AArch32 -- Base Instructions (alphabetic order)

[ADC, ADCS \(immediate\)](#): Add with Carry (immediate).

[ADC, ADCS \(register\)](#): Add with Carry (register).

[ADC, ADCS \(register-shifted register\)](#): Add with Carry (register-shifted register).

[ADD \(immediate, to PC\)](#): Add to PC: an alias of ADR.

[ADD, ADDS \(immediate\)](#): Add (immediate).

[ADD, ADDS \(register\)](#): Add (register).

[ADD, ADDS \(register-shifted register\)](#): Add (register-shifted register).

[ADD, ADDS \(SP plus immediate\)](#): Add to SP (immediate).

[ADD, ADDS \(SP plus register\)](#): Add to SP (register).

[ADR](#): Form PC-relative address.

[AND, ANDS \(immediate\)](#): Bitwise AND (immediate).

[AND, ANDS \(register\)](#): Bitwise AND (register).

[AND, ANDS \(register-shifted register\)](#): Bitwise AND (register-shifted register).

[ASR \(immediate\)](#): Arithmetic Shift Right (immediate): an alias of MOV, MOVS (register).

[ASR \(register\)](#): Arithmetic Shift Right (register): an alias of MOV, MOVS (register-shifted register).

[ASRS \(immediate\)](#): Arithmetic Shift Right, setting flags (immediate): an alias of MOV, MOVS (register).

[ASRS \(register\)](#): Arithmetic Shift Right, setting flags (register): an alias of MOV, MOVS (register-shifted register).

[B](#): Branch.

[BFC](#): Bit Field Clear.

[BFI](#): Bit Field Insert.

[BIC, BICS \(immediate\)](#): Bitwise Bit Clear (immediate).

[BIC, BICS \(register\)](#): Bitwise Bit Clear (register).

[BIC, BICS \(register-shifted register\)](#): Bitwise Bit Clear (register-shifted register).

[BKPT](#): Breakpoint.

[BL, BLX \(immediate\)](#): Branch with Link and optional Exchange (immediate).

[BLX \(register\)](#): Branch with Link and Exchange (register).

[BX](#): Branch and Exchange.

[BXJ](#): Branch and Exchange, previously Branch and Exchange Jazelle.

[CBNZ, CBZ](#): Compare and Branch on Nonzero or Zero.

[CLRBHB](#): Clear Branch History.

[CLREX](#): Clear-Exclusive.

[CLZ](#): Count Leading Zeros.

[CMN \(immediate\)](#): Compare Negative (immediate).

[CMN \(register\)](#): Compare Negative (register).

[CMN \(register-shifted register\)](#): Compare Negative (register-shifted register).

[CMP \(immediate\)](#): Compare (immediate).

[CMP \(register\)](#): Compare (register).

[CMP \(register-shifted register\)](#): Compare (register-shifted register).

[CPS, CPSID, CPSIE](#): Change PE State.

[CRC32](#): CRC32.

[CRC32C](#): CRC32C.

[CSDB](#): Consumption of Speculative Data Barrier.

[DBG](#): Debug hint.

[DCPS1](#): Debug Change PE State to EL1.

[DCPS2](#): Debug Change PE State to EL2.

[DCPS3](#): Debug Change PE State to EL3.

[DMB](#): Data Memory Barrier.

[DSB](#): Data Synchronization Barrier.

[EOR, EORS \(immediate\)](#): Bitwise Exclusive-OR (immediate).

[EOR, EORS \(register\)](#): Bitwise Exclusive-OR (register).

[EOR, EORS \(register-shifted register\)](#): Bitwise Exclusive-OR (register-shifted register).

[ERET](#): Exception Return.

[ESB](#): Error Synchronization Barrier.

[HLT](#): Halting Breakpoint.

[HVC](#): Hypervisor Call.

[ISB](#): Instruction Synchronization Barrier.

[IT](#): If-Then.

[LDA](#): Load-Acquire Word.

[LDAB](#): Load-Acquire Byte.

[LDAEX](#): Load-Acquire Exclusive Word.

[LDAEXB](#): Load-Acquire Exclusive Byte.

[LDAEXD](#): Load-Acquire Exclusive Doubleword.

[LDAEXH](#): Load-Acquire Exclusive Halfword.

[LDAH](#): Load-Acquire Halfword.

[LDC \(immediate\)](#): Load data to System register (immediate).

[LDC \(literal\)](#): Load data to System register (literal).

[LDM \(exception return\)](#): Load Multiple (exception return).

[LDM \(User registers\)](#): Load Multiple (User registers).

[LDM, LDMIA, LDMFD](#): Load Multiple (Increment After, Full Descending).

[LDMDA, LDMFA](#): Load Multiple Decrement After (Full Ascending).

[LDMDB, LDMEA](#): Load Multiple Decrement Before (Empty Ascending).

[LDMIB, LDMED](#): Load Multiple Increment Before (Empty Descending).

[LDR \(immediate\)](#): Load Register (immediate).

[LDR \(literal\)](#): Load Register (literal).

[LDR \(register\)](#): Load Register (register).

[LDRB \(immediate\)](#): Load Register Byte (immediate).

[LDRB \(literal\)](#): Load Register Byte (literal).

[LDRB \(register\)](#): Load Register Byte (register).

[LDRBT](#): Load Register Byte Unprivileged.

[LDRD \(immediate\)](#): Load Register Dual (immediate).

[LDRD \(literal\)](#): Load Register Dual (literal).

[LDRD \(register\)](#): Load Register Dual (register).

[LDREX](#): Load Register Exclusive.

[LDREXB](#): Load Register Exclusive Byte.

[LDREXD](#): Load Register Exclusive Doubleword.

[LDREXH](#): Load Register Exclusive Halfword.

[LDRH \(immediate\)](#): Load Register Halfword (immediate).

[LDRH \(literal\)](#): Load Register Halfword (literal).

[LDRH \(register\)](#): Load Register Halfword (register).

[LDRHT](#): Load Register Halfword Unprivileged.

[LDRSB \(immediate\)](#): Load Register Signed Byte (immediate).

[LDRSB \(literal\)](#): Load Register Signed Byte (literal).

[LDRSB \(register\)](#): Load Register Signed Byte (register).

[LDRSBT](#): Load Register Signed Byte Unprivileged.

[LDRSH \(immediate\)](#): Load Register Signed Halfword (immediate).

[LDRSH \(literal\)](#): Load Register Signed Halfword (literal).

[LDRSH \(register\)](#): Load Register Signed Halfword (register).

[LDRSHT](#): Load Register Signed Halfword Unprivileged.

[LDRT](#): Load Register Unprivileged.

[LSL \(immediate\)](#): Logical Shift Left (immediate): an alias of MOV, MOVS (register).

[LSL \(register\)](#): Logical Shift Left (register): an alias of MOV, MOVS (register-shifted register).

[LSLS \(immediate\)](#): Logical Shift Left, setting flags (immediate): an alias of MOV, MOVS (register).

[LSLS \(register\)](#): Logical Shift Left, setting flags (register): an alias of MOV, MOVS (register-shifted register).

[LSR \(immediate\)](#): Logical Shift Right (immediate): an alias of MOV, MOVS (register).

[LSR \(register\)](#): Logical Shift Right (register): an alias of MOV, MOVS (register-shifted register).

[LSRS \(immediate\)](#): Logical Shift Right, setting flags (immediate): an alias of MOV, MOVS (register).

[LSRS \(register\)](#): Logical Shift Right, setting flags (register): an alias of MOV, MOVS (register-shifted register).

[MCR](#): Move to System register from general-purpose register or execute a System instruction.

[MCRR](#): Move to System register from two general-purpose registers.

[MLA, MLAS](#): Multiply Accumulate.

[MLS](#): Multiply and Subtract.

[MOV, MOVS \(immediate\)](#): Move (immediate).

[MOV, MOVS \(register\)](#): Move (register).

[MOV, MOVS \(register-shifted register\)](#): Move (register-shifted register).

[MOVT](#): Move Top.

[MRC](#): Move to general-purpose register from System register.

[MRRC](#): Move to two general-purpose registers from System register.

[MRS](#): Move Special register to general-purpose register.

[MRS \(Banked register\)](#): Move Banked or Special register to general-purpose register.

[MSR \(Banked register\)](#): Move general-purpose register to Banked or Special register.

[MSR \(immediate\)](#): Move immediate value to Special register.

[MSR \(register\)](#): Move general-purpose register to Special register.

[MUL, Muls](#): Multiply.

[MVN, MVNS \(immediate\)](#): Bitwise NOT (immediate).

[MVN, MVNS \(register\)](#): Bitwise NOT (register).

[MVN, MVNS \(register-shifted register\)](#): Bitwise NOT (register-shifted register).

[NOP](#): No Operation.

[ORN, ORNS \(immediate\)](#): Bitwise OR NOT (immediate).

[ORN, ORNS \(register\)](#): Bitwise OR NOT (register).

[ORR, ORRS \(register\)](#): Bitwise OR (register).

[ORR, ORRS \(register-shifted register\)](#): Bitwise OR (register-shifted register).

[PKHBT, PKHTB](#): Pack Halfword.

[PLD \(literal\)](#): Preload Data (literal).

[PLD, PLDW \(immediate\)](#): Preload Data (immediate).

[PLD, PLDW \(register\)](#): Preload Data (register).

[PLI \(immediate, literal\)](#): Preload Instruction (immediate, literal).

[PLI \(register\)](#): Preload Instruction (register).

[POP](#): Pop Multiple Registers from Stack.

[POP \(multiple registers\)](#): Pop Multiple Registers from Stack: an alias of LDM, LDMIA, LDMFD.

[POP \(single register\)](#): Pop Single Register from Stack: an alias of LDR (immediate).

[PSSBB](#): Physical Speculative Store Bypass Barrier.

[PUSH](#): Push Multiple Registers to Stack.

[PUSH \(multiple registers\)](#): Push multiple registers to Stack: an alias of STMDB, STMFD.

[PUSH \(single register\)](#): Push Single Register to Stack: an alias of STR (immediate).

[QADD](#): Saturating Add.

[QADD16](#): Saturating Add 16.

[QADD8](#): Saturating Add 8.

[QASX](#): Saturating Add and Subtract with Exchange.

[QDADD](#): Saturating Double and Add.

[QDSUB](#): Saturating Double and Subtract.

[QSAX](#): Saturating Subtract and Add with Exchange.

[QSUB](#): Saturating Subtract.

[QSUB16](#): Saturating Subtract 16.

[QSUB8](#): Saturating Subtract 8.

[RBIT](#): Reverse Bits.

[REV](#): Byte-Reverse Word.

[REV16](#): Byte-Reverse Packed Halfword.

[REVSH](#): Byte-Reverse Signed Halfword.

[RFE](#), [RFEDA](#), [RFEDB](#), [RFEIA](#), [RFEIB](#): Return From Exception.

[ROR \(immediate\)](#): Rotate Right (immediate): an alias of MOV, MOVS (register).

[ROR \(register\)](#): Rotate Right (register): an alias of MOV, MOVS (register-shifted register).

[RORS \(immediate\)](#): Rotate Right, setting flags (immediate): an alias of MOV, MOVS (register).

[RORS \(register\)](#): Rotate Right, setting flags (register): an alias of MOV, MOVS (register-shifted register).

[RRX](#): Rotate Right with Extend: an alias of MOV, MOVS (register).

[RRXS](#): Rotate Right with Extend, setting flags: an alias of MOV, MOVS (register).

[RSB](#), [RSBS \(immediate\)](#): Reverse Subtract (immediate).

[RSB](#), [RSBS \(register\)](#): Reverse Subtract (register).

[RSB](#), [RSBS \(register-shifted register\)](#): Reverse Subtract (register-shifted register).

[RSC](#), [RSCS \(immediate\)](#): Reverse Subtract with Carry (immediate).

[RSC](#), [RSCS \(register\)](#): Reverse Subtract with Carry (register).

[RSC](#), [RSCS \(register-shifted register\)](#): Reverse Subtract (register-shifted register).

[SADD16](#): Signed Add 16.

[SADD8](#): Signed Add 8.

[SASX](#): Signed Add and Subtract with Exchange.

[SB](#): Speculation Barrier.

[SBC](#), [SBCS \(immediate\)](#): Subtract with Carry (immediate).

[SBC](#), [SBCS \(register\)](#): Subtract with Carry (register).

[SBC](#), [SBCS \(register-shifted register\)](#): Subtract with Carry (register-shifted register).

[SBFX](#): Signed Bit Field Extract.

[SDIV](#): Signed Divide.

[SEL](#): Select Bytes.

[SETEND](#): Set Endianness.

[SETPAN](#): Set Privileged Access Never.

[SEV](#): Send Event.

[SEVL](#): Send Event Local.

[SHADD16](#): Signed Halving Add 16.

[SHADD8](#): Signed Halving Add 8.

[SHASX](#): Signed Halving Add and Subtract with Exchange.

[SHSAX](#): Signed Halving Subtract and Add with Exchange.

[SHSUB16](#): Signed Halving Subtract 16.

[SHSUB8](#): Signed Halving Subtract 8.

[SMC](#): Secure Monitor Call.

[SMLABB](#), [SMLABT](#), [SMLATB](#), [SMLATT](#): Signed Multiply Accumulate (halfwords).

[SMLAD](#), [SMLADX](#): Signed Multiply Accumulate Dual.

[SMLAL](#), [SMLALS](#): Signed Multiply Accumulate Long.

[SMLALBB](#), [SMLALBT](#), [SMLALTB](#), [SMLALTT](#): Signed Multiply Accumulate Long (halfwords).

[SMLALD](#), [SMLALDX](#): Signed Multiply Accumulate Long Dual.

[SMLAWB, SMLAWT](#): Signed Multiply Accumulate (word by halfword).

[SMLSDD, SMLSDDX](#): Signed Multiply Subtract Dual.

[SMLSDD, SMLSDDX](#): Signed Multiply Subtract Long Dual.

[SMMLA, SMMLAR](#): Signed Most Significant Word Multiply Accumulate.

[SMMLS, SMMLSR](#): Signed Most Significant Word Multiply Subtract.

[SMMUL, SMMULR](#): Signed Most Significant Word Multiply.

[SMUAD, SMUADX](#): Signed Dual Multiply Add.

[SMULBB, SMULBT, SMULTB, SMULTT](#): Signed Multiply (halfwords).

[SMULL, SMULLS](#): Signed Multiply Long.

[SMULWB, SMULWT](#): Signed Multiply (word by halfword).

[SMUSD, SMUSDX](#): Signed Multiply Subtract Dual.

[SRS, SRSDA, SRSDDB, SRSIA, SRSIB](#): Store Return State.

[SSAT](#): Signed Saturate.

[SSAT16](#): Signed Saturate 16.

[SSAX](#): Signed Subtract and Add with Exchange.

[SSBB](#): Speculative Store Bypass Barrier.

[SSUB16](#): Signed Subtract 16.

[SSUB8](#): Signed Subtract 8.

[STC](#): Store data to System register.

[STL](#): Store-Release Word.

[STLB](#): Store-Release Byte.

[STLEX](#): Store-Release Exclusive Word.

[STLEXB](#): Store-Release Exclusive Byte.

[STLEXD](#): Store-Release Exclusive Doubleword.

[STLEXH](#): Store-Release Exclusive Halfword.

[STLH](#): Store-Release Halfword.

[STM \(User registers\)](#): Store Multiple (User registers).

[STM, STMIA, STMEA](#): Store Multiple (Increment After, Empty Ascending).

[STMDA, STMED](#): Store Multiple Decrement After (Empty Descending).

[STMDB, STMFD](#): Store Multiple Decrement Before (Full Descending).

[STMIB, STMFA](#): Store Multiple Increment Before (Full Ascending).

[STR \(immediate\)](#): Store Register (immediate).

[STR \(register\)](#): Store Register (register).

[STRB \(immediate\)](#): Store Register Byte (immediate).

[STRB \(register\)](#): Store Register Byte (register).

[STRBT](#): Store Register Byte Unprivileged.

[STRD \(immediate\)](#): Store Register Dual (immediate).

[STRD \(register\)](#): Store Register Dual (register).

[STREX](#): Store Register Exclusive.

[STREXB](#): Store Register Exclusive Byte.

[STREXD](#): Store Register Exclusive Doubleword.

[STREXH](#): Store Register Exclusive Halfword.

[STRH \(immediate\)](#): Store Register Halfword (immediate).

[STRH \(register\)](#): Store Register Halfword (register).

[STRHT](#): Store Register Halfword Unprivileged.

[STRT](#): Store Register Unprivileged.

[SUB \(immediate, from PC\)](#): Subtract from PC: an alias of ADR.

[SUB, SUBS \(immediate\)](#): Subtract (immediate).

[SUB, SUBS \(register\)](#): Subtract (register).

[SUB, SUBS \(register-shifted register\)](#): Subtract (register-shifted register).

[SUB, SUBS \(SP minus immediate\)](#): Subtract from SP (immediate).

[SUB, SUBS \(SP minus register\)](#): Subtract from SP (register).

[SVC](#): Supervisor Call.

[SXTAB](#): Signed Extend and Add Byte.

[SXTAB16](#): Signed Extend and Add Byte 16.

[SXTAH](#): Signed Extend and Add Halfword.

[SXTB](#): Signed Extend Byte.

[SXTB16](#): Signed Extend Byte 16.

[SXTH](#): Signed Extend Halfword.

[TBB, TBH](#): Table Branch Byte or Halfword.

[TEQ \(immediate\)](#): Test Equivalence (immediate).

[TEQ \(register\)](#): Test Equivalence (register).

[TEQ \(register-shifted register\)](#): Test Equivalence (register-shifted register).

[TSB](#): Trace Synchronization Barrier.

[TST \(immediate\)](#): Test (immediate).

[TST \(register\)](#): Test (register).

[TST \(register-shifted register\)](#): Test (register-shifted register).

ADC, ADCS (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register. If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result. The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	1	0	1	0	1	S	Rn				Rd				imm12											
cond								opc																							

Encoding for the ADC variant

Applies when (S == 0)

ADC{<c>}{<q>}{<Rd>, }<Rn>, #<const>

Encoding for the ADCS variant

Applies when (S == 1)

ADCS{<c>}{<q>}{<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	1	0	i	0	1	0	1	0	S	Rn				0	imm3				Rd				imm8							
op1																																

Encoding for the ADC variant

Applies when (S == 0)

ADC{<c>}{<q>}{<Rd>, }<Rn>, #<const>

Encoding for the ADCS variant

Applies when (S == 1)

ADCS{<c>}{<q>}{<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd>	For the "A1 ADC" and "A1 ADCS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used: - For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. - For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. For the "T1 ADC" and "T1 ADCS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>	For the "A1 ADC" and "A1 ADCS" variants: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For the "T1 ADC" and "T1 ADCS" variants: is the general-purpose source register, encoded in the "Rn" field.
<const>	For the "A1 ADC" and "A1 ADCS" variants: an immediate value. See Modified immediate constants in A32 instructions for the range of values. For the "T1 ADC" and "T1 ADCS" variants: an immediate value. See Modified immediate constants in T32 instructions for the range of values.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), imm32, PSTATE.C);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

2026-03_rel 2026-03-26 20:48:11

ADC, ADCS (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	For the "A1 ADC, rotate right with extend", "A1 ADC, shift or rotate by value", "A1 ADCS, rotate right with extend", and "A1 ADCS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used: - For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. - For the ADCS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. For the "T2 ADC, rotate right with extend", "T2 ADC, shift or rotate by value", "T2 ADCS, rotate right with extend", and "T2 ADCS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>	For the "A1 ADC, rotate right with extend", "A1 ADC, shift or rotate by value", "A1 ADCS, rotate right with extend", and "A1 ADCS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For the "T2 ADC, rotate right with extend", "T2 ADC, shift or rotate by value", "T2 ADCS, rotate right with extend", and "T2 ADCS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	For the "A1 ADC, rotate right with extend", "A1 ADC, shift or rotate by value", "A1 ADCS, rotate right with extend", and "A1 ADCS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For the "T1", "T2 ADC, rotate right with extend", "T2 ADC, shift or rotate by value", "T2 ADCS, rotate right with extend", and "T2 ADCS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "A1 ADC, shift or rotate by value" and "A1 ADCS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For the "T2 ADC, shift or rotate by value" and "T2 ADCS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.
- Inside an IT block, if ADC<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcv) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, PSTATE.C);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcv;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

ADC, ADCS (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding for the Flag setting variant

Applies when (S == 1)

ADCS{<c>}{<q>}{<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

ADC{<c>}{<q>}{<Rd>, }<Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SType = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .										
<q>	See Standard assembler syntax fields .										
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.										
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.										
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.										
<shift>	Is the type of shift to be applied to the second source register, encoded in "stype": <table><tr><th>stype</th><th><shift></th></tr><tr><td>00</td><td>LSL</td></tr><tr><td>01</td><td>LSR</td></tr><tr><td>10</td><td>ASR</td></tr><tr><td>11</td><td>ROR</td></tr></table>	stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR
stype	<shift>										
00	LSL										
01	LSR										
10	ASR										
11	ROR										
<Rs>	Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcv) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, PSTATE.C);
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcv;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

ADD (immediate, to PC)

Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias.

This is a pseudo-instruction of [ADR](#). This means:

- The encodings in this description are named to match the encodings of [ADR](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [ADR](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

is equivalent to

[ADR](#){<c>} {<q>} <Rd>, <label>

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	For the "T1" and "T3" variants: is the general-purpose destination register, encoded in the "Rd" field. For the "A1" variant: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC .
<imm12>	Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.
<const>	An immediate value. See Modified immediate constants in A32 instructions for the range of values.
<imm8>	Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

Operation

The description of [ADR](#) gives the operational pseudocode for this instruction.

ADD, ADDS (immediate)

Add (immediate) adds an immediate value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) , [T3](#) and [T4](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd>	For the "A1 ADD" and "A1 ADDS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:
	- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see <i>Pseudocode description of operations on the AArch32 general-purpose registers and the PC</i>. - For the ADDS variant, the instruction performs an exception return, that restores <i>PSTATE</i> from SPSR_<current_mode>. Arm deprecates use of this instruction.
	For the "T1", "T3 ADD", "T3 ADDS", and "T4" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>	For the "A1 ADD", "A1 ADDS", and "T4" variants: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see <i>ADD (SP plus immediate)</i> . If the PC is used, see <i>ADR</i> . For the "T1" variant: is the general-purpose source register, encoded in the "Rn" field. For the "T3 ADD" and "T3 ADDS" variants: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see <i>ADD (SP plus immediate)</i> .
<const>	For the "A1 ADD" and "A1 ADDS" variants: an immediate value. See <i>Modified immediate constants in A32 instructions</i> for the range of values. For the "T3 ADD" and "T3 ADDS" variants: an immediate value. See <i>Modified immediate constants in T32 instructions</i> for the range of values.
<imm3>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.
<Rdn>	Is the general-purpose source and destination register, encoded in the "Rdn" field.
<imm8>	Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.
<imm12>	Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the *ADDW* syntax). Encoding T1 is preferred to encoding T2 if <Rd> is specified and encoding T2 is preferred to encoding T1 if <Rd> is omitted.

Operation

```

if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcw) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), imm32, '0');
    if d == 15 then // Can only occur for A32 encoding
      if setflags then
        ALUExceptionReturn(result);
      else
        ALUWritePC(result);
      end;
    else
      R(d) = result;
      if setflags then
        PSTATE.[N,Z,C,V] = nzcw;
      end;
    end;
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcw) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), imm32, '0');
    R(d) = result;
    if setflags then
      PSTATE.[N,Z,C,V] = nzcw;
    end;
  end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

2026-03_rel 2026-03-26 20:48:11

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

ADD, ADDS (register)

Add (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd>	For the "A1 ADD, rotate right with extend", "A1 ADD, shift or rotate by value", "A1 ADDS, rotate right with extend", and "A1 ADDS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used: - For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. - For the ADDS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. Arm deprecates use of this instruction. For the "T1" variant: is the general-purpose destination register, encoded in the "Rd" field. When used inside an IT block, <Rd> must be specified. When used outside an IT block, <Rd> is optional, and: - If omitted, this register is the same as <Rn>. - If present, encoding T1 is preferred to encoding T2.										
<Rn>	For the "A1 ADD, rotate right with extend", "A1 ADD, shift or rotate by value", "A1 ADDS, rotate right with extend", and "A1 ADDS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used. If the SP is used, see ADD (SP plus register). For the "T1" variant: is the first general-purpose source register, encoded in the "Rn" field. For the "T3 ADD, rotate right with extend", "T3 ADD, shift or rotate by value", "T3 ADDS, rotate right with extend", and "T3 ADDS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see ADD (SP plus register).										
<Rm>	For the "A1 ADD, rotate right with extend", "A1 ADD, shift or rotate by value", "A1 ADDS, rotate right with extend", and "A1 ADDS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For the "T1", "T3 ADD, rotate right with extend", "T3 ADD, shift or rotate by value", "T3 ADDS, rotate right with extend", and "T3 ADDS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. For the "T2" variant: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.										
<shift>	Is the type of shift to be applied to the second source register, encoded in "stype": <table> <tr> <th>stype</th><th><shift></th></tr> <tr> <td>00</td><td>LSL</td></tr> <tr> <td>01</td><td>LSR</td></tr> <tr> <td>10</td><td>ASR</td></tr> <tr> <td>11</td><td>ROR</td></tr> </table>	stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR
stype	<shift>										
00	LSL										
01	LSR										
10	ASR										
11	ROR										
<amount>	For the "A1 ADD, shift or rotate by value" and "A1 ADDS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For the "T3 ADD, shift or rotate by value" and "T3 ADDS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.										
<Rdn>	Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. The assembler language allows <Rdn> to be specified once or twice in the assembler syntax. When used inside an IT block, and <Rdn> and <Rm> are in the range R0 to R7, <Rdn> must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when <Rdn> is specified once or twice. Inside an IT block, if ADD<c> <Rd>, <Rn>, <Rd> cannot be assembled using encoding T1, it is assembled using encoding T2 as though ADD<c> <Rd>, <Rn> had been written. To prevent this happening, use the .W qualifier.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.\[N,Z,C,V\] = nzcvc;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

ADD, ADDS (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

Encoding for the Flag setting variant

Applies when (S == 1)

```
ADDS{<c>}{<q>}{<Rd>}, <Rn>, <Rm>, <shift> <Rs>
```

Encoding for the Not flag setting variant

Applies when (S == 0)

```
ADD{<c>}{<q>}{<Rd>}, <Rn>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SType = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .										
<q>	See Standard assembler syntax fields .										
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.										
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.										
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.										
<shift>	Is the type of shift to be applied to the second source register, encoded in "stype": <table><tr><th>stype</th><th><shift></th></tr><tr><td>00</td><td>LSL</td></tr><tr><td>01</td><td>LSR</td></tr><tr><td>10</td><td>ASR</td></tr><tr><td>11</td><td>ROR</td></tr></table>	stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR

10	ASR										
11	ROR										
<Rs>	Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcv) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), shifted, '0');
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcv;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

ADD, ADDS (SP plus immediate)

Add to SP (immediate) adds an immediate value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) , [T3](#) and [T4](#)).

ADD, ADDS (SP plus register)

Add to SP (register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ADDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ADDS{<c>}{<q>} {<Rd>, }SP, <Rm>, RRX

Encoding for the ADDS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

ADDS{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("CMN (register)"); end;
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd> For the "A1 ADD, rotate right with extend", "A1 ADD, shift or rotate by value", "A1 ADDS, rotate right with extend", and "A1 ADDS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ADDS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the "T3 ADD, rotate right with extend", "T3 ADD, shift or rotate by value", "T3 ADDS, rotate right with extend", and "T3 ADDS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<Rm> For the "A1 ADD, rotate right with extend", "A1 ADD, shift or rotate by value", "A1 ADDS, rotate right with extend", "A1 ADDS, shift or rotate by value", and "T2" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For the "T3 ADD, rotate right with extend", "T3 ADD, shift or rotate by value", "T3 ADDS, rotate right with extend", and "T3 ADDS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in "stype":

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "A1 ADD, shift or rotate by value" and "A1 ADDS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For the "T3 ADD, shift or rotate by value" and "T3 ADDS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

<Rdm> Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

SP Is the stack pointer.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(13), shifted, '0');
    if d == 15 then
        if setflags then
            ALUEXCEPTIONReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
end;

```

ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

This instruction is used by the alias [SUB \(immediate, from PC\)](#).

This instruction is used by the pseudo-instruction [ADD \(immediate, to PC\)](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let add : boolean = TRUE;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> For the "A1" and "A2" variants: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
For the "T1", "T2", and "T3" variants: is the general-purpose destination register, encoded in the "Rd" field.
- <label> For the "A1" and "A2" variants: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset. If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32. Permitted values of the size of the offset are any of the constants described in [Modified immediate constants in A32 instructions](#).
For the "T1" variant: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.
For the "T2" and "T3" variants: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset. If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32. Permitted values of the size of the offset are 0-4095.

The instruction aliases permit the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Alias Conditions

Alias	Of variant	Is preferred when
ADD (immediate, to PC)		Never
SUB (immediate, from PC)	A2	<code>imm12 == '000000000000'</code>
SUB (immediate, from PC)	T2	<code>i :: imm3 :: imm8 == '000000000000'</code>

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let result : bits(32) = (if add then (AlignDownSize(PC32(),4) + imm32)
                           else (AlignDownSize(PC32(),4) - imm32));
  if d == 15 then           // Can only occur for A32 encodings
    ALUWritePC(result);
  else
    R(d) = result;
  end;
end;
```

AND, ANDS (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register. If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

AND, ANDS (register)

Bitwise AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd> For the "A1 AND, rotate right with extend", "A1 AND, shift or rotate by value", "A1 ANDS, rotate right with extend", and "A1 ANDS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ANDS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the "T2 AND, rotate right with extend", "T2 AND, shift or rotate by value", "T2 ANDS, rotate right with extend", and "T2 ANDS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For the "A1 AND, rotate right with extend", "A1 AND, shift or rotate by value", "A1 ANDS, rotate right with extend", and "A1 ANDS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For the "T2 AND, rotate right with extend", "T2 AND, shift or rotate by value", "T2 ANDS, rotate right with extend", and "T2 ANDS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For the "A1 AND, rotate right with extend", "A1 AND, shift or rotate by value", "A1 ANDS, rotate right with extend", and "A1 ANDS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For the "T1", "T2 AND, rotate right with extend", "T2 AND, shift or rotate by value", "T2 ANDS, rotate right with extend", and "T2 ANDS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "A1 AND, shift or rotate by value" and "A1 ANDS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For the "T2 AND, shift or rotate by value" and "T2 ANDS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

In T32 assembly:

- Outside an IT block, if ANDS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ANDS <Rd>, <Rn> had been written.
- Inside an IT block, if AND<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though AND<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C(32){R(m), shift_t, shift_n, PSTATE.C};
    let result : bits(32) = R(n) AND shifted;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit(32)(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

AND, ANDS (register-shifted register)

Bitwise AND (register-shifted register) performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ASRS (immediate)

Arithmetic Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in copies of its sign bit, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

<q>	See Standard assembler syntax fields.
<label>	For the "A1" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are multiples of 4 in the range –33554432 to 33554428. For the "T1" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –256 to 254. For the "T2" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –2048 to 2046. For the "T3" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –1048576 to 1048574. For the "T4" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –16777216 to 16777214.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC32() + imm32, BranchType_DIR);
end;
```

BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
!= 1111				0	1	1	1	1	1	0	msb				Rd				lsb				0	0	1	1	1	1	Rn			
cond																																

Encoding

BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let msbit : integer{} = UInt(msb);
let lsbit : integer{} = UInt(lsb);
if d == 15 then UnpredictableProcedure(); end;
if msbit < lsbit then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	(0)	1	1	0	1	1	0	1	1	1	0	imm3				Rd				imm2		(0)	msb				
op1												Rn																			

Encoding

BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let msbit : integer{} = UInt(msb);
let lsbit : integer{} = UInt(imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
if msbit < lsbit then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<lsb>	For the "A1" variant: is the least significant bit to be cleared, in the range 0 to 31, encoded in the "lsb" field. For the "T1" variant: is the least significant bit that is to be cleared, in the range 0 to 31, encoded in the "imm3:imm2" field.
<width>	Is the number of bits to be cleared, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+<width>-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d)[msbit:lsbit] = Replicate{(msbit-lsbit)+1}('0');
    // Other bits of R[d] are unchanged
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

BIC, BICS (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<Rd>	For the "A1 BIC" and "A1 BICS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used: - For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. - For the BICS variant, the instruction performs an exception return, that restores <i>PSTATE</i> from SPSR_<current_mode>. For the "T1 BIC" and "T1 BICS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>	For the "A1 BIC" and "A1 BICS" variants: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For the "T1 BIC" and "T1 BICS" variants: is the general-purpose source register, encoded in the "Rn" field.
<const>	For the "A1 BIC" and "A1 BICS" variants: an immediate value. See Modified immediate constants in A32 instructions for the range of values. For the "T1 BIC" and "T1 BICS" variants: an immediate value. See Modified immediate constants in T32 instructions for the range of values.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                            else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) AND NOT(imm32);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

BIC, BICS (register)

Bitwise Bit Clear (register) performs a bitwise AND of a register value and the complement of an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the type of shift to be applied to the second source register, encoded in "stype":

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND NOT(shifted);
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

BKPT

Breakpoint causes a Breakpoint Instruction exception.
Breakpoint is always unconditional, even when inside an IT block.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	0	1	0	imm12											0	1	1	1	imm4				
cond									opc																						

Encoding

BKPT{<q>} {#}<imm>

Decode for this encoding

```
let imm16 : bits(16) = imm12::imm4;
if cond != '1110' then UnpredictableProcedure(); end; // BKPT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	0	imm8							

Encoding

BKPT{<q>} {#}<imm>

Decode for this encoding

```
let imm16 : bits(16) = ZeroExtend{}(imm8);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

`<q>`
`<imm>`

See [Standard assembler syntax fields](#). A BKPT instruction must be unconditional.

For the "A1" variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

For the "T1" variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

Operation

```
EncodingSpecificOperations();
AArch32_SoftwareBreakpoint(imm16);
```

BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address, and setting LR to the return address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, setting LR to the return address, and changes the instruction set from A32 to T32, or from T32 to A32.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let I2 : bit = NOT(J2 XOR S);
let imm32 : bits(32) = SignExtend{(S::I1::I2::imm10H::imm10L::'00')};
let targetInstrSet : InstrSet = InstrSet_A32;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For the "A1" variant: see *Standard assembler syntax fields*.
For the "A2" variant: see *Standard assembler syntax fields*. <c> must be AL or omitted.

For the "T1" and "T2" variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<label>

For the "A1" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are multiples of 4 in the range –33554432 to 33554428.

For the "A2" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range –33554432 to 33554430.

For the "T1" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are even numbers in the range –16777216 to 16777214.

For the "T2" variant: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset. Permitted offsets are multiples of 4 in the range –16777216 to 16777212.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentInstrSet() == InstrSet_A32 then
        LR() = PC32() - 4;
    else
        LR() = PC32()[31:1] :: '1';
    end;
    var targetAddress : bits(32);
    if targetInstrSet == InstrSet_A32 then
        targetAddress = AlignDownSize(PC32(), 4) + imm32;
    else
        targetAddress = PC32() + imm32;
    end;
    SelectInstrSet(targetInstrSet);
    BranchWritePC(targetAddress, BranchType_DIRCALL);
end;
```

BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address specified in the register, and if necessary changes to the instruction set indicated by bit[0] of the register value. If the value in bit[0] is 0, the instruction set after the branch will be A32. If the value in bit[0] is 1, the instruction set after the branch will be T32.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	1	Rm			
cond										op0																					

Encoding

BLX{<c>} {<q>} <Rm>

Decode for this encoding

```
let m : integer = UInt(Rm);
if m == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	1	1	1	1	Rm				(0)	(0)	(0)
L															

Encoding

BLX{<c>} {<q>} <Rm>

Decode for this encoding

```
let m : integer = UInt(Rm);
if m == 15 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let target : bits(32) = R(m);
    var next_instr_addr : bits(32);
    if CurrentInstrSet() == InstrSet_A32 then
        next_instr_addr = PC32() - 4;
        LR() = next_instr_addr;
    else
        next_instr_addr = PC32() - 2;
        LR() = next_instr_addr[31:1] :: '1';
    end;
    BXWritePC(target, BranchType_INDCALL);
end;
```

BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	0 1		0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	0	1	Rm			
cond										op0																					

Encoding

BX{<c>}{<q>} <Rm>

Decode for this encoding

```
let m : integer = UInt(Rm);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	1	1	1	0	Rm				(0)	(0)	(0)
L															

Encoding

BX{<c>}{<q>} <Rm>

Decode for this encoding

```
let m : integer = UInt(Rm);
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rm> For the "A1" variant: is the general-purpose register holding the address to be branched to, encoded in the "Rm" field. The PC can be used.
For the "T1" variant: is the general-purpose register holding the address to be branched to, encoded in the "Rm" field. The PC can be used.

Note

If <Rm> is the PC at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the BXWritePC() pseudocode function has bits<1:0> = '10'.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R(m), BranchType_INDIR);
end;
```

BXJ

Branch and Exchange, previously Branch and Exchange Jazelle.
BXJ behaves as a BX instruction, see [BX](#). This means it causes a branch to an address and instruction set specified by a register.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	0	Rm			
cond										op0																					

Encoding

BXJ{<c>}{<q>} <Rm>

Decode for this encoding

```
let m : integer = UInt(Rm);
if m == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	1	0	0	Rm				1	0	(0)	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)

Encoding

BXJ{<c>}{<q>} <Rm>

Decode for this encoding

```
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R(m), BranchType_INDIR);
end;
```

CBNZ, CBZ

Compare and Branch on Nonzero and Compare and Branch on Zero compare the value in a register with zero, and conditionally branch forward a constant value. They do not affect the condition flags.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	op	0	i	1	imm5					Rn		

Encoding for the CBNZ variant

Applies when (op == 1)

CBNZ{<q>} <Rn>, <label>

Encoding for the CBZ variant

Applies when (op == 0)

CBZ{<q>} <Rn>, <label>

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(i::imm5::'0')};
let nonzero : boolean = (op == '1');
if InITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <q> See *Standard assembler syntax fields*.
- <Rn> Is the general-purpose register to be tested, encoded in the "Rn" field.
- <label> Is the program label to be conditionally branched to. Its offset from the PC, a multiple of 2 and in the range 0 to 126, is encoded as "i:imm5" times 2.

Operation

```
EncodingSpecificOperations();
if nonzero != IsZero(R(n)) then
    CBWritePC(PC32() + imm32);
end;
```

CLRBHB

Clear Branch History clears the branch history for the current context to the extent that branch history information created before the CLRBHB instruction cannot be used by code before the CLRBHB instruction to exploitatively control the execution of any indirect branches in code in the current context that appear in program order after the instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1 (FEAT_CLRBHB)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!=	1	1	1	1	0	0	1	1	0	0	1	0	0	0	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	1	0	1	1	0
cond				R				imm4								imm12															

Encoding

CLRBHB{<c>}{<q>}

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_CLRBHB) then ExecuteAsNOP\(\); end;
```

T1 (FEAT_CLRBHB)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding

CLREX{<c>}{<q>}

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c>
- For the "A1" variant: see [Standard assembler syntax fields](#). Must be AL or omitted.
- For the "T1" variant: see [Standard assembler syntax fields](#).
- <q>
- See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    ClearExclusiveLocal(ProcessorID());
end;
```

CLZ

Count Leading Zeros returns the number of binary zero bits before the first binary one bit in a value. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	1	1	0	(1)	(1)	(1)	(1)	Rd				(1)	(1)	(1)	(1)	0	0	0	1	Rm			
cond									op0																						

Encoding

CLZ{<c>}{<q>}<Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	0	1	1	Rn				1	1	1	1	Rd				1	0	0	0	Rm			
op1																op2															

Encoding

CLZ{<c>}{<q>}<Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if m != n || d == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `m != n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes with the additional decode: `m = UInt(Rn)`;
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	For the "A1" variant: is the general-purpose source register, encoded in the "Rm" field. For the "T1" variant: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let result : integer = CountLeadingZeroBits(R(m));
    R(d) = result[31:0];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

Encoding

CMN{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = A32ExpandImm(imm12);
```

T1

Encoding

CMN{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let imm32 : bits(32) = T32ExpandImm(i::imm3::imm8);
if n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rn> For the "A1" variant: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For the "T1" variant: is the general-purpose source register, encoded in the "Rn" field.
- <const> For the "A1" variant: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.
For the "T1" variant: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), imm32, '0');
    PSTATE.[N,Z,C,V] = nzcvc;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

CMN (register)

Compare Negative (register) adds a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

  PSTATE.[N,Z,C,V] = nzcvc;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

CPS, CPSID, CPSIE

Change PE State changes one or more of the *PSTATE*.{A, I, F} interrupt mask bits and, optionally, the *PSTATE*.M mode field, without changing any other *PSTATE* bits.

CPS is treated as NOP if executed in User mode unless it is defined as being CONSTRAINED UNPREDICTABLE elsewhere in this section.

The PE checks whether the value being written to PSTATE.M is legal. See *Illegal changes to PSTATE.M*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let affectI : boolean = (I == '1');
let affectF : boolean = (F == '1');
if (imod == '00' && M == '0') || imod == '01' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If *imod* == '01', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If *imod* == '00' && *M* == '0', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If *mode* != '00000' && *M* == '0', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: changemode = TRUE.
- The instruction executes as described, and the value specified by mode is ignored. There are no additional side-effects.

If `imod<1> == '1' && A:I:F == '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '0'`.
- The instruction behaves as if `A:I:F` has an UNKNOWN nonzero value.

If `imod<1> == '0' && A:I:F != '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '1'`.
- The instruction behaves as if `A:I:F == '000'`.

let pemode : bits(5) = mode;
let affectA : boolean = (A == '1');
let affectI : boolean = (I == '1');
let affectF : boolean = (F == '1');
if imod == '01' || InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `imod == '01'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode != '00000' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `changemode = TRUE`.
- The instruction executes as described, and the value specified by mode is ignored. There are no additional side-effects.

If `imod<1> == '1' && A:I:F == '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '0'`.
- The instruction behaves as if A:I:F has an UNKNOWN nonzero value.

If `imod<1> == '0' && A:I:F != '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if `imod<1> == '1'`.
- The instruction behaves as if A:I:F == '000'.

Hint instructions: In encoding T2, if the imod field is 0b00 and the M bit is 0b0, a hint instruction is encoded. To determine which hint instruction, see [Branches and miscellaneous control](#).

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<q>	See Standard assembler syntax fields .
<mode>	Is the number of the mode to change to, in the range 0 to 31, encoded in the "mode" field.
<iflags>	Is a sequence of one or more of the following, specifying which interrupt mask bits are affected: a Sets the A bit in the instruction, causing the specified effect on PSTATE.A , the SError interrupt mask bit. i Sets the I bit in the instruction, causing the specified effect on PSTATE.I , the IRQ interrupt mask bit. f Sets the F bit in the instruction, causing the specified effect on PSTATE.F , the FIQ interrupt mask bit.

