits(datasize) operand = V[n, datasize];

constant boolean merge = elements == 1 && IsMerging(FPCR);
bits(128) result = if merge then V[d, 128] else Zeros(128);
constant integer fracbits = 0;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, fracbits, unsigned, FPCR, rounding, esize);

V[d, 128] = result;
```

FCVTPS (scalar SIMD&FP)

Floating-point convert to signed integer, rounding toward plus infinity (scalar SIMD&FP)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round toward Plus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

FCVTPS (scalar)

Floating-point convert to signed integer, rounding toward plus infinity (scalar)

This instruction converts the floating-point value in the SIMD&FP source register to a 32-bit or 64-bit signed integer using the Round towards Plus Infinity rounding mode, and writes the result to the general-purpose destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

Assembler Symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the "Rd" field.

<Hn>	Is the 16-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the "Rd" field.
<Sn>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Rn" field.
<Dn>	Is the 64-bit name of the SIMD&FP source register, encoded in the "Rn" field.

Operation

```
CheckFPEnabled64();

constant bits(fltsize) fltval = V[n, fltsize];
constant integer fracbits = 0;

X[d, intsize] = FPToFixed(fltval, fracbits, unsigned, FPCR, rounding, intsize);
```

Operational information

If FEAT_SME is implemented and the PE is in Streaming SVE mode, then any subsequent instruction which is dependent on the general-purpose register written by this instruction might be significantly delayed.

FCVTPS (vector)

Floating-point convert to signed integer, rounding toward plus infinity (vector)

This instruction converts a scalar or each element in a vector from a floating-point value to a signed integer value using the Round towards Plus Infinity rounding mode, and writes the result to the SIMD&FP destination register.

This instruction can generate a floating-point exception. Depending on the settings in FPCR, the exception results in either a flag being set in FPSR or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on the settings in the CPACR_EL1, CPTR_EL2, and CPTR_EL3 registers, and the current Security state and Exception level, an attempt to execute the instruction might be trapped.

It has encodings from 4 classes: Scalar half precision , Scalar single-precision and double-precision , Vector half precision and Vector single-precision and double-precision

Scalar half precision