Operation

```
if CurrentInstrSet\(\) == InstrSet\_A32 then
    EncodingSpecificOperations();
    if PSTATE.EL != EL0 then
        if enable then
            if affectA then PSTATE.A = '0'; end;
            if affectI then PSTATE.I = '0'; end;
            if affectF then PSTATE.F = '0'; end;
        end;
        if disable then
            if affectA then PSTATE.A = '1'; end;
            if affectI then PSTATE.I = '1'; end;
            if affectF then PSTATE.F = '1'; end;
        end;
        if changemode then
            // AArch32_WriteModeByInstr() sets PSTATE.IL to 1 if this is an illegal mode change.
            AArch32\_WriteModeByInstr(pemode);
        end;
    end;
else
    EncodingSpecificOperations();
    if PSTATE.EL != EL0 then
        if enable then
            if affectA then PSTATE.A = '0'; end;
            if affectI then PSTATE.I = '0'; end;
            if affectF then PSTATE.F = '0'; end;
        end;
        if disable then
            if affectA then PSTATE.A = '1'; end;
            if affectI then PSTATE.I = '1'; end;
            if affectF then PSTATE.F = '1'; end;
        end;
        if changemode then
            // AArch32_WriteModeByInstr() sets PSTATE.IL to 1 if this is an illegal mode change.
            AArch32\_WriteModeByInstr(pemode);
        end;
    end;
end;
```

CRC32

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In an Armv8.0 implementation, this is an OPTIONAL instruction. From Armv8.1, it is mandatory for all implementations to implement this instruction.

Note

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Assembler Symbols

- <c>

See [Standard assembler syntax fields](#).
- <q>

See [Standard assembler syntax fields](#).
- <option>

Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the "option" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
end;
```

DCPS1

Debug Change PE State to EL1 allows the debugger to move the PE into EL1 from EL0 or to a specific mode at the current Exception level. DCPS1 is UNDEFINED if any of:

- The PE is in Non-debug state.
- EL2 is implemented, EL2 is implemented and enabled in the current Security state, and any of:
 - EL2 is using AArch32 and HCR.TGE is set to 1.
 - EL2 is using AArch64 and HCR_EL2.TGE is set to 1.

When the PE executes DCPS1 at EL0, EL1 or EL3:

- If EL3 or EL1 is using AArch32, the PE enters SVC mode and LR_svc, SPSR_svc, DLR, and DSPSR become UNKNOWN. If DCPS1 is executed in Monitor mode, SCR.NS is cleared to 0.
- If EL1 is using AArch64, the PE enters EL1 using AArch64, selects SP_EL1, and ELR_EL1, ESR_EL1, SPSR_EL1, DLR_EL0 and DSPSR_EL0 become UNKNOWN.

When the PE executes DCPS1 at EL2 the PE does not change mode, and ELR_hyp, HSR, SPSR_hyp, DLR and DSPSR become UNKNOWN. For more information on the operation of the DCPS<n> instructions, see DCPS.

DCPS3

Debug Change PE State to EL3 allows the debugger to move the PE into EL3 from a lower Exception level or to a specific mode at the current Exception level.
DCPS3 is UNDEFINED if any of:

- The PE is in Non-debug state.
- EL3 is not implemented.
- EDSCR.SDD is set to 1.

When the PE executes DCPS3:

- If EL3 is using AArch32, the PE enters Monitor mode and LR_mon, SPSR_mon, DLR and DSPSR become UNKNOWN. If DCPS3 is executed in Monitor mode, SCR.NS is cleared to 0.
- If EL3 is using AArch64, the PE enters EL3 using AArch64, selects SP_EL3, and ELR_EL3, ESR_EL3, SPSR_EL3, DLR_EL0 and DSPSR_EL0 become UNKNOWN.

For more information on the operation of the DCPS<n> instructions, see [DCPS](#).

1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	1	0	1	option			

opc

Encoding

DMB{<c>}{<q>}{<option>}

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c>
- For the "A1" variant: see *Standard assembler syntax fields*. Must be AL or omitted.
- For the "T1" variant: see *Standard assembler syntax fields*.
- <q>
- See *Standard assembler syntax fields*.

<option>

Specifies an optional limitation on the barrier operation. Values are:

SY	Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Can be omitted. This option is referred to as the full system barrier. Encoded as option = 0b1111.
ST	Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. SYST is a synonym for ST. Encoded as option = 0b1110.
LD	Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1101.
ISH	Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b1011.
ISHST	Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b1010.
ISHL	Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1001.
NSH	Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as option = 0b0111.
NSHST	Non-shareable is the required shareability domain, writes are the required access type both before and after the barrier instruction. Encoded as option = 0b0110.
NSHL	Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0101.
OSH	Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b0011.
OSHST	Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b0010.
OSHL	Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0001.

For more information on whether an access is before or after a barrier instruction, see [Data Memory Barrier \(DMB\)](#). All other encodings of option are reserved. All unsupported and reserved options must execute as a full system DMB operation, but software must not rely on this behavior.

Note

The instruction supports the following alternative <option> values, but Arm recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST as an alias for NSHST.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var types : MReqTypes;
    case option[1:0] of
        when '00' => types = MReqTypes_All;
        when '01' => types = MReqTypes_Reads;
        when '10' => types = MReqTypes_Writes;
        when '11' => types = MReqTypes_All;
    end;

    DataMemoryBarrier(types);
end;
```

DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see [Data Synchronization Barrier \(DSB\)](#).
An AArch32 DSB instruction does not require the completion of any AArch64 TLB maintenance instructions, regardless of the nXS qualifier, appearing in program order before the AArch32 DSB.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

																								opc				option			

Encoding

DSB{<c>} {<q>} {<option>}

Decode for this encoding

// No additional decoding required

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c>For the "A1" variant: see [Standard assembler syntax fields](#). Must be AL or omitted.
- For the "T1" variant: see [Standard assembler syntax fields](#).
- <q>See [Standard assembler syntax fields](#).

<option>

Specifies an optional limitation on the barrier operation. Values are:

SY	Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Can be omitted. This option is referred to as the full system barrier. Encoded as option = 0b1111.
ST	Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. SYST is a synonym for ST. Encoded as option = 0b1110.
LD	Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1101.
ISH	Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b1011.
ISHST	Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b1010.
ISHL	Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1001.
NSH	Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as option = 0b0111.
NSHST	Non-shareable is the required shareability domain, writes are the required access type both before and after the barrier instruction. Encoded as option = 0b0110.
NSHL	Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0101.
OSH	Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b0011.
OSHST	Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b0010.
OSHL	Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0001.

For more information on whether an access is before or after a barrier instruction, see [Data Synchronization Barrier \(DSB\)](#). All other encodings of option are reserved, other than the values 0b0000 and 0b0100. All unsupported and reserved options must execute as a full system DSB operation, but software must not rely on this behavior.

Note

The value 0b0000 is used to encode SSBB and the value 0b0100 is used to encode PSSBB. The instruction supports the following alternative <option> values, but Arm recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST as an alias for NSHST.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var nXS : boolean;
    if IsFeatureImplemented(FEAT_XS) then
        nXS = (PSTATE.EL IN {EL0, EL1} && !ELUsingAArch32(EL2) &&
            IsHCRXEL2Enabled() && HCRX_EL2().FnXS == '1');
    else
        nXS = FALSE;
    end;
    var scope : MBMaintenanceScope;
    var types : MBRegTypes;
    case option[1:0] of
        when '00' =>
            types = MBRegTypes_All;
            scope = MBMaintenanceScope_OuterShareable;
        when '01' =>
            types = MBRegTypes_Reads;
            scope = MBMaintenanceScope_None;
        when '10' =>
            types = MBRegTypes_Writes;
            scope = MBMaintenanceScope_None;
        when '11' =>
            types = MBRegTypes_All;
            case option[3:2] of
                when '00' => scope = MBMaintenanceScope_OuterShareable;
                when '01' => scope = MBMaintenanceScope_Nonshareable;
                when '10' => scope = MBMaintenanceScope_InnerShareable;
                when '11' => scope = MBMaintenanceScope_OuterShareable;
            end;
    end;
    DataSynchronizationBarrier(scope, types, nXS);
end;
```

EOR, EORS (immediate)

Bitwise Exclusive-OR (immediate) performs a bitwise exclusive-OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd>	For the "A1 EOR" and "A1 EORS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used: - For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. - For the EORS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>. For the "T1 EOR" and "T1 EORS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>	For the "A1 EOR" and "A1 EORS" variants: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For the "T1 EOR" and "T1 EORS" variants: is the general-purpose source register, encoded in the "Rn" field.
<const>	For the "A1 EOR" and "A1 EORS" variants: an immediate value. See Modified immediate constants in A32 instructions for the range of values. For the "T1 EOR" and "T1 EORS" variants: an immediate value. See Modified immediate constants in T32 instructions for the range of values.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                             else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) XOR imm32;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEXCEPTIONRETURN(result);
        else
            ALUWRITEPC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

Encoding for the EOR, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

EOR{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

EOR<c>.W {<Rd>, }<Rn>, <Rm> // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Encoding for the EORS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11)

EORS{<c>}{<q>} {<Rd>, }<Rn>, <Rm>, RRX

Encoding for the EORS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

EORS{<c>}{<q>} {<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

EORS.W {<Rd>, }<Rn>, <Rm> // (Outside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("TEQ (register)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd> For the "A1 EOR, rotate right with extend", "A1 EOR, shift or rotate by value", "A1 EORS, rotate right with extend", and "A1 EORS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the EORS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the "T2 EOR, rotate right with extend", "T2 EOR, shift or rotate by value", "T2 EORS, rotate right with extend", and "T2 EORS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For the "A1 EOR, rotate right with extend", "A1 EOR, shift or rotate by value", "A1 EORS, rotate right with extend", and "A1 EORS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For the "T2 EOR, rotate right with extend", "T2 EOR, shift or rotate by value", "T2 EORS, rotate right with extend", and "T2 EORS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For the "A1 EOR, rotate right with extend", "A1 EOR, shift or rotate by value", "A1 EORS, rotate right with extend", and "A1 EORS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For the "T1", "T2 EOR, rotate right with extend", "T2 EOR, shift or rotate by value", "T2 EORS, rotate right with extend", and "T2 EORS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For the "A1 EOR, shift or rotate by value" and "A1 EORS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For the "T2 EOR, shift or rotate by value" and "T2 EORS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

In T32 assembly:

- Outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written
- Inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) XOR shifted;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

EOR, EORS (register-shifted register)

Bitwise Exclusive-OR (register-shifted register) performs a bitwise exclusive-OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<Rs>	Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C[32](R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) XOR shifted;
    R(d) = result;
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit[32](result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

ERET

Exception Return.

The PE branches to the address held in the register holding the preferred return address, and restores *PSTATE* from SPSR_<current_mode>.

The register holding the preferred return address is:

- *ELR_hyp*, when executing in Hyp mode.
- LR, when executing in a mode other than Hyp mode, User mode, or System mode.

The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.

Exception Return is CONSTRAINED UNPREDICTABLE in User mode and System mode.

In Debug state, the T1 encoding of ERET executes the DRPS operation.

It has encodings from the following instruction sets: A32 (*A1*) and T32 (*T1*) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding

ERET{<c>}{<q>}

Decode for this encoding

```
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if !Halted() then
        if PSTATE.M IN {M32_User, M32_System} then
            UnpredictableProcedure(); // UNDEFINED or NOP
        else
            let new_pc_value : bits(32) = if PSTATE.EL == EL2 then ELR_hyp() else R(14);
            AArch32_ExceptionReturn(new_pc_value, SPSR_curr());
        end;
    else // Perform DRPS operation in Debug state
        if PSTATE.M == M32_User then
            Undefined();
        elseif PSTATE.M == M32_System then
            UnpredictableProcedure(); // UNDEFINED or NOP
        else
            SynchronizeContext();
            DebugRestorePSR();
        end;
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User,M32_System}`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.

ESB

Error Synchronization Barrier is an error synchronization event that might also update DISR and VDISR. This instruction can be used at all Exception levels and in Debug state.

In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. For more information, see *RAS PE architecture* and Arm® Reliability, Availability, and Serviceability (RAS) System Architecture, for A-profile architecture (ARM IHI 0100).

If *FEAT_RAS* is not implemented, this instruction executes as a NOP.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1
(FEAT_RAS)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

HLT

Halting breakpoint causes a software breakpoint to occur.
Halting breakpoint is always unconditional, even inside an IT block.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	0	0	imm12												0	1	1	1	imm4				
cond									opc																						

Encoding

HLT{<q>} {#}<imm>

Decode for this encoding

```
if EDSCR().HDE == '0' || !HaltingAllowed() then Undefined(); end;
if cond != '1110' then UnpredictableProcedure(); end; // HLT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	0	1	0	1	0	imm6					

Encoding

HLT{<q>} {#}<imm>

Decode for this encoding

```
if EDSCR().HDE == '0' || !HaltingAllowed() then Undefined(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <q>
- See [Standard assembler syntax fields](#). An HLT instruction must be unconditional.
- <imm>
- For the "A1" variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.
For the "T1" variant: is a 6-bit unsigned immediate, in the range 0 to 63, encoded in the "imm6" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

Operation

```
EncodingSpecificOperations();
let is_async : boolean = FALSE;
let fault : FaultRecord = NoFault();
Halt(DebugHalt HaltInstruction, is_async, fault);
```

HVC

Hypervisor Call causes a Hypervisor Call exception. For more information, see *Hypervisor Call (HVC) exception*. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- When EL3 is implemented and using AArch64, and SCR_EL3.HCE is set to 0.
- In Non-secure EL1 modes when EL3 is implemented and using AArch32, and SCR.HCE is set to 0.
- When EL3 is not implemented and either HCR_EL2.HCD is set to 1 or HCR.HCD is set to 1.
- When EL2 is not implemented.
- In Secure state, if EL2 is not enabled in the current Security state.
- In User mode.

The HVC instruction is CONSTRAINED UNPREDICTABLE in Hyp mode when EL3 is implemented and using AArch32, and SCR.HCE is set to 0.

On executing an HVC instruction, the *HSR, Hyp Syndrome Register* reports the exception as a Hypervisor Call exception, using the EC value 0x12, and captures the value of the immediate argument, see *Use of the HSR*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	1	0	0	imm12												0	1	1	1	imm4			
cond										opc																					

Encoding

HVC{<q>} {#}<imm16>

Decode for this encoding

```
if cond != '1110' then UnpredictableProcedure(); end;
let imm16 : bits(16) = imm12::imm4;
```

CONSTRAINED UNPREDICTABLE behavior

If cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

o1												o2																			

Encoding

HVC{<q>} {#}<imm16>

Decode for this encoding

```
let imm16 : bits(16) = imm4::imm12;
if InITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <q>
- See *Standard assembler syntax fields*. An HVC instruction must be unconditional.
- <imm16>
- For the "A1" variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

For the "T1" variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

Operation

```
EncodingSpecificOperations();
if PSTATE.EL IN {EL0, EL3} || !EL2Enabled() then
    Undefined();
end;

var hvc_enable : bit;
if HaveEL(EL3) then
    if ELUsingAArch32(EL3) then
        if SCR().HCE == '0' && PSTATE.EL == EL2 then UnpredictableProcedure(); end;
        hvc_enable = SCR().HCE;
    else
        hvc_enable = SCR_EL3().HCE;
    end;
else
    hvc_enable = if ELUsingAArch32(EL2) then NOT(HCR().HCD) else NOT(HCR_EL2().HCD);
end;

if hvc_enable == '0' then
    Undefined();
else
    AArch32_CallHypervisor(immm16);
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `ELUsingAArch32(EL3) && SCR.HCE == '0' && PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c>
- For the "A1" variant: see *Standard assembler syntax fields*. Must be AL or omitted.
- For the "T1" variant: see *Standard assembler syntax fields*.
- <q>
- See *Standard assembler syntax fields*.
- <option>
- Specifies an optional limitation on the barrier operation. Values are:
- SY
- Full system barrier operation, encoded as option = 0b1111. Can be omitted.
- All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
end;
```

IT

If-Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the `IT` instruction specifies for the first instruction in the block.

The `IT` instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than `CMP`, `CMN` and `TST`, do not set the condition flags. An `IT` instruction with the `AL` condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the `CPSR` restores `PSTATE.IT` to a state consistent with the conditions specified by the `IT` instruction. Any other exception return to an instruction in an IT block is `UNPREDICTABLE`. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is `UNPREDICTABLE` what condition is used when executing that target instruction and any subsequent instruction in the IT block.

Many uses of the IT instruction are deprecated for performance reasons, and an implementation might include ITD controls that can disable those uses of IT, making them `UNDEFINED`.

For more information see [Conditional execution](#) and [Conditional instructions](#). The first of these sections includes more information about the ITD controls.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	1	1	firstcond				!= 0000			
mask															

Encoding

IT{<x>{<y>{<z>}}}{<q> <cond>

Decode for this encoding

```
if mask == '0000' then See("Related encodings"); end;
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then
  UnpredictableProcedure();
end;
if InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1)`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The '1111' condition is treated as being the same as the '1110' condition, meaning always, and the `ITSTATE` state machine is progressed in the same way as for any other `cond_base` value.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Miscellaneous 16-bit instructions](#).

Assembler Symbols

<x>	The condition for the second instruction in the IT block. If omitted, the "mask" field is set to 0b1000. If present it is encoded in the "mask[3]" field:
T	firstcond[0]
E	NOT firstcond[0]
<y>	The condition for the third instruction in the IT block. If omitted and <x> is present, the "mask[2:0]" field is set to 0b100. If <y> is present it is encoded in the "mask[2]" field:
T	firstcond[0]
E	NOT firstcond[0]
<z>	The condition for the fourth instruction in the IT block. If omitted and <y> is present, the "mask[1:0]" field is set to 0b10. If <z> is present, the "mask[0]" field is set to 1, and it is encoded in the "mask[1]" field:
T	firstcond[0]
E	NOT firstcond[0]

<q> See *Standard assembler syntax fields*.

<cond> The condition for the first instruction in the IT block, encoded in the "firstcond" field. See *Condition codes* for the range of conditions available, and the encodings.

The conditions specified in an `IT` instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check `IT` instruction syntax for validity but do not generate assembled instructions for them. See *Conditional instructions*.

Operation

```
EncodingSpecificOperations();  
AArch32_CheckITEnabled(mask);  
PSTATE.IT[7:0] = firstcond::mask;  
ShouldAdvanceIT = FALSE;
```

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address, 1);
    R(t) = ZeroExtend{32}{MemO{8}(address)};
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

LDAEXD

Load-Acquire Exclusive Doubleword loads a doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also acts as a barrier instruction with the ordering requirements described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
!= 1111				0 0		0 1		1 1		0 1		1 1		Rn			Rt			(1) (1)		1 0		1 0		0 0		1 1		(1) (1)		(1) (1)			
cond								size				L												ex ord								xRt			

Encoding

LDAEXD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
if Rt[0] == '1' || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `t<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in [Using R15](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
1	1	1	0	1	0	0	0	1	1	0	1	Rn			Rt			Rt2			1	1	1	1	(1)	(1)	(1)	(1)							
op0												L				op												sz				Rd			

Encoding

LDAEXD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q>	See <i>Standard assembler syntax fields</i> .
<Rt>	For the "A1" variant: is the first general-purpose register to be transferred, encoded in the "Rt" field. <Rt> must be even-numbered and not R14. For the "T1" variant: is the first general-purpose register to be transferred, encoded in the "Rt" field.
<Rt2>	For the "A1" variant: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>. For the "T1" variant: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address, 8);
    let value : bits(64) = MemO{64}(address);
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R(t) = if BigEndian(AccessType_GPR) then value[63:32] else value[31:0];
    R(t2) = if BigEndian(AccessType_GPR) then value[31:0] else value[63:32];
end;

```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

LDAEXH

    let address : bits(32) = R(n);
    R(t) = ZeroExtend{32}(MemQ{16}(address));
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDC (immediate)

Load data to System register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to the *DBGDTRTXint* System register. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses, see *Memory accesses*.

In an implementation that includes EL2, the permitted LDC access to *DBGDTRTXint* can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *HDCR.TDA*.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1	1	1	0	1	1	0	P	U	0	W	1	!= 1111				0	1	0	1	1	1	1	0	imm8							
				D				L				Rn				CRd				cp15											

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDC{<c>}{<q>} p14, c5, [<Rn>{, #{+/-}<imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

LDC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDC{<c>}{<q>} p14, c5, [<Rn>, #{+/-}<imm>]!

Encoding for the Unindexed variant

Applies when (P == 0 && U == 1 && W == 0)

LDC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDC (literal)"); end;
if P == '0' && U == '0' && W == '0' then Undefined(); end;
let n : integer = UInt(Rn);
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
```

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rn> Is the general-purpose base register, encoded in the "Rn" field. If the PC is used, see [LDC \(literal\)](#).
- +/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+
- <imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.
- <option> Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
  let address : bits(32) = if index then offset_addr else R(n);

  // System register write to DBGDTRTXint.
  AArch32_SysRegWriteM(cp, ThisInstr(), address);

  if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDC (literal)

Load data to System register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to the *DBGDTRTXint* System register. For information about memory accesses, see *Memory accesses*.

In an implementation that includes EL2, the permitted LDC access to *DBGDTRTXint* can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *HDCR.TDA*.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	0	P	U	0	W	1	1	1	1	1	0	1	0	1	1	1	1	0	imm8							
cond				D				L				Rn				CRd				cp15											

Encoding

Applies when $(!(P == 0 \ \&\& \ U == 0 \ \&\& \ W == 0))$

LDC{<c>}{<q>} p14, c5, <label> // (Preferred syntax)

LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]

LDC{<c>}{<q>} p14, c5, [PC], <option>

Decode for this encoding

```
if P == '0' && U == '0' && W == '0' then Undefined(); end;
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $\bar{W} == '1'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	P	U	0	W	1	1	1	1	1	0	1	0	1	1	1	1	0	imm8							
				D				L				Rn				CRd				cp15											

Encoding

Applies when $(!(P == 0 \ \&\& \ U == 0 \ \&\& \ W == 0))$

LDC{<c>}{<q>} p14, c5, <label> // (Preferred syntax)

LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]

Decode for this encoding

```
if P == '0' && U == '0' && W == '0' then Undefined(); end;
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $\bar{W} == '1' \ || \ P == '0'$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes as LDC (immediate) with writeback to the PC. The instruction is handled as described in *Using R15*.

Assembler Symbols

<c>

See *Standard assembler syntax fields*.

<q>	See Standard assembler syntax fields .						
<label>	The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE (encoded as U == 1). If the offset is negative, imm32 is equal to minus the offset and add == FALSE (encoded as U == 0).						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:						
	<table> <tr> <th>U</th><th>+/-</th></tr> <tr> <td>0</td><td>-</td></tr> <tr> <td>1</td><td>+</td></tr> </table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.						
<option>	Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.						

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = (if add then (AlignDownSize(PC32(), 4) + imm32)
                                else (AlignDownSize(PC32(), 4) - imm32));
    let address : bits(32) = if index then offset_addr else AlignDownSize(PC32(), 4);

    // System register write to DBGDTRTXint.
    AArch32_SysRegWriteM(cp, ThisInstr(), address);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The *SPSR* of the current mode is copied to the *CPSR*. An address adjusted by the size of the data loaded can optionally be written back to the base register. The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address. The PE checks the encoding that is copied to the *CPSR* for an illegal return event. See *Illegal return events from AArch32 state*. Load Multiple (exception return) is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in debug state, and in User mode and System mode.

A1

Encoding

```
LDM{<amode>}{<c>}{<q>} <Rn>{!}, <registers_with_pc>^
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(15) = register_list;
let wback : boolean = (W == '1');
let increment : boolean = (U == '1');
let wordhigher : boolean = (P == U);
if n == 15 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<amode>	is one of:
DA	Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
FA	Full Ascending. For this instruction, a synonym for DA.
DB	Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
EA	Empty Ascending. For this instruction, a synonym for DB.
IA	Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
FD	Full Descending. For this instruction, a synonym for IA.
IB	Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
ED	Empty Descending. For this instruction, a synonym for IB.
<c>	See <i>Standard assembler syntax fields</i> .
<q>	See <i>Standard assembler syntax fields</i> .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers_with_pc> Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also [Encoding of lists of general-purpose registers and the PC](#).

Instructions with similar syntax but without the PC included in the registers list are described in [LDM \(User registers\)](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        Undefined();
    elseif PSTATE.M IN {M32_User, M32_System} then
        UnpredictableProcedure(); // UNDEFINED or NOP
    else
        let length : integer = 4*BitCount(registers) + 4;
        var address : bits(32) = if increment then R(n) else R(n)-length;
        if wordhigher then address = address+4; end;
        var data : bits(32);

        for i = 0 to 14 do
            if registers[i] == '1' then
                if i != n then
                    R(i) = MemS{32}(address);
                else
                    data = MemS{32}(address);
                end;
                address = address + 4;
            end;
        end;
        let new_pc_value : bits(32) = MemS{32}(address);

        if wback && registers[n] == '1' then
            R(n) = ARBITRARY : bits(32);
        end;
        if wback && registers[n] == '0' then
            R(n) = if increment then R(n)+length else R(n)-length;
        end;
        if !wback && registers[n] == '1' then
            R(n) = data;
        end;

        AArch32_ExceptionReturn(new_pc_value, SPSR_curr());
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User, M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Load Multiple (User registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#).

A1

Encoding

LDM{<amode>}{<c>}{<q>} <Rn>, <registers_without_pc>^

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(15) = register_list;
let increment : boolean = (U == '1');
let wordhigher : boolean = (P == U);
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<amode>	is one of:
DA	Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
FA	Full Ascending. For this instruction, a synonym for DA.
DB	Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
EA	Empty Ascending. For this instruction, a synonym for DB.
IA	Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
FD	Full Descending. For this instruction, a synonym for IA.
IB	Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
ED	Empty Descending. For this instruction, a synonym for IB.
<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<registers_without_pc>	Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded by the LDM instruction. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must not be in the register list. See also Encoding of lists of general-purpose registers and the PC .

Instructions with similar syntax but with the PC included in <registers_without_pc> are described in [LDM \(exception return\)](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then Undefined();
    elsif PSTATE.M IN {M32_User, M32_System} then UnpredictableProcedure();
    else
        let length : integer = 4*BitCount(registers);
        var address : bits(32) = if increment then R(n) else R(n)-length;
        if wordhigher then address = address+4; end;
        for i = 0 to 14 do
            if registers[i] == '1' then // Load User mode register
                Rmode(i, M32_User) = MemS{32}(address); address = address + 4;
            end;
        end;
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User, M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDM, LDMIA, LDMFD

Load Multiple (Increment After, Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#). The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#). Related system instructions are [LDM \(User registers\)](#) and [LDM \(exception return\)](#).

This instruction is used by the alias [POP \(multiple registers\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	0	0	0	1	0	W	1	Rn				register_list															
cond				P				U				op				L															

Encoding

```
LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
LDMFD{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = '00000000'::register_list;
let wback : boolean = (registers[n] == '0');
if BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

T2

Encoding

```
LDM{IA}{<c>}.W <Rn>{!}, <registers> // (Preferred syntax, if <Rn>, '!' and <registers> can be represented in T1)
LDMFD{<c>}.W <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack, if <Rn>, '!' and <registers> can be represented in
LDM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
LDMFD{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = P::M::register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
if registers[13] == '1' then UnpredictableProcedure(); end;
if registers[15] == '1' && !InitBlock() && !LastInitBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

IA	Is an optional suffix for the Increment After form.
<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

!

For the "A1" and "T2" variants: the address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

For the "T1" variant: the address adjusted by the size of the data loaded is written back to the base register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.

<registers>

For the "A1" variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The PC can be in the list. Arm deprecates using these instructions with both the LR and the PC in the list.

For the "T1" variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field.

For the "T2" variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Alias Conditions

Alias	Of variant	Is preferred when
POP (multiple registers)	A1	<code>W == '1' && Rn == '1101' && BitCount(register_list) > 1</code>
POP (multiple registers)	T2	<code>W == '1' && Rn == '1101' && BitCount(P :: M :: register_list) > 1</code>
POP (multiple registers)	T2	<code>BitCount(P :: M :: register_list) > 1</code>

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n);
    var data : bits(32);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i != n then
                R(i) = MemS{32}(address);
            else
                data = MemS{32}(address);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        LoadWritePC(MemS{32}(address));
    end;

    if wback && registers[n] == '1' then
        R(n) = ARBITRARY : bits(32);
    end;
    if wback && registers[n] == '0' then
        R(n) = R(n) + 4*BitCount(registers);
    end;
    if !wback && registers[n] == '1' then
        R(n) = data;
    end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDMDA, LDMFA

Load Multiple Decrement After (Full Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).
Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#). The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#). Related system instructions are [LDM \(User registers\)](#) and [LDM \(exception return\)](#).

A1

Encoding

```
LDMDA{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
LDMFA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Ascending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `BitCount(registers) < 1`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.
- If `wback && registers[n] == '1'`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- ! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
- <registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The PC can be in the list. Arm deprecates using these instructions with both the LR and the PC in the list.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = (R(n) - 4*BitCount(registers)) + 4;
    var data : bits(32);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i != n then
                R(i) = MemS{32}(address);
            else
                data = MemS{32}(address);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        LoadWritePC(MemS{32}(address));
    end;

    if wback && registers[n] == '1' then
        R(n) = ARBITRARY : bits(32);
    end;
    if wback && registers[n] == '0' then
        R(n) = R(n) - 4*BitCount(registers);
    end;
    if !wback && registers[n] == '1' then
        R(n) = data;
    end;
end;
```

opc							L																								

Encoding

```
LDMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
LDMEA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = P::M::register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
if registers[13] == '1' then UnpredictableProcedure(); end;
if registers[15] == '1' && !InitBlock() && !LastInitBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOP`.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<code><c></code>	See Standard assembler syntax fields .
<code><q></code>	See Standard assembler syntax fields .
<code><Rn></code>	Is the general-purpose base register, encoded in the "Rn" field.
<code>!</code>	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<code><registers></code>	For the "A1" variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The PC can be in the list. Arm deprecates using these instructions with both the LR and the PC in the list. For the "T1" variant: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. If the PC is in the list: • The LR must not be in the list. • The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n) - 4*BitCount(registers);
    var data : bits(32);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i != n then
                R(i) = MemS{32}(address);
            else
                data = MemS{32}(address);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        LoadWritePC(MemS{32}(address));
    end;

    if wback && registers[n] == '1' then
        R(n) = ARBITRARY : bits(32);
    end;
    if wback && registers[n] == '0' then
        R(n) = R(n) - 4*BitCount(registers);
    end;
    if !wback && registers[n] == '1' then
        R(n) = data;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDMIB, LDMED

Load Multiple Increment Before (Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).
Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#). The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#). Related system instructions are [LDM \(User registers\)](#) and [LDM \(exception return\)](#).

A1

Encoding

```
LDMIB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

LDMED{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an LDM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

LDR (immediate)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

This instruction is used by the alias [POP \(single register\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) , [T3](#) and [T4](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	0	P	U	0	W	1	!= 1111				Rt				imm12											
cond				op2				op1				Rn																			

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDR{<c>}{<q>} <Rt>, [<Rn> {, # {+/-} <imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

```
LDR{<c>}{<q>} <Rt>, [<Rn>], # {+/-} <imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDR{<c>}{<q>} <Rt>, [<Rn>, # {+/-} <imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDR (literal)"); end;
if P == '0' && W == '1' then See("LDRT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if wback && n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. For the "T1" and "T2" variants: is the general-purpose register to be transferred, encoded in the "Rt" field. For the "T3", "T4 Offset", "T4 Post-indexed", and "T4 Pre-indexed" variants: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC.						
<Rn>	For the "A1 Offset", "A1 Post-indexed", "A1 Pre-indexed", "T3", "T4 Offset", "T4 Post-indexed", and "T4 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDR (literal). For the "T1" variant: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table> <tr> <th>U</th><th>+/-</th></tr> <tr> <td>0</td><td>-</td></tr> <tr> <td>1</td><td>+</td></tr> </table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field. For the "T1" variant: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4. For the "T2" variant: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4. For the "T3" variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For the "T4 Offset", "T4 Post-indexed", and "T4 Pre-indexed" variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.						
+	Specifies the offset is added to the base register.						

Alias Conditions

Alias	Of variant	Is preferred when
POP (single register)	A1 Post-indexed	<code>P == '0' && U == '1' && W == '0' && Rn == '1101' && imm12 == '000000000100'</code>
POP (single register)	T4 Post-indexed	<code>Rn == '1101' && P == '0' && U == '1' && W == '1' && imm8 == '00000100'</code>

Operation

```
if CurrentInstrSet\(\) == InstrSet A32 then
  if ConditionPassed\(\) then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(32) = MemU{32}(address);
    if wback then R(n) = offset_addr; end;
    if t == 15 then
      if address[1:0] == '00' then
        LoadWritePC(data);
      else
        UnpredictableProcedure();
      end;
    else
      R(t) = data;
    end;
  end;
else
  if ConditionPassed\(\) then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(32) = MemU{32}(address);
    if wback then R(n) = offset_addr; end;
    if t == 15 then
      if address[1:0] == '00' then
        LoadWritePC(data);
      else
        UnpredictableProcedure();
      end;
    else
      R(t) = data;
    end;
  end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see [Memory accesses](#). It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
!= 1111				0	1	0	P	U	0	W	1	1	1	1	1	Rt					imm12											
cond				op2				op1				Rn																				

Encoding

Applies when `(!(P == 0 && W == 1))`

```
LDR{<c>}{<q>} <Rt>, <label> // (Normal form)

LDR{<c>}{<q>} <Rt>, [PC, #<+/-><imm>] // (Alternative form)
```

Decode for this encoding

```
if P == '0' && W == '1' then See("LDRT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if wback then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `wback = FALSE`;
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in [LDR \(immediate\)](#). The instruction uses post-indexed addressing when `P == '0'` and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	Rt			imm8							

Encoding

```
LDR{<c>}{<q>} <Rt>, <label> // (Normal form)
```

Decode for this encoding

```
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let add : boolean = TRUE;
```

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	1	1	0	0	0	U	1	0	1	1	1	1	1	Rt					imm12											
size									L																							

Encoding

```
LDR{<c>}.W <Rt>, <label> // (Preferred syntax)

LDR{<c>}{<q>} <Rt>, <label> // (Preferred syntax, and <Rt>, <label> can be represented in T1)

LDR{<c>}{<q>} <Rt>, [PC, #<+/-><imm>] // (Alternative syntax)
```

Decode for this encoding

```
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
if t == 15 && !InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	For the "A1" variant: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. For the "T1" variant: is the general-purpose register to be transferred, encoded in the "Rt" field. For the "T2" variant: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC.						
<label>	For the "A1" and "T2" variants: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0. For the "T1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1" variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field. For the "T2" variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.						

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(), 4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    let data : bits(32) = MemU{32}(address);
    if t == 15 then
        if address[1:0] == '00' then
            LoadWritePC(data);
        else
            UnpredictableProcedure();
        end;
    else
        R(t) = data;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see [Memory accesses](#).
The T32 form of LDR (register) does not support register writeback.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	P	U	0	W	1	Rn				Rt				imm5				stype		0	Rm				
cond				op2				op1																							

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("LDRT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
if m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	0	0	Rm			Rn			Rt		
L				B		H									

Encoding

LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let shift_t : SRTYPE = SRTYPE.LSL;
let shift_n : integer = 0;
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
```

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
1	1	1	1	1	0	0	0	0	1	0	1	!= 1111				Rt				0				0	0	0	0	0	imm2		Rm								
size												L				Rn																							

Encoding

```
LDR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

LDR{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)
```

Decode for this encoding

```
if Rn == '1111' then See("LDR (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
if t == 15 && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. For the "T1" variant: is the general-purpose register to be transferred, encoded in the "Rt" field. For the "T2" variant: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC.						
<Rn>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant. For the "T1" and "T2" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
<shift>	The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts applied to a register .						
+	Specifies the index register is added to the base register.						
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.						

Operation

```
if CurrentInstrSet() == InstrSet A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(32) = MemU{32}(address);
    if wback then R(n) = offset_addr; end;
    if t == 15 then
      if address[1:0] == '00' then
        LoadWritePC(data);
      else
        UnpredictableProcedure();
      end;
    else
      R(t) = data;
    end;
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = (R(n) + offset);
    let address : bits(32) = offset_addr;
    let data : bits(32) = MemU{32}(address);
    if t == 15 then
      if address[1:0] == '00' then
        LoadWritePC(data);
      else
        UnpredictableProcedure();
      end;
    else
      R(t) = data;
    end;
  end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRB (immediate)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	0	P	U	1	W	1	!= 1111				Rt				imm12											
cond				op2				op1				Rn																			

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRB{<c>}{<q>} <Rt>, [<Rn> {, #<+/->imm}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRB{<c>}{<q>} <Rt>, [<Rn>], #<+/->imm

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRB{<c>}{<q>} <Rt>, [<Rn>, #<+/->imm]!

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRB (literal)"); end;
if P == '0' && W == '1' then See("LDRBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `wback && n == t`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

if (t == 15 && W == '1') || (wback && n == t) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	For the "A1 Offset", "A1 Post-indexed", "A1 Pre-indexed", "T2", "T3 Offset", "T3 Post-indexed", and "T3 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRB (literal) . For the "T1" variant: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For the "T1" variant: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.
For the "T2" variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.
For the "T3 Offset", "T3 Post-indexed", and "T3 Pre-indexed" variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

+ Specifies the offset is added to the base register.

Operation

```
if CurrentInstrSet() == InstrSet A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    R(t) = ZeroExtend{32}(MemU{8}(address));
    if wback then R(n) = offset_addr; end;
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    R(t) = ZeroExtend{32}(MemU{8}(address));
    if wback then R(n) = offset_addr; end;
  end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

LDRB (literal)

Load Register Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
!= 1111				0	1	0	P	U	1	W	1	1	1	1	1	Rt					imm12															
cond				op2				op1				Rn																								

Encoding

Applies when (! (P == 0 && W == 1))

```
LDRB{<c>}{<q>}<Rt>, <label> // (Normal form)

LDRB{<c>}{<q>}<Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```
if P == '0' && W == '1' then See("LDRBT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{imm12};
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || wback then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If *wback*, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in *LDRB (immediate)*. The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15*.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0																
1	1	1	1	1	1	0	0	0	U	0	0	1	1	1	1	1	!= 1111					imm12																									
size																L																Rt															

Encoding

```
LDRB{<c>}{<q>}<Rt>, <label> // (Preferred syntax)

LDRB{<c>}{<q>}<Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

Decode for this encoding

```
if Rt == '1111' then See("PLD"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{imm12};
let add : boolean = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See <i>Standard assembler syntax fields</i> .
<q>	See <i>Standard assembler syntax fields</i> .
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<label>	The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For the "A1" variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For the "T1" variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(),4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    R(t) = ZeroExtend{32}(MemU{8}(address));
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	P	U	1	W	1	Rn				Rt				imm5				stype		0	Rm				
cond								op2				op1																			

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("LDRBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	1	0	Rm			Rn			Rt		
L				B		H									

Encoding

LDRB{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
1	1	1	1	1	0	0	0	0	0	0	1	!= 1111				!= 1111				0	0	0	0	0	0	imm2		Rm							
size												L				Rn				Rt															

Encoding

```
LDRB{<c>}{<q>}<Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]
LDRB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)
```

Decode for this encoding

```
if Rt == '1111' then See("PLD"); end;
if Rn == '1111' then See("LDRB (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SType = SType_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.						
<Rn>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant. For the "T1" and "T2" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
<shift>	The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts applied to a register .						
+	Specifies the index register is added to the base register.						
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.						

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let offset : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
  let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
  let address : bits(32) = if index then offset_addr else R(n);
  R(t) = ZeroExtend{32}(MemU{8}(address));
  if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	0	0	U	1	1	1	Rn				Rt				imm12											
cond				P				op2				W				op1															

Encoding

LDRBT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	0	U	1	1	1	Rn				Rt				imm5				styp		0	Rm				
cond				P				op2				W				op1															

Encoding

LDRBT{<c>}{<q>} <Rt>, [<Rn>], {<+/-><Rm>{, <shift>}}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `n == t && n != 15`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

```
LDRBT{<c>}{<q>}<Rt>, [<Rn> {, #(<+>)<imm>}]
```

Decode for this encoding

```
if Rn == '1111' then See("LDRB (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> For the "A1" variant: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.
For the "A2" and "T1" variants: is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- +/- For the "A1" variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":
- | U | +/- |
|---|-----|
| 0 | - |
| 1 | + |
- For the "A2" variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":
- | U | +/- |
|---|-----|
| 0 | - |
| 1 | + |
- <imm> For the "A1" variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For the "T1" variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- <shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).
- +
- Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end;           // Hyp mode
    let offset : bits(32) = (if register_form then Shift{32}(R(m), shift_t, shift_n, PSTATE.C)
                             else imm32);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    R(t) = ZeroExtend{32}(MemU_unpriv{8}(address));
    if postindex then R(n) = offset_addr; end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDRB (immediate).

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	1	W	0	!= 1111				Rt				imm4H				1	1	0	1	imm4L			
cond												o1				Rn												op2			

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRD (literal)"); end;
if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if P == '0' && W == '1' then UnpredictableProcedure(); end;
if wback && (n == t || n == t2) then UnpredictableProcedure(); end;
if t2 == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `t<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when `Rt == '1111'`.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	P	U	1	W	1	!= 1111				Rt				Rt2				imm8							
L												Rn																			

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
LDRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn> {, #{+/-}<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

```
LDRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>], #{+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '0' then See("Related encodings"); end;
if Rn == '1111' then See("LDRD (literal)"); end;
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if wback && (n == t || n == t2) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 || t == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If wback && (n == t || n == t2), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If t == t2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Load/store dual, load/store exclusive, table branch*.

Assembler Symbols

<c>	See <i>Standard assembler syntax fields</i> .						
<q>	See <i>Standard assembler syntax fields</i> .						
<Rt>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14. For the "T1 Offset", "T1 Post-indexed", and "T1 Pre-indexed" variants: is the first general-purpose register to be transferred, encoded in the "Rt" field.						
<Rt2>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the second general-purpose register to be transferred. This register must be <R(t+1)>. For the "T1 Offset", "T1 Post-indexed", and "T1 Pre-indexed" variants: is the second general-purpose register to be transferred, encoded in the "Rt2" field.						
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. For PC use see <i>LDRD (literal)</i> .						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For the "T1 Offset", "T1 Post-indexed", and "T1 Pre-indexed" variants: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the "imm8" field as <imm>/4.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then R(n) + imm32 else R(n) - imm32;
    let address : bits(32) = if index then offset_addr else R(n);
    if IsAlignedSize(address, 8) then
        let data : bits(64) = MemA{64}(address);
        if BigEndian(AccessType GPR) then
            R(t) = data[63:32];
            R(t2) = data[31:0];
        else
            R(t) = data[31:0];
            R(t2) = data[63:32];
        end;
    else
        let data1 : bits(32) = MemA{32}(address);
        let data2 : bits(32) = MemA{32}(address+4);
        R(t) = data1;
        R(t2) = data2;
    end;
    if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRD (literal)

Load Register Dual (literal) calculates an address from the PC value and an immediate offset, loads two words from memory, and writes them to two registers. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	(1)	U	1	(0)	0	1	1	1	1	Rt				imm4H				1	1	0	1	imm4L			
cond				P				W				o1				Rn								op2							

Encoding

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> // (Normal form)

LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```
if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let add : boolean = (U == '1');
if t2 == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `t<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when `Rt == '1111'`.

If `P == '0' || W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as if `P == 1` and `W == 0`.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	P	U	1	W	1	1	1	1	1	Rt				Rt2				imm8							
L																															

Encoding

Applies when `(!(P == 0 && W == 0))`

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, <label> // (Normal form)

LDRD{<c>}{<q>} <Rt>, <Rt2>, [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```
if P == '0' && W == '0' then See("Related encodings"); end;
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let add : boolean = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 || t == t2 then UnpredictableProcedure(); end;
if W == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

If `W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses post-indexed addressing when `P == '0'` and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15](#).

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: [Load/Store dual](#), [Load/Store-Exclusive](#), [Load-Acquire/Store-Release](#), [table branch](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	For the "A1" variant: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14. For the "T1" variant: is the first general-purpose register to be transferred, encoded in the "Rt" field.						
<Rt2>	For the "A1" variant: is the second general-purpose register to be transferred. This register must be <Rt+1>. For the "T1" variant: is the second general-purpose register to be transferred, encoded in the "Rt2" field.						
<label>	For the "A1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0. For the "T1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1" variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For the "T1" variant: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.						

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = (if add then (AlignDownSize(PC32(), 4) + imm32)
                                else (AlignDownSize(PC32(), 4) - imm32));
    if IsAlignedSize(address, 8) then
        let data : bits(64) = MemA{64}(address);
        if BigEndian(AccessType_GPR) then
            R(t) = data[63:32];
            R(t2) = data[31:0];
        else
            R(t) = data[31:0];
            R(t2) = data[63:32];
        end;
    else
        let data1 : bits(32) = MemA{32}(address);
        let data2 : bits(32) = MemA{32}(address+4);
        R(t) = data1;
        R(t2) = data2;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRD (register)

Load Register Dual (register) calculates an address from a base register value and a register offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	0	W	0	Rn				Rt				(0)	(0)	(0)	(0)	1	1	0	1	Rm			
cond				o1								op2																			

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>], {+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```
if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if P == '0' && W == '1' then UnpredictableProcedure(); end;
if t2 == 15 || m == 15 || m == t || m == t2 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t || n == t2) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

If `m == t || m == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction loads register Rm with an UNKNOWN value.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `t<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when `Rt == '1111'`.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	Is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.						
<Rt2>	Is the second general-purpose register to be transferred. This register must be <R(t+1)>.						
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.						
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + R(m)) else (R(n) - R(m));
    let address : bits(32) = if index then offset_addr else R(n);
    if IsAlignedSize(address, 8) then
        let data : bits(64) = MemA{64}(address);
        if BigEndian(AccessType GPR) then
            R(t) = data[63:32];
            R(t2) = data[31:0];
        else
            R(t) = data[31:0];
            R(t2) = data[63:32];
        end;
    else
        let data1 : bits(32) = MemA{32}(address);
        let data2 : bits(32) = MemA{32}(address+4);
        R(t) = data1;
        R(t2) = data2;
    end;

    if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDREX

Load Register Exclusive calculates an address from a base register value and an immediate offset, loads a word from memory, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	1	0	0	1	Rn				Rt				(1)	(1)	1	1	1	0	0	1	(1)	(1)	(1)	(1)
cond				size				L												ex				ord				xRt			

Encoding

LDREX{<c>}{<q>} <Rt>, [<Rn> {, {#}<imm>}]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = Zeros{}; // Zero offset
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

				op0				L												Rd											

Encoding

LDREX{<c>}{<q>} <Rt>, [<Rn> {, #<imm>}]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{imm8::'00'};
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<imm>	For the "A1" variant: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted. For the "T1" variant: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n) + imm32;
    AArch32_SetExclusiveMonitors(address,4);
    R(t) = MemA{32}(address);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDREXB

Load Register Exclusive Byte derives an address from a base register value, loads a byte from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding

LDREXB{<c>}{<q>} <Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c>
- See [Standard assembler syntax fields](#).
- <q>
- See [Standard assembler syntax fields](#).
- <Rt>
- Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn>
- Is the general-purpose base register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address,1);
    R(t) = ZeroExtend{32}(MemA{8}(address));
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDREXD

Load Register Exclusive Doubleword derives an address from a base register value, loads a 64-bit doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding

LDREXD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
if Rt[0] == '1' || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `t<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in [Using R15](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op0												L				Rt2								sz				Rd			

Encoding

LDREXH{<c>}{<q>}<Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    AArch32_SetExclusiveMonitors(address,2);
    R(t) = ZeroExtend{32}(MemA{16}(address));
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRH (immediate)

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	1	W	1	!= 1111				Rt				imm4H				1	0	1	1	imm4L			
cond											o1		Rn								op2										

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRH{<c>}{<q>}<Rt>, [<Rn> {, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRH{<c>}{<q>}<Rt>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRH{<c>}{<q>}<Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRH (literal)"); end;
if P == '0' && W == '1' then See("LDRHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

```
LDRH{<c>}{<q>}<Rt>, [<Rn>, #<+/-><imm>]!
```

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRH (literal)"); end;
if Rt == '1111' && P == '1' && U == '0' && W == '0' then See("PLDW (immediate)"); end;
if P == '1' && U == '1' && W == '0' then See("LDRHT"); end;
if P == '0' && W == '0' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	For the "A1 Offset", "A1 Post-indexed", "A1 Pre-indexed", "T2", "T3 Offset", "T3 Post-indexed", and "T3 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. For PC use see LDRH (literal) . For the "T1" variant: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For the "T1" variant: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2.

For the "T2" variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For the "T3 Offset", "T3 Post-indexed", and "T3 Pre-indexed" variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

+ Specifies the offset is added to the base register.

Operation

```
if CurrentInstrSet() == InstrSet A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(16) = MemU{16}(address);
    if wback then R(n) = offset_addr; end;
    R(t) = ZeroExtend{32}(data);
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(16) = MemU{16}(address);
    if wback then R(n) = offset_addr; end;
    R(t) = ZeroExtend{32}(data);
  end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

LDRH (literal)

Load Register Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	1	W	1	1	1	1	Rt					imm4H				1	0	1	1	imm4L			
cond				o1								Rn												op2							

Encoding

Applies when (! (P == 0 && W == 1))

```
LDRH{<c>}{<q>}<Rt>, <label> // (Normal form)

LDRH{<c>}{<q>}<Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```
if P == '0' && W == '1' then See("LDRHT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{imm4H::imm4L};
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || wback then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If *wback*, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: wback = FALSE;
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in *LDRH (immediate)*. The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15*.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	0	0	0	U	0	1	1	1	1	1	!= 1111				imm12											
size								L								Rt															

Encoding

```
LDRH{<c>}{<q>}<Rt>, <label> // (Preferred syntax)

LDRH{<c>}{<q>}<Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

Decode for this encoding

```
if Rt == '1111' then See("PLD (literal)"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{imm12};
let add : boolean = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <label> For the "A1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.
For the "T1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For the "A1" variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
For the "T1" variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(),4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    let data : bits(16) = MemU{16}(address);
    R(t) = ZeroExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	0	W	1	Rn				Rt				(0) (0) (0) (0) 1				0	1	1	Rm				
cond											o1					op2															

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRH{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRH{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("LDRHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	0	1	Rm			Rn			Rt		
				L	B	H									

Encoding

LDRH{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding

```
LDRH{<c>}{<q>}<Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

LDRH{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)
```

Decode for this encoding

```
if Rn == '1111' then See("LDRH (literal)"); end;
if Rt == '1111' then See("PLDW (register)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
For the "T1" and "T2" variants: is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- + Specifies the index register is added to the base register.
- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let offset : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
  let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
  let address : bits(32) = if index then offset_addr else R(n);
  let data : bits(16) = MemU{16}(address);
  if wback then R(n) = offset_addr; end;
  R(t) = ZeroExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	U	1	1	1	Rn				Rt				imm4H				1	0	1	1	imm4L			
cond				P				W				o1												op2							

Encoding

LDRHT{<c>}{<q>}<Rt>, [<Rn>] {, #(<+/->)<imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : Bits(32) = ZeroExtend{}(imm4H::imm4L);
let m : integer = ARBITRARY : integer;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	U	0	1	1	Rn				Rt				(0)	(0)	(0)	(0)	1	0	1	1	Rm			
cond				P				W				o1												op2							

Encoding

LDRHT{<c>}{<q>}<Rt>, [<Rn>], {<+/->}<Rm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let imm32 : Bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

LDRHT{<c>}{<q>}<Rt>, [<Rn> {, #(+)<imm>}]

Decode for this encoding

```
if Rn == '1111' then See("LDRH (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8);
let m : integer = ARBITRARY : integer;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

	For the "A2" variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table border="1"> <tr> <th>U</th><th>+/-</th></tr> <tr> <td>0</td><td>-</td></tr> <tr> <td>1</td><td>+</td></tr> </table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1" variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For the "T1" variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
+	Specifies the offset is added to the base register.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end; // Hyp mode
    let offset : bits(32) = if register_form then R(m) else imm32;
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    let data : bits(16) = MemU_unpriv{16}(address);
    if postindex then R(n) = offset_addr; end;
    R(t) = ZeroExtend{32}(data);
end;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes as `LDRH` (immediate).

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRSB (immediate)

Load Register Signed Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	1	W	1	!= 1111				Rt				imm4H				1	1	0	1	imm4L			
cond											o1		Rn				op2														

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRSB{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRSB{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRSB{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRSB (literal)"); end;
if P == '0' && W == '1' then See("LDRSBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `wback && n == t`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

size											Rn																				

Encoding for the Offset variant

Applies when (Rt != 1111 && P == 1 && U == 0 && W == 0)

```
LDRSB{<c>}{<q>}<Rt>, [<Rn> {, #-<imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

```
LDRSB{<c>}{<q>}<Rt>, [<Rn>], #{+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
LDRSB{<c>}{<q>}<Rt>, [<Rn>, #{+/-}<imm>]!
```

Decode for all variants of this encoding

```
if Rt == '1111' && P == '1' && U == '0' && W == '0' then See("PLI"); end;
if Rn == '1111' then See("LDRSB (literal)"); end;
if P == '1' && U == '1' && W == '0' then See("LDRSBT"); end;
if P == '0' && W == '0' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if (t == 15 && W == '1') || (wback && n == t) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If wback && n == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .

LDRSB (literal)

Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#). It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
!= 1111				0	0	0	P	U	1	W	1	1	1	1	1	Rt					imm4H				1	1	0	1	imm4L			
cond				o1					Rn														op2									

Encoding

Applies when (! (P == 0 && W == 1))

```
LDRSB{<c>}{<q>} <Rt>, <label> // (Normal form)

LDRSB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```
if P == '0' && W == '1' then See("LDRSBT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{imm4H::imm4L};
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || wback then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `wback = FALSE`;
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in [LDRSB \(immediate\)](#). The instruction uses post-indexed addressing when `P == '0'` and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	1	U	0	0	1	1	1	1	1	!= 1111				imm12											
size												Rt																			

Encoding

```
LDRSB{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDRSB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

Decode for this encoding

```
if Rt == '1111' then See("PLI"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{imm12};
let add : boolean = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <label> For the "A1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.
For the "T1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For the "A1" variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.
For the "T1" variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(),4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    R(t) = SignExtend{32}(MemU{8}(address));
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	0	W	1	Rn				Rt				(0)	(0)	(0)	(0)	1	1	0	1	Rm			
cond											o1				op2																

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRSB{<c>}{<q>}<Rt>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRSB{<c>}{<q>}<Rt>, [<Rn>], {+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRSB{<c>}{<q>}<Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("LDRSBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let shift_t : SRTYPE = SRTYPE\_LSL;
let shift_n : integer = 0;
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	1	1	Rm			Rn			Rt		
				L	B		H								

Encoding

LDRSB{<c>}{<q>}<Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE\_LSL;
let shift_n : integer = 0;
```

T2

Encoding

```
LDRSB{<c>}{<q>}<Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

LDRSB{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)
```

Decode for this encoding

```
if Rt == '1111' then See("PLI"); end;
if Rn == '1111' then See("LDRSB (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SType = SType_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.
For the "T1" and "T2" variants: is the general-purpose base register, encoded in the "Rn" field.
- +/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- + Specifies the index register is added to the base register.
- <imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let offset : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
  let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
  let address : bits(32) = if index then offset_addr else R(n);
  R(t) = SignExtend{32}(MemU{8}(address));
  if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	U	1	1	1	Rn				Rt				imm4H				1	1	0	1	imm4L			
cond				P				W				o1												op2							

Encoding

LDRSBT{<c>}{<q>} <Rt>, [<Rn>] {, # {+/-} <imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : Bits(32) = ZeroExtend{}(imm4H::imm4L);
let m : integer = ARBITRARY : integer;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if `bit[24] == '1'` and `bit[21] == '0'`. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

cond				P				W				o1												op2							

Encoding

LDRSBT{<c>}{<q>} <Rt>, [<Rn>], {+/-} <Rm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let imm32 : Bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1	+						
<imm>	For the "A1" variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For the "T1" variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
+	Specifies the offset is added to the base register.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end; // Hyp mode
    let offset : bits(32) = if register_form then R(m) else imm32;
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    R(t) = SignExtend{32}{MemU_unpriv{8}(address)};
    if postindex then R(n) = offset_addr; end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes as `LDRSB` (immediate).

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRSH (immediate)

Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	1	W	1	!= 1111				Rt				imm4H				1	1	1	imm4L				
cond											o1		Rn								op2										

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRSH{<c>}{<q>} <Rt>, [<Rn> {, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRSH{<c>}{<q>} <Rt>, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRSH{<c>}{<q>} <Rt>, [<Rn>, #<+/-><imm>]!

Decode for all variants of this encoding

```
if Rn == '1111' then See("LDRSH (literal)"); end;
if P == '0' && W == '1' then See("LDRSHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `wback && n == t`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

LDRSH (literal)

Load Register Signed Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#). It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
!= 1111				0	0	0	P	U	1	W	1	1	1	1	1	Rt					imm4H				1	1	1	1	imm4L			
cond				o1					Rn					op2																		

Encoding

Applies when (! (P == 0 && W == 1))

```
LDRSH{<c>}{<q>} <Rt>, <label> // (Normal form)

LDRSH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```
if P == '0' && W == '1' then See("LDRSHT"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{(imm4H::imm4L)};
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 || wback then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `wback = FALSE`;
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in [LDRSH \(immediate\)](#). The instruction uses post-indexed addressing when `P == '0'` and uses pre-indexed addressing otherwise. The instruction is handled as described in [Using R15](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	0	0	1	U	0	1	1	1	1	1	!= 1111				imm12											
size																Rt															

Encoding

```
LDRSH{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDRSH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

Decode for this encoding

```
if Rt == '1111' then See("Related instructions"); end;
let t : integer = UInt(Rt);
let imm32 : bits(32) = ZeroExtend{(imm12)};
let add : boolean = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).
Related instructions: [Load, signed \(literal\)](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <label> For the "A1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For the "T1" variant: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+

<imm> For the "A1" variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For the "T1" variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = AlignDownSize(PC32(), 4);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    let data : bits(16) = MemU{16}(address);
    R(t) = SignExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRSH (register)

Load Register Signed Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses](#).
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
!= 1111				0	0	0	P	U	0	W	1	Rn				Rt				(0)	(0)	(0)	(0)	1	1	1	1	Rm					
cond											o1				op2																		

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

LDRSH{<c>}{<q>}<Rt>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

LDRSH{<c>}{<q>}<Rt>, [<Rn>], {+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

LDRSH{<c>}{<q>}<Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("LDRSHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.						
<Rn>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant. For the "T1" and "T2" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
+	Specifies the index register is added to the base register.						
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    let data : bits(16) = MemU{16}(address);
    if wback then R(n) = offset_addr; end;
    R(t) = SignExtend{32}(data);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRSHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	U	1	1	1	Rn				Rt				imm4H				1	1	1	1	imm4L			
cond				P				W				o1												op2							

Encoding

LDRSHT{<c>}{<q>} <Rt>, [<Rn>] {, # {+/-} <imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : Bits(32) = ZeroExtend{}(imm4H::imm4L);
let m : integer = ARBITRARY : integer;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

U	+/-						
0	-						
1	+						
<imm>	For the "A1" variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For the "T1" variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
+	Specifies the offset is added to the base register.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end; // Hyp mode
    let offset : bits(32) = if register_form then R(m) else imm32;
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    let data : bits(16) = MemU_unpriv{16}(address);
    if postindex then R(n) = offset_addr; end;
    R(t) = SignExtend{32}(data);
end;
```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes as `LDRSH` (immediate).

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

2026-03_rel 2026-03-26 20:48:11

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see [Memory accesses](#). The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

LDRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	0	0	U	0	1	1	Rn				Rt				imm12											
cond				P				op2				W				op1															

Encoding

LDRT{<c>}{<q>} <Rt>, [<Rn>] {, #<+/-><imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	0	U	0	1	1	Rn				Rt				imm5					stype	0	Rm				
cond				P				op2				W	op1																		

Encoding

LDRT{<c>}{<q>} <Rt>, [<Rn>], {<+/-><Rm>{, <shift>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `n == t && n != 15`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

T1

Encoding

```
LDRT{<c>}{<q>}<Rt>, [<Rn> {, #<+><imm>}]
```

Decode for this encoding

```
if Rn == '1111' then See("LDR (literal)"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> For the "A1" variant: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.
For the "A2" and "T1" variants: is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.
- +/- For the "A1" variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":
- | U | +/- |
|---|-----|
| 0 | - |
| 1 | + |
- For the "A2" variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":
- | U | +/- |
|---|-----|
| 0 | - |
| 1 | + |
- <imm> For the "A1" variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.
For the "T1" variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.
- <Rm> Is the general-purpose index register, encoded in the "Rm" field.
- <shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see [Shifts applied to a register](#).
- +
- Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  if PSTATE.EL == EL2 then UnpredictableProcedure(); end; // Hyp mode
  let offset : bits(32) = (if register_form then Shift{32}(R(m), shift_t, shift_n, PSTATE.C)
                          else imm32);
  let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
  let address : bits(32) = if postindex then R(n) else offset_addr;
  let data : bits(32) = MemU\_unpriv{32}(address);
  if postindex then R(n) = offset_addr; end;
  R(t) = data;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as LDR (immediate).

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

LSLS (immediate)

Logical Shift Left, setting flags (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores *PSTATE* from SPSR <current_mode>.
- The PE checks SPSR <current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register.

This is an alias of [MOV, MOVS \(register-shifted register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register-shifted register\)](#).
- The description of [MOV, MOVS \(register-shifted register\)](#) gives the operational pseudocode, any `CONSTRAINED UNPREDICTABLE` behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

LSRS (immediate)

Logical Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of [MOV, MOVS \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [MOV, MOVS \(register\)](#).
- The description of [MOV, MOVS \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MCR

Move to System register from general-purpose register or execute a System instruction. This instruction copies the value of a general-purpose register to a System register, or executes a System instruction.

The System register and System instruction descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* and *General behavior of System registers*.

In an implementation that includes EL2, MCR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps*.

Because of the range of possible traps to Hyp mode, the MCR pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

Encoding

MCR{<c>}{<q>}<coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

MCR{<c>}{<q>}<coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c>

See *Standard assembler syntax fields*.
- <q>

See *Standard assembler syntax fields*.
- <coproc>

Is the System register encoding space, encoded in “cp15”:

cp15	<coproc>
0	p14
1	p15
- <opc1>

Is the opc1 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc1" field.
- <Rt>

Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <CRn>

Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.
- <CRm>

Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.
- <opc2>

Is the opc2 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc2" field.
- The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> }

encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32_SysRegWrite(cp, ThisInstr(), t);
end;
```

2026-03_rel 2026-03-26 20:48:11

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

MCRR

Move to System register from two general-purpose registers. This instruction copies the values of two general-purpose registers to a System register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface](#) and [General behavior of System registers](#).

In an implementation that includes EL2, MCRR accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MCRR instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable instruction enables, disables, and traps](#).

Because of the range of possible traps to Hyp mode, the MCRR pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

MCRR{<c>}{<q>}<coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let cp : integer = if cp15 == '0' then 14 else 15;
if t == 15 || t2 == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

T1

Encoding

MCRR{<c>}{<q>}<coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let cp : integer = if cp15 == '0' then 14 else 15;
if t == 15 || t2 == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <coproc> Is the System register encoding space, encoded in “cp15”:

cp15	<coproc>
0	p14
1	p15
- <opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.
- <Rt> Is the first general-purpose register that is transferred into, encoded in the "Rt" field.
- <Rt2> Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.
- <CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of { <coproc>, <opc1>, <CRm> } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32_SysRegWrite64(cp, ThisInstr(), t, t2);
end;
```

Encoding

MLS{<c>}{<q>}<Rd>, <Rn>, <Rm>, <Ra>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
- <Ra> Is the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 : integer = SInt(R(n)); // operand1 = UInt(R[n]) produces the same final results
    let operand2 : integer = SInt(R(m)); // operand2 = UInt(R[m]) produces the same final results
    let addend : integer = SInt(R(a)); // addend = UInt(R[a]) produces the same final results
    let result : integer = addend - operand1 * operand2;
    R(d) = result[31:0];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

MOV, MOVS (immediate)

Move (immediate) writes an immediate value to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The MOV variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MOV, MOVS (register)

Move (register) copies a value from a register to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The MOV variant of the instruction is a branch. In the T32 instruction set (encoding T1) this is a simple branch, and in the A32 instruction set it is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is used by the aliases [ASRS \(immediate\)](#), [ASR \(immediate\)](#), [LSLS \(immediate\)](#), [LSL \(immediate\)](#), [LSRS \(immediate\)](#), [LSR \(immediate\)](#), [RORS \(immediate\)](#), [ROR \(immediate\)](#), [RRXS](#), and [RRX](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0	0	0	!= 11		imm5					Rm			Rd		
op															

Encoding

```
MOV<C>{<q>} <Rd>, <Rm> {, <shift> #<amount>} // (InITBlock())
MOVS{<q>} <Rd>, <Rm> {, <shift> #<amount>} // (Outside IT block)
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = !InITBlock();
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(op, imm5);
if op == '00' && imm5 == '00000' && InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `op == '00' && imm5 == '00000' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passed its condition code check.
- The instruction executes as NOP, as if it failed its condition code check.
- The instruction executes as MOV Rd, Rm.

T3

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

<c> See [Standard assembler syntax fields](#).
 <q> See [Standard assembler syntax fields](#).

<Rd> For the "A1 MOV, rotate right with extend", "A1 MOV, shift or rotate by value", "A1 MOVS, rotate right with extend", and "A1 MOVS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*. Arm deprecates use of the instruction if <Rn> is the PC.
- For the MOVS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>. Arm deprecates use of the instruction if <Rn> is not the LR, or if the optional shift or RRX argument is specified.

For the "T1" variant: is the general-purpose destination register, encoded in the "D:Rd" field. If the PC is used:

- The instruction causes a branch to the address moved to the PC. This is a simple branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The instruction must either be outside an IT block or the last instruction of an IT block.

For the "T2", "T3 MOV, rotate right with extend", "T3 MOV, shift or rotate by value", "T3 MOVS, rotate right with extend", and "T3 MOVS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For the "A1 MOV, rotate right with extend", "A1 MOV, shift or rotate by value", "A1 MOVS, rotate right with extend", "A1 MOVS, shift or rotate by value", and "T1" variants: is the general-purpose source register, encoded in the "Rm" field. The PC can be used. Arm deprecates use of the instruction if <Rd> is the PC.

For the "T2", "T3 MOV, rotate right with extend", "T3 MOV, shift or rotate by value", "T3 MOVS, rotate right with extend", and "T3 MOVS, shift or rotate by value" variants: is the general-purpose source register, encoded in the "Rm" field.

<shift> For the "A1 MOV, shift or rotate by value", "A1 MOVS, shift or rotate by value", "T3 MOV, shift or rotate by value", and "T3 MOVS, shift or rotate by value" variants: is the type of shift to be applied to the source register, encoded in "stype":

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

For the "T2" variant: is the type of shift to be applied to the source register, encoded in "op":

op	<shift>
00	LSL
01	LSR
10	ASR

<amount> For the "A1 MOV, shift or rotate by value" and "A1 MOVS, shift or rotate by value" variants: is the shift amount, in the range 0 to 31 (when <shift> = LSL), or 1 to 31 (when <shift> = ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For the "T2" variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For the "T3 MOV, shift or rotate by value" and "T3 MOVS, shift or rotate by value" variants: is the shift amount, in the range 0 to 31 (when <shift> = LSL) or 1 to 31 (when <shift> = ROR), or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

MOV, MOVS (register-shifted register)

Move (register-shifted register) copies a register-shifted register value to the destination register. It can optionally update the condition flags based on the value.

This instruction is used by the aliases [ASRS \(register\)](#), [ASR \(register\)](#), [LSLS \(register\)](#), [LSL \(register\)](#), [LSRS \(register\)](#), [LSR \(register\)](#), [RORS \(register\)](#), and [ROR \(register\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	1	0	1	S	(0)	(0)	(0)	(0)	Rd				Rs				0	stype	1	Rm				
cond								opc				Rn																			

Encoding for the Flag setting variant

Applies when (S == 1)

```
MOVS{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>
```

Encoding for the Not flag setting variant

Applies when (S == 0)

```
MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	0	0	x	x	x	Rs			Rdm		
						op									

Encoding for the Arithmetic shift right variant

Applies when (op == 0100)

```
MOV<c>{<q>} <Rdm>, <Rdm>, ASR <Rs> // (InITBlock())
```

```
MOVS{<q>} <Rdm>, <Rdm>, ASR <Rs> // (Outside IT block)
```

Encoding for the Logical shift left variant

Applies when (op == 0010)

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSL <Rs> // (InITBlock())
```

```
MOVS{<q>} <Rdm>, <Rdm>, LSL <Rs> // (Outside IT block)
```

Encoding for the Logical shift right variant

Applies when (op == 0011)

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSR <Rs> // (InITBlock())
```

```
MOVS{<q>} <Rdm>, <Rdm>, LSR <Rs> // (Outside IT block)
```

Encoding for the Rotate right variant

Applies when (op == 0111)

```
MOV<c>{<q>} <Rdm>, <Rdm>, ROR <Rs> // (InITBlock())
```

```
MOVS{<q>} <Rdm>, <Rdm>, ROR <Rs> // (Outside IT block)
```

Decode for all variants of this encoding

```
if ! op IN {'0010', '0011', '0100', '0111'} then See("Related encodings"); end;
let d : integer = UInt(Rdm);
let m : integer = UInt(Rdm);
let s : integer = UInt(Rs);
let setflags : boolean = !InITBlock();
let shift_t : SRTYPE = DecodeRegShift(op[2]::op[0]);
```

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding for the Flag setting variant

Applies when (S == 1)

```
MOVS{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>

MOVS.W <Rd>, <Rm>, <shift> <Rs> // (Outside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1)
```

Encoding for the Not flag setting variant

Applies when (S == 0)

```
MOV{<c>}{<q>} <Rd>, <Rm>, <shift> <Rs>

MOV<c>.W <Rd>, <Rm>, <shift> <Rs> // (Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1)
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SType = DecodeRegShift(stype);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

Related encodings: In encoding T1, for an op field value that is not described above, see [Data-processing \(two low registers\)](#).
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .										
<q>	See Standard assembler syntax fields .										
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.										
<Rm>	Is the general-purpose source register, encoded in the "Rm" field.										
<shift>	Is the type of shift to be applied to the second source register, encoded in "stype": <table><tr><th>stype</th><th><shift></th></tr><tr><td>00</td><td>LSL</td></tr><tr><td>01</td><td>LSR</td></tr><tr><td>10</td><td>ASR</td></tr><tr><td>11</td><td>ROR</td></tr></table>	stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR
stype	<shift>										
00	LSL										
01	LSR										
10	ASR										
11	ROR										
<Rs>	Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.										
<Rdm>	Is the general-purpose source register and the destination register, encoded in the "Rdm" field.

MOV_T

Move Top writes an immediate value to the top halfword of the destination register. It does not affect the contents of the bottom halfword. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

MOV_T{<c>}{<q>} <Rd>, #<imm16>

Decode for this encoding

```
let d : integer = UInt(Rd);
let imm16 : bits(16) = imm4::imm12;
if d == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

MOV_T{<c>}{<q>} <Rd>, #<imm16>

Decode for this encoding

```
let d : integer = UInt(Rd);
let imm16 : bits(16) = imm4::i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <imm16> For the "A1" variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.
For the "T1" variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d)[31:16] = imm16;
    // R[d]<15:0> unchanged
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

MRC

Move to general-purpose register from System register. This instruction copies the value of a System register to a general-purpose register. The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface](#) and [General behavior of System registers](#).

In an implementation that includes EL2, MRC accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an MRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable instruction enables, disables, and traps](#).

Because of the range of possible traps to Hyp mode, the MRC pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
!= 1111				1	1	1	0	opc1				1	CRn				Rt				1	1	1	cp15	opc2			1	CRm							
cond											L																									

Encoding

MRC{<c>}{<q>}<coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	1	0	opc1			1	CRn			Rt				1	1	1	cp15	opc2			1	CRm				
											L																				

Encoding

MRC{<c>}{<q>}<coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
```

Assembler Symbols

- <c>

See [Standard assembler syntax fields](#).
- <q>

See [Standard assembler syntax fields](#).
- <coproc>

Is the System register encoding space, encoded in “cp15”:

cp15	<coproc>
0	p14
1	p15
- <opc1>

Is the opc1 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc1" field.
- <Rt>

Is the general-purpose register to be transferred or APSR_nzcv (encoded as 0b1111), encoded in the "Rt" field. If APSR_nzcv is used, bits [31:28] of the transferred value are written to the [PSTATE](#) condition flags.
- <CRn>

Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.
- <CRm>

Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.
- <opc2>

Is the opc2 parameter within the System register encoding space, in the range 0 to 7, encoded in the "opc2" field.
- The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> }

encode the entire System register and System instruction encoding space.

Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    if t != 15 || AArch32\_SysRegReadCanWriteAPSR(cp, ThisInstr()) then
        AArch32_SysRegRead(cp, ThisInstr(), t);
    else
        UnpredictableProcedure();
    end;
end;
```

MRRC

Move to two general-purpose registers from System register. This instruction copies the value of a System register to two general-purpose registers. The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see [About the AArch32 System register interface](#) and [General behavior of System registers](#).

In an implementation that includes EL2, MRRC accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an MRRC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [EL2 configurable instruction enables, disables, and traps](#).

Because of the range of possible traps to Hyp mode, the MRRC pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	0	0	0	1	0	1	Rt2				Rt				1	1	1	cp15	opc1				CRm			
cond								D				L																			

Encoding

MRRC{<c>}{<q> <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 || t == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	0	0	1	0	1	Rt2				Rt				1	1	1	cp15	opc1				CRm			
								D				L																			

Encoding

MRRC{<c>}{<q> <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let cp : integer = if cp15 == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || t2 == 15 || t == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<coproc>

Is the System register encoding space, encoded in “cp15”:

cp15	<coproc>
0	p14
1	p15

<opc1>

Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.

<Rt>

Is the first general-purpose register that is transferred into, encoded in the "Rt" field.

<Rt2>

Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.

<CRm>

Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of { <coproc>, <opc1>, <CRm> } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32_SysRegRead64(cp, ThisInstr(), t, t2);
end;
```

MRS

Move Special register to general-purpose register moves the value of the [APSR](#), [CPSR](#), or [SPSR](#) `<current_mode>` into a general-purpose register. Arm recommends the APSR form when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [APSR](#).

An MRS that accesses the [SPSRs](#) is UNPREDICTABLE if executed in User mode or System mode.

An MRS that is executed in User mode and accesses the [CPSR](#) returns an UNKNOWN value for the [CPSR](#).{E, A, I, F, M} fields.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
MRS{<c>}{<q>} <Rd>, <spec_reg>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let read_spsr : boolean = (R == '1');
if d == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
MRS{<c>}{<q>} <Rd>, <spec_reg>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let read_spsr : boolean = (R == '1');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- `<c>` See [Standard assembler syntax fields](#).
- `<q>` See [Standard assembler syntax fields](#).
- `<Rd>` Is the general-purpose destination register, encoded in the "Rd" field.
- `<spec_reg>` Is the special register to be accessed, encoded in "R":

R	<spec_reg>
0	CPSR APSR
1	SPSR

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if read_spsr then
        if PSTATE.M IN {M32\_User,M32\_System} then
            UnpredictableProcedure();
        else
            R(d) = SPSR\_curr();
        end;
    else
        // CPSR has same bit assignments as SPSR, but with the IT, J, SS, IL, and T bits masked out.
        let maskval : bits(32) = '11111000 11101111 00000011 11011111';
        var psr_val : bits(32) = GetPSRFromPSTATE{32}(AArch32\_NonDebugState) AND maskval;
        if PSTATE.EL == EL0 then
            // If accessed from User mode return UNKNOWN values for E, A, I, F bits, bits<9:6>,
            // and for the M field, bits<4:0>
            psr_val[22] = ARBITRARY : bits(1);
            psr_val[9:6] = ARBITRARY : bits(4);
            psr_val[4:0] = ARBITRARY : bits(5);
        end;
        R(d) = psr_val;
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If [PSTATE.M](#) IN {[M32_User](#), [M32_System](#)} && [read_spsr](#), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

MRS (Banked register)

Move to Register from Banked or Special register moves the value from the Banked general-purpose register or *Saved Program Status Registers (SPSRs)* of the specified mode, or the value of *ELR_hyp*, to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MRS (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

MSR (Banked register)

Move to Banked or Special register from general-purpose register moves the value of a general-purpose register to the Banked general-purpose register or *Saved Program Status Registers (SPSRs)* of the specified mode, or to *ELR_hyp*.

MSR (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MSR (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an MSR (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	R	1	0	M1				(1)	(1)	(1)	(1)	(0)	(0)	1	M	0	0	0	0	Rn			
cond				Rd												B															

Encoding

MSR{<c>}{<q>} <banked_reg>, <Rn>

Decode for this encoding

```
let n : integer = UInt(Rn);
let write_spsr : boolean = (R == '1');
if n == 15 then UnpredictableProcedure(); end;
let SYSm : bits(5) = M::M1;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	0	R	Rn				1	0	(0)	0	M1				(0)	(0)	1	M	(0)	(0)	(0)	(0)

Encoding

MSR{<c>}{<q>} <banked_reg>, <Rn>

Decode for this encoding

```
let n : integer = UInt(Rn);
let write_spsr : boolean = (R == '1');
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 then UnpredictableProcedure(); end;
let SYSm : bits(5) = M::M1;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.

<banked_reg>

Is the name of the banked register to be transferred to or from, encoded in “(R :: M :: M1)”:

MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the *APSR*, *CPSR*, or *SPSR* <current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, the immediate form of *MSR* is normally only useful at the Application level for writing to *APSR_nzcvq* (*CPSR_f*).

If an *MSR* (immediate) moves selected bits of an immediate value to the *CPSR*, the PE checks whether the value being written to *PSTATE.M* is legal. See *Illegal changes to PSTATE.M*.

An *MSR* (immediate) executed in User mode:

- Is *CONSTRAINED UNPREDICTABLE* if it attempts to update the *SPSR*.
- Otherwise, does not update any *CPSR* field that is accessible only at EL1 or higher,

An *MSR* (immediate) executed in System mode is *CONSTRAINED UNPREDICTABLE* if it attempts to update the *SPSR*.

The *CPSR.E* bit is writable from any mode using an *MSR* instruction. Arm deprecates using this to change its value.

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	1	1	0	R	1	0	mask				(1)	(1)	(1)	(1)	imm12											
cond																															

Encoding

Applies when (! (R == 0 && mask == 0000))

MSR{<c>}{<q>} <spec_reg>, #<imm>

Decode for this encoding

```
if mask == '0000' && R == '0' then See("Related encodings"); end;
let imm32 : bits(32) = A32ExpandImm(imm12);
let write_spsr : boolean = (R == '1');
if mask == '0000' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000' && R == '1', then one of the following behaviors must occur:

- The instruction is *UNDEFINED*.
- The instruction executes as *NOP*.

For more information about the *CONSTRAINED UNPREDICTABLE* behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Move Special Register and Hints (immediate)*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<spec_reg> Is one of:

- *APSR* <bits>.
- *CPSR* <fields>.
- *SPSR* <fields>.

For *CPSR* and *SPSR*, <fields> is a sequence of one or more of the following:

c	mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
x	mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
s	mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
f	mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For *APSR*, <bits> is one of *nzcvq*, *g*, or *nzcvqg*. These map to the following *CPSR* <fields> values:

- *APSR_nzcvq* is the same as *CPSR_f* (mask == '1000').
- *APSR_g* is the same as *CPSR_s* (mask == '0100').
- *APSR_nzcvqg* is the same as *CPSR_fs* (mask == '1100').

Arm recommends the *APSR* <bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *The Application Program Status Register, APSR*.

<imm> Is an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32\_User,M32\_System} then
            UnpredictableProcedure();
        else
            SPSRWriteByInstr(imm32, mask);
        end;
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(imm32, mask);
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M` IN {`M32_User`,`M32_System`} && `write_spsr`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

MSR (register)

Move general-purpose register to Special register moves selected bits of a general-purpose register to the *APSR*, *CPSR* or *SPSR* *<current_mode>*. Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally required when the *MSR* instruction is being used at Application level and its destination is not *APSR_nzcvq* (*CPSR_f*). If an *MSR* (register) moves selected bits of an immediate value to the *CPSR*, the PE checks whether the value being written to *PSTATE.M* is legal. See *Illegal changes to PSTATE.M*. An *MSR* (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the *SPSR*.
- Otherwise, does not update any *CPSR* field that is accessible only at EL1 or higher.

An *MSR* (register) executed in System mode is UNPREDICTABLE if it attempts to update the *SPSR*. The *CPSR.E* bit is writable from any mode using an *MSR* instruction. Arm deprecates using this to change its value. It has encodings from the following instruction sets: A32 (*A1*) and T32 (*T1*) .

A1

Encoding

MSR{<c>}{<q>} <spec_reg>, <Rn>

Decode for this encoding

```
let n : integer = UInt(Rn);
let write_spsr : boolean = (R == '1');
if mask == '0000' then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If mask == '0000', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.

<spec_reg>

Is one of:

- APSR_<bits>.
- CPSR_<fields>.
- SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

c	mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.
x	mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.
s	mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.
f	mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvcq, g, or nzcvcqg. These map to the following CPSR_<fields> values:

- APSR_nzcvcq is the same as CPSR_f (mask == '1000').
- APSR_g is the same as CPSR_s (mask == '0100').
- APSR_nzcvcqg is the same as CPSR_fs (mask == '1100').

Arm recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see [The Application Program Status Register, APSR](#).

<Rn>

Is the general-purpose source register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User, M32_System} then
            UnpredictableProcedure();
        else
            SPSRWriteByInstr(R(n), mask);
        end;
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(R(n), mask);
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `write_spsr` && `PSTATE.M IN {M32_User, M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

MUL, MULS

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op1												Ra								op2											

Encoding

MUL{<c>}{<q>} <Rd>, <Rn>{, <Rm>}

MUL<c>.W <Rd>, <Rn>{, <Rm>} // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = FALSE;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field. If omitted, <Rd> is used.
<Rdm>	Is the second general-purpose source register holding the multiplier and the destination register, encoded in the "Rdm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 : integer = SInt(R(n)); // operand1 = UInt(R[n]) produces the same final results
    let operand2 : integer = SInt(R(m)); // operand2 = UInt(R[m]) produces the same final results
    let result : integer = operand1 * operand2;
    R(d) = result[31:0];
    if setflags then
        PSTATE.N = result[31];
        PSTATE.Z = IsZeroBit{32}(result[31:0]);
        // PSTATE.C, PSTATE.V unchanged
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

MVN, MVNS (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register.
If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.
The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

MVN{<c>}{<q>}<Rd>, #<const>

Encoding for the MVNS variant

Applies when (S == 1)

MVNS{<c>}{<q>}<Rd>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let setflags : boolean = (S == '1');
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.

<Rd> For the "A1 MVN" and "A1 MVNS" variants: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the MVNS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the "T1 MVN" and "T1 MVNS" variants: is the general-purpose destination register, encoded in the "Rd" field.

<const> For the "A1 MVN" and "A1 MVNS" variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the "T1 MVN" and "T1 MVNS" variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm\_C(imm, PSTATE.C)
                                           else T32ExpandImm\_C(imm, PSTATE.C));

    let result : bits(32) = NOT(imm32);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUEXCEPTIONRETURN(result);
        else
            ALUWRITEPC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

MVN, MVNS (register)

Bitwise NOT (register) writes the bitwise inverse of a register value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

10	ASR										
11	ROR										
<amount>	For the "A1 MVN, shift or rotate by value" and "A1 MVNS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.										

For the "T2 MVN, shift or rotate by value" and "T2 MVNS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift\_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = NOT(shifted);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
end;
```

MVN, MVNS (register-shifted register)

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

A1

Encoding for the Flag setting variant

Applies when (S == 1)

```
MVNS{<c>}{<q>}<Rd>, <Rm>, <shift> <Rs>
```

Encoding for the Not flag setting variant

Applies when (S == 0)

```
MVN{<c>}{<q>}<Rd>, <Rm>, <shift> <Rs>
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> Is the general-purpose source register, encoded in the "Rm" field.
- <shift> Is the type of shift to be applied to the second source register, encoded in "stype":

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR
- <Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let shift_n : integer = UInt(R(s)[7:0]);
  let (shifted, carry) : (bits(32), bit) = Shift_C[32](R(m), shift_t, shift_n, PSTATE.C);
  let result : bits(32) = NOT(shifted);
  R(d) = result;
  if setflags then
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit[32](result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
  end;
end;
```

NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

Note

The timing effects of including a `NOP` instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, `NOP` instructions are not suitable for timing loops.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ORR, ORRS (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0 0 1 1 1				0 0 S				Rn				Rd				imm12											
cond								opc																							

Encoding for the ORR variant

Applies when (S == 0)

ORR{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the ORRS variant

Applies when (S == 1)

ORRS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	1	0	i	0	0	0	1	0	S	!= 1111				0	imm3				Rd				imm8							
op1												Rn

Encoding for the ORRS variant

Applies when (S == 1)

ORRS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
if Rn == '1111' then See("MOV (immediate)"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let setflags : boolean = (S == '1');
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q>	See Standard assembler syntax fields .
<Rd>	For the "A1 ORR" and "A1 ORRS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used: - For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. - For the ORRS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.
	For the "T1 ORR" and "T1 ORRS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>	For the "A1 ORR" and "A1 ORRS" variants: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
	For the "T1 ORR" and "T1 ORRS" variants: is the general-purpose source register, encoded in the "Rn" field.
<const>	For the "A1 ORR" and "A1 ORRS" variants: an immediate value. See Modified immediate constants in A32 instructions for the range of values.
	For the "T1 ORR" and "T1 ORRS" variants: an immediate value. See Modified immediate constants in T32 instructions for the range of values.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm C(imm, PSTATE.C)
                                           else T32ExpandImm C(imm, PSTATE.C));

    let result : bits(32) = R(n) OR imm32;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

- For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the ORRS variant, the instruction performs an exception return, that restores **PSTATE** from SPSR_<current_mode>.

For the "T2 ORR, rotate right with extend", "T2 ORR, shift or rotate by value", "T2 ORRS, rotate right with extend", and "T2 ORRS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For the "A1 ORR, rotate right with extend", "A1 ORR, shift or rotate by value", "A1 ORRS, rotate right with extend", and "A1 ORRS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For the "T2 ORR, rotate right with extend", "T2 ORR, shift or rotate by value", "T2 ORRS, rotate right with extend", and "T2 ORRS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For the "A1 ORR, rotate right with extend", "A1 ORR, shift or rotate by value", "A1 ORRS, rotate right with extend", and "A1 ORRS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For the "T1", "T2 ORR, rotate right with extend", "T2 ORR, shift or rotate by value", "T2 ORRS, rotate right with extend", and "T2 ORRS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the "A1 ORR, shift or rotate by value" and "A1 ORRS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For the "T2 ORR, shift or rotate by value" and "T2 ORRS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

<Rdn>

Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

In T32 assembly:

- Outside an IT block, if ORRS <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORRS <Rd>, <Rn> had been written.
- Inside an IT block, if ORR<c> <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) OR shifted;
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUEXceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.N = result[31];
            PSTATE.Z = IsZeroBit{32}(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

ORR, ORRS (register-shifted register)

Bitwise OR (register-shifted register) performs a bitwise (inclusive) OR of a register value and a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op1												S												T							

Encoding for the PKHBT variant

Applies when (tb == 0)

PKHBT{<c>}{<q>}{<Rd>, }<Rn>, <Rm> {, LSL #<imm>} // (tbform == FALSE)

Encoding for the PKHTB variant

Applies when (tb == 1)

PKHTB{<c>}{<q>}{<Rd>, }<Rn>, <Rm> {, ASR #<imm>} // (tbform == TRUE)

Decode for all variants of this encoding

```
if S == '1' || T == '1' then Undefined(); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let tbform : boolean = (tb == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(tb::'0', imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<imm>	For the "A1 PKHBT" and "A1 PKHTB" variants: the shift to apply to the value read from <Rm>, encoded in the "imm5" field. For PKHBT, it is one of:
omitted	No shift, encoded as 0b00000.
1-31	Left shift by specified number of bits, encoded as a binary number.
	For PKHTB, it is one of:
omitted	Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn> had been written.
1-32	Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.
Note	
An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.	
	For the "T1 PKHBT" and "T1 PKHTB" variants: the shift to apply to the value read from <Rm>, encoded in the "imm3:imm2" field. For PKHBT, it is one of:
omitted	No shift, encoded as 0b00000.
1-31	Left shift by specified number of bits, encoded as a binary number.
	For PKHTB, it is one of:
omitted	Instruction is a pseudo-instruction and is assembled as though PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn> had been written.
1-32	Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.
Note	
An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.	

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let operand2 : bits(32) = Shift{ } (R(m), shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
    R(d)[15:0] = if tbform then operand2[15:0] else R(n)[15:0];
    R(d)[31:16] = if tbform then R(n)[31:16] else operand2[31:16];
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

PLD (literal)

Preload Data (literal) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The effect of a PLD instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

Encoding

```
PLD{<c>}{<q>} <label> // (Normal form)

PLD{<c>}{<q>} [PC, #{+/-}<imm>] // (Alternative form)
```

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
```

T1

Encoding

```
PLD{<c>}{<q>} <label> // (Preferred syntax)

PLD{<c>}{<q>} [PC, #{+/-}<imm>] // (Alternative syntax)
```

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{}(imm12);
let add : boolean = (U == '1');
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c>

For the "A1" variant: see [Standard assembler syntax fields](#). Must be AL or omitted.
For the "T1" variant: see [Standard assembler syntax fields](#).
- <q>

See [Standard assembler syntax fields](#).
- <label>

The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range −4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.
- +/-

Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	−
1	+
- <imm>

For the "A1" variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.
For the "T1" variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = (if add then (AlignDownSize(PC32(),4) + imm32)
                                else (AlignDownSize(PC32(),4) - imm32));
    Hint_PreloadData(address);
end;
```

1	+										
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.										
<shift>	Is the type of shift to be applied to the index register, encoded in "stype": <table><tr><th>stype</th><th><shift></th></tr><tr><td>00</td><td>LSL</td></tr><tr><td>01</td><td>LSR</td></tr><tr><td>10</td><td>ASR</td></tr><tr><td>11</td><td>ROR</td></tr></table>	stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR
stype	<shift>										
00	LSL										
01	LSR										
10	ASR										
11	ROR										
<amount>	For the "Preload read, optional shift or rotate" and "Preload write, optional shift or rotate" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.										
	For the "Preload read" and "Preload write" variants: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the "imm2" field.										
+	Specifies the index register is added to the base register.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{(R(m), shift_t, shift_n, PSTATE.C);
    let address : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    if is_pldw then
        Hint_PreloadDataForWrite(address);
    else
        Hint_PreloadData(address);
    end;
end;
```

PLI (immediate, literal)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let add : boolean = (U == '1');
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	For the "A1" variant: see Standard assembler syntax fields . Must be AL or omitted. For the "T1", "T2", and "T3" variants: see Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table> <tr> <th>U</th><th>+/-</th></tr> <tr> <td>0</td><td>-</td></tr> <tr> <td>1</td><td>+</td></tr> </table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1" variant: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For the "T1" variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For the "T2" variant: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field. For the "T3" variant: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.						
<label>	The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range –4095 to 4095. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.						
+	Specifies the offset is added to the base register.						

For the literal forms of the instruction, encoding T3 is used, or Rn is encoded as 0b1111 in encoding A1, to indicate that the PC is the base register. The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see [Use of labels in UAL instruction syntax](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let base : bits(32) = if n == 15 then AlignDownSize(PC32(),4) else R(n);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    Hint_PreloadInstr(address);
end;
```

PLI (register)

Preload Instruction signals the memory system that instruction memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as pre-loading the cache line containing the specified address into the instruction cache.

The effect of a PLI instruction is IMPLEMENTATION DEFINED. For more information, see [Preloading caches](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1	1	1	1	1	0	0	1	0	0	0	1	!= 1111				1	1	1	1	0	0	0	0	0	0	0	imm2	Rm			
size							Rn				Rt																				

Encoding

PLI{<c>}{<q>} [<Rn>, {+}<Rm> {, LSL #<amount>}]

Decode for this encoding

```
if Rn == '1111' then See("PLI (immediate, literal)"); end;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let add : boolean = TRUE;
let shift_t : SRTType = SRTType_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c>

For the "Rotate right with extend" and "Shift or rotate by value" variants: see [Standard assembler syntax fields](#). <c> must be AL or omitted.
- <q>

See [Standard assembler syntax fields](#).
- <Rn>

Is the general-purpose base register, encoded in the "Rn" field.
- +/-

Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+
- <Rm>

Is the general-purpose index register, encoded in the "Rm" field.

<shift>

Is the type of shift to be applied to the index register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the "Shift or rotate by value" variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For the "T1" variant: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the "imm2" field.

+

Specifies the index register is added to the base register.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let offset : bits(32) = Shift{(R(m), shift_t, shift_n, PSTATE.C);
  let address : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
  Hint_PreloadInstr(address);
end;
```

POP

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	0	P	register list							

L

Encoding

```
POP{<c>}{<q>} <registers> // (Preferred syntax)

LDM{<c>}{<q>} SP!, <registers> // (Alternate syntax)
```

Decode for this encoding

```
let registers : bits(16) = P::'0000000'::register_list;
let UnalignedAllowed : boolean = FALSE;
if BitCount(registers) < 1 then UnpredictableProcedure(); end;
if registers[15] == '1' && InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<registers>	Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the PC. If the PC is in the list, the "P" field is set to 1, otherwise this field defaults to 0. If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(13);
    for i = 0 to 14 do
        if registers[i] == '1' then
            R(i) = if UnalignedAllowed then MemU{32}(address) else MemA{32}(address);
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        if UnalignedAllowed then
            if address[1:0] == '00' then
                LoadWritePC(MemU{32}(address));
            else
                UnpredictableProcedure();
            end;
        else
            LoadWritePC(MemA{32}(address));
        end;
    end;
    if registers[13] == '0' then R(13) = R(13) + 4*BitCount(registers); end;
    if registers[13] == '1' then R(13) = ARBITRARY : bits(32); end;
end;
```

POP (multiple registers)

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

This is an alias of [LDM, LDMIA, LDMFD](#). This means:

- The encodings in this description are named to match the encodings of [LDM, LDMIA, LDMFD](#).
- The description of [LDM, LDMIA, LDMFD](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T2](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	0	0	0	1	0	1	1	1	1	0	1	register_list															
cond				P		U		op		W		L		Rn																	

Encoding for the A1 variant

POP{<c>} {<q>} <registers>

is equivalent to

LDM{IA} {<c>} {<q>} SP!, <registers>

and is the preferred disassembly when `BitCount(register_list) > 1`.

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	0	1	1	1	1	0	1	P	M	register_list													
opc								W		L		Rn																			

Encoding for the T2 variant

POP{<c>} {<q>} <registers>

POP{<c>}.W <registers> // (M == 0 && register_list[13:8] == '000000')

is equivalent to

LDM{IA} {<c>}.W SP!, <registers>

and is the preferred disassembly when `BitCount(P :: M :: register_list) > 1`.

Assembler Symbols

- <c>

See [Standard assembler syntax fields](#).
- <q>

See [Standard assembler syntax fields](#).
- <registers>

For the "A1" variant: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#). If the SP is in the list, the value of the SP after such an instruction is UNKNOWN. The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#). Arm deprecates the use of this instruction with both the LR and the PC in the list.

For the "T2" variant: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#). The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#). If the PC is in the list:

 - The LR must not be in the list.
 - The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

The description of [LDM, LDMIA, LDMFD](#) gives the operational pseudocode for this instruction.

Operational Information

The description of [LDM, LDMIA, LDMFD](#) gives the operational information for this instruction.

```

Decode for this encoding

```
let registers : bits(16) = '0'::M::'000000'::register_list;
let UnalignedAllowed : boolean = FALSE;
if BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<registers>	Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the LR. If the LR is in the list, the "M" field is set to 1, otherwise this field defaults to 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(13) - 4*BitCount(registers);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == 13 && i != LowestSetBit(registers) then // Only possible for encoding A1
                MemA{32}(address) = ARBITRARY : bits(32);
            else
                if UnalignedAllowed then
                    MemU{32}(address) = R(i);
                else
                    MemA{32}(address) = R(i);
                end;
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then // Only possible for encoding A1 or A2
        if UnalignedAllowed then
            MemU{32}(address) = PCStoreValue();
        else
            MemA{32}(address) = PCStoreValue();
        end;
    end;
    R(13) = R(13) - 4*BitCount(registers);
end;
```

PUSH (multiple registers)

Push multiple registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

This is an alias of [STMDB, STMFD](#). This means:

- The encodings in this description are named to match the encodings of [STMDB, STMFD](#).
- The description of [STMDB, STMFD](#) gives the operational pseudocode, any **CONSTRAINED UNPREDICTABLE** behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	0	0	1	0	0	1	0	1	1	0	1	register_list															
cond				P		U		op		W		L		Rn																	

Encoding for the A1 variant

PUSH{<c>} {<q>} <registers>

is equivalent to

[STMDB](#){<c>} {<q>} SP!, <registers>

and is the preferred disassembly when `BitCount(register_list) > 1`.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	1	0	0	1	0	1	1	0	1	(0)	M	register_list													
opc							W		L		Rn				P																

Encoding for the T1 variant

PUSH{<c>} {<q>} <registers>

PUSH{<c>}.W <registers> // (register_list[13:8] == '000000')

is equivalent to

[STMDB](#){<c>} {<q>} SP!, <registers>

and is the preferred disassembly when `BitCount(M :: register_list) > 1`.

Assembler Symbols

- <c>
- See [Standard assembler syntax fields](#).
- <q>
- See [Standard assembler syntax fields](#).
- <registers>
- For the "A1" variant: is a list of two or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#). The SP and PC can be in the list. However:

- Arm deprecates the use of instructions that include the PC in the list.
- If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

For the "T1" variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#). The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation

The description of [STMDB, STMFD](#) gives the operational pseudocode for this instruction.

Operational Information

The description of [STMDB, STMFD](#) gives the operational information for this instruction.

PUSH (single register)

Push Single Register to Stack stores a single general-purpose register to the stack, storing to the 32-bit word below the address in SP, and updates SP to point to the start of the stored data.

This is an alias of [STR \(immediate\)](#). This means:

- The encodings in this description are named to match the encodings of [STR \(immediate\)](#).
- The description of [STR \(immediate\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T4](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

cond				P		U		op2		W		op1		Rn				imm12															

Encoding for the Pre-indexed variant

`PUSH{<c>} {<q>} <single_register_list>`
is equivalent to
`STR{<c>} {<q>} <Rt>, [SP, #-4] !`
and is always the preferred disassembly.

T4

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0								
1	1	1	1	1	0	0	0	0	1	0	0	1	1	0	1					1	1	0	1	0	0	0	0	0	1	0	0								
size												L				Rn				P				U				W				imm8							

Encoding for the Pre-indexed variant

`PUSH{<c>} {<q>} <single_register_list> // (Standard syntax)`
is equivalent to
`STR{<c>} {<q>} <Rt>, [SP, #-4] !`
and is always the preferred disassembly.

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <single_register_list> Is the general-purpose register <Rt> to be stored surrounded by { and }.

Operation

The description of [STR \(immediate\)](#) gives the operational pseudocode for this instruction.

Operational Information

The description of [STR \(immediate\)](#) gives the operational information for this instruction.

QADD

Saturating Add adds two register values, saturates the result to the 32-bit signed integer range -2^{31} to $(2^{31} - 1)$, and writes the result to the destination register. If saturation occurs, it sets *PSTATE.Q* to 1.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

cond										opc																					

Encoding

QADD{<c>}{<q> } {<Rd>, }<Rm>, <Rn>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	0	0	0	Rn				1	1	1	1	Rd				1	0	0	0	Rm			
op1															op2																

Encoding

QADD{<c>}{<q> } {<Rd>, }<Rm>, <Rn>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> Is the first general-purpose source register, encoded in the "Rm" field.
- <Rn> Is the second general-purpose source register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (r, sat) : (bits(32), boolean) = SignedSatQ{32}(SInt(R(m)) + SInt(R(n)));
    R(d) = r;
    if sat then
        PSTATE.Q = '1';
    end;
end;
```

QADD16

Saturating Add 16 performs two 16-bit integer additions, saturates the results to the 16-bit signed integer range $-2^{15} \leq x \leq 2^{15} - 1$, and writes the results to the destination register.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	0	0	0	Rn				1	1	1	1	Rd				1	0	1	0	Rm			
op1												op2																			

Encoding

QSUB{<c>}{<q> } {<Rd>, }<Rm>, <Rn>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the *CONSTRAINED UNPREDICTABLE* behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> Is the first general-purpose source register, encoded in the "Rm" field.
- <Rn> Is the second general-purpose source register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (r, sat) : (bits(32), boolean) = SignedSatQ{32}(SInt(R(m)) - SInt(R(n)));
    R(d) = r;
    if sat then
        PSTATE.Q = '1';
    end;
end;
```

QSUB16

Saturating Subtract 16 performs two 16-bit integer subtractions, saturates the results to the 16-bit signed integer range $-2^{15} \leq x \leq 2^{15} - 1$, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op1												U												H			S				

Encoding

QSUB16{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = SInt(R(n)[15:0]) - SInt(R(m)[15:0]);
    let diff2 : integer = SInt(R(n)[31:16]) - SInt(R(m)[31:16]);
    R(d)[15:0] = SignedSat{16}(diff1);
    R(d)[31:16] = SignedSat{16}(diff2);
end;
```

QSUB8

Saturating Subtract 8 performs four 8-bit integer subtractions, saturates the results to the 8-bit signed integer range $-2^7 \leq x \leq 2^7 - 1$, and writes the results to the destination register. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding

QSUB8{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = SInt(R(n)[7:0]) - SInt(R(m)[7:0]);
    let diff2 : integer = SInt(R(n)[15:8]) - SInt(R(m)[15:8]);
    let diff3 : integer = SInt(R(n)[23:16]) - SInt(R(m)[23:16]);
    let diff4 : integer = SInt(R(n)[31:24]) - SInt(R(m)[31:24]);
    R(d)[7:0] = SignedSat{8}(diff1);
    R(d)[15:8] = SignedSat{8}(diff2);
    R(d)[23:16] = SignedSat{8}(diff3);
    R(d)[31:24] = SignedSat{8}(diff4);
end;
```

RBIT

Reverse Bits reverses the bit order in a 32-bit register.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	0	1	1	1	(1)	(1)	(1)	(1)	Rd				(1) (1) (1) (1)				0	0	1	1	Rm				
cond								o1								o2															

Encoding

RBIT{<c>}{<q> <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	0	0	1	Rn				1	1	1	1	Rd				1	0	1	0	Rm			
								op1																op2							

Encoding

RBIT{<c>}{<q> <Rd>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if m != n || d == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `m != n`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction executes with the additional decode: `m = UInt(Rn)`.
 - The instruction executes with the additional decode: `m = UInt(Rm)`.
 - The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	For the "A1" variant: is the general-purpose source register, encoded in the "Rm" field. For the "T1" variant: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var result : bits(32);
    for i = 0 to 31 do
        result[31-i] = R(m)[i];
    end;
    R(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

REV

Byte-Reverse Word reverses the byte order in a 32-bit register.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op1												op2																			

Encoding

REV{<c>} {<q>} <Rd>, <Rm>

REV{<c>}.W <Rd>, <Rm> // (<Rd>, <Rm> can be represented in T1)

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if m != n || d == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `m != n`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction executes with the additional decode: `m = UInt(Rn)`;
 - The instruction executes with the additional decode: `m = UInt(Rm)`;
 - The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	For the "A1" and "T1" variants: is the general-purpose source register, encoded in the "Rm" field.

For the "T2" variant: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var result : bits(32);
    result[31:24] = R(m)[7:0];
    result[23:16] = R(m)[15:8];
    result[15:8]  = R(m)[23:16];
    result[7:0]   = R(m)[31:24];
    R(d) = result;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

RFE, RFEDA, RFEDB, RFEIA, RFEIB

Return From Exception loads two consecutive memory locations using an address in a base register:

- The word loaded from the lower address is treated as an instruction address. The PE branches to it.
- The word loaded from the higher address is used to restore *PSTATE*. This word must be in the format of an SPSR.

An address adjusted by the size of the data loaded can optionally be written back to the base register.

The PE checks the value of the word loaded from the higher address for an illegal return event. See *Illegal return events from AArch32 state*.

RFE is UNDEFINED in Hyp mode and CONSTRAINED UNPREDICTABLE in User mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

opc											L	Rn				P	M	register_list													

Encoding

```
RFE{IA}{<c>}{<q>}<Rn>{!} // (Outside or last in IT block, preferred syntax)
RFEFD{<c>}{<q>}<Rn>{!} // (Outside or last in IT block, alternate syntax, Full Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let wback : boolean = (W == '1');
let increment : boolean = TRUE;
let wordhigher : boolean = FALSE;
if n == 15 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	For the "A1 Decrement After", "A1 Decrement Before", "A1 Increment After", and "A1 Increment Before" variants: see Standard assembler syntax fields . <c> must be AL or omitted. For the "T1" and "T2" variants: see Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
!	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
IA	For the "Increment After" variant: is an optional suffix to indicate the Increment After variant. For the "T2" variant: is an optional suffix for the Increment After form.

RFEFA, RFEEA, RFEFD, and RFEED are pseudo-instructions for RFEDA, RFEDB, RFEIA, and RFEIB respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        Undefined();
    elsif PSTATE.EL == EL0 then
        UnpredictableProcedure(); // UNDEFINED or NOP
    else
        var address : bits(32) = if increment then R(n) else R(n)-8;
        if wordhigher then address = address+4; end;
        let new_pc_value : bits(32) = MemA{32}(address);
        let spsr : bits(32) = MemA{32}(address+4);
        if wback then R(n) = if increment then R(n)+8 else R(n)-8; end;
        AArch32_ExceptionReturn(new_pc_value, spsr);
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

RSB, RSBS (immediate)

Reverse Subtract (immediate) subtracts a register value from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	For the "A1 RSB" and "A1 RSBS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used: - For the RSB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. - For the RSBS variant, the instruction performs an exception return, that restores <i>PSTATE</i> from <i>SPSR_<current_mode></i>. For the "T1", "T2 RSB", and "T2 RSBS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.
<Rn>	For the "A1 RSB" and "A1 RSBS" variants: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For the "T1", "T2 RSB", and "T2 RSBS" variants: is the general-purpose source register, encoded in the "Rn" field.
<const>	For the "A1 RSB" and "A1 RSBS" variants: an immediate value. See Modified immediate constants in A32 instructions for the range of values. For the "T2 RSB" and "T2 RSBS" variants: an immediate value. See Modified immediate constants in T32 instructions for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcv) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), imm32, '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcv;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

RSB, RSBS (register)

Reverse Subtract (register) subtracts a register value from an optionally-shifted register value, and writes the result to the destination register. If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result. The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

RSC{<c>}{<q>}{<Rd>, }<Rn>, <Rm>, RRX

Encoding for the RSC, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

RSC{<c>}{<q>}{<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Encoding for the RSCS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

RSCS{<c>}{<q>}{<Rd>, }<Rn>, <Rm>, RRX

Encoding for the RSCS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

RSCS{<c>}{<q>}{<Rd>, }<Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
```

Assembler Symbols

- <c>

See *Standard assembler syntax fields*.
- <q>

See *Standard assembler syntax fields*.
- <Rd>

Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:
 - For the RSC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
 - For the RSCS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.
- <Rn>

Is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
- <Rm>

Is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

<shift>	Is the type of shift to be applied to the second source register, encoded in “stype”:
stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>	Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), shifted, PSTATE.C);
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);

- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR
- <Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{R(m), shift_t, shift_n, PSTATE.C};
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(NOT(R(n)), shifted, PSTATE.C);
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SADD16

Signed Add 16 performs two 16-bit signed integer additions, and writes the results to the destination register. It sets *PSTATE*.GE according to the results of the additions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

Encoding

SADD16{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

SADD16{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the *CONSTRAINED UNPREDICTABLE* behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[15:0]) + SInt(R(m)[15:0]);
    let sum2 : integer = SInt(R(n)[31:16]) + SInt(R(m)[31:16]);
    R(d)[15:0] = sum1[15:0];
    R(d)[31:16] = sum2[15:0];
    PSTATE.GE[1:0] = if sum1 >= 0 then '11' else '00';
    PSTATE.GE[3:2] = if sum2 >= 0 then '11' else '00';
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

SADD8

Signed Add 8 performs four 8-bit signed integer additions, and writes the results to the destination register. It sets *PSTATE*.GE according to the results of the additions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<q> See *Standard assembler syntax fields*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    SpeculationBarrier();
end;
```

SBC, SBCS (immediate)

Subtract with Carry (immediate) subtracts an immediate value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SBCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The SBC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The SBCS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd> For the "A1 SBC, rotate right with extend", "A1 SBC, shift or rotate by value", "A1 SBCS, rotate right with extend", and "A1 SBCS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SBCS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the "T2 SBC, rotate right with extend", "T2 SBC, shift or rotate by value", "T2 SBCS, rotate right with extend", and "T2 SBCS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For the "A1 SBC, rotate right with extend", "A1 SBC, shift or rotate by value", "A1 SBCS, rotate right with extend", and "A1 SBCS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For the "T2 SBC, rotate right with extend", "T2 SBC, shift or rotate by value", "T2 SBCS, rotate right with extend", and "T2 SBCS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For the "A1 SBC, rotate right with extend", "A1 SBC, shift or rotate by value", "A1 SBCS, rotate right with extend", and "A1 SBCS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For the "T1", "T2 SBC, rotate right with extend", "T2 SBC, shift or rotate by value", "T2 SBCS, rotate right with extend", and "T2 SBCS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.

<shift>	Is the type of shift to be applied to the second source register, encoded in “stype”:										
	<table> <tr> <th>stype</th><th><shift></th></tr> <tr> <td>00</td><td>LSL</td></tr> <tr> <td>01</td><td>LSR</td></tr> <tr> <td>10</td><td>ASR</td></tr> <tr> <td>11</td><td>ROR</td></tr> </table>	stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR
stype	<shift>										
00	LSL										
01	LSR										
10	ASR										
11	ROR										
<amount>	For the "A1 SBC, shift or rotate by value" and "A1 SBCS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For the "T2 SBC, shift or rotate by value" and "T2 SBCS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.										
<Rdn>	Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.										

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), PSTATE.C);
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);

SBC, SBCS (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	1	1	0	S	Rn				Rd				Rs				0	stype		1	Rm			
cond								opc																							

Encoding for the Flag setting variant

Applies when (S == 1)

SBCS{<c>}{<q>}{<Rd>}, <Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

SBC{<c>}{<q>}{<Rd>}, <Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .										
<q>	See Standard assembler syntax fields .										
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.										
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.										
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.										
<shift>	Is the type of shift to be applied to the second source register, encoded in "stype": <table><tr><th>stype</th><th><shift></th></tr><tr><td>00</td><td>LSL</td></tr><tr><td>01</td><td>LSR</td></tr><tr><td>10</td><td>ASR</td></tr><tr><td>11</td><td>ROR</td></tr></table>	stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR
stype	<shift>										
00	LSL										
01	LSR										
10	ASR										
11	ROR										
<Rs>	Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{R(m), shift_t, shift_n, PSTATE.C};
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), PSTATE.C);
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SBFX

Signed Bit Field Extract extracts any number of adjacent bits at any position from a register, sign-extends them to 32 bits, and writes the result to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	1	1	0	1	widthm1				Rd				lsb				1 0		1	Rn					
cond									U																						

Encoding

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let lsbit : integer{} = UInt(lsb);
let widthminus1 : integer{} = UInt(widthm1);
let msbit : integer{} = lsbit + widthminus1;
if d == 15 || n == 15 then UnpredictableProcedure(); end;
if msbit > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	(0)	1	1	0	1	0	0	Rn				0	imm3				Rd				imm2		(0)	widthm1			
op1																															

Encoding

SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let lsbit : integer{} = UInt(imm3::imm2);
let widthminus1 : integer{} = UInt(widthm1);
let msbit : integer{} = lsbit + widthminus1;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
if msbit > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "A1" variant: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.

For the "T1" variant: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width> Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d) = SignExtend{32}(R(n)[msbit:lsbit]);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	1	0	0	0	1	Rd				(1)	(1)	(1)	(1)	Rm				0	0	0	1	Rn			
cond				op1								Ra								op2											

Encoding

SDIV{<c>}{<q> } {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a != 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If **Ra != '1111'**, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction executes as described, with no change to its behavior and no additional side effects.
 - The instruction executes as described, and the register specified by Ra becomes UNKNOWN.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	1	0	0	1	Rn				(1)	(1)	(1)	(1)	Rd				1	1	1	1	Rm			
op1												Ra								op2											

Encoding

SDIV{<c>}{<q> } {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 || a != 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If **Ra != '1111'**, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction executes as described, with no change to its behavior and no additional side effects.
 - The instruction executes as described, and the register specified by Ra becomes UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.
Overflow	

If the signed integer division $0x80000000 / 0xFFFFFFFF$ is performed, the pseudocode produces the intermediate integer result $+2^{31}$, that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to $\langle Rd \rangle$ must be the bottom 32 bits of the binary representation of $+2^{31}$. So the result of the division is $0x80000000$.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let dividend : integer = SInt(R(n));
    let divisor : integer = SInt(R(m));
    var result : integer;
    if divisor == 0 then
        result = 0;
    elsif (dividend < 0) == (divisor < 0) then
        result = Abs(dividend) DIVRM Abs(divisor); // same signs - positive result
    else
        result = -(Abs(dividend) DIVRM Abs(divisor)); // different signs - negative result
    end;
    R(d) = result[31:0];
end;
```

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    SendEventLocal();
end;
```

SHADD16

Signed Halving Add 16 performs two signed 16-bit integer additions, halves the results, and writes the results to the destination register. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
SHADD16{<c>}{<q>}{<Rd>, }<Rn>, <Rm>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
SHADD16{<c>}{<q>}{<Rd>, }<Rn>, <Rm>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[15:0]) + SInt(R(m)[15:0]);
    let sum2 : integer = SInt(R(n)[31:16]) + SInt(R(m)[31:16]);
    R(d)[15:0] = sum1[16:1];
    R(d)[31:16] = sum2[16:1];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SHADD8

Signed Halving Add 8 performs four signed 8-bit integer additions, halves the results, and writes the results to the destination register. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
SHADD8{<c>}{<q>}{<Rd>, }<Rn>, <Rm>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
SHADD8{<c>}{<q>}{<Rd>, }<Rn>, <Rm>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = SInt(R(n)[7:0]) + SInt(R(m)[7:0]);
    let sum2 : integer = SInt(R(n)[15:8]) + SInt(R(m)[15:8]);
    let sum3 : integer = SInt(R(n)[23:16]) + SInt(R(m)[23:16]);
    let sum4 : integer = SInt(R(n)[31:24]) + SInt(R(m)[31:24]);
    R(d)[7:0] = sum1[8:1];
    R(d)[15:8] = sum2[8:1];
    R(d)[23:16] = sum3[8:1];
    R(d)[31:24] = sum4[8:1];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SHASX

Signed Halving Add and Subtract with Exchange exchanges the two halfwords of the second operand, performs one signed 16-bit integer addition and one signed 16-bit subtraction, halves the results, and writes the results to the destination register. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

    let diff1 : integer = SInt(R(n)[7:0]) - SInt(R(m)[7:0]);
    let diff2 : integer = SInt(R(n)[15:8]) - SInt(R(m)[15:8]);
    let diff3 : integer = SInt(R(n)[23:16]) - SInt(R(m)[23:16]);
    let diff4 : integer = SInt(R(n)[31:24]) - SInt(R(m)[31:24]);
    R(d)[7:0] = diff1[8:1];
    R(d)[15:8] = diff2[8:1];
    R(d)[23:16] = diff3[8:1];
    R(d)[31:24] = diff4[8:1];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SMC

Secure Monitor Call causes a Secure Monitor Call exception. For more information, see [Secure Monitor Call \(SMC\) exception](#).

SMC is available only for software executing at EL1 or higher. It is UNDEFINED in User mode.

If the values of [HCR.TSC](#) and [SCR.SCD](#) are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception that is taken to EL3. When EL3 is using AArch32 this exception is taken to Monitor mode. When EL3 is using AArch64, it is the SCR_EL3.SMD bit, rather than the [SCR.SCD](#) bit, that can change the effect of executing an SMC instruction.

If the value of [HCR.TSC](#) is 1, execution of an SMC instruction in a Non-secure EL1 mode generates an exception that is taken to EL2, regardless of the value of [SCR.SCD](#). When EL2 is using AArch32, this is a Hyp Trap exception that is taken to Hyp mode. For more information, see [HCR.TSC](#).

If the value of [HCR.TSC](#) is 0 and the value of [SCR.SCD](#) is 1, the SMC instruction is:

- UNDEFINED in Non-secure state.
- CONSTRAINED UNPREDICTABLE if executed in Secure state at EL1 or higher.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	1	1	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	0	1	1	1	imm4				
cond				opc								imm12																			

Encoding

SMC{<c>}{<q>}{#}<imm4>

Decode for this encoding

```
// imm4 is for assembly/disassembly only and is ignored by hardware
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0												
1	1	1	1	0	1	1	1	1	1	1	1	imm4				1	0	0	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)												
o1												o2																imm12															

Encoding

SMC{<c>}{<q>}{#}<imm4>

Decode for this encoding

```
// imm4 is for assembly/disassembly only and is ignored by hardware
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c>

See [Standard assembler syntax fields](#).
- <q>

See [Standard assembler syntax fields](#).
- <imm4>

Is a 4-bit unsigned immediate value, in the range 0 to 15, encoded in the "imm4" field. This is ignored by the PE. The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but Arm does not recommend this.

Operation

```
if ConditionPassed\(\) then
    EncodingSpecificOperations\(\);

    AArch32\_CheckForSMCUndefinedOrTrap\(\);

    if !ELUsingAArch32\(EL3\) then
        if SCR\_EL3\(\).SMD == '1' then
            // SMC disabled.
            Undefined\(\);
        end;
    else
        if SCR\(\).SCD == '1' then
            // SMC disabled
            if CurrentSecurityState\(\) == SS\_Secure then
                // Executes either as a NOP or UNALLOCATED.
                let c : Constraint = ConstrainUnpredictable\(Unpredictable\_SMD\);
                assert c IN {Constraint\_NOP, Constraint\_UNDEF};
                if c == Constraint\_NOP then ExecuteAsNOP\(\); end;
            end;
            Undefined\(\);
        end;
    end;

    if !ELUsingAArch32\(EL3\) then
        AArch64\_CallSecureMonitor(Zeros{16});
    else
        AArch32\_TakeSMCException\(\);
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `SCR.SCD == '1' && CurrentSecurityState() == SS_Secure`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets *PSTATE.Q* to 1. It is not possible for overflow to occur during the multiplication.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

SMLAD, SMLADX

Signed Multiply Accumulate Dual performs two signed 16 x 16-bit multiplications. It adds the products to a 32-bit accumulate operand. Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets *PSTATE.Q* to 1 if the accumulate operation overflows. Overflow cannot occur during the multiplications.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

SMLAL, SMLALS

Signed Multiply Accumulate Long multiplies two signed 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value. In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	1	1	1	S	RdHi				RdLo				Rm				1	0	0	1	Rn			
cond								opc																							

Encoding for the Flag setting variant

Applies when (S == 1)

SMLALS{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Encoding for the Not flag setting variant

Applies when (S == 0)

SMLAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for all variants of this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **dHi == dLo**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SMLALBB, SMLALBT, SMLALTB, SMLALTT

Signed Multiply Accumulate Long (halfwords) multiplies two signed 16-bit values to produce a 32-bit value, and accumulates this with a 64-bit value. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is sign-extended and accumulated with a 64-bit accumulate value. Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^{64} . It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets *PSTATE.Q* to 1. No overflow can occur during the multiplication.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

Encoding for the SMLAWB variant

Encoding for the SMLS LD variant

Applies when (M == 0)

SMLS LD{<c>}{<q>}<RdLo>, <RdHi>, <Rn>, <Rm>

Encoding for the SMLS LDx variant

Applies when (M == 1)

SMLS LDx{<c>}{<q>}<RdLo>, <RdHi>, <Rn>, <Rm>

Decode for all variants of this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let m_swap : boolean = (M == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If dHi == dLo, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

// Armv8-A removes UPREDICTABLE for R13
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The value in the destination register is UNKNOWN.
- For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<RdLo>	Is the general-purpose source register holding the lower 32 bits of the addend, and the destination register for the lower 32 bits of the result, encoded in the "RdLo" field.
<RdHi>	Is the general-purpose source register holding the upper 32 bits of the addend, and the destination register for the upper 32 bits of the result, encoded in the "RdHi" field.
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand2 : bits(32) = if m_swap then ROR(R(m),16) else R(m);
    let product1 : integer = SInt(R(n)[15:0]) * SInt(operand2[15:0]);
    let product2 : integer = SInt(R(n)[31:16]) * SInt(operand2[31:16]);
    let result : integer = (product1 - product2) + SInt(R(dHi)::R(dLo));
    R(dHi) = result[63:32];
    R(dLo) = result[31:0];
end;
```

SMMLA, SMMLAR

Signed Most Significant Word Multiply Accumulate multiplies two signed 32-bit values, extracts the most significant 32 bits of the result, and adds an accumulate value.

Optionally, the instruction can specify that the result is rounded instead of being truncated. In this case, the constant 0x80000000 is added to the product before the high word is extracted.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SMUAD, SMUADX

Signed Dual Multiply Add performs two signed 16 x 16-bit multiplications. It adds the products together, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets *PSTATE.Q* to 1 if the addition overflows. The multiplications cannot overflow.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SMULBB, SMULBT, SMULTB, SMULTT

Signed Multiply (halfwords) multiplies two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is written to the destination register. No overflow is possible during this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SMULL, SMULLS

Signed Multiply Long multiplies two 32-bit signed values to produce a 64-bit result.
In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	1	1	0	S	RdHi				RdLo				Rm				1	0	0	1	Rn			
cond								opc																							

Encoding for the Flag setting variant

Applies when (S == 1)

SMULLS{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Encoding for the Not flag setting variant

Applies when (S == 0)

SMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for all variants of this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **dHi == dLo**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	1	1	0	0	0	Rn				RdLo				RdHi				0	0	0	0	Rm			
op1																												op2			

Encoding

SMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>

Decode for this encoding

```
let dLo : integer = UInt(RdLo);
let dHi : integer = UInt(RdHi);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let setflags : boolean = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **dHi == dLo**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q>	See <i>Standard assembler syntax fields</i> .
<RdLo>	Is the general-purpose destination register for the lower 32 bits of the result, encoded in the "RdLo" field.
<RdHi>	Is the general-purpose destination register for the upper 32 bits of the result, encoded in the "RdHi" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    let result : integer = SInt(R(n)) * SInt(R(m));
    R(dHi) = result[63:32];
    R(dLo) = result[31:0];
    if setflags then
        PSTATE.N = result[63];
        PSTATE.Z = IsZeroBit{64}(result[63:0]);
        // PSTATE.C, PSTATE.V unchanged
    end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

SMULWB, SMULWT

Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SMUSD, SMUSDX

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow cannot occur.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SRS, SRSDA, SRSDb, SRSIA, SRSIB

Store Return State stores the LR_<current_mode> and SPSR_<current_mode> to the stack of a specified mode. For information about memory accesses see *Memory accesses*.

SRS is UNDEFINED in Hyp mode.

SRS is CONSTRAINED UNPREDICTABLE if it is executed in User or System mode, or if the specified mode is any of the following:

- Not implemented.
- A mode that AArch32 PE modes does not show.
- Hyp mode.
- Monitor mode, if the SRS instruction is executed in Non-secure state.

If EL3 is using AArch64 and an SRS instruction that is executed in a Secure EL1 mode specifies Monitor mode, it is trapped to EL3.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let wback : boolean = (W == '1');
let increment : boolean = TRUE;
let wordhigher : boolean = FALSE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [SRS \(T32\)](#) and [SRS \(A32\)](#).

Assembler Symbols

<c>	For the "Decrement After", "Decrement Before", "Increment After", and "Increment Before" variants: see Standard assembler syntax fields . <c> must be AL or omitted. For the "T1" and "T2" variants: see Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
!	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<mode>	Is the number of the mode whose Banked SP is used as the base register, encoded in the "mode" field. For details of PE modes and their numbers see AArch32 state PE modes .
IA	For the "Increment After" variant: is an optional suffix to indicate the Increment After variant. For the "T2" variant: is an optional suffix for the Increment After form.

SRSFA, SRSEA, SRSFD, and SRSED are pseudo-instructions for SRSIB, SRSIA, SRSDb, and SRSDA respectively, referring to their use for pushing data onto Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

```

end;
```

CONSTRAINED UNPREDICTABLE behavior

If [PSTATE.M](#) IN {[M32_User](#),[M32_System](#)}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If mode == [M32_Hyp](#), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If mode == [M32_Monitor](#) && ([!HaveEL\(EL3\)](#) || [CurrentSecurityState\(\)](#) != [SS_Secure](#)), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If [BadMode\(mode\)](#), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction stores to the stack of the mode in which it is executed.

- The instruction stores to an UNKNOWN address, and if the instruction specifies writeback then any general-purpose register that can be accessed from the current Exception level without a privilege violation becomes UNKNOWN.

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the bit position for saturation, in the range 1 to 32, encoded in the "sat_imm" field as <imm>-1.
<Rn>	Is the general-purpose source register, encoded in the "Rn" field.
<amount>	For the "A1 Arithmetic shift right" variant: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32. For the "A1 Logical shift left" variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field. For the "T1 Arithmetic shift right" variant: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

For the "T1 Logical shift left" variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let operand : bits(32) = Shift{}(R(n), shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
  let (result, sat) : (bits(saturate_to), boolean) = SignedSatQ{saturate_to}(SInt(operand));
  R(d) = SignExtend{32}(result);
  if sat then
    PSTATE.Q = '1';
  end;
end;
```

op1												U H S																			

Encoding

SSAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = SInt(R(n)[15:0]) + SInt(R(m)[31:16]);
    let diff : integer = SInt(R(n)[31:16]) - SInt(R(m)[15:0]);
    R(d)[15:0] = sum[15:0];
    R(d)[31:16] = diff[15:0];
    PSTATE.GE[1:0] = if sum >= 0 then '11' else '00';
    PSTATE.GE[3:2] = if diff >= 0 then '11' else '00';
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SSBB

Speculative Store Bypass Barrier is a memory barrier that prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions. For more information and details of the semantics, see *Speculative Store Bypass Barrier (SSBB)*. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

    let diff3 : integer = SInt(R(n)[23:16]) - SInt(R(m)[23:16]);
    let diff4 : integer = SInt(R(n)[31:24]) - SInt(R(m)[31:24]);
    R(d)[7:0] = diff1[7:0];
    R(d)[15:8] = diff2[7:0];
    R(d)[23:16] = diff3[7:0];
    R(d)[31:24] = diff4[7:0];
    PSTATE.GE[0] = if diff1 >= 0 then '1' else '0';
    PSTATE.GE[1] = if diff2 >= 0 then '1' else '0';
    PSTATE.GE[2] = if diff3 >= 0 then '1' else '0';
    PSTATE.GE[3] = if diff4 >= 0 then '1' else '0';
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

STC

Store data to System register calculates an address from a base register value and an immediate offset, and stores a word from the [DBGDTRRXint](#) System register to memory. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses, see [Memory accesses](#).

In an implementation that includes EL2, the permitted STC access to [DBGDTRRXint](#) can be trapped to Hyp mode, meaning that an attempt to execute an STC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see [HDCR.TDA](#).

For simplicity, the STC pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
!= 1111				1	1	0	P	U	0	W	0	Rn				0	1	0	1	1	1	1	0	imm8									
cond								D				L				CRd				cp15													

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

STC{<c>}{<q>} p14, c5, [<Rn>], #<+/-><imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STC{<c>}{<q>} p14, c5, [<Rn>, #<+/-><imm>]!

Encoding for the Unindexed variant

Applies when (P == 0 && U == 1 && W == 0)

STC{<c>}{<q>} p14, c5, [<Rn>], <option>

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then Undefined(); end;
let n : integer = UInt(Rn);
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend()(imm8::'00');
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If n == 15 && wback, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	P	U	0	W	0	Rn			0	1	0	1	1	1	1	0	imm8								
								D				L				CRd				cp15											

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STC{<c>}{<q>} p14, c5, [<Rn>{, #<+/-><imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

```
STC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
STC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>!
```

Encoding for the Unindexed variant

Applies when (P == 0 && U == 1 && W == 0)

```
STC{<c>}{<q>} p14, c5, [<Rn>], <option>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then Undefined(); end;
let n : integer = UInt(Rn);
let cp : integer = 14;
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If n == 15, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15](#).

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rn>	For the "A1 Offset" and "A1 Unindexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated. For the "A1 Post-indexed", "A1 Pre-indexed", "T1 Offset", "T1 Post-indexed", "T1 Pre-indexed", and "T1 Unindexed" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table border="1"> <thead> <tr> <th>U</th><th>+/-</th></tr> </thead> <tbody> <tr> <td>0</td><td>-</td></tr> <tr> <td>1</td><td>+</td></tr> </tbody> </table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.						
<option>	Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);

    // System register read from DBGDTRRXint.
    AArch32_SysRegRead(cp, ThisInstr(), address[31:0]);
    if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STL

Store-Release Word stores a word from a register to memory. The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#). For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#). It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    MemO{8}(address) = R(t)[7:0];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STLEX

Store-Release Exclusive Word stores a word from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*.

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	1	0	0	0	Rn				Rd				(1)	(1)	1	0	1	0	0	1	Rt			
cond				size								L								ex				ord							

Encoding

STLEX{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **d == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If **d == n**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	0	Rn				Rt				(1)	(1)	(1)	(1)	1	1	1	0	Rd			
				op0								L								Rt2				op				sz			

Encoding

STLEX{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **d == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If **d == n**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemO{32}(address) = R(t);
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STLEXB

Store-Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*.

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	1	1	0	0	Rn				Rd				(1)	(1)	1	0	1	0	0	1	Rt			
cond				size								L								ex				ord							

Encoding

STLEXB{<c>}{<q>}<Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **d == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If **d == n**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	0	Rn				Rt				(1)	(1)	(1)	(1)	1	1	0	0	Rd			
				op0								L								Rt2				op				sz			

Encoding

STLEXB{<c>}{<q>}<Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **d == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If **d == n**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    if AArch32.ExclusiveMonitorsPass(address,1) then
        MemO{8}(address) = R(t)[7:0];
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STLEXD

Store-Release Exclusive Doubleword stores a doubleword from two registers to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	1	0	1	0	Rn				Rd				(1)	(1)	1	0	1	0	0	1	Rt			
cond				size								L	ex ord																		

Encoding

STLEXD{<op>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
if d == 15 || Rt[0] == '1' || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t || d == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `Rt<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in [Using R15](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
1	1	1	0	1	0	0	0	1	1	0	0	Rn				Rt				Rt2				1	1	1	1	Rd						
op0												L																	op		sz			

Encoding

STLEXD{<op>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t || d == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory.
<Rt>	For the "A1" variant: is the first general-purpose register to be transferred, encoded in the "Rt" field. <Rt> must be even-numbered and not R14. For the "T1" variant: is the first general-purpose register to be transferred, encoded in the "Rt" field.
<Rt2>	For the "A1" variant: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>. For the "T1" variant: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    let value : bits(64) = if BigEndian(AccessType_GPR) then R(t)::R(t2) else R(t2)::R(t);
    if AArch32.ExclusiveMonitorsPass(address, 8) then
        MemO{64}(address) = value;
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STLEXH

Store-Release Exclusive Halfword stores a halfword from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in [Load-Acquire, Store-Release](#).

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
!= 1111				0	0	0	1	1	1	1	0	Rn				Rd				(1)	(1)	1	0	1	0	0	1	Rt							
cond				size								L								(1)		(1)		1		0		1		0		0		1	

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    if AArch32.ExclusiveMonitorsPass(address,2) then
        MemO{16}(address) = R(t)[15:0];
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

Encoding

STLH{<c>}{<q>}<Rt>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if t == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.
- <Rn> Is the general-purpose base register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    MemO{16}(address) = R(t)[15:0];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STM (User registers)

In an EL1 mode other than System mode, Store Multiple (User registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Store Multiple (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#).

A1

Encoding

STM{<amode>}{<c>}{<q>} <Rn>, <registers>^

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let increment : boolean = (U == '1');
let wordhigher : boolean = (P == U);
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<amode>	is one of:
DA	Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.
ED	Empty Descending. For this instruction, a synonym for DA.
DB	Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.
FD	Full Descending. For this instruction, a synonym for DB.
IA	Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.
EA	Empty Ascending. For this instruction, a synonym for IA.
IB	Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.
FA	Full Ascending. For this instruction, a synonym for IB.
<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<registers>	Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be stored by the STM instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also Encoding of lists of general-purpose registers and the PC .

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        Undefined();
    elsif PSTATE.M IN {M32_User, M32_System} then
        UnpredictableProcedure();
    else
        let length : integer = 4*BitCount(registers);
        var address : bits(32) = if increment then R(n) else R(n)-length;
        if wordhigher then address = address+4; end;
        for i = 0 to 14 do
            if registers[i] == '1' then // Store User mode register
                MemS{32}(address) = Rmode(i, M32_User);
                address = address + 4;
            end;
        end;
        if registers[15] == '1' then
            MemS{32}(address) = PCStoreValue();
        end;
    end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User, M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STM, STMIA, STMEA

Store Multiple (Increment After, Empty Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#). For details of related system instructions see [STM \(User registers\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	0	0	0	1	0	W	0	Rn				register_list															
cond				P				U	op	L																					

Encoding

```
STM{IA}{<c>}{<q> <Rn>!, <registers> // (Preferred syntax)
```

```
STMEA{<c>}{<q> <Rn>!, <registers> // (Alternate syntax, Empty Ascending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15](#).

T1

`STMEA{<c>}.W <Rn>{!}, <registers>` // (Alternate syntax, Empty Ascending stack, if <Rn>, '!' and <registers> can be represented in T1)

`STM{IA}{<c>}{<q>} <Rn>{!}, <registers>` // (Preferred syntax)

`STMEA{<c>}{<q>} <Rn>{!}, <registers>` // (Alternate syntax, Empty Ascending stack)

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = P::M::register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 2 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
if registers[13] == '1' then UnpredictableProcedure(); end;
if registers[15] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored for the base register is UNKNOWN.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If `registers<15> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in [Using R15](#).

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

IA	Is an optional suffix for the Increment After form.
<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
!	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<registers>	For the "A1" variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register. For the "T1" variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register. For the "T2" variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS{32}(address) = ARBITRARY : bits(32); // Only possible for encodings T1 and A1
            else
                MemS{32}(address) = R(i);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then // Only possible for encoding A1
        MemS{32}(address) = PCStoreValue();
    end;
    if wback then R(n) = R(n) + 4*BitCount(registers); end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STMDA, STMED

Store Multiple Decrement After (Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#). For details of related system instructions see [STM \(User registers\)](#).

A1

Encoding

```
STMDA{<c>}{<q>}<Rn>{!}, <registers> // (Preferred syntax)

STMED{<c>}{<q>}<Rn>{!}, <registers> // (Alternate syntax, Empty Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
!	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<registers>	Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = (R(n) - 4*BitCount(registers)) + 4;
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS{32}(address) = ARBITRARY : bits(32);
            else
                MemS{32}(address) = R(i);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        MemS{32}(address) = PCStoreValue();
    end;
    if wback then R(n) = R(n) - 4*BitCount(registers); end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STMDB, STMFD

Store Multiple Decrement Before (Full Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the first of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#). For details of related system instructions see [STM \(User registers\)](#).

This instruction is used by the alias [PUSH \(multiple registers\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	0	0	1	0	0	W	0	Rn				register list															
cond				P				U	op	L																					

Encoding

```
STMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
STMFD{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an *STM* with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

opc							L								P																

Encoding

```
STMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
STMFD{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Descending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = P::M::register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 2 then UnpredictableProcedure(); end;
if wback && registers[n] == '1' then UnpredictableProcedure(); end;
if registers[13] == '1' then UnpredictableProcedure(); end;
if registers[15] == '1' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an *STM* with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The store instruction executes but the value stored for the base register is UNKNOWN.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If `registers<15> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
!	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<registers>	For the "A1" variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register. For the "T1" variant: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Alias Conditions

Alias	Of variant	Is preferred when
PUSH (multiple registers)	A1	<code>W == '1' && Rn == '1101' && BitCount(register_list) > 1</code>
PUSH (multiple registers)	T1	<code>W == '1' && Rn == '1101' && BitCount(M :: register_list) > 1</code>
PUSH (multiple registers)	T1	<code>BitCount(M :: register_list) > 1</code>

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n) - 4*BitCount(registers);
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS{32}(address) = ARBITRARY : bits(32); // Only possible for encoding A1
            else
                MemS{32}(address) = R(i);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then // Only possible for encoding A1
        MemS{32}(address) = PCStoreValue();
    end;
    if wback then R(n) = R(n) - 4*BitCount(registers); end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STMIB, STMFA

Store Multiple Increment Before (Full Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also [Encoding of lists of general-purpose registers and the PC](#).

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see [FEAT_LSMAOC](#). For details of related system instructions see [STM \(User registers\)](#).

A1

Encoding

```
STMIB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

STMFA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Full Ascending stack)
```

Decode for this encoding

```
let n : integer = UInt(Rn);
let registers : bits(16) = register_list;
let wback : boolean = (W == '1');
if n == 15 || BitCount(registers) < 1 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
!	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<registers>	Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    var address : bits(32) = R(n) + 4;
    for i = 0 to 14 do
        if registers[i] == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS{32}(address) = ARBITRARY : bits(32);
            else
                MemS{32}(address) = R(i);
            end;
            address = address + 4;
        end;
    end;
    if registers[15] == '1' then
        MemS{32}(address) = PCStoreValue();
    end;
    if wback then R(n) = R(n) + 4*BitCount(registers); end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STR (immediate)

Store Register (immediate) calculates an address from a base register value and an immediate offset, and stores a word from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#).

This instruction is used by the alias [PUSH \(single register\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) , [T3](#) and [T4](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	0	P	U	0	W	0	Rn				Rt				imm12											
cond				op2				op1																							

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STR{<c>}{<q>} <Rt>, [<Rn> {, # {+/-} <imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STR{<c>}{<q>} <Rt>, [<Rn>], # {+/-} <imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STR{<c>}{<q>} <Rt>, [<Rn>, # {+/-} <imm>]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

let imm32 : bits(32) = ZeroExtend{}(imm8);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated. For the "T1", "T2", "T3", "T4 Offset", "T4 Post-indexed", and "T4 Pre-indexed" variants: is the general-purpose register to be transferred, encoded in the "Rt" field.						
<Rn>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For the "T1", "T3", "T4 Offset", "T4 Post-indexed", and "T4 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field. For the "T1" variant: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4. For the "T2" variant: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4. For the "T3" variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For the "T4 Offset", "T4 Post-indexed", and "T4 Pre-indexed" variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.						
+	Specifies the offset is added to the base register.						

Alias Conditions

Alias	Of variant	Is preferred when
PUSH (single register)	A1 Pre-indexed	<code>P == '1' && U == '0' && W == '1' && Rn == '1101' && imm12 == '00000000100'</code>
PUSH (single register)	T4 Pre-indexed	<code>Rn == '1101' && P == '1' && U == '0' && W == '1' && imm8 == '00000100'</code>

Operation

```
if CurrentInstrSet\(\) == InstrSet A32 then
  if ConditionPassed\(\) then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{32}(address) = if t == 15 then PCStoreValue() else R(t);
    if wback then R(n) = offset_addr; end;
  end;
else
  if ConditionPassed\(\) then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{32}(address) = R(t);
    if wback then R(n) = offset_addr; end;
  end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STR (register)

Store Register (register) calculates an address from a base register value and an offset register value, stores a word from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	P	U	0	W	0	Rn				Rt				imm5				stype		0	Rm				
cond				op2				op1																							

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
if m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	0	0	Rm			Rn			Rt		
L				B		H									

Encoding

STR{<c>}{<q>} <Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTType = SRTType_LSL;
let shift_n : integer = 0;
```

T2

Encoding

```
STR{<c>}{<q>}<Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

STR{<c>}.W <Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)
```

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `t == 15`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated. For the "T1" and "T2" variants: is the general-purpose register to be transferred, encoded in the "Rt" field.						
<Rn>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For the "T1" and "T2" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
<shift>	The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts applied to a register .						
+	Specifies the index register is added to the base register.						
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.						

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let offset : bits(32) = Shift{ }(R(m), shift_t, shift_n, PSTATE.C);
  let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
  let address : bits(32) = if index then offset_addr else R(n);
  var data : bits(32);
  if t == 15 then // Only possible for encoding A1
    data = PCStoreValue();
  else
    data = R(t);
  end;
  MemU{32}(address) = data;
  if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STRB (immediate)

Store Register Byte (immediate) calculates an address from a base register value and an immediate offset, and stores a byte from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	0	P	U	1	W	0	Rn				Rt				imm12											
cond				op2				op1																							

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STRB{<c>}{<q>}<Rt>, [<Rn> {, # {+/-}<imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STRB{<c>}{<q>}<Rt>, [<Rn>], # {+/-}<imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STRB{<c>}{<q>}<Rt>, [<Rn>, # {+/-}<imm>]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm12);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `t == 15`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.
- If `wback && n == t`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The store instruction executes but the value stored is UNKNOWN.
- If `wback && n == 15`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The instruction executes without writeback of the base address.
 - The instruction uses the addressing mode described in the equivalent immediate offset instruction.

For the "T2" variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For the "T3 Offset", "T3 Post-indexed", and "T3 Pre-indexed" variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.						
+	Specifies the offset is added to the base register.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{8}(address) = R(t)[7:0];
    if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STRB (register)

Store Register Byte (register) calculates an address from a base register value and an offset register value, and stores a byte from a register to memory. The offset register value can optionally be shifted. For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	P	U	1	W	0	Rn				Rt				imm5				stype	0	Rm					
cond				op2				op1																							

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STRB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STRB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRBT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	1	0	Rm			Rn			Rt		
			L			B			H						

Encoding

STRB{<c>}{<q>}<Rt>, [<Rn>, {+}<Rm>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding

```
STRB{<c>}{<q>}<Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

STRB{<c>}.W<Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)
```

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-Ā removes UNPREDICTABLE for R13
if t == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

- If `t == 15`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as NOP.
 - The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.						
<Rn>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For the "T1" and "T2" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
<shift>	The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see Shifts applied to a register .						
+	Specifies the index register is added to the base register.						
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let offset : bits(32) = Shift{(R(m), shift_t, shift_n, PSTATE.C);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{8}(address) = R(t)[7:0];
    if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see [Memory accesses](#). The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	0	0	U	1	1	0	Rn				Rt				imm12											
cond				P				op2				W				op1															

Encoding

STRBT{<c>}{<q>}<Rt>, [<Rn>] {, #(<+/-><imm>)}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

cond				P				op2				W				op1															

Encoding

STRBT{<c>}{<q> <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **t == 15**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If **n == t**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If **n == 15**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

T1

size L												Rn				Rt				1 1 1 0				imm8							

Encoding

STRBT{<c>}{<q> <Rt>, [<Rn> {, #(+)<imm>}]

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{(imm8)};
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **t == 15**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See <i>Standard assembler syntax fields</i> .
<q>	See <i>Standard assembler syntax fields</i> .
<Rt>	For the "A1" variant: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated. For the "A2" and "T1" variants: is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn>	Is the general-purpose base register, encoded in the "Rn" field.												
+/-	For the "A1" variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table> <tr> <th>U</th><th>+/-</th></tr> <tr> <td>0</td><td>-</td></tr> <tr> <td>1</td><td>+</td></tr> </table> For the "A2" variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table> <tr> <th>U</th><th>+/-</th></tr> <tr> <td>0</td><td>-</td></tr> <tr> <td>1</td><td>+</td></tr> </table>	U	+/-	0	-	1	+	U	+/-	0	-	1	+
U	+/-												
0	-												
1	+												
U	+/-												
0	-												
1	+												
<imm>	For the "A1" variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field. For the "T1" variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.												
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.												
<shift>	The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see <i>Shifts applied to a register</i> .												
+	Specifies the offset is added to the base register.												

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end; // Hyp mode
    let offset : bits(32) = (if register_form then Shift{32}(R(m), shift_t, shift_n, PSTATE.C)
                           else imm32);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    MemU_unpriv{8}(address) = R(t)[7:0];
    if postindex then R(n) = offset_addr; end;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If PSTATE.EL == EL2, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STRB (immediate).

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

STRD (immediate)

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#). It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	1	W	0	Rn				Rt				imm4H				1	1	1	1	imm4L			
cond												o1																op2			

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, # {+/-} <imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], # {+/-} <imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, # {+/-} <imm>]!

Decode for all variants of this encoding

```
if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if P == '0' && W == '1' then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t || n == t2) then UnpredictableProcedure(); end;
if t2 == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15 || t2 == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `t<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when `Rt == '1111'`.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The instruction executes as an LDRD using one of offset, post-indexed, or pre-indexed addressing.

T1

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

```
STRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn> {, #<+/-><imm>}]
```

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 1)

```
STRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>], #<+/-><imm>
```

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

```
STRD{<c>}{<q>}<Rt>, <Rt2>, [<Rn>, #<+/-><imm>]!
```

Decode for all variants of this encoding

```
if P == '0' && W == '0' then See("Related encodings"); end;
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
if wback && (n == t || n == t2) then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 || t == 15 || t2 == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15 || t2 == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], {+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```
if Rt[0] == '1' then UnpredictableProcedure(); end;
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if P == '0' && W == '1' then UnpredictableProcedure(); end;
if t2 == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t || n == t2) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15 || t2 == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `t<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when `Rt == '1111'`.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `P = '1'; W = '0'`.
- The instruction executes with the additional decode: `P = '1'; W = '1'`.

- The instruction executes with the additional decode: P = '0'; W = '0'.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

op0												L																			

Encoding

STREX{<c>}{<q>}<Rd>, <Rt>, [<Rn> {, #<imm>}]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{imm8::'00'};
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d == t, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If d == n, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<imm>	For the "A1" variant: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted. For the "T1" variant: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns `TRUE`, the exception is generated.
- Otherwise, it is `IMPLEMENTATION DEFINED` whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is `IMPLEMENTATION DEFINED` whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n) + imm32;
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemA{32}(address) = R(t);
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	0	Rn				Rt				(1)	(1)	(1)	(1)	0	1	0	0	Rd			
				op0								L								Rt2				sz							

Encoding

STREXB{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If `AArch32.ExclusiveMonitorsPass()` returns `FALSE` and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    if AArch32.ExclusiveMonitorsPass(address,1) then
        MemA{8}(address) = R(t)[7:0];
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STREXD

Store Register Exclusive Doubleword derives an address from a base register value, stores a 64-bit doubleword from two registers to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	0	1	1	0	1	0	Rn				Rd				(1)	(1)	1	1	1	0	0	1	Rt			
cond				size								L								ex				ord							

Encoding

STREXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let t : integer = UInt(Rt);
let t2 : integer = t + 1;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
if d == 15 || Rt[0] == '1' || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t || d == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: `Rt<0> = '0'`.
- The instruction executes with the additional decode: `t2 = t`.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in [Using R15](#).

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	0	Rn				Rt				Rt2				0	1	1	1	Rd			
op0												L												sz							

Encoding

STREXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let t2 : integer = UInt(Rt2);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || t2 == 15 || n == 15 then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if d == n || d == t || d == t2 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory. <Rd> must not be the same as <Rn>, <Rt>, or <Rt2>.
<Rt>	For the "A1" variant: is the first general-purpose register to be transferred, encoded in the "Rt" field. <Rt> must be even-numbered and not R14. For the "T1" variant: is the first general-purpose register to be transferred, encoded in the "Rt" field.
<Rt2>	For the "A1" variant: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>. For the "T1" variant: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non doubleword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If `AArch32.ExclusiveMonitorsPass()` returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If `AArch32.ExclusiveMonitorsPass()` returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);

    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    let value : bits(64) = if BigEndian(AccessType_GPR) then R(t)::R(t2) else R(t2)::R(t);

    if AArch32.ExclusiveMonitorsPass(address,8) then
        MemA{64}(address) = value;
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STREXH

Store Register Exclusive Halfword derives an address from a base register value, stores a halfword from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see [Synchronization and semaphores](#). For information about memory accesses see [Memory accesses](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	1	1	1	0	Rn				Rd				(1)	(1)	1	1	1	0	0	1	Rt			
cond								size				L								ex				ord							

Encoding

STREXH{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

				op0				L								Rt2				sz											

Encoding

STREXH{<c>}{<q>} <Rd>, <Rt>, [<Rn>]

Decode for this encoding

```
let d : integer = UInt(Rd);
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || t == 15 || n == 15 then UnpredictableProcedure(); end;
if d == n || d == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If $d == t$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If $d == n$, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is: 0 If the operation updates memory. 1 If the operation fails to update memory.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non halfword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let address : bits(32) = R(n);
    if AArch32.ExclusiveMonitorsPass(address,2) then
        MemA{16}(address) = R(t)[15:0];
        R(d) = ZeroExtend{32}('0');
    else
        R(d) = ZeroExtend{32}('1');
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STRH (immediate)

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see [Memory accesses](#). It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	1	W	0	Rn				Rt				imm4H				1	0	1	1	imm4L			
cond											o1					op2															

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STRH{<c>}{<q>}<Rt>, [<Rn> {, # {+/-}<imm>}]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STRH{<c>}{<q>}<Rt>, [<Rn>], # {+/-}<imm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STRH{<c>}{<q>}<Rt>, [<Rn>, # {+/-}<imm>]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
if t == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	0	0	0	imm5						Rn			Rt

let wback : boolean = (W == '1');
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 || (wback && n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.						
<Rn>	For the "A1 Offset" variant: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For the "A1 Post-indexed", "A1 Pre-indexed", "T1", "T2", "T3 Offset", "T3 Post-indexed", and "T3 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For the "T1" variant: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2. For the "T2" variant: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field. For the "T3 Offset", "T3 Post-indexed", and "T3 Pre-indexed" variants: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.						
+	Specifies the offset is added to the base register.						

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{16}(address) = R(t)[15:0];
    if wback then R(n) = offset_addr; end;
  end;
else
  if ConditionPassed() then
    EncodingSpecificOperations();
    let offset_addr : bits(32) = if add then (R(n) + imm32) else (R(n) - imm32);
    let address : bits(32) = if index then offset_addr else R(n);
    MemU{16}(address) = R(t)[15:0];
    if wback then R(n) = offset_addr; end;
  end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STRH (register)

Store Register Halfword (register) calculates an address from a base register value and an offset register value, and stores a halfword from a register to memory. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see [Memory accesses](#). It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	P	U	0	W	0	Rn				Rt				(0) (0) (0) (0)				1	0	1	1	Rm			
cond											o1					op2															

Encoding for the Offset variant

Applies when (P == 1 && W == 0)

STRH{<c>}{<q>}<Rt>, [<Rn>, {+/-}<Rm>]

Encoding for the Post-indexed variant

Applies when (P == 0 && W == 0)

STRH{<c>}{<q>}<Rt>, [<Rn>], {+/-}<Rm>

Encoding for the Pre-indexed variant

Applies when (P == 1 && W == 1)

STRH{<c>}{<q>}<Rt>, [<Rn>, {+/-}<Rm>]!

Decode for all variants of this encoding

```
if P == '0' && W == '1' then See("STRHT"); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = (P == '1');
let add : boolean = (U == '1');
let wback : boolean = (P == '0') || (W == '1');
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
if t == 15 || m == 15 then UnpredictableProcedure(); end;
if wback && (n == 15 || n == t) then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = 0;
```

T2

Encoding

```
STRH{<c>}{<q>}<Rt>, [<Rn>, {+}<Rm>{, LSL #<imm>}]

STRH{<c>}.W<Rt>, [<Rn>, {+}<Rm>] // (<Rt>, <Rn>, <Rm> can be represented in T1)
```

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let index : boolean = TRUE;
let add : boolean = TRUE;
let wback : boolean = FALSE;
let shift_t : SRTYPE = SRTYPE_LSL;
let shift_n : integer = UInt(imm2);
// Armv8-Ā removes UNPREDICTABLE for R13
if t == 15 || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.						
<Rn>	For the "A1 Offset", "A1 Post-indexed", and "A1 Pre-indexed" variants: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated. For the "T1" and "T2" variants: is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.						
+	Specifies the index register is added to the base register.						
<imm>	If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.						

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let offset : bits(32) = Shift{(R(m), shift_t, shift_n, PSTATE.C);
  let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
  let address : bits(32) = if index then offset_addr else R(n);
  MemU{16}(address) = R(t)[15:0];
  if wback then R(n) = offset_addr; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory accesses see [Memory accesses](#). The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRHT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	U	1	1	0	Rn				Rt				imm4H				1	0	1	1	imm4L			
cond				P				W				o1												op2							

Encoding

STRHT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm4H::imm4L);
let m : integer = ARBITRARY : integer;
if t == 15 || n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

cond				P				W				o1												op2							

Encoding

STRHT{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let imm32 : bits(32) = ARBITRARY : bits(32);
if t == 15 || n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if `bit[24] == 1` and `bit[21] == 0`. The instruction uses immediate offset addressing with the base register as PC, without writeback.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	0	0	0	0	1	0	!= 1111				Rt				1	1	1	0	imm8							
size												L	Rn																		

Encoding

STRHT{<c>}{<q>}<Rt>, [<Rn> {, #(+)<imm>}]

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend()(imm8);
let m : integer = ARBITRARY : integer;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
+/-	For the "A1" variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+

For the "A2" variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+

<imm>	For the "A1" variant: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field. For the "T1" variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.
+	Specifies the offset is added to the base register.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end;           // Hyp mode
    let offset : bits(32) = if register_form then R(m) else imm32;
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    MemU_unpriv{16}(address) = R(t)[15:0];
    if postindex then R(n) = offset_addr; end;
end;

```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STRH (immediate).

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see [Memory accesses](#).

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	0	0	U	0	1	0	Rn				Rt				imm12											
cond				P				op2				W				op1															

Encoding

STRT{<c>}{<q>} <Rt>, [<Rn>] {, # {+/-} <imm>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm12);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
if n == 15 || n == t then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	0	U	0	1	0	Rn				Rt				imm5				stype		0	Rm				
cond				P				op2				W				op1															

Encoding

STRT{<c>}{<q>} <Rt>, [<Rn>], {+/-} <Rm>{, <shift>}

Decode for this encoding

```
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let postindex : boolean = TRUE;
let add : boolean = (U == '1');
let register_form : boolean = TRUE;
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm5);
let imm32 : bits(32) = ARBITRARY : bits(32);
if n == 15 || n == t || m == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in [Using R15](#).
- The instruction is treated as if `bit[24] == 1` and `bit[21] == 0`. The instruction uses immediate offset addressing with the base register as PC, without writeback.

T1

Encoding

STRT{<c>}{<q>}<Rt>, [<Rn> {, #(<+>)<imm>}]

Decode for this encoding

```
if Rn == '1111' then Undefined(); end;
let t : integer = UInt(Rt);
let n : integer = UInt(Rn);
let postindex : boolean = FALSE;
let add : boolean = TRUE;
let register_form : boolean = FALSE;
let imm32 : bits(32) = ZeroExtend{}(imm8);
let m : integer = ARBITRARY : integer;
let shift_n : integer = ARBITRARY : integer;
let shift_t : SRTYPE = ARBITRARY : SRTYPE;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .												
<q>	See Standard assembler syntax fields .												
<Rt>	For the "A1" and "A2" variants: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated. For the "T1" variant: is the general-purpose register to be transferred, encoded in the "Rt" field.												
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.												
+/-	For the "A1" variant: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table> For the "A2" variant: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+	U	+/-	0	-	1	+
U	+/-												
0	-												
1	+												
U	+/-												
0	-												
1	+												
<imm>	For the "A1" variant: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.												

For the "T1" variant: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see *Shifts applied to a register*.

Specifies the offset is added to the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then UnpredictableProcedure(); end; // Hyp mode
    let offset : bits(32) = (if register_form then Shift{32}(R(m), shift_t, shift_n, PSTATE.C)
                           else imm32);
    let offset_addr : bits(32) = if add then (R(n) + offset) else (R(n) - offset);
    let address : bits(32) = if postindex then R(n) else offset_addr;
    var data : bits(32);
    if t == 15 then // Only possible for encodings A1 and A2
        data = PCStoreValue();
    else
        data = R(t);
    end;
    MemU_unpriv{32}(address) = data;
    if postindex then R(n) = offset_addr; end;
end;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STR (immediate).

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias.

This is an alias of [ADR](#). This means:

- The encodings in this description are named to match the encodings of [ADR](#).
- The description of [ADR](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A2](#)) and T32 ([T2](#)) .

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
!= 1111				0	0	1	0	0	1	0	0	1	1	1	1	Rd					imm12											
cond				opc								S	Rn																			

Encoding for the A2 variant

SUB{<c>} {<q>} <Rd>, PC, #<const>

is equivalent to

[ADR](#){<c>} {<q>} <Rd>, <label>

and is the preferred disassembly when `imm12 == '000000000000'`.

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
1	1	1	1	0	i	1	0	1	0	1	0	1	1	1	1	0	imm3				Rd				imm8										
o1																o2				Rn															

Encoding for the T2 variant

SUB{<c>} {<q>} <Rd>, PC, #<imm12>

is equivalent to

[ADR](#){<c>} {<q>} <Rd>, <label>

and is the preferred disassembly when `i :: imm3 :: imm8 == '000000000000'`.

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	For the "A2" variant: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC . For the "T2" variant: is the general-purpose destination register, encoded in the "Rd" field.
<const>	An immediate value. See Modified immediate constants in A32 instructions for the range of values.
<imm12>	Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

Operation

The description of [ADR](#) gives the operational pseudocode for this instruction.

SUB, SUBS (immediate)

Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The SUBS variant of the instruction performs an exception return without the use of the stack. In this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
 - The instruction is UNDEFINED in Hyp mode, except for encoding T5 with <imm8> set to zero, which is the encoding for the ERET instruction, see *ERET*.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) , [T3](#) , [T4](#) and [T5](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	1	0	0	1	0	S	Rn				Rd				imm12											
cond				opc																											

Encoding for the SUB variant

Applies when (S == 0 && Rn != 11x1)

SUB{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Encoding for the SUBS variant

Applies when (S == 1 && Rn != 1101)

SUBS{<c>}{<q>} {<Rd>, }<Rn>, #<const>

Decode for all variants of this encoding

```
if Rn == '1111' && S == '0' then See("ADR"); end;

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [SUBS PC, LR and related instructions \(A32\)](#) and [SUBS PC, LR and related instructions \(T32\)](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	For the "A1 SUB" and "A1 SUBS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used: - For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. - For the SUBS variant, the instruction performs an exception return, that restores <i>PSTATE</i> from SPSR_<current_mode>. Arm deprecates use of this instruction unless <Rn> is the LR.
<Rn>	For the "T1", "T3 SUB", "T3 SUBS", and "T4" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. For the "A1 SUB", "A1 SUBS", and "T4" variants: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see SUB (SP minus immediate). If the PC is used, see ADR. For the "T1" variant: is the general-purpose source register, encoded in the "Rn" field. For the "T3 SUB" and "T3 SUBS" variants: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see SUB (SP minus immediate).
<const>	For the "A1 SUB" and "A1 SUBS" variants: an immediate value. See Modified immediate constants in A32 instructions for the range of values. For the "T3 SUB" and "T3 SUBS" variants: an immediate value. See Modified immediate constants in T32 instructions for the range of values.
<imm3>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.
<Rdn>	Is the general-purpose source and destination register, encoded in the "Rdn" field.
<imm8>	For the "T2" variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. For the "T5" variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. If <Rn> is the LR, and zero is used, see ERET.
<imm12>	Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.
In the T32 instruction set, MOVS{<c>}{<q>} PC, LR is a pseudo-instruction for SUBS{<c>}{<q>} PC, LR, #0.	

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(imm32), '1');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SUB, SUBS (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd> For the "A1 SUB, rotate right with extend", "A1 SUB, shift or rotate by value", "A1 SUBS, rotate right with extend", and "A1 SUBS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SUBS variant, the instruction performs an exception return, that restores [PSTATE](#) from SPSR_<current_mode>.

For the "T1", "T2 SUB, rotate right with extend", "T2 SUB, shift or rotate by value", "T2 SUBS, rotate right with extend", and "T2 SUBS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For the "A1 SUB, rotate right with extend", "A1 SUB, shift or rotate by value", "A1 SUBS, rotate right with extend", and "A1 SUBS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. If the SP is used, see [SUB \(SP minus register\)](#).

For the "T1" variant: is the first general-purpose source register, encoded in the "Rn" field.

For the "T2 SUB, rotate right with extend", "T2 SUB, shift or rotate by value", "T2 SUBS, rotate right with extend", and "T2 SUBS, shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see [SUB \(SP minus register\)](#).

<Rm> For the "A1 SUB, rotate right with extend", "A1 SUB, shift or rotate by value", "A1 SUBS, rotate right with extend", and "A1 SUBS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For the "T1", "T2 SUB, rotate right with extend", "T2 SUB, shift or rotate by value", "T2 SUBS, rotate right with extend", and "T2 SUBS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the "A1 SUB, shift or rotate by value" and "A1 SUBS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For the "T2 SUB, shift or rotate by value" and "T2 SUBS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
  let (result, nzcv) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), '1');
  if d == 15 then // Can only occur for A32 encoding
    if setflags then
      ALUExceptionReturn(result);
    else
      ALUWritePC(result);
    end;
  else
    R(d) = result;
    if setflags then
      PSTATE.[N,Z,C,V] = nzcv;
    end;
  end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

SUB, SUBS (register-shifted register)

Subtract (register-shifted register) subtracts a register-shifted register value from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	0	1	0	S	Rn				Rd				Rs				0	stype		1	Rm			
cond								opc																							

Encoding for the Flag setting variant

Applies when (S == 1)

SUBS{<c>}{<q>}{<Rd>}, <Rn>, <Rm>, <shift> <Rs>

Encoding for the Not flag setting variant

Applies when (S == 0)

SUB{<c>}{<q>}{<Rd>}, <Rn>, <Rm>, <shift> <Rs>

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let setflags : boolean = (S == '1');
let shift_t : SRTYPE = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .										
<q>	See Standard assembler syntax fields .										
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.										
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.										
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.										
<shift>	Is the type of shift to be applied to the second source register, encoded in “stype”:										
<table><tr><th>stype</th><th><shift></th></tr><tr><td>00</td><td>LSL</td></tr><tr><td>01</td><td>LSR</td></tr><tr><td>10</td><td>ASR</td></tr><tr><td>11</td><td>ROR</td></tr></table>		stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR
stype	<shift>										
00	LSL										
01	LSR										
10	ASR										
11	ROR										
<Rs>	Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let shifted : bits(32) = Shift{R(m), shift_t, shift_n, PSTATE.C};
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(n), NOT(shifted), '1');
    R(d) = result;
    if setflags then
        PSTATE.[N,Z,C,V] = nzcvc;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SUB, SUBS (SP minus immediate)

Subtract from SP (immediate) subtracts an immediate value from the SP value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

Assembler Symbols

<c> See [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<Rd> For the "A1 SUB" and "A1 SUBS" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. If the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- For the SUBS variant, the instruction performs an exception return, that restores **PSTATE** from SPSR_<current_mode>. Arm deprecates use of this instruction unless <Rn> is the LR.

For the "T2 SUB", "T2 SUBS", and "T3" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<const> For the "A1 SUB" and "A1 SUBS" variants: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.

For the "T2 SUB" and "T2 SUBS" variants: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

SP Is the stack pointer.

<imm7> Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(13), NOT(imm32), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.[N,Z,C,V] = nzcvc;
        end;
    end;
end;
```

SUB, SUBS (SP minus register)

Subtract from SP (register) subtracts an optionally-shifted register value from the SP value, and writes the result to the destination register. If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see [Pseudocode description of operations on the AArch32 general-purpose registers and the PC](#).
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
 - The PE branches to the address written to the PC, and restores [PSTATE](#) from SPSR_<current_mode>.
 - The PE checks SPSR_<current_mode> for an illegal return event. See [Illegal return events from AArch32 state](#).
 - The instruction is UNDEFINED in Hyp mode.
 - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	0	0	1	0	S	1	1	0	1	Rd			imm5			stype		0	Rm						
cond				opc				Rn																							

Encoding for the SUB, rotate right with extend variant

Applies when (S == 0 && imm5 == 00000 && stype == 11)

```
SUB{<c>}{<q>} {<Rd>, }SP, <Rm> , RRX
```

Encoding for the SUB, shift or rotate by value variant

Applies when (S == 0 && !(imm5 == 00000 && stype == 11))

```
SUB{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>}
```

Encoding for the SUBS, rotate right with extend variant

Applies when (S == 1 && imm5 == 00000 && stype == 11)

```
SUBS{<c>}{<q>} {<Rd>, }SP, <Rm> , RRX
```

Encoding for the SUBS, shift or rotate by value variant

Applies when (S == 1 && !(imm5 == 00000 && stype == 11))

```
SUBS{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>}
```

Decode for all variants of this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTType, integer) = DecodeImmShift(stype, imm5);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	0	1	0	1	1	1	0	1	S	1	1	0	1	(0)	imm3			Rd			imm2			stype		Rm				
op1							Rn																									

Encoding for the SUB, rotate right with extend variant

Applies when (S == 0 && imm3 == 000 && imm2 == 00 && stype == 11)

```
SUB{<c>}{<q>} {<Rd>, }SP, <Rm> , RRX
```

Encoding for the SUB, shift or rotate by value variant

Applies when (S == 0 && !(imm3 == 000 && imm2 == 00 && stype == 11))

```
SUB{<c>}{<q>} {<Rd>, }SP, <Rm> {, <shift> #<amount>} // (Preferred syntax)
```

```
SUB{<c>}.W {<Rd>, }SP, <Rm>
```

Encoding for the SUBS, rotate right with extend variant

Applies when (S == 1 && imm3 == 000 && Rd != 1111 && imm2 == 00 && stype == 11)

SUBS{<c>}{<q>}{<Rd>, }SP, <Rm>, RRR

Encoding for the SUBS, shift or rotate by value variant

Applies when (S == 1 && Rd != 1111 && !(imm3 == 000 && imm2 == 00 && stype == 11))

SUBS{<c>}{<q>}{<Rd>, }SP, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
if Rd == '1111' && S == '1' then See("CMP (register)"); end;
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let setflags : boolean = (S == '1');
let (shift_t, shift_n) : (SRTYPE, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if (d == 15 && !setflags) || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .										
<q>	See Standard assembler syntax fields .										
<Rd>	For the "A1 SUB, rotate right with extend", "A1 SUB, shift or rotate by value", "A1 SUBS, rotate right with extend", and "A1 SUBS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used: • For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see Pseudocode description of operations on the AArch32 general-purpose registers and the PC. • For the SUBS variant, the instruction performs an exception return, that restores PSTATE from SPSR_<current_mode>.										
<Rm>	For the "T1 SUB, rotate right with extend", "T1 SUB, shift or rotate by value", "T1 SUBS, rotate right with extend", and "T1 SUBS, shift or rotate by value" variants: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. For the "A1 SUB, rotate right with extend", "A1 SUB, shift or rotate by value", "A1 SUBS, rotate right with extend", and "A1 SUBS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For the "T1 SUB, rotate right with extend", "T1 SUB, shift or rotate by value", "T1 SUBS, rotate right with extend", and "T1 SUBS, shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.										
<shift>	Is the type of shift to be applied to the second source register, encoded in “stype”: <table><tr><th>stype</th><th><shift></th></tr><tr><td>00</td><td>LSL</td></tr><tr><td>01</td><td>LSR</td></tr><tr><td>10</td><td>ASR</td></tr><tr><td>11</td><td>ROR</td></tr></table>	stype	<shift>	00	LSL	01	LSR	10	ASR	11	ROR
stype	<shift>										
00	LSL										
01	LSR										
10	ASR										
11	ROR										
<amount>	For the "A1 SUB, shift or rotate by value" and "A1 SUBS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For the "T1 SUB, shift or rotate by value" and "T1 SUBS, shift or rotate by value" variants: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shifted : bits(32) = Shift{}(R(m), shift_t, shift_n, PSTATE.C);
    let (result, nzcvc) : (bits(32), bits(4)) = AddWithCarry{32}(R(13), NOT(shifted), '1');
    if d == 15 then // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
        end;
    else
        R(d) = result;
        if setflags then
            PSTATE.\[N,Z,C,V\] = nzcvc;
        end;
    end;
end;
```

SVC

Supervisor Call causes a Supervisor Call exception. For more information, see [Supervisor Call \(SVC\) exception](#).

Note

SVC was previously called SWI, Software Interrupt, and this name is still found in some documentation.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

- If the SVC is executed in Hyp mode.
- If HCR.TGE is set to 1, and the SVC is executed in Non-secure User mode. For more information, see [Supervisor Call exception, when HCR.TGE is set to 1](#)

In these cases, the [HSR, Hyp Syndrome Register](#) identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see [Use of the HSR](#). The immediate field in the [HSR](#):

- If the SVC is unconditional:
 - For the T32 instruction, is the zero-extended value of the imm8 field.
 - For the A32 instruction, is the least-significant 16 bits the imm24 field.
- If the SVC is conditional, is UNKNOWN.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	1	1	imm24																							
cond																															

Encoding

SVC{<c>}{<q>}{#}<imm>

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{(imm24);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	1	1	1	1	imm8							
S															

Encoding

SVC{<c>}{<q>}{#}<imm>

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{(imm8);
```

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <imm> For the "A1" variant: is a 24-bit unsigned immediate, in the range 0 to 16777215, encoded in the "imm24" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm24 in software, for example to determine the required service.
For the "T1" variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm8 in software, for example to determine the required service.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32_CheckForSVCTrap(imm32[15:0]);
    AArch32_CallSupervisor(imm32[15:0]);
end;
```

SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
SXTAB{<c>}{<q>}{<Rd>, }<Rn>, <Rm> {, ROR #<amount>}
```

Decode for this encoding

```
if Rn == '1111' then See("SXTB"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
SXTAB{<c>}{<q>}{<Rd>, }<Rn>, <Rm> {, ROR #<amount>}
```

Decode for this encoding

```
if Rn == '1111' then See("SXTB"); end;
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <amount> Is the rotate amount, encoded in "rotate":

rotate	<amount>
00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d) = R(n) + SignExtend{32}(rotated[7:0]);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SXTAB16

Signed Extend and Add Byte 16 extracts two 8-bit values from a register, sign-extends them to 16 bits each, adds the results to two 16-bit values from another register, and writes the final results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SXTH

Signed Extend Halfword extracts a 16-bit value from a register, sign-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	0	1	0	1	1	1	1	1	1	Rd				rotate		(0)	(0)	0	1	1	1	Rm			
cond				U				op				Rn																			

Encoding

SXTH{<c>}{<q>} {<Rd>, }<Rm> {, ROR #<amount>}

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	0	1	0	0	0	Rm			Rd		
				U				B							

Encoding

SXTH{<c>}{<q>} {<Rd>, }<Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let rotation : integer = 0;
```

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	0	0	0	0	1	1	1	1	1	1	1	1	Rd				1	(0)	rotate	Rm				
op1												U				Rn															

Encoding

SXTH{<c>}{<q>} {<Rd>, }<Rm> {, ROR #<amount>}

SXTH{<c>}.W {<Rd>, }<Rm> // (<Rd>, <Rm> can be represented in T1)

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> Is the general-purpose source register, encoded in the "Rm" field.

<amount> Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d) = SignExtend{32}(rotated[15:0]);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

TBB, TBH

Table Branch Byte or Halfword causes a PC-relative forward branch using a table of single byte or halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value returned from the table.

T1

Encoding for the Byte variant

Applies when (H == 0)

```
TBB{<c>}{<q>} [<Rn>, <Rm>] // (Outside or last in IT block)
```

Encoding for the Halfword variant

Applies when (H == 1)

```
TBH{<c>}{<q>} [<Rn>, <Rm>, LSL #1] // (Outside or last in IT block)
```

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let is_tbh : boolean = (H == '1');
// Armv8-A removes UNPREDICTABLE for R13
if m == 15 then UnpredictableProcedure(); end;
if InITBlock() && !LastInITBlock() then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rn> Is the general-purpose base register holding the address of the table of branch lengths, encoded in the "Rn" field. The PC can be used. If it is, the table immediately follows this instruction.
- <Rm> For the "Byte" variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.
For the "Halfword" variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  var halfwords : integer;
  if is_tbh then
    halfwords = UInt(MemU{16}(R(n)+LSL(R(m), 1)));
  else
    halfwords = UInt(MemU{8}(R(n)+R(m)));
  end;
  BranchWritePC(PC32() + 2*halfwords, BranchType_INDIR);
end;
```

TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

Encoding

TEQ{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding

TEQ{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 then UnpredictableProcedure(); end;
```

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rn> For the "A1" variant: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For the "T1" variant: is the general-purpose source register, encoded in the "Rn" field.
- <const> For the "A1" variant: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.
For the "T1" variant: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                           else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) XOR imm32;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

TEQ (register)

Test Equivalence (register) performs a bitwise exclusive-OR operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
!= 1111				0	0	0	1	0	0	1	1	Rn				(0)	(0)	(0)	(0)	imm5				stype		0	Rm								
cond									opc																										

Encoding for the Rotate right with extend variant

Applies when (imm5 == 00000 && stype == 11)

TEQ{<c>}{<q>} <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when (!(imm5 == 00000 && stype == 11))

TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTtype, integer) = DecodeImmShift(stype, imm5);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	0	1	0	1	0	1	0	0	1	Rn				(0)	imm3				1	1	1	1	imm2		stype		Rm			
op1												S	Rd																			

Encoding for the Rotate right with extend variant

Applies when (imm3 == 000 && imm2 == 00 && stype == 11)

TEQ{<c>}{<q>} <Rn>, <Rm>, RRX

Encoding for the Shift or rotate by value variant

Applies when (!(imm3 == 000 && imm2 == 00 && stype == 11))

TEQ{<c>}{<q>} <Rn>, <Rm> {, <shift> #<amount>}

Decode for all variants of this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let (shift_t, shift_n) : (SRTtype, integer) = DecodeImmShift(stype, imm3::imm2);
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rn> For the "A1 Rotate right with extend" and "A1 Shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For the "T1 Rotate right with extend" and "T1 Shift or rotate by value" variants: is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> For the "A1 Rotate right with extend" and "A1 Shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.
For the "T1 Rotate right with extend" and "T1 Shift or rotate by value" variants: is the second general-purpose source register, encoded in the "Rm" field.

<shift>

Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount>

For the "A1 Shift or rotate by value" variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For the "T1 Shift or rotate by value" variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) XOR shifted;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

TEQ (register-shifted register)

Test Equivalence (register-shifted register) performs a bitwise exclusive-OR operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

Encoding

TEQ{<c>} {<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let shift_t : SType = DecodeRegShift(stype);
if n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <type> Is the type of shift to be applied to the second source register, encoded in "stype":

stype	<type>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) XOR shifted;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

TSB

Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions, see *Trace Synchronization Barrier (TSB)*.
If *FEAT_TRF* is not implemented, this instruction executes as a NOP.
It has encodings from the following instruction sets: A32 (*Al*) and T32 (*Tl*) .

A1
(FEAT_TRF)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	1	1	0	0	1	0	0	0	0	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	1	0	0	1	0
cond				R				imm4				imm12																			

Encoding

TSB{<c>}{<q>} CSYNC

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_TRF) then ExecuteAsNOP(); end;  
if cond != '1110' then UnpredictableProcedure(); end; // TSB must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If *cond* != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1
(FEAT_TRF)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	0	(1)	(1)	(1)	(1)	1	0	(0)	0	(0)	0	0	0	0	0	0	1	0	0	1	0
																hint								option							

Encoding

TSB{<c>}{<q>} CSYNC

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_TRF) then ExecuteAsNOP(); end;  
if InITBlock() then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If *InITBlock()*, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes unconditionally.
- The instruction executes conditionally.

Assembler Symbols

<c> See *Standard assembler syntax fields*.
<q> See *Standard assembler syntax fields*.

Operation

```
if ConditionPassed() then  
  EncodingSpecificOperations();  
  TraceSynchronizationBarrier();  
end;
```

TST (immediate)

Test (immediate) performs a bitwise AND operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

Encoding

TST{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let a32 : boolean = TRUE;
let imm : bits(12) = imm12;
```

T1

Encoding

TST{<c>}{<q>} <Rn>, #<const>

Decode for this encoding

```
let n : integer = UInt(Rn);
let a32 : boolean = FALSE;
let imm : bits(12) = i::imm3::imm8;
// Armv8-A removes UNPREDICTABLE for R13
if n == 15 then UnpredictableProcedure(); end;
```

For more information about the `CONstrained UNPREDICTABLE` behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rn> For the "A1" variant: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.
For the "T1" variant: is the general-purpose source register, encoded in the "Rn" field.
- <const> For the "A1" variant: an immediate value. See [Modified immediate constants in A32 instructions](#) for the range of values.
For the "T1" variant: an immediate value. See [Modified immediate constants in T32 instructions](#) for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (imm32, carry) : (bits(32), bit) = (if a32 then A32ExpandImm_C(imm, PSTATE.C)
                                           else T32ExpandImm_C(imm, PSTATE.C));

    let result : bits(32) = R(n) AND imm32;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

TST (register)

Test (register) performs a bitwise AND operation on a register value and an optionally-shifted register value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

<amount>	For the "A1 Shift or rotate by value" variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32. For the "T2 Shift or rotate by value" variant: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.										

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let (shifted, carry) : (bits(32), bit) = Shift\_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND shifted;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

TST (register-shifted register)

Test (register-shifted register) performs a bitwise AND operation on a register value and a register-shifted register value. It updates the condition flags based on the result, and discards the result.

A1

Encoding

TST{<c>} {<q>} <Rn>, <Rm>, <type> <Rs>

Decode for this encoding

```
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let s : integer = UInt(Rs);
let shift_t : SType = DecodeRegShift(stype);
if n == 15 || m == 15 || s == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.
- <type> Is the type of shift to be applied to the second source register, encoded in "stype":

stype	<type>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let shift_n : integer = UInt(R(s)[7:0]);
    let (shifted, carry) : (bits(32), bit) = Shift_C{32}(R(m), shift_t, shift_n, PSTATE.C);
    let result : bits(32) = R(n) AND shifted;
    PSTATE.N = result[31];
    PSTATE.Z = IsZeroBit{32}(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

UADD16

Unsigned Add 16 performs two 16-bit unsigned integer additions, and writes the results to the destination register. It sets *PSTATE*.GE according to the results of the additions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op1												U																H				S			

Encoding

UADD16{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the *CONSTRAINED UNPREDICTABLE* behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum1 : integer = UInt(R(n)[15:0]) + UInt(R(m)[15:0]);
    let sum2 : integer = UInt(R(n)[31:16]) + UInt(R(m)[31:16]);
    R(d)[15:0] = sum1[15:0];
    R(d)[31:16] = sum2[15:0];
    PSTATE.GE[1:0] = if sum1 >= 0x10000 then '11' else '00';
    PSTATE.GE[3:2] = if sum2 >= 0x10000 then '11' else '00';
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

UADD8

Unsigned Add 8 performs four unsigned 8-bit integer additions, and writes the results to the destination register. It sets *PSTATE*.GE according to the results of the additions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

op1												U												H				S			

Encoding

UASX{<c>}{<q>}{<Rd>, <Rn>, <Rm>}

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff : integer = UInt(R(n)[15:0]) - UInt(R(m)[31:16]);
    let sum : integer = UInt(R(n)[31:16]) + UInt(R(m)[15:0]);
    R(d)[15:0] = diff[15:0];
    R(d)[31:16] = sum[15:0];
    PSTATE.GE[1:0] = if diff >= 0 then '11' else '00';
    PSTATE.GE[3:2] = if sum >= 0x10000 then '11' else '00';
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	1	1	1	1	widthm1				Rd				lsb				1 0		1	Rn					
cond										U																					

Encoding

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let lsbit : integer{} = UInt(lsb);
let widthminus1 : integer{} = UInt(widthm1);
let msbit : integer{} = lsbit + widthminus1;
if d == 15 || n == 15 then UnpredictableProcedure(); end;
if msbit > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	(0)	1	1	1	1	0	0	Rn				0	imm3				Rd				imm2		(0)	widthm1			
op1																															

Encoding

UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let lsbit : integer{} = UInt(imm3::imm2);
let widthminus1 : integer{} = UInt(widthm1);
let msbit : integer{} = lsbit + widthminus1;
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 then UnpredictableProcedure(); end;
if msbit > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the general-purpose source register, encoded in the "Rn" field.
<lsb>	For the "A1" variant: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.

For the "T1" variant: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width> Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R(d) = ZeroExtend{32}(R(n)[msbit:lsbit]);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

UDF

Permanently Undefined generates an Undefined Instruction exception.
The encodings for UDF used in this section are defined as permanently UNDEFINED. However:

- With the T32 instruction set, Arm deprecates using the UDF instruction in an IT block.
- In the A32 instruction set, UDF is not conditional.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	0	1	1	1	1	1	1	1	imm12												1	1	1	1	imm4			
cond																															

Encoding

UDF{<c>}{<q>}{#}<imm>

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{(imm12::imm4)};
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	0	1	1	1	1	0	imm8							
S															

Encoding

UDF{<c>}{<q>}{#}<imm>

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{(imm8)};
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	1	1	1	1	1	1	imm4				1	0	1	0	imm12											
o1												o2																			

Encoding

UDF{<c>}{<q>}{#}<imm>

UDF{<c>}.W {#}<imm> // (<imm> can be represented in T1)

Decode for this encoding

```
let imm32 : bits(32) = ZeroExtend{(imm4::imm12)};
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Assembler Symbols

- <c>
- For the "A1" variant: see *Standard assembler syntax fields*. <c> must be AL or omitted.
For the "T1" and "T2" variants: see *Standard assembler syntax fields*. Arm deprecates using any <c> value other than AL.
- <q>
- See *Standard assembler syntax fields*.
- <imm>
- For the "A1" variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. The PE ignores the value of this constant.
For the "T1" variant: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores the value of this constant.
For the "T2" variant: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. The PE ignores the value of this constant.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    Undefined();
end;
```

UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.
See [Divide instructions](#) for more information about this instruction.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	1	0	0	1	1	Rd				(1)	(1)	(1)	(1)	Rm				0	0	0	1	Rn			
cond				op1								Ra								op2											

Encoding

UDIV{<c>}{<q> } {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a != 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **Ra != '1111'**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction performs a divide and the register specified by Ra becomes UNKNOWN.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

								op1								Ra								op2							

Encoding

UDIV{<c>}{<q> } {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let a : integer = UInt(Ra);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 || a != 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **Ra != '1111'**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction performs a divide and the register specified by Ra becomes UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let dividend : integer = UInt(R(n));
    let divisor : integer = UInt(R(m));
    var result : integer;
    if divisor == 0 then
        result = 0;
    else
        result = dividend DIVRM divisor;
    end;
    R(d) = result[31:0];
end;
```

cond				op1																B				op2							

Encoding

UHASX{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	1	0	1	0	Rn				1	1	1	1	Rd				0	1	1	0	Rm			
op1												U												H				S			

Encoding

UHASX{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff : integer = UInt(R(n)[15:0]) - UInt(R(m)[31:16]);
    let sum : integer = UInt(R(n)[31:16]) + UInt(R(m)[15:0]);
    R(d)[15:0] = diff[16:1];
    R(d)[31:16] = sum[16:1];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

UHSAX

Unsigned Halving Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, halves the results, and writes the results to the destination register. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op1												U												H				S			

Encoding

UHSAX{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = UInt(R(n)[15:0]) + UInt(R(m)[31:16]);
    let diff : integer = UInt(R(n)[31:16]) - UInt(R(m)[15:0]);
    R(d)[15:0] = sum[16:1];
    R(d)[31:16] = diff[16:1];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

UHSUB16

Unsigned Halving Subtract 16 performs two unsigned 16-bit integer subtractions, halves the results, and writes the results to the destination register. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
UHSUB16{<c>}{<q>}{<Rd>, }<Rn>, <Rm>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

```
UHSUB16{<c>}{<q>}{<Rd>, }<Rn>, <Rm>
```

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let diff1 : integer = UInt(R(n)[15:0]) - UInt(R(m)[15:0]);
    let diff2 : integer = UInt(R(n)[31:16]) - UInt(R(m)[31:16]);
    R(d)[15:0] = diff1[16:1];
    R(d)[31:16] = diff2[16:1];
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

UHSUB8

Unsigned Halving Subtract 8 performs four unsigned 8-bit integer subtractions, halves the results, and writes the results to the destination register. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

UHSUB8{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

T1

Encoding

UHSUB8{<c>}{<q>}{<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the **CONSTRAINED UNPREDICTABLE** behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

if d == 15 || n == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the bit position for saturation, in the range 0 to 31, encoded in the "sat_imm" field.
<Rn>	Is the general-purpose source register, encoded in the "Rn" field.
<amount>	For the "A1 Arithmetic shift right" variant: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32. For the "A1 Logical shift left" variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field. For the "T1 Arithmetic shift right" variant: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

For the "T1 Logical shift left" variant: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  let operand : bits(32) = Shift{}(R(n), shift_t, shift_n, PSTATE.C); // PSTATE.C ignored
  let (result, sat) : (bits(saturate_to), boolean) = UnsignedSatQ{saturate_to}(SInt(operand));
  R(d) = ZeroExtend{32}(result);
  if sat then
    PSTATE.Q = '1';
  end;
end;
```

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <imm> Is the bit position for saturation, in the range 0 to 15, encoded in the "sat_imm" field.
- <Rn> Is the general-purpose source register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let operand1 = SInt(R(n)[15:0]);
    let operand2 = SInt(R(n)[31:16]);
    let (result1, sat1) : (bits(saturate_to), boolean) = UnsignedSatQ{saturate_to}(operand1);
    let (result2, sat2) : (bits(saturate_to), boolean) = UnsignedSatQ{saturate_to}(operand2);
    R(d)[15:0] = ZeroExtend{16}(result1);
    R(d)[31:16] = ZeroExtend{16}(result2);
    if sat1 || sat2 then
        PSTATE.Q = '1';
    end;
end;
```

USAX

Unsigned Subtract and Add with Exchange exchanges the two halfwords of the second operand, performs one unsigned 16-bit integer subtraction and one unsigned 16-bit addition, and writes the results to the destination register. It sets *PSTATE*.GE according to the results. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op1												U H S																			

Encoding

USAX{<c>}{<q>} {<Rd>, }<Rn>, <Rm>

Decode for this encoding

```
let d : integer = UInt(Rd);
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || n == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rn> Is the first general-purpose source register, encoded in the "Rn" field.
- <Rm> Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let sum : integer = UInt(R(n)[15:0]) + UInt(R(m)[31:16]);
    let diff : integer = UInt(R(n)[31:16]) - UInt(R(m)[15:0]);
    R(d)[15:0] = sum[15:0];
    R(d)[31:16] = diff[15:0];
    PSTATE.GE[1:0] = if sum >= 0x10000 then '11' else '00';
    PSTATE.GE[3:2] = if diff >= 0 then '11' else '00';
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

USUB16

Unsigned Subtract 16 performs two 16-bit unsigned integer subtractions, and writes the results to the destination register. It sets *PSTATE*.GE according to the results of the subtractions.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

op1																U																Rn															

Encoding

UXTB16{<c>}{<q>}{<Rd>, }<Rm> {, ROR #<amount>}

Decode for this encoding

```
let d : integer = UInt(Rd);
let m : integer = UInt(Rm);
let rotation : integer = UInt(rotate::'000');
// Armv8-A removes UNPREDICTABLE for R13
if d == 15 || m == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <c> See [Standard assembler syntax fields](#).
- <q> See [Standard assembler syntax fields](#).
- <Rd> Is the general-purpose destination register, encoded in the "Rd" field.
- <Rm> For the "A1" variant: is the general-purpose source register, encoded in the "Rm" field.
For the "T1" variant: is the second general-purpose source register, encoded in the "Rm" field.
- <amount> Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	[absent]
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    let rotated : bits(32) = ROR(R(m), rotation);
    R(d)[15:0] = ZeroExtend{16}(rotated[7:0]);
    R(d)[31:16] = ZeroExtend{16}(rotated[23:16]);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

UXTH

Unsigned Extend Halfword extracts a 16-bit value from a register, zero-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 16-bit value. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait For Event and Send Event*.

As described in *Wait For Event and Send Event*, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see HCR.TWE, SCR.TWE, and SCTLR.nTWE.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see *The Yield instruction*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

[VMOV \(between general-purpose register and half-precision\)](#): Copy 16 bits of a general-purpose register to or from a 32-bit SIMD&FP register.

[VMOV \(between general-purpose register and single-precision\)](#): Copy a general-purpose register to or from a 32-bit SIMD&FP register.

[VMOV \(between two general-purpose registers and a doubleword floating-point register\)](#): Copy two general-purpose registers to or from a SIMD&FP register.

[VMOV \(between two general-purpose registers and two single-precision registers\)](#): Copy two general-purpose registers to a pair of 32-bit SIMD&FP registers.

[VMOV \(general-purpose register to scalar\)](#): Copy a general-purpose register to a vector element.

[VMOV \(immediate\)](#): Copy immediate value to a SIMD&FP register.

[VMOV \(register\)](#): Copy between FP registers.

[VMOV \(register, SIMD\)](#): Copy between SIMD registers: an alias of VORR (register).

[VMOV \(scalar to general-purpose register\)](#): Copy a vector element to a general-purpose register with sign or zero extension.

[VMOVL](#): Vector Move Long.

[VMOVN](#): Vector Move and Narrow.

[VMOVX](#): Vector Move extraction.

[VMRS](#): Move SIMD&FP Special register to general-purpose register.

[VMSR](#): Move general-purpose register to SIMD&FP Special register.

[VMUL \(by scalar\)](#): Vector Multiply (by scalar).

[VMUL \(floating-point\)](#): Vector Multiply (floating-point).

[VMUL \(integer and polynomial\)](#): Vector Multiply (integer and polynomial).

[VMULL \(by scalar\)](#): Vector Multiply Long (by scalar).

[VMULL \(integer and polynomial\)](#): Vector Multiply Long (integer and polynomial).

[VMVN \(immediate\)](#): Vector Bitwise NOT (immediate).

[VMVN \(register\)](#): Vector Bitwise NOT (register).

[VNEG](#): Vector Negate.

[VNMLA](#): Vector Negate Multiply Accumulate.

[VNMLS](#): Vector Negate Multiply Subtract.

[VNMUL](#): Vector Negate Multiply.

[VORN \(immediate\)](#): Vector Bitwise OR NOT (immediate): an alias of VORR (immediate).

[VORN \(register\)](#): Vector bitwise OR NOT (register).

[VORR \(immediate\)](#): Vector Bitwise OR (immediate).

[VORR \(register\)](#): Vector bitwise OR (register).

[VPADAL](#): Vector Pairwise Add and Accumulate Long.

[VPADD \(floating-point\)](#): Vector Pairwise Add (floating-point).

[VPADD \(integer\)](#): Vector Pairwise Add (integer).

[VPADDL](#): Vector Pairwise Add Long.

[VPMAX \(floating-point\)](#): Vector Pairwise Maximum (floating-point).

[VPMAX \(integer\)](#): Vector Pairwise Maximum (integer).

[VPMIN \(floating-point\)](#): Vector Pairwise Minimum (floating-point).

[VPMIN \(integer\)](#): Vector Pairwise Minimum (integer).

[VPOP](#): Pop SIMD&FP registers from stack: an alias of VLDM, VLDMDB, VLDMIA.

[VPUSH](#): Push SIMD&FP registers to stack: an alias of VSTM, VSTMDB, VSTMIA.

[VQABS](#): Vector Saturating Absolute.

[VQADD](#): Vector Saturating Add.

[VQDMLAL](#): Vector Saturating Doubling Multiply Accumulate Long.

[VQDMLSL](#): Vector Saturating Doubling Multiply Subtract Long.

[VQDMULH](#): Vector Saturating Doubling Multiply Returning High Half.

[VQDMULL](#): Vector Saturating Doubling Multiply Long.

[VQMOVN, VQMOVUN](#): Vector Saturating Move and Narrow.

[VQNEG](#): Vector Saturating Negate.

[VQRDMLAH](#): Vector Saturating Rounding Doubling Multiply Accumulate Returning High Half.

[VQRDMLSH](#): Vector Saturating Rounding Doubling Multiply Subtract Returning High Half.

[VQRDMULH](#): Vector Saturating Rounding Doubling Multiply Returning High Half.

[VQRSHL](#): Vector Saturating Rounding Shift Left.

[VQRSHRN \(zero\)](#): Vector Saturating Rounding Shift Right, Narrow: an alias of VQMOVN, VQMOVUN.

[VQRSHRN, VQRSHRUN](#): Vector Saturating Rounding Shift Right, Narrow.

[VQRSHRUN \(zero\)](#): Vector Saturating Rounding Shift Right, Narrow: an alias of VQMOVN, VQMOVUN.

[VQSHL \(register\)](#): Vector Saturating Shift Left (register).

[VQSHL, VQSHLU \(immediate\)](#): Vector Saturating Shift Left (immediate).

[VQSHRN \(zero\)](#): Vector Saturating Shift Right, Narrow: an alias of VQMOVN, VQMOVUN.

[VQSHRN, VQSHRUN](#): Vector Saturating Shift Right, Narrow.

[VQSHRUN \(zero\)](#): Vector Saturating Shift Right, Narrow: an alias of VQMOVN, VQMOVUN.

[VQSUB](#): Vector Saturating Subtract.

[VRADDHN](#): Vector Rounding Add and Narrow, returning High Half.

[VRECPE](#): Vector Reciprocal Estimate.

[VRECPS](#): Vector Reciprocal Step.

[VREV16](#): Vector Reverse in halfwords.

[VREV32](#): Vector Reverse in words.

[VREV64](#): Vector Reverse in doublewords.

[VRHADD](#): Vector Rounding Halving Add.

[VRINTA \(Advanced SIMD\)](#): Vector Round floating-point to integer towards Nearest with Ties to Away.

[VRINTA \(floating-point\)](#): Round floating-point to integer to Nearest with Ties to Away.

[VRINTM \(Advanced SIMD\)](#): Vector Round floating-point to integer towards -Infinity.

[VRINTM \(floating-point\)](#): Round floating-point to integer towards -Infinity.

[VRINTN \(Advanced SIMD\)](#): Vector Round floating-point to integer to Nearest.

[VRINTN \(floating-point\)](#): Round floating-point to integer to Nearest.

[VRINTP \(Advanced SIMD\)](#): Vector Round floating-point to integer towards +Infinity.

[VRINTP \(floating-point\)](#): Round floating-point to integer towards +Infinity.

[VRINTR](#): Round floating-point to integer.

[VRINTX \(Advanced SIMD\)](#): Vector round floating-point to integer inexact.

[VRINTX \(floating-point\)](#): Round floating-point to integer inexact.

[VRINTZ \(Advanced SIMD\)](#): Vector round floating-point to integer towards Zero.

[VRINTZ \(floating-point\)](#): Round floating-point to integer towards Zero.

[VRSHL](#): Vector Rounding Shift Left.

[VRSHR](#): Vector Rounding Shift Right.

[VRSHR \(zero\)](#): Vector Rounding Shift Right: an alias of VORR (register).

[VRSHRN](#): Vector Rounding Shift Right and Narrow.

[VRSHRN \(zero\)](#): Vector Rounding Shift Right and Narrow: an alias of VMOVN.

[VSQRTE](#): Vector Reciprocal Square Root Estimate.

[VSQRTS](#): Vector Reciprocal Square Root Step.

[VSRRA](#): Vector Rounding Shift Right and Accumulate.

[VRSUBHN](#): Vector Rounding Subtract and Narrow, returning High Half.

[VSDOT \(by element\)](#): Dot Product index form with signed integers.

[VSDOT \(vector\)](#): Dot Product vector form with signed integers.

[VSELEQ, VSELGE, VSELGT, VSELVS](#): Floating-point conditional select.

[VSHL \(immediate\)](#): Vector Shift Left (immediate).

[VSHL \(register\)](#): Vector Shift Left (register).

[VSHLL](#): Vector Shift Left Long.

[VSHR](#): Vector Shift Right.

[VSHR \(zero\)](#): Vector Shift Right: an alias of VORR (register).

[VSHRN](#): Vector Shift Right Narrow.

[VSHRN \(zero\)](#): Vector Shift Right Narrow: an alias of VMOVN.

[VSLI](#): Vector Shift Left and Insert.

[VSMMLA](#): Widening 8-bit signed integer matrix multiply-accumulate into 2x2 matrix.

[VSQRT](#): Square Root.

[VSRA](#): Vector Shift Right and Accumulate.

[VSRI](#): Vector Shift Right and Insert.

[VST1 \(multiple single elements\)](#): Store multiple single elements from one, two, three, or four registers.

[VST1 \(single element from one lane\)](#): Store single element from one lane of one register.

[VST2 \(multiple 2-element structures\)](#): Store multiple 2-element structures from two or four registers.

[VST2 \(single 2-element structure from one lane\)](#): Store single 2-element structure from one lane of two registers.

[VST3 \(multiple 3-element structures\)](#): Store multiple 3-element structures from three registers.

[VST3 \(single 3-element structure from one lane\)](#): Store single 3-element structure from one lane of three registers.

[VST4 \(multiple 4-element structures\)](#): Store multiple 4-element structures from four registers.

[VST4 \(single 4-element structure from one lane\)](#): Store single 4-element structure from one lane of four registers.

[VSTM, VSTMDB, VSTMIA](#): Store multiple SIMD&FP registers.

[VSTR](#): Store SIMD&FP register.

[VSUB \(floating-point\)](#): Vector Subtract (floating-point).

[VSUB \(integer\)](#): Vector Subtract (integer).

[VSUBHN](#): Vector Subtract and Narrow, returning High Half.

[VSUBL](#): Vector Subtract Long.

[VSUBW](#): Vector Subtract Wide.

[VSUDOT \(by element\)](#): Dot Product index form with signed and unsigned integers (by element).

[VSWP](#): Vector Swap.

[VTBL, VTBX](#): Vector Table Lookup and Extension.

[VTRN](#): Vector Transpose.

[VTST](#): Vector Test Bits.

[VUDOT \(by element\)](#): Dot Product index form with unsigned integers.

[VUDOT \(vector\)](#): Dot Product vector form with unsigned integers.

[VUMMLA](#): Widening 8-bit unsigned integer matrix multiply-accumulate into 2x2 matrix.

[VUSDOT \(by element\)](#): Dot Product index form with unsigned and signed integers (by element).

[VUSDOT \(vector\)](#): Dot Product vector form with mixed-sign integers.

[VUSMMLA](#): Widening 8-bit mixed integer matrix multiply-accumulate into 2x2 matrix.

[VUZP](#): Vector Unzip.

[VUZP \(alias\)](#): Vector Unzip: an alias of VTRN.

[VZIP](#): Vector Zip.

[VZIP \(alias\)](#): Vector Zip: an alias of VTRN.

AESD

AES single round decryption.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_AES)

Encoding

AESD.<dt> <Qd>, <Qm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

T1
(FEAT_AES)

Encoding

AESD.<dt> <Qd>, <Qm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <dt>

Is the data type, encoded in “size”:

size	<dt>
00	8
01	RESERVED
1x	RESERVED
- <Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations(); CheckCryptoEnabled32();
  let operand1 : bits(128) = Q(d>>1);
  let operand2 : bits(128) = Q(m>>1);
  Q(d>>1) = AESInvSubBytes(AESInvShiftRows(operand1 XOR operand2));
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

AESE

AES single round encryption.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_AES)

Encoding

AESE.<dt> <Qd>, <Qm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

T1
(FEAT_AES)

Encoding

AESE.<dt> <Qd>, <Qm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_AES) then Undefined(); end;
if size != '00' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations(); CheckCryptoEnabled32();
    Q(d>>1) = AESMixColumns(Q(m>>1));
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

FLDM*X (FLDMDBX, FLDMIAX)

FLDMDBX is the Decrement Before variant of this instruction, and FLDMIAX is the Increment After variant. FLDM*X loads multiple SIMD&FP registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register. Arm deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	0	P	U	D	W	1	Rn				Vd				1	0	1	1	x	x	x	x	x	x	x	1
cond				L												size				imm8											

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet\(\) != InstrSet\_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If `regs > 16 || (d+regs) > 16`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

												L								size				imm8							

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

FLDMIAX{<c>}{<q>}<Rn>{!}, <dreglist>

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{imm8::'00'};
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If `regs > 16 || (d+regs) > 16`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move](#) for the A32 instruction set.

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
<dreglist>	Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.
!	Specifies base register writeback, encoded in "W":

W	!
0	[absent]
1	[present]

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEnabled(TRUE);
    var address : bits(32) = if add then R(n) else R(n)-imm32;

    for r = 0 to regs-1 do
        if single_regs then
            S(d+r) = MemA{32}(address);
            address = address+4;
        else
            let word1 : bits(32) = MemA{32}(address);
            let word2 : bits(32) = MemA{32}(address+4);
            address = address+8;

            // Combine the word-aligned words in the correct order for current endianness.
            D(d+r) = if BigEndian(AccessType_ASIMD) then word1::word2 else word2::word1;
        end;
    end;

    if wback then R(n) = if add then R(n)+imm32 else R(n)-imm32; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	0	P	U	D	W	0	Rn				Vd				1	0	1	1	x	x	x	x	x	x	x	1
cond				L												size				imm8											

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
FSTMDBX{<c>}{<q>}<Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
FSTMIAX{<c>}{<q>}<Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VSTR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{}(imm8::'00');
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FSTDBMX, FSTMIAX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet\_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a *VSTM* with the same addressing mode but stores no registers.

If `regs > 16 || (d+regs) > 16`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	0	P	U	D	W	0	Rn				Vd				1	0	1	1	x	x	x	x	x	x	x	1
												L								size				imm8							

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
FSTMDBX{<c>}{<q>}<Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

FSTMIAX{<c>}{<q>}<Rn>{!}, <dreglist>

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VSTR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FSTDBMX, FSTMIAX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If `regs > 16 || (d+regs) > 16`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).
Related encodings: See [Advanced SIMD and floating-point 64-bit move](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move](#) for the A32 instruction set.

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, Arm deprecates use of the PC.						
<dreglist>	Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.						
!	Specifies base register writeback, encoded in "W": <table><tr><th>W</th><th>!</th></tr><tr><td>0</td><td>[absent]</td></tr><tr><td>1</td><td>[present]</td></tr></table>	W	!	0	[absent]	1	[present]
W	!						
0	[absent]						
1	[present]						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    var address : bits(32) = if add then R(n) else R(n)-imm32;
    for r = 0 to regs-1 do
        if single_regs then
            MemA{32}(address) = S(d+r);
            address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            if BigEndian(AccessType_ASIMD) then
                MemA{32}(address) = D(d+r)[63:32];
                MemA{32}(address+4) = D(d+r)[31:0];
            else
                MemA{32}(address) = D(d+r)[31:0];
                MemA{32}(address+4) = D(d+r)[63:32];
            end;
            address = address+8;
        end;
    end;
    if wback then R(n) = if add then R(n)+imm32 else R(n)-imm32; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SHA1C

SHA1 hash update (choose).
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_SHA1)

Encoding

SHA1C.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

T1
(FEAT_SHA1)

Encoding

SHA1C.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckCryptoEnabled32();
  var x : bits(128) = Q(d>>1);
  var y : bits(32) = Q(n>>1)[31:0]; // Note: 32 bits wide

        (y, x) = (yx[128+32], yx[0+128]);
    end;
    Q(d>>1) = x;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SHA1SU0

SHA1 schedule update 0.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_SHA1)

Encoding

SHA1SU0.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

T1
(FEAT_SHA1)

Encoding

SHA1SU0.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckCryptoEnabled32();
    let op1 : bits(128) = Q(d>>1);
    var op2 : bits(128) = Q(n>>1);
    let op3 : bits(128) = Q(m>>1);
    op2 = op2[63:0] :: op1[127:64];
    Q(d>>1) = op1 XOR op2 XOR op3;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SHA1SU1

SHA1 schedule update 1.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_SHA1)

Encoding

SHA1SU1.32 <Qd>, <Qm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if size != '10' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

T1
(FEAT_SHA1)

Encoding

SHA1SU1.32 <Qd>, <Qm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA1) then Undefined(); end;
if size != '10' then Undefined(); end;
if Vd[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckCryptoEnabled32();
  let X : bits(128) = Q(d>>1);
  let Y : bits(128) = Q(m>>1);
  let T : bits(128) = X XOR LSR(Y, 32);
  let W0 : bits(32) = ROL(T[31:0], 1);
  let W1 : bits(32) = ROL(T[63:32], 1);
  let W2 : bits(32) = ROL(T[95:64], 1);
  let W3 : bits(32) = ROL(T[127:96], 1) XOR ROL(T[31:0], 2);
  Q(d>>1) = W3::W2::W1::W0;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SHA256H

SHA256 hash update part 1.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_SHA256)

Encoding

SHA256H.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA256) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

T1
(FEAT_SHA256)

Encoding

SHA256H.32 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA256) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckCryptoEnabled32();
  let X : bits(128) = Q(d>>1);
  let Y : bits(128) = Q(n>>1);
  let W : bits(128) = Q(m>>1);
  let part1 : boolean = TRUE;
  Q(d>>1) = SHA256hash(X, Y, W, part1);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SHA256H2

SHA256 hash update part 2.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_SHA256)

Encoding

SHA256H2.32 [<Qd>](#), [<Qn>](#), [<Qm>](#)

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_SHA256) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

T1
(FEAT_SHA256)

Encoding

SHA256H2.32 [<Qd>](#), [<Qn>](#), [<Qm>](#)

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_SHA256) then Undefined(); end;
if Q != '1' then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

- [<Qd>](#) Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as [<Qd>*2](#).
- [<Qn>](#) Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as [<Qn>*2](#).
- [<Qm>](#) Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as [<Qm>*2](#).

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckCryptoEnabled32();
  let X : bits(128) = Q(n>>1);
  let Y : bits(128) = Q(d>>1);
  let W : bits(128) = Q(m>>1);
  let part1 : boolean = FALSE;
  Q(d>>1) = SHA256hash(X, Y, W, part1);
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

SHA256SU0

SHA256 schedule update 0.
It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_SHA256)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VABA

Vector Absolute Difference and Accumulate subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are all integers of the same length.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

- If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as if it passes the Condition code check.
 - The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

- <c> For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.
- <q> For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see *Standard assembler syntax fields*. See *Standard assembler syntax fields*.

<dt>

Is the data type for the elements of the operands, encoded in “(U :: size)”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            let op2elt : bits(esize) = Din(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let absdiff : integer = Abs(element1 - element2);
            if long_destination then
                Q(d>>1)[e*:(2*esize)] = absdiff[2*esize-1:0];
            else
                D(d+r)[e*:esize] = absdiff[esize-1:0];
            end;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

VABDL (integer)

Vector Absolute Difference Long (integer) subtracts the elements of one vector from the corresponding elements of another vector, and places the absolute values of the results in the elements of the destination vector.

Operand elements are all integers of the same length, and the result elements are double the length of the operands.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VABDL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;
```

T1

Encoding

VABDL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;
```

Related encodings: See *Advanced SIMD data-processing* for the T32 instruction set, or *Advanced SIMD data-processing* for the A32 instruction set.

Assembler Symbols

- <c>

For the "A1" variant: see *Standard assembler syntax fields*. This encoding must be unconditional.
For the "T1" variant: see *Standard assembler syntax fields*.
- <q>

See *Standard assembler syntax fields*.

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

2026-03_rel 2026-03-26 20:48:11

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

VACGE

Vector Absolute Compare Greater Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instruction [VACLE](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VACGT

Vector Absolute Compare Greater Than takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instruction [VACLT](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.

- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

VACLE

Vector Absolute Compare Less Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of [VACGE](#). This means:

- The encodings in this description are named to match the encodings of [VACGE](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VACGE](#) gives the operational pseudocode, any `CONSTRAINED UNPREDICTABLE` behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

```

VADD (integer)

Vector Add (integer) adds corresponding elements in two vectors, and places the results in the destination vector. Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler Symbols

- <c> For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.
- <q> For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see *Standard assembler syntax fields*.
- <dt> See *Standard assembler syntax fields*.
Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	I8
01	I16
10	I32
11	I64

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*:esize] = D(n+r)[e*:esize] + D(m+r)[e*:esize];
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see [VRADDHN](#).

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

VADDHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
```

T1

Encoding

VADDHN{<c>}{<q>}.<dt> <Dd>, <Qn>, <Qm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
```

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

- <c>

For the "A1" variant: see [Standard assembler syntax fields](#). This encoding must be unconditional.
- <q>

For the "T1" variant: see [Standard assembler syntax fields](#).
- <dt>

See [Standard assembler syntax fields](#).
- Is the data type for the elements of the operands, encoded in “size”:
- | size | <dt> |
|------|------|
| 00 | I16 |
| 01 | I32 |
| 10 | I64 |
- <Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        let result : bits(2*esize) = Qin(n>>1)[e*:(2*esize)] + Qin(m>>1)[e*:(2*esize)];
        D(d)[e*:esize] = result[2*esize-1:esize];
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VADDL

Vector Add Long adds corresponding elements in two doubleword vectors, and places the results in a quadword vector. Before adding, it sign-extends or zero-extends the elements of both operands.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
VADDL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>
```

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vaddw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
```

T1

Encoding

```
VADDL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>
```

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if Vd[0] == '1' || (op == '1' && Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = (U == '1');
let is_vaddw : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
```

Related encodings: See *Advanced SIMD data-processing* for the T32 instruction set, or *Advanced SIMD data-processing* for the A32 instruction set.

Assembler Symbols

- <c>

For the "A1" variant: see *Standard assembler syntax fields*. This encoding must be unconditional.
For the "T1" variant: see *Standard assembler syntax fields*.
- <q>

See *Standard assembler syntax fields*.
- <dt>

Is the data type for the elements of the second operand vector, encoded in "(U :: size)":

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32
- <Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        var element1 : integer;
        if is_vaddw then
            let op1elt : bits(2*esize) = Qin(n>>1)[e*:(2*esize)];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        else
            let op1elt : bits(esize) = Din(n)[e*:esize];
            element1 = if unsigned then UInt(op1elt) else SInt(op1elt);
        end;
        let op2elt : bits(esize) = Din(m)[e*:esize];
        let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
        let result : integer = element1 + element2;
        Q(d>>1)[e*:(2*esize)] = result[2*esize-1:0];
    end;
end;
```

VAND (immediate)

Vector Bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector.

This is a pseudo-instruction of [VBIC \(immediate\)](#). This means:

- The encodings in this description are named to match the encodings of [VBIC \(immediate\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VBIC \(immediate\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

- <c>

For the "A1 128-bit SIMD vector", "A1 64-bit SIMD vector", "A2 128-bit SIMD vector", and "A2 64-bit SIMD vector" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.
For the "T1 128-bit SIMD vector", "T1 64-bit SIMD vector", "T2 128-bit SIMD vector", and "T2 64-bit SIMD vector" variants: see *Standard assembler syntax fields*.
- <q>

See *Standard assembler syntax fields*.
- <Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <imm>

Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions*.
- <Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

Operation

The description of [VBIC \(immediate\)](#) gives the operational pseudocode for this instruction.

Operational Information

The description of [VBIC \(immediate\)](#) gives the operational information for this instruction.

VAND (register)

Vector Bitwise AND (register) performs a bitwise AND operation between two registers, and places the result in the destination register. Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

- <c>
- For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.
- For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see *Standard assembler syntax fields*.
- <q>
- See *Standard assembler syntax fields*.
- <dt>
- An optional data type. It is ignored by assemblers, and does not affect the encoding.
- <Dd>
- Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn>
- Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm>
- Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- <Qd>
- Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn>
- Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm>
- Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed\(\) then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled\(\);
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) AND D(m+r);
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VBIC (immediate)

Vector Bitwise Bit Clear (immediate) performs a bitwise AND between a register value and the complement of an immediate value, and returns the result into the destination vector.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the pseudo-instruction [VAND \(immediate\)](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Decode for all variants of this encoding

```
if cmode[0] == '0' || cmode[3:2] == '11' then See("Related encodings"); end;
if Q == '1' && Vd[0] == '1' then Undefined(); end;
let imm64 : bits(64) = AdvSIMDExpandImm('1', cmode, i::imm3::imm4);
let d : integer = UInt(D::Vd);
let regs : integer = if Q == '0' then 1 else 2;
```

Related encodings: See [Advanced SIMD one register and modified immediate](#) for the T32 instruction set, or [Advanced SIMD one register and modified immediate](#) for the A32 instruction set.

Assembler Symbols

- <c> For the "A1 128-bit SIMD vector", "A1 64-bit SIMD vector", "A2 128-bit SIMD vector", and "A2 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.
 - <q> For the "T1 128-bit SIMD vector", "T1 64-bit SIMD vector", "T2 128-bit SIMD vector", and "T2 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#).
 - <Dd> See [Standard assembler syntax fields](#).
 - <imm> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
 - <Qd> Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see [Modified immediate constants in T32 and A32 Advanced SIMD instructions](#).
 - <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(d+r) AND NOT(imm64);
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VBIC (register)

Vector Bitwise Bit Clear (register) performs a bitwise AND between a register value and the complement of a register value, and places the result in the destination register.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VBIC{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VBIC{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

```
VBIC{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>
```

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

```
VBIC{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>
```

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>	For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see <i>Standard assembler syntax fields</i> . This encoding must be unconditional. For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see <i>Standard assembler syntax fields</i> .
<q>	See <i>Standard assembler syntax fields</i> .
<dt>	An optional data type. It is ignored by assemblers, and does not affect the encoding.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed\(\) then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled\(\);
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) AND NOT(D(m+r));
    end;
end;
```

Operational information

VCADD

Vector Complex Add.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following calculation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

```

VCGE (immediate #0)

Vector Compare Greater Than or Equal to Zero takes each element in a vector, and compares it with zero. If it is greater than or equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.

- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

VCLE (register)

Vector Compare Less Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of [VCGE \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [VCGE \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VCGE \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

VCLS

Vector Count Leading Sign Bits determines the number of consecutive bits following the topmost bit, that are the same as the topmost bit, in each element in a vector, and places the results in a second vector. The result does not include the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.

- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

VCLT (register)

Vector Compare Less Than takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of [VCGT \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [VCGT \(register\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VCGT \(register\)](#) gives the operational pseudocode, any CONSTRAINED UNPREDICTABLE behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

VCLZ

Vector Count Leading Zeros counts the number of consecutive zeros, starting from the most significant bit, in each element in a vector, and places the results in a second vector.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers. The result vector elements are the same data type as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

VCMLA

Vector Complex Multiply Accumulate.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following calculation on the corresponding complex number element pairs from the two source registers and the destination register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
 - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
 - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

VCMLA (by element)

Vector Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following calculation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
 - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
 - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

VCMP

Vector Compare compares two floating-point registers, or one floating-point register and zero. It writes the result to the **FPSCR** flags. These are normally transferred to the **PSTATE**. {N, Z, C, V} Condition flags by a subsequent **VMRS** instruction.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

Depending on settings in the **CPACR**, **NSACR**, and **HCPTTR** registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be **UNDEFINED**, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

        when 64 =>
            let op64 : bits(64) = if with_zero then FPZero{64}('0') else D(m);
            nzcvcv = FPCompare{64}(D(d), op64, quiet_nan_exc, fpcr);
    end;

    FPSCR()[31:28] = nzcvcv; // FPSCR.[N,Z,C,V] set to nzcvcv
end;
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the [FPSCR](#) condition flags to N=0, Z=0, C=1, and V=1.

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VCMPE{<c>}{<q>}.F64 <Dd>, #0.0
```

Decode for all variants of this encoding

```
if size == '00' then Undefined(); end;
if size == '01' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if size == '01' && InITBlock() then UnpredictableProcedure(); end;
let quiet_nan_exc : boolean = (E == '1');
let with_zero : boolean = TRUE;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = ARBITRARY : integer;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    var nzcvcv : bits(4);
    case esize of
        when 16 =>
            let op16 : bits(16) = if with_zero then FPZero{16}('0') else H(m);
            nzcvcv = FPCompare{16}(H(d), op16, quiet_nan_exc, fpcr);
        when 32 =>
            let op32 : bits(32) = if with_zero then FPZero{32}('0') else S(m);
            nzcvcv = FPCompare{32}(S(d), op32, quiet_nan_exc, fpcr);
        when 64 =>
            let op64 : bits(64) = if with_zero then FPZero{64}('0') else D(m);
            nzcvcv = FPCompare{64}(D(d), op64, quiet_nan_exc, fpcr);
    end;

    FPSCR()[31:28] = nzcvcv; // FPSCR.[N,Z,C,V] set to nzcvcv
end;
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the [FPSCR](#) condition flags to N=0, Z=0, C=1, and V=1.

VCNT

Vector Count Set Bits counts the number of bits that are one in each element in a vector, and places the results in a second vector.

The operand vector elements must be 8-bit fields.

The result vector elements are 8-bit integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

VCVT (between double-precision and single-precision)

Convert between double-precision and single-precision does one of the following:

- Converts the value in a double-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to double-precision and writes the result to a double-precision register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPExC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

VCVT (between floating-point and fixed-point, Advanced SIMD)

Vector Convert between floating-point and fixed-point converts each element in a vector from floating-point to fixed-point, or from fixed-point to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

<c> For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<dt1> Is the data type for the elements of the destination vector, encoded in “(op :: U)”:

op	U	<dt1>
00	x	F16
01	0	S16
01	1	U16
10	x	F32
11	0	S32
11	1	U32

<dt2> Is the data type for the elements of the source vector, encoded in “(op :: U)”:

op	U	<dt2>
00	0	S16
00	1	U16
01	x	F16
10	0	S32
10	1	U32
11	x	F32

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<fbits> The number of fraction bits in the fixed point number, in the range 1 to 32 for 32-bit elements, or in the range 1 to 16 for 16-bit elements:

- (64 - <fbits>) is encoded in imm6.

An assembler can permit an <fbits> value of 0. This is encoded as floating-point to integer or integer to floating-point instruction, see [VCVT \(between floating-point and integer, Advanced SIMD\)](#).

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    var result : bits(esize);
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let operand1 : bits(esize) = D(m+r)[e*:esize];
            if to_fixed then
                result = FPToFixed(esize, esize)(operand1, frac_bits, unsigned, fpcr,
                                                    FPRounding_ZERO);
            else
                result = FixedToFP(esize, esize)(operand1, frac_bits, unsigned, fpcr,
                                                    FPRounding_TIEEVEN);
            end;
            D(d+r)[e*:esize] = result;
        end;
    end;
end;

```

VCVT (between floating-point and fixed-point, floating-point)

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

if frac_bits < 0 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `frac_bits < 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VCVT (between floating-point and fixed-point)*.

Assembler Symbols

- <c>

See *Standard assembler syntax fields*.
- <q>

See *Standard assembler syntax fields*.
- <dt>

Is the data type for the fixed-point number, encoded in “(U :: sx)”:

U	sx	<dt>
0	0	S16
0	1	S32
1	0	U16
1	1	U32

<Sdm>

Is the 32-bit name of the SIMD&FP destination and source register, encoded in the "Vd:D" field.

<fbits>

The number of fraction bits in the fixed-point number:

- If <dt> is S16 or U16, <fbits> must be in the range 0-16. (16 - <fbits>) is encoded in [imm4, i]
- If <dt> is S32 or U32, <fbits> must be in the range 1-32. (32 - <fbits>) is encoded in [imm4, i].

<Ddm>

Is the 64-bit name of the SIMD&FP destination and source register, encoded in the "D:Vd" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    if to_fixed then
        var result : bits(size);
        case fp_size of
            when 16 =>
                result = FPToFixed{size, 16}(H(d), frac_bits, unsigned, fpcr, FPRounding_ZERO);
                S(d) = Extend{32}(result, unsigned);
            when 32 =>
                result = FPToFixed{size, 32}(S(d), frac_bits, unsigned, fpcr, FPRounding_ZERO);
                S(d) = Extend{32}(result, unsigned);
            when 64 =>
                result = FPToFixed{size, 64}(D(d), frac_bits, unsigned, fpcr, FPRounding_ZERO);
                D(d) = Extend{64}(result, unsigned);
        end;
    else
        case fp_size of
            when 16 =>
                H(d) = FixedToFP{16, size}(S(d)[size-1:0], frac_bits, unsigned, fpcr,
                    FPRounding_TIEEVEN);
            when 32 =>
                S(d) = FixedToFP{32, size}(S(d)[size-1:0], frac_bits, unsigned, fpcr,
                    FPRounding_TIEEVEN);
            when 64 =>
                D(d) = FixedToFP{64, size}(D(d)[size-1:0], frac_bits, unsigned, fpcr,
                    FPRounding_TIEEVEN);
        end;
    end;
end;
```

VCVT (between floating-point and integer, Advanced SIMD)

Vector Convert between floating-point and integer converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<dt1> Is the data type for the elements of the destination vector, encoded in "(size :: op)":

size	op	<dt1>
01	0x	F16
01	10	S16
01	11	U16
10	0x	F32
10	10	S32
10	11	U32

<dt2> Is the data type for the elements of the source vector, encoded in "(size :: op)":

size	op	<dt2>
01	00	S16
01	01	U16
01	1x	F16
10	00	S32
10	01	U32
10	1x	F32

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```

VCVT (floating-point to integer, floating-point)

Convert floating-point to integer with Round towards Zero converts a value in a register from floating-point to a 32-bit integer, using the Round towards Zero rounding mode, and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VCVT (from single-precision to BFloat16, Advanced SIMD)

Vector Convert from single-precision to BFloat16 converts each 32-bit element in a vector from single-precision floating-point to BFloat16 format, and writes the result into a second vector. The result vector elements are half the width of the source vector elements.

Unlike the BFloat16 multiplication instructions, this instruction uses the Round to Nearest rounding mode, and can generate a floating-point exception that causes cumulative exception bits in the *FPSCR* to be set.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1
(FEAT_AA32BF16)

        let op : bits(32) = operand[e*32];
        result[e*16] = FPConvertBF(op, fpcr);
    end;
    D(d) = result;
end;
```

VCVT (integer to floating-point, floating-point)

Convert integer to floating-point converts a 32-bit integer to floating-point using the rounding mode specified by the *FPSCR*, and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the *CPACR*, *NSACR*, *HCPTTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	1	0	1	D	1	1	1	0	0	0	Vd				1	0	size	op	1	M	0	Vm				
cond												o1																			

Encoding for the Half-precision scalar variant (FEAT_FP16)

Applies when (size == 01)

$\text{VCVT}\{\langle c \rangle\}\{\langle q \rangle\}.\text{F16}.\langle dt \rangle \langle Sd \rangle, \langle Sm \rangle$

Encoding for the Single-precision scalar variant

Applies when (size == 10)

$\text{VCVT}\{\langle c \rangle\}\{\langle q \rangle\}.\text{F32}.\langle dt \rangle \langle Sd \rangle, \langle Sm \rangle$

Encoding for the Double-precision scalar variant

Applies when (size == 11)

$\text{VCVT}\{\langle c \rangle\}\{\langle q \rangle\}.\text{F64}.\langle dt \rangle \langle Dd \rangle, \langle Sm \rangle$

Decode for all variants of this encoding

```
if opc2 != '000' && opc2 != '10x' then See("Related encodings"); end;
if size == '00' then Undefined(); end;
if size == '01' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if size == '01' && cond != '1110' then UnpredictableProcedure(); end;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' && opc2[2] == '0' then UInt(D::Vd) else UInt(Vd::D);
let m : integer = if size == '11' && opc2[2] == '1' then UInt(M::Vm) else UInt(Vm::M);
let to_integer : boolean = (opc2[2] == '1');
let unsigned : boolean = (if to_integer then opc2[0] else op) == '0';
let zero_rounding : boolean = to_integer && op == '1';
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

VCVTB

Convert to or from a half-precision value in the bottom half of a single-precision register does one of the following:

- Converts the half-precision value in the bottom half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the bottom half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

VCVTB (BFloat16)

Converts the single-precision value in a single-precision register to BFloat16 format and writes the result into the bottom half of a single precision register, preserving the top 16 bits of the destination register.

Unlike the BFloat16 multiplication instructions, this instruction honors all the control bits in the *FPSCR* that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception which causes a cumulative exception bit in the *FPSCR* to be set, or a synchronous exception to be taken, depending on the enable bits in the *FPSCR*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_AA32BF16)

Encoding

```
VCVTB{<c>}{<q>}.BF16.F32 <Sd>, <Sm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AA32BF16) then Undefined(); end;
let d : integer = UInt(Vd::D);
let m : integer = UInt(Vm::M);
```

T1
(FEAT_AA32BF16)

Encoding

```
VCVTB{<c>}{<q>}.BF16.F32 <Sd>, <Sm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AA32BF16) then Undefined(); end;
let d : integer = UInt(Vd::D);
let m : integer = UInt(Vm::M);
```

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);

    S(d)[15:0] = FPConvertBF(S(m), EffectiveFPCR());
end;
```

VCVTM (Advanced SIMD)

Vector Convert floating-point to integer with Round towards -Infinity converts each element in a vector from floating-point to integer using the Round towards -Infinity rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are integers, and the same size as the operand vector elements. Signed and unsigned integers are distinct.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPExc](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	D	1	1	size		1	1	Vd			0		0	1	1	op	Q	M	0	Vm			
opc1														RM																	

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

`VCVTM{<q>}.<dt>.<dt2> <Dd>, <Dm>`

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

`VCVTM{<q>}.<dt>.<dt2> <Qd>, <Qm>`

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size IN {'00', '11'} then Undefined(); end;
if size == '01' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

T1

1	1	1	1	1	1	1	1	1	D	1	1	size			1			1			Vd			0		0		1		1		op		Q		M		0		Vm		
opc1														RM																												

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

`VCVTM{<q>}.<dt>.<dt2> <Dd>, <Dm>`

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

`VCVTM{<q>}.<dt>.<dt2> <Qd>, <Qm>`

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vm[0] == '1') then Undefined(); end;
if size IN {'00', '11'} then Undefined(); end;
if size == '01' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '1');
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If [InITBlock\(\)](#), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.

- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q> See [Standard assembler syntax fields](#).

<dt> Is the data type for the elements of the destination, encoded in “(op :: size)”:

op	size	<dt>
0	01	S16
0	10	S32
1	01	U16
1	10	U32

<dt2> Is the data type for the elements of the source vector, encoded in “size”:

size	<dt2>
01	F16
10	F32

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
EncodingSpecificOperations();
CheckAdvSIMDEnabled();
let fpcr : FPCR_Type = StandardFPCR();
for r = 0 to regs-1 do
    for e = 0 to elements-1 do
        D(d+r)[e*esize] = FPToFixed(esize, esize) (D(m+r)[e*esize],
                                                    0, unsigned, fpcr, rounding);
    end;
end;
```

VCVTP (floating-point)

Convert floating-point to integer with Round towards +Infinity converts a value in a register from floating-point to a 32-bit integer using the Round towards +Infinity rounding mode, and places the result in a second register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	0	1	D	1	1	1	1	1	0	Vd			1	0	size		op	1	M	0	Vm				
										op1		RM																			

Encoding for the Half-precision scalar variant (FEAT_FP16)

Applies when (size == 01)

`VCVTP{<q>}.<dt>.F16 <Sd>, <Sm>`

Encoding for the Single-precision scalar variant

Applies when (size == 10)

`VCVTP{<q>}.<dt>.F32 <Sd>, <Sm>`

Encoding for the Double-precision scalar variant

Applies when (size == 11)

`VCVTP{<q>}.<dt>.F64 <Sd>, <Dm>`

Decode for all variants of this encoding

```
if size == '00' then Undefined(); end;
if size == '01' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	0	1	D	1	1	1	1	1	0	Vd			1		0	size		op	1	M	0	Vm			
										op1		RM																			

Encoding for the Half-precision scalar variant (FEAT_FP16)

Applies when (size == 01)

`VCVTP{<q>}.<dt>.F16 <Sd>, <Sm>`

Encoding for the Single-precision scalar variant

Applies when (size == 10)

`VCVTP{<q>}.<dt>.F32 <Sd>, <Sm>`

Encoding for the Double-precision scalar variant

Applies when (size == 11)

`VCVTP{<q>}.<dt>.F64 <Sd>, <Dm>`

Decode for all variants of this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if size == '00' then Undefined(); end;
if size == '01' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
let rounding : FPRounding = FPDecodeRM(RM);
let unsigned : boolean = (op == '0');
let esize : integer{} = 8 << UInt(size);
let d : integer = UInt(Vd::D);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

- If `InitTBlock()`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as if it passes the Condition code check.
 - The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q>	See <i>Standard assembler syntax fields</i> .						
<dt>	Is the data type for the elements of the destination, encoded in “op”: <table><tr><th>op</th><th><dt></th></tr><tr><td>0</td><td>U32</td></tr><tr><td>1</td><td>S32</td></tr></table>	op	<dt>	0	U32	1	S32
op	<dt>						
0	U32						
1	S32						
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.						
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.						
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.						

Operation

```
EncodingSpecificOperations();
CheckVFPEEnabled(TRUE);
let fpcr : FPCR_Type = EffectiveFPCR();
case esize of
  when 16 =>
    S(d) = FPToFixed{32, 16}(H(m), 0, unsigned, fpcr, rounding);
  when 32 =>
    S(d) = FPToFixed{32, 32}(S(m), 0, unsigned, fpcr, rounding);
  when 64 =>
    S(d) = FPToFixed{32, 64}(D(m), 0, unsigned, fpcr, rounding);
end;
```

VCVTR

Convert floating-point to integer converts a value in a register from floating-point to a 32-bit integer, using the rounding mode specified by the *FPSCR* and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the *CPACR*, *NSACR*, *HCPTTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be *UNDEFINED*, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VCVTT

Convert to or from a half-precision value in the top half of a single-precision register does one of the following:

- Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. VCVTT (BFloat16)

Converts the single-precision value in a single-precision register to BFloat16 format and writes the result in the top half of a single-precision register, preserving the bottom 16 bits of the register.

Unlike the BFloat16 multiplication instructions, this instruction honors all the control bits in the *FPSCR* that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception which causes a cumulative exception bit in the *FPSCR* to be set, or a synchronous exception to be taken, depending on the enable bits in the *FPSCR*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_AA32BF16)

Encoding

```
VCVTT{<c>}{<q>}.BF16.F32 <Sd>, <Sm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AA32BF16) then Undefined(); end;
let d : integer = UInt(Vd::D);
let m : integer = UInt(Vm::M);
```

T1
(FEAT_AA32BF16)

Encoding

```
VCVTT{<c>}{<q>}.BF16.F32 <Sd>, <Sm>
```

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AA32BF16) then Undefined(); end;
let d : integer = UInt(Vd::D);
let m : integer = UInt(Vm::M);
```

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);

    S(d)[31:16] = FPConvertBF(S(m), EffectiveFPCR());
end;
```

VDIV

Divide divides one floating-point value by another floating-point value and writes the result to a third floating-point register. Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let fpcr : FPCR_Type = EffectiveFPCR();
    case esize of
        when 16 =>
            H(d) = FPDIV{16}(H(n), H(m), fpcr);
        when 32 =>
            S(d) = FPDIV{32}(S(n), S(m), fpcr);
        when 64 =>
            D(d) = FPDIV{64}(D(n), D(m), fpcr);
    end;
end;
```

VDOT (by element)

BFloat16 floating-point indexed dot product (vector, by element). This instruction delimits the source vectors into pairs of 16-bit BF16 elements. Each pair of elements in the first source vector is multiplied by the indexed pair of elements in the second source vector. The resulting single-precision products are then summed and added destructively to the single-precision element in the destination vector which aligns with the pair of BFloat16 values in the first source vector. The instruction does not update the *FPSCR* exception status.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

VDUP (general-purpose register)

Duplicate general-purpose register to vector duplicates an element from a general-purpose register into every element of the destination vector. The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

Depending on settings in the *CPACR*, *NSACR*, and *HCPT* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

let elements : integer = 64 DIV esize;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*. Arm strongly recommends that any VDUP instruction is unconditional, see *Conditional execution*.
- <q> See *Standard assembler syntax fields*.

<size>	The data size for the elements of the destination vector. It must be one of:
8	Encoded as [b, e] = 0b10.
16	Encoded as [b, e] = 0b01.
32	Encoded as [b, e] = 0b00.
<Dd>	The destination vector for a doubleword operation.
<Rt>	The Arm source register.
<Qd>	The destination vector for a quadword operation.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let scalar : bits(esize) = R(t)[esize-1:0];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*esize] = scalar;
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

VDUP (scalar)

Duplicate vector element to vector duplicates a single element of a vector into every element of the destination vector. The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types. For more information about scalars see *Advanced SIMD scalars*. Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*. It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

let elements : integer{} = 64 DIV esize;
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

- <c> For the "A1" variant: see *Standard assembler syntax fields*. This encoding must be unconditional.
- <q> For the "T1" variant: see *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.

<size>	The data size. It must be one of:
8	Encoded as imm4<0> = '1'. imm4<3:1> encodes the index[x] of the scalar.
16	Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index [x] of the scalar.
32	Encoded as imm4<2:0> = '100'. imm4<3> encodes the index [x] of the scalar.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm[x]>	The scalar. For details of how [x] is encoded, see the description of <size>.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let scalar : bits(esize) = D(m)[index*esize];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            D(d+r)[e*esize] = scalar;
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VEOR

Vector Bitwise Exclusive-OR performs a bitwise exclusive-OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

The following figure shows an example of the operation of VEXT doubleword operation for $\text{imm} = 3$.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the pseudo-instruction [VEXT \(multibyte elements\)](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

This is a pseudo-instruction of [VEXT \(byte elements\)](#). This means:

- The encodings in this description are named to match the encodings of [VEXT \(byte elements\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VEXT \(byte elements\)](#) gives the operational pseudocode, any `CONSTRAINED UNPREDICTABLE` behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	0	1	D	1	1	Vn				Vd				imm4				N	Q	M	0	Vm			

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VEXT{<c>}{<q>}.<size> {<Dd>, }<Dn>, <Dm>, #<imm>

is equivalent to

VEXT{<c>}{<q>}.8 {<Dd>, }<Dn>, <Dm>, #<imm*(size/8)>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VEXT{<c>}{<q>}.<size> {<Qd>, }<Qn>, <Qm>, #<imm>

is equivalent to

VEXT{<c>}{<q>}.8 {<Qd>, }<Qn>, <Qm>, #<imm*(size/8)>

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VFMA

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the *CPACR*, *NSACR*, *HCPTTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

VFMAb, VFMAb (BFloat16, by scalar)

The BFloat16 floating-point widening multiply-add long instruction widens the even-numbered (bottom) or odd-numbered (top) 16-bit elements in the first source vector, and an indexed element in the second source vector from Bfloat16 to single-precision format. The instruction then multiplies and adds these values to the overlapping single-precision elements of the destination vector.

Unlike other BFloat16 multiplication instructions, this performs a fused multiply-add, without intermediate rounding that uses the Round to Nearest rounding mode and can generate a floating-point exception that causes cumulative exception bits in the *FPSCR* to be set.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_AA32BF16)

Encoding

VFMA<bt>{<q>}.BF16 <Qd>, <Qn>, <Dm>[<index>]

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AA32BF16) then Undefined(); end;

VFMAb, VFMAb (BFloat16, vector)

The Bfloat16 floating-point widening multiply-add long instruction widens the even-numbered (bottom) or odd-numbered (top) 16-bit elements in the first and second source vectors from Bfloat16 to single-precision format. The instruction then multiplies and adds these values to the overlapping single-precision elements of the destination vector.

Unlike other BFloat16 multiplication instructions, this performs a fused multiply-add, without intermediate rounding that uses the Round to Nearest rounding mode and can generate a floating-point exception that causes cumulative exception bits in the *FPSCR* to be set.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_AA32BF16)

Encoding

VFMA<bt>{<q>}.BF16 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_AA32BF16) then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 128 DIV 32;
let sel : integer = UInt(Q);
```

T1
(FEAT_AA32BF16)

Encoding

VFMA<bt>{<q>}.BF16 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_AA32BF16) then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 128 DIV 32;
let sel : integer = UInt(Q);
```

Assembler Symbols

<bt>	Is the bottom or top element specifier, encoded in “Q”:						
<table><tr><th>Q</th><th><bt></th></tr><tr><td>0</td><td>B</td></tr><tr><td>1</td><td>T</td></tr></table>	Q	<bt>	0	B	1	T	
Q	<bt>						
0	B						
1	T						
<q>	See <i>Standard assembler syntax fields</i> .						
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.						
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.						
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.						

Operation

```
CheckAdvSIMDEnabled();
let fpcr : FPCR_Type = StandardFPCR();

let operand1 : bits(128) = Q(n>>1);
let operand2 : bits(128) = Q(m>>1);
let operand3 : bits(128) = Q(d>>1);
var result : bits(128);

for e = 0 to elements-1 do
  let element1 : bits(32) = operand1[(2 * e + sel)*:16] :: Zeros{16};
  let element2 : bits(32) = operand2[(2 * e + sel)*:16] :: Zeros{16};
  let addend : bits(32) = operand3[e*:32];
  result[e*:32] = FPMulAdd{32}(addend, element1, element2, fpcr);
end;

Q(d>>1) = result;
```

VFMAL (by scalar)

Vector Floating-point Multiply-Add Long to accumulator (by scalar). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note ID_ISAR6.FHM indicates whether this instruction is supported.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1 (FEAT_FHM)

VFMSL (by scalar)

Vector Floating-point Multiply-Subtract Long from accumulator (by scalar). This instruction multiplies the negated vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

Note ID_ISAR6.FHM indicates whether this instruction is supported.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1 (FEAT_FHM)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VHADD

Vector Halving Add adds corresponding elements in two vectors of integers, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated. For rounded results, see [VRHADD](#)). The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckAdvSIMDEnabled();
  for r = 0 to regs-1 do
    for e = 0 to elements-1 do
      let op1elt : bits(esize) = D(n+r)[e*:esize];
      let op2elt : bits(esize) = D(m+r)[e*:esize];
      let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
      let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
      let result : integer = (if add then element1+element2 else element1-element2) >> 1;
      D(d+r)[e*:esize] = result[esize-1:0];
    end;
  end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VINS

Vector move Insertion. This instruction copies the lower 16 bits of the 32-bit source SIMD&FP register into the upper 16 bits of the 32-bit destination SIMD&FP register, while preserving the values in the remaining bits.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_FP16)

Encoding

VINS{<q>}.F16 <Sd>, <Sm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let d : integer = UInt(Vd::D);
let m : integer = UInt(Vm::M);
```

T1
(FEAT_FP16)

Encoding

VINS{<q>}.F16 <Sd>, <Sm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let d : integer = UInt(Vd::D);
let m : integer = UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

- If `InITBlock()`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as if it passes the Condition code check.
 - The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

- <q> See *Standard assembler syntax fields*.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEnabled(TRUE);
    S(d)[31:16] = H(m);
end;
```

VJCVT

JavaScript Convert to signed fixed-point, rounding toward Zero. This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register. If the result is too large to be accommodated as a signed 32-bit integer, then the result is the integer modulo 2³², as held in a 32-bit signed integer.

This instruction can generate a floating-point exception. Depending on the settings in *FPSCR*, the exception results in either a flag being set or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1
(FEAT_JSCVT)

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD1 \(multiple single elements\)](#).

Related encodings: See [Advanced SIMD element or structure load/store](#) for the T32 instruction set, or [Advanced SIMD element or structure load/store](#) for the A32 instruction set.

Assembler Symbols

<c> For the "A1 Offset", "A1 Post-indexed", "A2 Offset", "A2 Post-indexed", "A3 Offset", "A3 Post-indexed", "A4 Offset", and "A4 Post-indexed" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the "T1 Offset", "T1 Post-indexed", "T2 Offset", "T2 Post-indexed", "T3 Offset", "T3 Post-indexed", "T4 Offset", and "T4 Post-indexed" variants: see [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<size> Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32
11	64

<list> Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:

- { <Dd> }
Single register. Selects the A1 and T1 encodings of the instruction.
- { <Dd>, <Dd+1> }
Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.
- { <Dd>, <Dd+1>, <Dd+2> }
Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.
- { <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "align" field as 0b00. Whenever <align> is present, the permitted values are:

64	64-bit alignment, encoded in the "align" field as 0b01.
128	128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.
256	256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let tagchecked : boolean = FALSE;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal,
                                                    tagchecked, privileged);

    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            var data : bits(ebytes*8);
            if ebytes != 8 then
                data = MemU{8*ebytes}(address);
            else
                if !IsAlignedSize(address, ebytes) && AlignmentEnforced() then
                    let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
                    AArch32_Abort(fault);
                end;

                if BigEndian(AccessType_ASIMD) then
                    data[31:0] = MemU{32}(address+4);
                    data[63:32] = MemU{32}(address);
                else
                    data[31:0] = MemU{32}(address);
                    data[63:32] = MemU{32}(address+4);
                end;
            end;

            D(d+r)[e*(8*ebytes)] = data;
            address = address + ebytes;
        end;
    end;

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 8*regs;
        end;
    end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

VLD1 (single element to all lanes)

Load single 1-element structure and replicate to all lanes of one register loads one element from memory into every element of one or two vectors. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

CONSTRAINED UNPREDICTABLE behavior

If `d+regs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD1 (single element to all lanes)*.

Assembler Symbols

<c>

For the "A1 Offset" and "A1 Post-indexed" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.

For the "T1 Offset" and "T1 Post-indexed" variants: see *Standard assembler syntax fields*.

<q>

See *Standard assembler syntax fields*.

<size>

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>

Is a list containing the 64-bit names of the SIMD&FP registers. The list must be one of:

{ <Dd>[] }

Encoded in the "T" field as 0.

{ <Dd>[], <Dd+1>[] }

Encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn>

Is the general-purpose base register, encoded in the "Rn" field.

<align>

When <size> == 8, <align> must be omitted, otherwise it is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "a" field as 0. Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16

<align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.

<size> == 32

<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm>

Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let tagchecked : boolean = FALSE;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp\_LOAD, nontemporal,
                                                    tagchecked, privileged);

    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32\_Abort(fault);
    end;

    let esize : integer{} = 8 * ebytes;
    let element : bits(esize) = MemU{8*ebytes}(address);
    let replicated_element : bits(64) = Replicate{}(element);
    for r = 0 to regs-1 do
        D(d+r) = replicated_element;
    end;
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + ebytes;
        end;
    end;
end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Assembler Symbols

<c> For the "A1 Offset", "A1 Post-indexed", "A2 Offset", "A2 Post-indexed", "A3 Offset", and "A3 Post-indexed" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.
For the "T1 Offset", "T1 Post-indexed", "T2 Offset", "T2 Post-indexed", "T3 Offset", and "T3 Post-indexed" variants: see [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<size> Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32

<list> Is a list containing the single 64-bit name of the SIMD&FP register holding the element. The list must be { <Dd>[<index>] }. The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:

<size> == 8
 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.
<size> == 16
 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.
<size> == 32
 <index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> When <size> == 8, <align> must be omitted, otherwise it is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and the encoding depends on <size>:

<size> == 8
 Encoded in the "index_align<0>" field as 0.
<size> == 16
 Encoded in the "index_align<1:0>" field as 0b00.
<size> == 32
 Encoded in the "index_align<2:0>" field as 0b000.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16
 <align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.
<size> == 32
 <align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let tagchecked : boolean = FALSE;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp\_LOAD, nontemporal,
                                                    tagchecked, privileged);

    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32\_Abort(fault);
    end;

    D(d)[index*:(8*ebytes)] = MemU{8*ebytes}(address);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + ebytes;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

2026-03_rel 2026-03-26 20:48:11

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

VLD2 (multiple 2-element structures)

Load multiple 2-element structures to two or four registers loads multiple 2-element structures from memory into two or four registers, with de-interleaving. For more information, see *Element and structure load/store instructions*. Every element of each register is loaded. For details of the addressing mode, see *Advanced SIMD addressing mode*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if align == '11' then Undefined(); end;
if size == '11' then Undefined(); end;
let pairs : integer = 1;
let inc : integer = if itype == '1001' then 2 else 1;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2+pairs > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d2+pairs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

A2

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```
if size == '11' then Undefined(); end;
let pairs : integer = 2;
let inc : integer = 2;
let alignment : integer{} = if align == '00' then 1 else 4 << UInt(align);
let ebytes : integer{} = 1 << UInt(size);
let elements : integer = 8 DIV ebytes;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2+pairs > 32 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If d2+pairs > 32, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

```

CONSTRAINED UNPREDICTABLE behavior

If **d2 > 31**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD2 \(single 2-element structure to all lanes\)](#).

Assembler Symbols

<c> For the "A1 Offset" and "A1 Post-indexed" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the "T1 Offset" and "T1 Post-indexed" variants: see [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<size> Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32

<list> Is a list containing the 64-bit names of two SIMD&FP registers. The list must be one of:

- { <Dd>[], <Dd+1>[] }
Single-spaced registers, encoded in the "T" field as 0.
- { <Dd>[], <Dd+2>[] }
Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see [Unaligned data access](#), and is encoded in the "a" field as 0. Whenever <align> is present, the permitted values and encoding depend on <size>:

- <size> == 8
 <align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.
- <size> == 16
 <align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
- <size> == 32
 <align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see [Advanced SIMD addressing mode](#).

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let tagchecked : boolean = FALSE;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp\_LOAD, nontemporal,
                                                    tagchecked, privileged);

    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32\_Abort(fault);
    end;

VLD2 (single 2-element structure to one lane)

Load single 2-element structure to one lane of two registers loads one 2-element structure from memory into corresponding elements of two registers. Elements of the registers that are not loaded are unchanged. For details of the addressing mode, see [Advanced SIMD addressing mode](#). Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) , [A2](#) and [A3](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	0	1	D	1	0	Rn				Vd				0	0	0	1	index_align		Rm					
L										size										N											

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD2{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```
if size == '11' then See("VLD2 (single 2-element structure to all lanes)"); end;
let ebytes : integer{} = 1;
let index : integer = UInt(index_align[3:1]);
let inc : integer = 1;
let alignment : integer{} = if index_align[0] == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d2 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLD2 \(single 2-element structure to one lane\)](#).

Assembler Symbols

- <c> For the "A1 Offset", "A1 Post-indexed", "A2 Offset", "A2 Post-indexed", "A3 Offset", and "A3 Post-indexed" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.
- <q> For the "T1 Offset", "T1 Post-indexed", "T2 Offset", "T2 Post-indexed", "T3 Offset", and "T3 Post-indexed" variants: see [Standard assembler syntax fields](#).
- <size> See [Standard assembler syntax fields](#).
- Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32

<list>	Is a list containing the 64-bit names of the two SIMD&FP registers holding the element. The list must be one of: <pre> { <Dd>[<index>], <Dd+1>[<index>] } Single-spaced registers, encoded as "spacing" = 0. { <Dd>[<index>], <Dd+2>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8. </pre> The encoding of "spacing" depends on <size>: <pre> <size> == 16 "spacing" is encoded in the "index_align<1>" field. <size> == 32 "spacing" is encoded in the "index_align<2>" field. </pre> The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>: <pre> <size> == 8 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field. <size> == 16 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field. <size> == 32 <index> is 0 or 1, encoded in the "index_align<3>" field. </pre>
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see Unaligned data access, and the encoding depends on <size>: <pre> <size> == 8 Encoded in the "index_align<0>" field as 0. <size> == 16 Encoded in the "index_align<0>" field as 0. <size> == 32 Encoded in the "index_align<1:0>" field as 0b00. </pre> Whenever <align> is present, the permitted values and encoding depend on <size>: <pre> <size> == 8 <align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1. <size> == 16 <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1. <size> == 32 <align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01. </pre> : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see Advanced SIMD addressing mode.
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let tagchecked : boolean = FALSE;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal,
                                                         tagchecked, privileged);
    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    D(d) [index*:(8*bytes)] = MemU{8*bytes}(address);
    D(d2) [index*:(8*bytes)] = MemU{8*bytes}(address+bytes);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 2*bytes;
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

Encoding for the Offset variant

Applies when (Rm == 1111)

VLD3{<c>}{<q>}.<size> <list>, [<Rn>]

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

VLD3{<c>}{<q>}.<size> <list>, [<Rn>]!

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD3{<c>}{<q>}.<size> <list>, [<Rn>], <Rm>

Decode for all variants of this encoding

```
if size == '11' || a == '1' then Undefined(); end;
let ebytes : integer() = 1 << UInt(size);
let inc : integer = if T == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If **d3 > 31**, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UnpredictableProcedure(); end;

```

CONSTRAINED UNPREDICTABLE behavior

If $d_3 > 31$, then one of the following behaviors must occur:

- The instruction is `UNDEFINED`.
- The instruction executes as `NOF`.
- One or more of the SIMD and floating-point registers are `UNKNOWN`. If the instruction specifies writeback, the base register becomes `UNKNOWN`. This behavior does not affect any general-purpose registers.

For more information about the `CONSTRAINED UNPREDICTABLE` behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD3 (single 3-element structure to all lanes)*.

Assembler Symbols

<c> For the "A1 Offset" and "A1 Post-indexed" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.

For the "T1 Offset" and "T1 Post-indexed" variants: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<code><size></code>	Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list> Is a list containing the 64-bit names of three SIMD&FP registers. The list must be one of:

{ <Dd>[], <Dd+1>[], <Dd+2>[] }	Single-spaced registers, encoded in the "T" field as 0.
{ <Dd>[], <Dd+2>[], <Dd+4>[] }	Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Alignment

Standard alignment rules apply, see [Alignment support](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let address : bits(32) = R(n);
    let esize : integer{} = ebytes * 8;
    let element1 : bits(esize) = MemU{8*ebytes}(address);
    let element2 : bits(esize) = MemU{8*ebytes}(address+ebytes);
    let element3 : bits(esize) = MemU{8*ebytes}(address+2*ebytes);

    D(d) = Replicate{64}(element1);
    D(d2) = Replicate{64}(element2);
    D(d3) = Replicate{64}(element3);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 3*ebytes;
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

Assembler Symbols

<c>

<q>

<size>

For the "A1 Offset", "A1 Post-indexed", "A2 Offset", "A2 Post-indexed", "A3 Offset", and "A3 Post-indexed" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the "T1 Offset", "T1 Post-indexed", "T2 Offset", "T2 Post-indexed", "T3 Offset", and "T3 Post-indexed" variants: see [Standard assembler syntax fields](#).

See [Standard assembler syntax fields](#).

Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32

<list> Is a list containing the 64-bit names of the three SIMD&FP registers holding the element. The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] }
Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] }
Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 8
"spacing" is encoded in the "index_align<0>" field.

<size> == 16
"spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0.

<size> == 32
"spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00.

The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>:

<size> == 8
<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Alignment

Standard alignment rules apply, see [Alignment support](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let address : bits(32) = R(n);
    D(d) [index*: (8*bytes)] = MemU{8*bytes}(address);
    D(d2) [index*: (8*bytes)] = MemU{8*bytes}(address+bytes);
    D(d3) [index*: (8*bytes)] = MemU{8*bytes}(address+2*bytes);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 3*bytes;
        end;
    end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VLD4 (multiple 4-element structures)

Load multiple 4-element structures to four registers loads multiple 4-element structures from memory into four registers, with de-interleaving. For more information, see [Element and structure load/store instructions](#). Every element of each register is loaded. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

The register <Dd> is encoded in the "D:Vd" field.								
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.								
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see Unaligned data access , and is encoded in the "align" field as 0b00. Whenever <align> is present, the permitted values are: 64 64-bit alignment, encoded in the "align" field as 0b01. 128 128-bit alignment, encoded in the "align" field as 0b10. 256 256-bit alignment, encoded in the "align" field as 0b11. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see Advanced SIMD addressing mode.								
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.								

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    var address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let tagchecked : boolean = FALSE;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp\_LOAD, nontemporal,
                                                    tagchecked, privileged);

    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32\_Abort(fault);
    end;

    for e = 0 to elements-1 do
        D(d)[e*:(8*ebytes)] = MemU{8*ebytes}(address);
        D(d2)[e*:(8*ebytes)] = MemU{8*ebytes}(address+ebytes);
        D(d3)[e*:(8*ebytes)] = MemU{8*ebytes}(address+2*ebytes);
        D(d4)[e*:(8*ebytes)] = MemU{8*ebytes}(address+3*ebytes);
        address = address + 4*ebytes;
    end;

    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 32;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VLD4 (single 4-element structure to all lanes)

Load single 4-element structure and replicate to all lanes of four registers loads one 4-element structure from memory into all lanes of four registers. For details of the addressing mode, see [Advanced SIMD addressing mode](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	0	1	D	1	0	Rn				Vd				1	1	1	1	size		T	a	Rm			
L										N																					

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

Decode for all variants of this encoding

```
if size == '11' && a == '0' then Undefined(); end;
let ebytes : integer{} = if size == '11' then 4 else 1 << UInt(size);
let alignment : integer{} = (if a == '0' && size != '11' then 1
                             else 4 << (UInt(size[1]) + UInt(size[0])));
let inc : integer = if T == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d4 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

L										N																					

Encoding for the Offset variant

Applies when (Rm == 1111)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Encoding for the Post-indexed variant

Applies when (Rm == 1101)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Encoding for the Post-indexed variant

Applies when (Rm != 11x1)

VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>

Decode for all variants of this encoding

```
if size == '11' && a == '0' then Undefined(); end;
let ebytes : integer{} = if size == '11' then 4 else 1 << UInt(size);
let alignment : integer{} = (if a == '0' && size != '11' then 1
                             else 4 << (UInt(size[1]) + UInt(size[0])));
let inc : integer = if T == '0' then 1 else 2;
let d : integer = UInt(D::Vd);
let d2 : integer = d + inc;
let d3 : integer = d2 + inc;
let d4 : integer = d3 + inc;
let n : integer = UInt(Rn);
let m : integer = UInt(Rm);
let wback : boolean = (m != 15);
let register_index : boolean = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `d4 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD4 (single 4-element structure to all lanes)*.

Assembler Symbols

<c> For the "A1 Offset" and "A1 Post-indexed" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.

For the "T1 Offset" and "T1 Post-indexed" variants: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in "size":

size	<size>
00	8
01	16
1x	32

<list> Is a list containing the 64-bit names of four SIMD&FP registers. The list must be one of:

- { <Dd>[], <Dd+1>[], <Dd+2>[], <Dd+3>[] }
Single-spaced registers, encoded in the "T" field as 0.
- { <Dd>[], <Dd+2>[], <Dd+4>[], <Dd+6>[] }
Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "a" field as 0. Whenever <align> is present, the permitted values and encoding depend on <size>:

- <size> == 8
<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.
 - <size> == 16
<align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.
 - <size> == 32
<align> can be 64 or 128. 64-bit alignment is encoded in the "a:size<0>" field as 0b10, and 128-bit alignment is encoded in the "a:size<0>" field as 0b11.
- : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let tagchecked : boolean = FALSE;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp\_LOAD, nontemporal,
                                                    tagchecked, privileged);

    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32\_Abort(fault);
    end;

    let esize : integer{} = ebytes * 8;
    let element1 : bits(esize) = MemU{8*ebytes}(address);
    let element2 : bits(esize) = MemU{8*ebytes}(address+ebytes);
    let element3 : bits(esize) = MemU{8*ebytes}(address+2*ebytes);
    let element4 : bits(esize) = MemU{8*ebytes}(address+3*ebytes);
    D(d) = Replicate{64}(element1);
    D(d2) = Replicate{64}(element2);
    D(d3) = Replicate{64}(element3);
    D(d4) = Replicate{64}(element4);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 4*ebytes;
        end;
    end;
end;
```

Assembler Symbols

<c>

<q>

<size>

For the "A1 Offset", "A1 Post-indexed", "A2 Offset", "A2 Post-indexed", "A3 Offset", and "A3 Post-indexed" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.

For the "T1 Offset", "T1 Post-indexed", "T2 Offset", "T2 Post-indexed", "T3 Offset", and "T3 Post-indexed" variants: see *Standard assembler syntax fields*.

See *Standard assembler syntax fields*.

Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list>	Is a list containing the 64-bit names of the four SIMD&FP registers holding the element. The list must be one of: { <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] } Single-spaced registers, encoded as "spacing" = 0. { <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] } Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8. The encoding of "spacing" depends on <size>: <size> == 16 "spacing" is encoded in the "index_align<1>" field. <size> == 32 "spacing" is encoded in the "index_align<2>" field. The register <Dd> is encoded in the "D:Vd" field. The permitted values and encoding of <index> depend on <size>: <size> == 8 <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field. <size> == 16 <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field. <size> == 32 <index> is 0 or 1, encoded in the "index_align<3>" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
<align>	Is the optional alignment. Whenever <align> is omitted, the standard alignment is used, see Unaligned data access, and the encoding depends on <size>: <size> == 8 Encoded in the "index_align<0>" field as 0. <size> == 16 Encoded in the "index_align<0>" field as 0. <size> == 32 Encoded in the "index_align<1:0>" field as 0b00. Whenever <align> is present, the permitted values and encoding depend on <size>: <size> == 8 <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1. <size> == 16 <align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1. <size> == 32 <align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10. : is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see Advanced SIMD addressing mode.
<Rm>	Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see [Advanced SIMD addressing mode](#).

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();

    let address : bits(32) = R(n);

    let nontemporal : boolean = FALSE;
    let privileged : boolean = PSTATE.EL != EL0;
    let tagchecked : boolean = FALSE;
    let accdesc : AccessDescriptor = CreateAccDescASIMD(MemOp_LOAD, nontemporal,
                                                         tagchecked, privileged);

    if !IsAlignedSize(address, alignment) then
        let fault : FaultRecord = AlignmentFault(accdesc, ZeroExtend{64}(address));
        AArch32_Abort(fault);
    end;

    D(d)[index*:(8*bytes)] = MemU{8*bytes}(address);
    D(d2)[index*:(8*bytes)] = MemU{8*bytes}(address+bytes);
    D(d3)[index*:(8*bytes)] = MemU{8*bytes}(address+2*bytes);
    D(d4)[index*:(8*bytes)] = MemU{8*bytes}(address+3*bytes);
    if wback then
        if register_index then
            R(n) = R(n) + R(m);
        else
            R(n) = R(n) + 4*bytes;
        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

2026-03_rel 2026-03-26 20:48:11

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

VLDM, VLDMDB, VLDMIA

Load Multiple SIMD&FP registers loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see [Enabling Advanced SIMD and floating-point support](#).

This instruction is used by the alias [VPOP](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	0	P	U	D	W	1	Rn				Vd				1	0	1	1	x	x	x	x	x	x	x	0
cond				L												size				imm8											

Encoding for the Decrement Before variant

Applies when (P == 1 && U == 0 && W == 1)

```
VLDMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>
```

Encoding for the Increment After variant

Applies when (P == 0 && U == 1)

```
VLDM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist> // (Preferred syntax)
```

```
VLDMIA{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>
```

Decode for all variants of this encoding

```
if P == '0' && U == '0' && W == '0' then See("Related encodings"); end;
if P == '1' && W == '0' then See("VLDR"); end;
if P == U && W == '1' then Undefined(); end;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
let single_regs : boolean = FALSE;
let add : boolean = (U == '1');
let wback : boolean = (W == '1');
let d : integer = UInt(D::Vd);
let n : integer = UInt(Rn);
let imm32 : bits(32) = ZeroExtend{(imm8::'00')};
let regs : integer = UInt(imm8) DIVRM 2; // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet A32) then UnpredictableProcedure(); end;
if regs == 0 || regs > 16 || (d+regs) > 32 then UnpredictableProcedure(); end;
if imm8[0] == '1' && (d+regs) > 16 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If `regs > 16 || (d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

A2

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If `(d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#), and particularly [VLDM](#).

Related encodings: See [Advanced SIMD and floating-point 64-bit move](#) for the T32 instruction set, or [Advanced SIMD and floating-point 64-bit move](#) for the A32 instruction set.

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<size>	An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.						
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.						
<dreglist>	Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.						
!	Specifies base register writeback, encoded in "W": <table border="1"> <tr> <th>W</th><th>!</th></tr> <tr> <td>0</td><td>[absent]</td></tr> <tr> <td>1</td><td>[present]</td></tr> </table>	W	!	0	[absent]	1	[present]
W	!						
0	[absent]						
1	[present]						
<sreglist>	Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.						

Alias Conditions

Alias	Is preferred when
VPOP	P == '0' && U == '1' && W == '1' && Rn == '1101'

Operation

```
if ConditionPassed() then
  EncodingSpecificOperations();
  CheckVFPEEnabled(TRUE);
  var address : bits(32) = if add then R(n) else R(n)-imm32;

  for r = 0 to regs-1 do
    if single_regs then
      S(d+r) = MemA{32}(address);
      address = address+4;
    else
      let word1 : bits(32) = MemA{32}(address);
      let word2 : bits(32) = MemA{32}(address+4);
      address = address+8;

      // Combine the word-aligned words in the correct order for current endianness.
      D(d+r) = if BigEndian(AccessType ASIMD) then word1::word2 else word2::word1;
    end;
  end;

  if wback then R(n) = if add then R(n)+imm32 else R(n)-imm32; end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VLDR (immediate)

Load SIMD&FP register (immediate) loads a single register from the Advanced SIMD and floating-point register file, using an address from a general-purpose register, with an optional offset.

Depending on settings in the *CPACR*, *NSACR*, *HCPTTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	0	1	U	D	0	1	!= 1111			Vd				1	0	size			imm8							
cond				P			W			L			Rn																		

Encoding for the Half-precision scalar variant (FEAT_FP16)

Applies when (size == 01)

```
VLDR{<c>}{<q>}.16 <Sd>, [<Rn> {, #<+/-><imm>}]
```

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VLDR{<c>}{<q>}.32 <Sd>, [<Rn> {, #<+/-><imm>}]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VLDR{<c>}{<q>}.64 <Dd>, [<Rn> {, #<+/-><imm>}]
```

Decode for all variants of this encoding

```
if size == '00' || (size == '01' && !IsFeatureImplemented(FEAT_FP16)) then Undefined(); end;
if size == '01' && cond != '1110' then UnpredictableProcedure(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Applies when (size == 01)

```
VLDR{<c>}{<q>}.16 <Sd>, [<Rn> {, #<+/-><imm>}]
```

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VLDR{<c>}{<q>}.32 <Sd>, [<Rn> {, #<+/-><imm>}]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VLDR{<c>}{<q>}{.64} <Dd>, [<Rn> {, #<+/-><imm>}]
```

Decode for all variants of this encoding

```
if size == '00' || (size == '01' && !IsFeatureImplemented(FEAT_FP16)) then Undefined(); end;
if size == '01' && InITBlock() then UnpredictableProcedure(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.						
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table border="1"> <thead> <tr> <th>U</th><th>+/-</th></tr> </thead> <tbody> <tr> <td>0</td><td>-</td></tr> <tr> <td>1</td><td>+</td></tr> </tbody> </table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1 Half-precision scalar" and "T1 Half-precision scalar" variants: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2. For the "A1 Double-precision scalar", "A1 Single-precision scalar", "T1 Double-precision scalar", and "T1 Single-precision scalar" variants: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.						
.32	Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.						
.64	Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.						
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    let base : bits(32) = if n == 15 then AlignDownSize(PC32(),4) else R(n);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    case esize of
        when 16 =>
            H(d) = MemA{16}(address);
        when 32 =>
            S(d) = MemA{32}(address);
        when 64 =>
            let word1 : bits(32) = MemA{32}(address);
            let word2 : bits(32) = MemA{32}(address+4);
            // Combine the word-aligned words in the correct order for current endianness.
            D(d) = if BigEndian(AccessType_ASIMD) then word1::word2 else word2::word1;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VLDR (literal)

Load SIMD&FP register (literal) loads a single register from the Advanced SIMD and floating-point register file, using an address from the PC value and an immediate offset.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	0	1	U	D	0	1	1	1	1	1	Vd				1	0	size		imm8							
cond				P				W				L	Rn																		

Encoding for the Half-precision scalar variant (FEAT_FP16)

Applies when (size == 01)

```
VLDR{<c>}{<q>}.16 <Sd>, <label> // (Preferred syntax)
VLDR{<c>}{<q>}.16 <Sd>, [PC, #{+/-}<imm>]
```

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VLDR{<c>}{<q>}.32 <Sd>, <label> // (Preferred syntax)
VLDR{<c>}{<q>}.32 <Sd>, [PC, #{+/-}<imm>]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VLDR{<c>}{<q>}.64 <Dd>, <label> // (Preferred syntax)
VLDR{<c>}{<q>}.64 <Dd>, [PC, #{+/-}<imm>]
```

Decode for all variants of this encoding

```
if size == '00' || (size == '01' && !IsFeatureImplemented(FEAT_FP16)) then Undefined(); end;
if size == '01' && cond != '1110' then UnpredictableProcedure(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Encoding for the Half-precision scalar variant (FEAT_FP16)

Applies when (size == 01)

```
VLDR{<c>}{<q>}.16 <Sd>, <label> // (Preferred syntax)
VLDR{<c>}{<q>}.16 <Sd>, [PC, #{+/-}<imm>]
```

Encoding for the Single-precision scalar variant

Applies when (size == 10)

```
VLDR{<c>}{<q>}{.32} <Sd>, <label> // (Preferred syntax)

VLDR{<c>}{<q>}{.32} <Sd>, [PC, #{+/-}<imm>]
```

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VLDR{<c>}{<q>}{.64} <Dd>, <label> // (Preferred syntax)

VLDR{<c>}{<q>}{.64} <Dd>, [PC, #{+/-}<imm>]
```

Decode for all variants of this encoding

```
if size == '00' || (size == '01' && !IsFeatureImplemented(FEAT_FP16)) then Undefined(); end;
if size == '01' && InITBlock() then UnpredictableProcedure(); end;
let add : boolean = (U == '1');
let esize : integer{} = 8 << UInt(size);
let imm32 : integer = UInt(imm8) << (if size == '01' then 1 else 2);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = UInt(Rn);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>	See Standard assembler syntax fields .						
<q>	See Standard assembler syntax fields .						
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.						
<label>	The label of the literal data item to be loaded. For the single-precision scalar or double-precision scalar variants: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020. For the half-precision scalar variant: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 2 in the range -510 to 510. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.						
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U": <table><tr><th>U</th><th>+/-</th></tr><tr><td>0</td><td>-</td></tr><tr><td>1</td><td>+</td></tr></table>	U	+/-	0	-	1	+
U	+/-						
0	-						
1	+						
<imm>	For the "A1 Half-precision scalar" and "T1 Half-precision scalar" variants: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2. For the "A1 Double-precision scalar", "A1 Single-precision scalar", "T1 Double-precision scalar", and "T1 Single-precision scalar" variants: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.						
.32	Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.						
.64	Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.						
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field. The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see Use of labels in UAL instruction syntax .						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEnabled(TRUE);
    let base : bits(32) = if n == 15 then AlignDownSize(PC32(),4) else R(n);
    let address : bits(32) = if add then (base + imm32) else (base - imm32);
    case esize of
        when 16 =>
            H(d) = MemA{16}(address);
        when 32 =>
            S(d) = MemA{32}(address);
        when 64 =>
            let word1 : bits(32) = MemA{32}(address);
            let word2 : bits(32) = MemA{32}(address+4);
            // Combine the word-aligned words in the correct order for current endianness.
            D(d) = if BigEndian(AccessType_ASIMD) then word1::word2 else word2::word1;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VMAX (floating-point)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Floating-point maximum and minimum							
- max(+0.0, -0.0) = +0.0 - If any input is a NaN, the corresponding result element is the default NaN.							

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1 : bits(esize) = D(n+r)[e*:esize];
            let op2 : bits(esize) = D(m+r)[e*:esize];
            if maximum then
                D(d+r)[e*:esize] = FPMMax{esize}(op1, op2, fpcr);
            else
                D(d+r)[e*:esize] = FPMMin{esize}(op1, op2, fpcr);
            end;
        end;
    end;
end;
```

VMAX (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = (if maximum then Max(element1, element2)
                                   else Min(element1, element2));
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VMAXNM

This instruction determines the floating-point maximum number.

It handles NaNs in consistence with the IEEE 754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMAX.

This instruction is not conditional.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VMIN (floating-point)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements are floating-point numbers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

- <c>

For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.
- <q>

For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#).
- <dt>

See [Standard assembler syntax fields](#).
- <dt>

Is the data type for the elements of the vectors, encoded in "sz":

sz	<dt>
0	F32
1	F16
- <Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
- <Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
- <Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
- <Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
- <Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
- Floating-point minimum

- min(+0.0, -0.0) = -0.0
 - If any input is a NaN, the corresponding result element is the default NaN.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1 : bits(esize) = D(n+r)[e*:esize];
            let op2 : bits(esize) = D(m+r)[e*:esize];
            if maximum then
                D(d+r)[e*:esize] = FPMMax{esize}(op1, op2, fpcr);
            else
                D(d+r)[e*:esize] = FPMMin{esize}(op1, op2, fpcr);
            end;
        end;
    end;
end;
```

VMIN (integer)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

            let op2elt : bits(esize) = D(m+r)[e*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = (if maximum then Max(element1, element2)
                                   else Min(element1, element2));
            D(d+r)[e*:esize] = result[esize-1:0];
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VMINNM

This instruction determines the floating point minimum number.

It handles NaNs in consistence with the IEEE 754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point `VMIN`.

This instruction is not conditional.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

VMLA (by scalar)

Vector Multiply Accumulate multiplies elements of a vector by a scalar, and adds the products to corresponding elements of the destination vector. For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	Q	1	D	!= 11					Vn					Vd		0	0	0	F	N	1	M	0		Vm
size												op																			

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm[x>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x>

Decode for all variants of this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01' && !IsFeatureImplemented(FEAT_FP16)) then
  Undefined();
end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let add : boolean = (op == '0');
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

size												op																			

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLA{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm[x>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLA{<c>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x>

Decode for all variants of this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01' && !IsFeatureImplemented(FEAT_FP16)) then
  Undefined();
end;
if F == '1' && size == '01' && InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let add : boolean = (op == '0');
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

CONSTRAINED UNPREDICTABLE behavior

If F == '1' && size == '01' && InITBlock(), then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c> For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<dt> Is the data type for the scalar and the elements of the operand vector, encoded in “(F :: size)”:

F	size	<dt>
0	01	I16
0	10	I32
1	01	F16
1	10	F32

<Dd> Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm[x> Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is I16 or F16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is I32 or F32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

<Qd> Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    let op2elt : bits(esize) = Din(m)[index*:esize];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            if floating_point then
                let fp_addend : bits(esize) = (if add then FPMul{esize}(op1elt, op2elt, fpcr)
                                                else FPNeg{esize}(FPMul{esize}(op1elt, op2elt,
                                                                    fpcr),
                                                                    fpcr));
                D(d+r)[e*:esize] = FPAdd{esize}(Din(d+r)[e*:esize], fp_addend, fpcr);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                let addend : integer = if add then element1*element2 else -element1*element2;
                if long_destination then
                    Q(d>>1)[e*:(2*esize)] = Qin(d>>1)[e*:(2*esize)] + addend;
                else
                    D(d+r)[e*:esize] = Din(d+r)[e*:esize] + addend;
                end;
            end;
        end;
    end;
end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

        end;
    end;
end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

VMLAL (by scalar)

Vector Multiply Accumulate Long multiplies elements of a vector by a scalar, and adds the products to corresponding elements of the destination vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VMLS (by scalar)

Vector Multiply Subtract multiplies elements of a vector by a scalar, and either subtracts the products from corresponding elements of the destination vector.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm[x>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x>

Decode for all variants of this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01' && !IsFeatureImplemented(FEAT_FP16)) then
  Undefined();
end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let add : boolean = (op == '0');
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

T1

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VMLS{<c>}{<q>}.<dt> <Dd>, <Dn>, <Dm[x>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VMLS{<c>}{<q>}.<dt> <Qd>, <Qn>, <Dm[x>

Decode for all variants of this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || (F == '1' && size == '01' && !IsFeatureImplemented(FEAT_FP16)) then
  Undefined();
end;
if F == '1' && size == '01' && InITBlock() then UnpredictableProcedure(); end;
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1') then Undefined(); end;
let unsigned : boolean = FALSE; // "Don't care" value: TRUE produces same functionality
let add : boolean = (op == '0');
let floating_point : boolean = (F == '1');
let long_destination : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = if Q == '0' then 1 else 2;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c> For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#).

<q> See [Standard assembler syntax fields](#).

<dt> Is the data type for the scalar and the elements of the operand vector, encoded in “(F :: size)”:

F	size	<dt>
0	01	I16
0	10	I32
1	01	F16
1	10	F32

<Dd> Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm[x> Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is I16 or F16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is I32 or F32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

<Qd> Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    let op2elt : bits(esize) = Din(m)[index*:esize];
    for r = 0 to regs-1 do

VMLS (floating-point)

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

Note

Arm recommends that software does not use the `VMLS` instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the `CPACR`, `NSACR`, `HCPTR`, and `FPEXC` registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be `UNDEFINED`, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

VMLS (integer)

Vector Multiply Subtract multiplies corresponding elements in two vectors, and subtracts the products from the corresponding elements of the destination vector.

Depending on settings in the *CPACR*, *NSACR*, and *HCPtr* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

            end;
        end;
    end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VMMLA

BFloat16 floating-point matrix multiply-accumulate. This instruction multiplies the 2x4 matrix of BF16 values in the first 128-bit source vector by the 4x2 BF16 matrix in the second 128-bit source vector. The resulting 2x2 single-precision matrix product is then added destructively to the 2x2 single-precision matrix in the 128-bit destination vector. This is equivalent to performing a 4-way dot product per destination element. The instruction does not update the *FPSCR* exception status.

Note

Arm expects that the VMMLA instruction will deliver a peak BF16 multiply throughput that is at least as high as can be achieved using two VDOT instructions, with a goal that it should have significantly higher throughput.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

Encoding

VMMLA{<q>}.BF16 <Qd>, <Qn>, <Qm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_AA32BF16) then Undefined(); end;
if Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1' then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = 2;
```

Assembler Symbols

<q>	See <i>Standard assembler syntax fields</i> .
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
CheckAdvSIMDEnabled();

let operand1 : bits(128) = Q(n>>1);
let operand2 : bits(128) = Q(m>>1);
let acc : bits(128) = Q(d>>1);
let fpcr : FPCR_Type = EffectiveFPCR();

Q(d>>1) = BFMatMulAddH(acc, operand1, operand2, fpcr);
```

VMOV (between general-purpose register and half-precision)

Copy 16 bits of a general-purpose register to or from a 32-bit SIMD&FP register. This instruction transfers the value held in the bottom 16 bits of a 32-bit SIMD&FP register to the bottom 16 bits of a general-purpose register, or the value held in the bottom 16 bits of a general-purpose register to the bottom 16 bits of a 32-bit SIMD&FP register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPExc](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

(FEAT_FP16)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1 1 1 0 0 0 0				op	Vn							Rt				1 0 0 1				N	(0) (0)		1	(0) (0)		(0)	(0)
cond																															

Encoding for the From general-purpose register variant

Applies when (op == 0)

VMOV{<c>}{<q>}.F16 <Sn>, <Rt>

Encoding for the To general-purpose register variant

Applies when (op == 1)

VMOV{<c>}{<q>}.F16 <Rt>, <Sn>

Decode for all variants of this encoding

```
if !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if cond != '1110' then UnpredictableProcedure(); end;
let to_arm_register : boolean = (op == '1');
let t : integer = UInt(Rt);
let n : integer = UInt(Vn::N);
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

VMOV (general-purpose register to scalar)

Copy a general-purpose register to a vector element copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, *HCPtr*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

VMOV (immediate)

Copy immediate value to a SIMD&FP register places an immediate constant into every element of the destination register.

Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#), [A2](#), [A3](#), [A4](#) and [A5](#)) and T32 ([T1](#), [T2](#), [T3](#), [T4](#) and [T5](#)).

A1

let advsimd : boolean = FALSE;
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let regs : integer = if size == '11' then 1 else 0;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

VMOV (register, SIMD)

Copy between SIMD registers copies the contents of one SIMD register to another.

This is an alias of [VORR \(register\)](#). This means:

- The encodings in this description are named to match the encodings of [VORR \(register\)](#).
- The description of [VORR \(register\)](#) gives the operational pseudocode, any `CONSTRAINED UNPREDICTABLE` behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VMOV (scalar to general-purpose register)

Copy a vector element to a general-purpose register with sign or zero extension copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, *HCPtr*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)) .

A1

if t == 15 then UnpredictableProcedure(); end;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

- <c> See *Standard assembler syntax fields*.
- <q> See *Standard assembler syntax fields*.

<dt>	The data type. It must be one of:
S8	Encoded as U = 0, opc1<1> = 1. [x] is encoded in opc1<0>, opc2.
S16	Encoded as U = 0, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.
U8	Encoded as U = 1, opc1<1> = 1. [x] is encoded in opc1<0>, opc2.
U16	Encoded as U = 1, opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.
32	Encoded as U = 0, opc1<1> = 0, opc2 = 0b00. [x] is encoded in opc1<0>.
omitted	Equivalent to 32.

<Rt>	The destination general-purpose register.
<Dn[x]>	The scalar. For details of how [x] is encoded see the description of <dt>.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDOrVFPEEnabled(TRUE, advsimd);
    if unsigned then
        R(t) = ZeroExtend{32}(D(n)[index*:esize]);
    else
        R(t) = SignExtend{32}(D(n)[index*:esize]);
    end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VMOVL

Vector Move Long takes each element in a doubleword vector, sign or zero-extends them to twice their original length, and places the results in a quadword vector.

Depending on settings in the *CPACR*, *NSACR*, and *HCPtr* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let unsigned : boolean = (U == '1');
```

Related encodings: See *Advanced SIMD one register and modified immediate* for the T32 instruction set, or *Advanced SIMD one register and modified immediate* for the A32 instruction set.

Assembler Symbols

<c>

For the "A1" variant: see *Standard assembler syntax fields*. This encoding must be unconditional.
For the "T1" variant: see *Standard assembler syntax fields*.

<q>

See *Standard assembler syntax fields*.

<dt>

Is the data type for the elements of the operand, encoded in “(U :: imm3H)”:

U	imm3H	<dt>
0	001	S8
0	010	S16
0	100	S32
1	001	U8
1	010	U16
1	100	U32

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        let oplelt : bits(esize) = Din(m)[e*:esize];
        let result : integer = if unsigned then UInt(oplelt) else SInt(oplelt);
        Q(d>>1)[e*(2*esize)] = result[2*esize-1:0];
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the pseudo-instructions *VRSHRN (zero)*, and *VSHRN (zero)*.

It has encodings from the following instruction sets: A32 (*A1*) and T32 (*T1*).

A1

Encoding

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

Decode for this encoding

```
if size == '11' then Undefined(); end;
if Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

T1

Encoding

VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>

Decode for this encoding

```
if size == '11' then Undefined(); end;
if Vm[0] == '1' then Undefined(); end;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let m : integer = UInt(M::Vm);
```

Assembler Symbols

- <c>For the "A1" variant: see *Standard assembler syntax fields*. This encoding must be unconditional.
For the "T1" variant: see *Standard assembler syntax fields*.
- <q>See *Standard assembler syntax fields*.
- <dt>Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	I16
01	I32
10	I64
11	RESERVED
- <Dd>Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <Qm>Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for e = 0 to elements-1 do
        D(d)[e*esize] = Q(qin(m>>1)[e*(2*esize)][esize-1:0]);
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

Copyright © 2010-2026 Arm Limited or its affiliates. All rights reserved. This document is Non-Confidential.

VMOVX

Vector Move extraction. This instruction copies the upper 16 bits of the 32-bit source SIMD&FP register into the lower 16 bits of the 32-bit destination SIMD&FP register, while clearing the remaining bits to zero.

Depending on settings in the *CPACR*, *NSACR*, *HCPtr*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1 (FEAT_FP16)

Encoding

VMOVX{<q>}.F16 <Sd>, <Sm>

Decode for this encoding

```
if !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let d : integer = UInt(Vd::D);
let m : integer = UInt(Vm::M);
```

T1 (FEAT_FP16)

Encoding

VMOVX{<q>}.F16 <Sd>, <Sm>

Decode for this encoding

```
if InITBlock() then UnpredictableProcedure(); end;
if !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
let d : integer = UInt(Vd::D);
let m : integer = UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

- If `InITBlock()`, then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as if it passes the Condition code check.
 - The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

- <q> See *Standard assembler syntax fields*.
- <Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
- <Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckVFPEEnabled(TRUE);
    H(d) = S(m) [31:16];
end;
```

VMRS

Move SIMD&FP Special register to general-purpose register moves the value of an Advanced SIMD and floating-point System register to a general-purpose register. When the specified System register is the *FPSCR*, a form of the instruction transfers the *FPSCR*. {N, Z, C, V} condition flags to the *APSR*. {N, Z, C, V} condition flags.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

When these settings permit the execution of Advanced SIMD and floating-point instructions, if the specified floating-point System register is not the *FPSCR*, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when *HCR.TID0* is set to 1, any VMRS access to *FPSID* from a Non-secure EL1 mode that would be permitted if *HCR.TID0* was set to 0 generates a Hyp Trap exception. For more information, see *EL2 configurable controls*.

For simplicity, the VMRS pseudocode does not show the possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	1	0	1	1	1	1	reg				Rt				1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)
cond												L																			

Encoding

VMRS{<c>} {<q>} <Rt>, <spec_reg>

Decode for this encoding

```
let t : integer = UInt(Rt);
if ! reg IN {'000x', '0101', '011x', '1000'} then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 && reg != '0001' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If ! reg IN {'000x', '0101', '011x', '1000'}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the *APSR*. {N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
1	1	1	0	1	1	1	0	1	1	1	1	reg				Rt				1	0	1	0	(0)	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)
																L																

Encoding

VMRS{<c>} {<q>} <Rt>, <spec_reg>

Decode for this encoding

```
let t : integer = UInt(Rt);
if ! reg IN {'000x', '0101', '011x', '1000'} then UnpredictableProcedure(); end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 && reg != '0001' then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If ! reg IN {'000x', '0101', '011x', '1000'}, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the *APSR*. {N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>

See *Standard assembler syntax fields*.

<q>

See *Standard assembler syntax fields*.

<Rt>

Is the general-purpose destination register, encoded in the "Rt" field. Is one of:

R0-R14

General-purpose register.

APSR_nzcv

Permitted only when <spec_reg> is FPSCR. Encoded as 0b1111. The instruction transfers the *FPSCR*. {N, Z, C, V} condition flags to the *APSR*. {N, Z, C, V} condition flags.

<spec_reg>

Is the source Advanced SIMD and floating-point System register, encoded in "reg":

reg	<spec_reg>
0000	FPSID
0001	FPSCR
001x	UNPREDICTABLE
0100	UNPREDICTABLE
0101	MVFR2
0110	MVFR1
0111	MVFR0
1000	FPEXC
1001	UNPREDICTABLE
101x	UNPREDICTABLE
11xx	UNPREDICTABLE

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then // FPSCR
        CheckVFPEEnabled(TRUE);
        if t == 15 then
            PSTATE.[N,Z,C,V] = FPSR().[N,Z,C,V];
        else
            R(t) = FPSCR();
        end;
    elseif PSTATE.EL == ELO then // Non-FPSCR registers accessible only at PL1 or above
        Undefined();
    else
        CheckVFPEEnabled(FALSE); // Non-FPSCR registers are not affected by FPEXC.EN
        AArch32.CheckAdvSIMDOrFPRegisterTraps(reg);
        case reg of
            when '0000' => R(t) = FPSID();
            when '0101' => R(t) = MVFR2();
            when '0110' => R(t) = MVFR1();
            when '0111' => R(t) = MVFR0();
            when '1000' => R(t) = FPEXC();
            otherwise => unreachable; // Dealt with above or in encoding-specific pseudocode
        end;
    end;
end;
end;

```

VMSR

Move general-purpose register to SIMD&FP Special register moves the value of a general-purpose register to a floating-point System register. Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPEXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

When these settings permit the execution of Advanced SIMD and floating-point instructions:

- If the specified floating-point System register is [FPSID](#) or [FPEXC](#), the instruction is UNDEFINED if executed in User mode.
- If the specified floating-point System register is the [FPSID](#) and the instruction is executed in a mode other than User mode, the instruction is ignored.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	1	0	1	1	1	0	reg				Rt				1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)
cond								L																							

Encoding

VMSR{<c>}{<q>} <spec_reg>, <Rt>

Decode for this encoding

```
let t : integer = UInt(Rt);
if reg != '000x' && reg != '1000' then
  let c : Constraint = ConstrainUnpredictable(Unpredictable VMSR);
  assert c IN {Constraint UNDEF, Constraint NOP};
  case c of
    when Constraint UNDEF =>
      Undefined();
    when Constraint NOP =>
      ExecuteAsNOP();
  end;
end;
// Armv8-A removes UNPREDICTABLE for R13
if t == 15 then UnpredictableProcedure(); end;
```

CONSTRAINED UNPREDICTABLE behavior

If `reg != '000x' && reg != '1000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction transfers the value in the general-purpose register to one of the allocated registers accessible using VMSR at the same Exception level.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	1	1	0	1	1	1	0	reg				Rt				1	0	1	0	(0)	(0)	(0)	1	(0)	(0)	(0)	(0)
L																															

Encoding

VMSR{<c>}{<q>} <spec_reg>, <Rt>

Decode for this encoding

```
let t : integer = UInt(Rt);
if reg != '000x' && reg != '1000' then
  let c : Constraint = ConstrainUnpredictable(Unpredictable VMSR);
  assert c IN {Constraint UNDEF, Constraint NOP};

VMUL (by scalar)

Vector Multiply multiplies each element in a vector by a scalar, and places the results in a second vector.

For more information about scalars see [Advanced SIMD scalars](#).

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	Q	1	D	!= 11			Vn			Vd			1 0 0			F	N	1	M	0	Vm				
size																															

Encoding for the 64-bit SIMD vector variant

let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
 - The instruction executes as if it passes the Condition code check.
 - The instruction executes as NOP. This means it behaves as if it fails the Condition code check.
- Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#). This encoding must be unconditional.

For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see [Standard assembler syntax fields](#).

<q>

See [Standard assembler syntax fields](#).

<dt>

Is the data type for the scalar and the elements of the operand vector, encoded in “(F :: size)”:

F	size	<dt>
0	01	I16
0	10	I32
1	01	F16
1	10	F32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register. When <dt> is I16 or F16, this is encoded in the "Vm<2:0>" field. Otherwise it is encoded in the "Vm" field.

<index>

Is the element index. When <dt> is I16 or F16, this is in the range 0 to 3 and is encoded in the "M:Vm<3>" field. Otherwise it is in the range 0 to 1 and is encoded in the "M" field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn>

Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    let op2elt : bits(esize) = Din(m)[index*:esize];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            if floating_point then
                D(d+r)[e*:esize] = FPMul{esize}(op1elt, op2elt, fpcr);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                if long_destination then
                    Q(d>>1)[e*(2*esize)] = (element1 * element2)[2*esize-1:0];
                else
                    D(d+r)[e*:esize] = (element1 * element2)[esize-1:0];
                end;
            end;
        end;
    end;
end;
```

VMUL (floating-point)

Vector Multiply multiplies corresponding elements in two vectors, and places the results in the destination vector. Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*. It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

VMULL (by scalar)

Vector Multiply Long multiplies each element in a vector by a scalar, and places the results in a second vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPtr* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

Encoding

```
VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]
```

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let floating_point : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = 1;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

T1

Encoding

```
VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]
```

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if size == '00' || Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let long_destination : boolean = TRUE;
let floating_point : boolean = FALSE;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let regs : integer = 1;
let esize : integer{} = 8 << UInt(size);
let elements : integer = 64 DIV esize;
let m : integer = if size == '01' then UInt(Vm[2:0]) else UInt(Vm);
let index : integer = if size == '01' then UInt(M::Vm[3]) else UInt(M);
```

Related encodings: See *Advanced SIMD data-processing* for the T32 instruction set, or *Advanced SIMD data-processing* for the A32 instruction set.

Assembler Symbols

- <c>

For the "A1" variant: see *Standard assembler syntax fields*. This encoding must be unconditional.
- <q>

For the "T1" variant: see *Standard assembler syntax fields*.
- <dt>

See *Standard assembler syntax fields*.
- <Qd>

Is the data type for the scalar and the elements of the operand vector, encoded in “(U :: size)”:

U	size	<dt>
0	01	S16
0	10	S32
1	01	U16
1	10	U32
- <Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16 or U16, otherwise the "Vm" field.
<index>	Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16 or U16, otherwise in range 0 to 1, encoded in the "M" field.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    let op2elt : bits(esize) = Din(m)[index*:esize];
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            if floating_point then
                D(d+r)[e*:esize] = FPMul(esize)(op1elt, op2elt, fpcr);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                if long_destination then
                    Q(d>>1)[e*:(2*esize)] = (element1 * element2)[2*esize-1:0];
                else
                    D(d+r)[e*:esize] = (element1 * element2)[esize-1:0];
                end;
            end;
        end;
    end;
end;
end;
end;

```

VMULL (integer and polynomial)

Vector Multiply Long multiplies corresponding elements in two vectors. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see [Polynomial arithmetic over {0, 1}](#).

Depending on settings in the *CPACR*, *NSACR*, and *HCPTTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	U	1	D	!= 11		Vn			Vd			1 1		op	0	N	0	M	0	Vm					
size																															

Encoding

VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if op == '1' && (U == '1' || size == '01') then Undefined(); end;
if op == '1' && size == '10' && !IsFeatureImplemented(FEAT_PMULL) then Undefined(); end;
if Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let polynomial : boolean = (op == '1');
let long_destination : boolean = TRUE;
let esize : integer{} = if polynomial && size == '10' then 64 else 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	U	1	1	1	1	1	D	!= 11			Vn			Vd			1			1	op	0	N	0	M	0	Vm		
										size																					

Encoding

VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>

Decode for this encoding

```
if size == '11' then See("Related encodings"); end;
if op == '1' && (U == '1' || size == '01') then Undefined(); end;
if op == '1' && size == '10' && InITBlock() then UnpredictableProcedure(); end;
if op == '1' && size == '10' && !IsFeatureImplemented(FEAT_PMULL) then
  UnpredictableProcedure();
end;
if Vd[0] == '1' then Undefined(); end;
let unsigned : boolean = (U == '1');
let polynomial : boolean = (op == '1');
let long_destination : boolean = TRUE;
let esize : integer{} = if polynomial && size == '10' then 64 else 8 << UInt(size);
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let elements : integer = 64 DIV esize;
let regs : integer = 1;
```

CONSTRAINED UNPREDICTABLE behavior

If `op == '1' && size == '10' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see [Architectural Constraints on UNPREDICTABLE behaviors](#).

Related encodings: See [Advanced SIMD data-processing](#) for the T32 instruction set, or [Advanced SIMD data-processing](#) for the A32 instruction set.

Assembler Symbols

<c>

For the "A1" variant: see *Standard assembler syntax fields*. This encoding must be unconditional.
For the "T1" variant: see *Standard assembler syntax fields*.

<q>

See *Standard assembler syntax fields*.

<dt>

Is the data type for the elements of the operands, encoded in "(op :: U :: size)":

op	U	size	<dt>
0	0	00	S8
0	0	01	S16
0	0	10	S32
0	1	00	U8
0	1	01	U16
0	1	10	U32
1	0	00	P8
1	0	10	P64

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dn>

Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm>

Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        for e = 0 to elements-1 do
            let op1elt : bits(esize) = Din(n+r)[e*:esize];
            let op2elt : bits(esize) = Din(m+r)[e*:esize];
            var product : bits(2 * esize);
            if polynomial then
                product = PolynomialMult(esize, esize)(op1elt, op2elt);
            else
                let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
                let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
                product = (element1 * element2)[2*esize-1:0];
            end;
            if long_destination then
                Q(d>>1)[e*(2*esize)] = product;
            else
                D(d+r)[e*:esize] = product[esize-1:0];
            end;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VMVN (immediate)

Vector Bitwise NOT (immediate) places the bitwise inverse of an immediate integer constant into every element of the destination register. Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) , [A2](#) and [A3](#)) and T32 ([T1](#) , [T2](#) and [T3](#)).

VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

VNEG

Vector Negate negates each element in a vector, and places the results in a second vector. The floating-point version only inverts the sign bit. Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPFXC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VNMLA

Vector Negate Multiply Accumulate multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

Note

Arm recommends that software does not use the VNMLA instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the CPACR, NSACR, HCPTR, and FPEXC registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VNMUL

Vector Negate Multiply multiplies together two floating-point register values, and writes the negation of the result to the destination register. Depending on settings in the [CPACR](#), [NSACR](#), [HCPTR](#), and [FPExC](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				1	1	1	0	0	D	1	0	Vn				Vd				1	0	size	N	1	M	0	Vm				
cond				o0				o1				o2																			

Encoding for the Half-precision scalar variant (FEAT_FP16)

Applies when (size == 01)

VNMUL{<c>}{<q>}.F16 {<Sd>, }<Sn>, <Sm>

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VNMUL{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

VNMUL{<c>}{<q>}.F64 {<Dd>, }<Dn>, <Dm>

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size == '01' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if size == '01' && cond != '1110' then UnpredictableProcedure(); end;
let vtype : VFPNegMul = VFPNegMul VNMUL;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If size == '01' && cond != '1110', then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
1	1	1	0	1	1	1	0	0	D	1	0	Vn				Vd				1	0	size	N	1	M	0	Vm

Encoding for the Half-precision scalar variant (FEAT_FP16)

Applies when (size == 01)

VNMUL{<c>}{<q>}.F16 {<Sd>, }<Sn>, <Sm>

Encoding for the Single-precision scalar variant

Applies when (size == 10)

VNMUL{<c>}{<q>}.F32 {<Sd>, }<Sn>, <Sm>

Encoding for the Double-precision scalar variant

Applies when (size == 11)

```
VNMUL{<c>}{<q>}.F64 {<Dd>, }<Dn>, <Dm>
```

Decode for all variants of this encoding

```
if FPSCR().Len != '000' || FPSCR().Stride != '00' then Undefined(); end;
if size == '01' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if size == '01' && InITBlock() then UnpredictableProcedure(); end;
let vtype : VFPNegMul = VFPNegMul_VNMUL;
let esize : integer{} = 8 << UInt(size);
let d : integer = if size == '11' then UInt(D::Vd) else UInt(Vd::D);
let n : integer = if size == '11' then UInt(N::Vn) else UInt(Vn::N);
let m : integer = if size == '11' then UInt(M::Vm) else UInt(Vm::M);
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>	See Standard assembler syntax fields .
<q>	See Standard assembler syntax fields .
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

VORN (immediate)

Vector Bitwise OR NOT (immediate) performs a bitwise OR between a register value and the complement of an immediate value, and returns the result into the destination vector.

This is a pseudo-instruction of [VORR \(immediate\)](#). This means:

- The encodings in this description are named to match the encodings of [VORR \(immediate\)](#).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of [VORR \(immediate\)](#) gives the operational pseudocode, any **CONSTRAINED UNPREDICTABLE** behavior, and any operational information for this instruction.

It has encodings from the following instruction sets: A32 ([A1](#) and [A2](#)) and T32 ([T1](#) and [T2](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

- <c>

For the "A1 128-bit SIMD vector", "A1 64-bit SIMD vector", "A2 128-bit SIMD vector", and "A2 64-bit SIMD vector" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.
For the "T1 128-bit SIMD vector", "T1 64-bit SIMD vector", "T2 128-bit SIMD vector", and "T2 64-bit SIMD vector" variants: see *Standard assembler syntax fields*.
- <q>

See *Standard assembler syntax fields*.
- <Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <imm>

Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions*.
- <Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

Operation

The description of [VORR \(immediate\)](#) gives the operational pseudocode for this instruction.

Operational Information

The description of [VORR \(immediate\)](#) gives the operational information for this instruction.

VORN (register)

Vector bitwise OR NOT (register) performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORN{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORN{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>	For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see <i>Standard assembler syntax fields</i> . This encoding must be unconditional. For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see <i>Standard assembler syntax fields</i> .
<q>	See <i>Standard assembler syntax fields</i> .
<dt>	An optional data type. It is ignored by assemblers, and does not affect the encoding.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed\(\) then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled\(\);
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) OR NOT(D(m+r));
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

let regs : integer = if Q == '0' then 1 else 2;

```

Assembler Symbols

- <c> For the "A1 128-bit SIMD vector", "A1 64-bit SIMD vector", "A2 128-bit SIMD vector", and "A2 64-bit SIMD vector" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.
- <q> For the "T1 128-bit SIMD vector", "T1 64-bit SIMD vector", "T2 128-bit SIMD vector", and "T2 64-bit SIMD vector" variants: see *Standard assembler syntax fields*.
- <Dd> See *Standard assembler syntax fields*.
- <Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
- <imm> Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions*.
- <Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

Operation

```

if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(d+r) OR imm64;
    end;
end;

```

Operational information

This instruction is a data-independent-time instruction as described in *About the DIT bit*.

VORR (register)

Vector bitwise OR (register) performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the *CPACR*, *NSACR*, and *HCPtr* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the alias *VMOV (register, SIMD)*.

This instruction is used by the pseudo-instructions *VRSHR (zero)*, and *VSHR (zero)*.

It has encodings from the following instruction sets: A32 (*A1*) and T32 (*T1*).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Encoding for the 64-bit SIMD vector variant

Applies when (Q == 0)

VORR{<c>}{<q>}{.<dt>} {<Dd>, }<Dn>, <Dm>

Encoding for the 128-bit SIMD vector variant

Applies when (Q == 1)

VORR{<c>}{<q>}{.<dt>} {<Qd>, }<Qn>, <Qm>

Decode for all variants of this encoding

```
if Q == '1' && (Vd[0] == '1' || Vn[0] == '1' || Vm[0] == '1') then Undefined(); end;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>	For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see <i>Standard assembler syntax fields</i> . This encoding must be unconditional. For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see <i>Standard assembler syntax fields</i> .
<q>	See <i>Standard assembler syntax fields</i> .
<dt>	An optional data type. It is ignored by assemblers, and does not affect the encoding.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm>

Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Alias Conditions

Alias	Is preferred when
VMOV (register, SIMD)	N :: Vn == M :: Vm
VRSHR (zero)	Never
VSHR (zero)	Never

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    for r = 0 to regs-1 do
        D(d+r) = D(n+r) OR D(m+r);
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows an example of the operation of VPADAL doubleword operation for data type S16.

Depending on settings in the [CPACR](#), [NSACR](#), and [HCPTR](#) registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see [Enabling Advanced SIMD and floating-point support](#).

It has encodings from the following instruction sets: A32 ([A1](#)) and T32 ([T1](#)).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

let regs : integer = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>

For the "A1 128-bit SIMD vector" and "A1 64-bit SIMD vector" variants: see *Standard assembler syntax fields*. This encoding must be unconditional.

For the "T1 128-bit SIMD vector" and "T1 64-bit SIMD vector" variants: see *Standard assembler syntax fields*.

See *Standard assembler syntax fields*.

Is the data type for the elements of the vectors, encoded in “(op :: size)”:

op	size	<dt>
0	00	S8
0	01	S16
0	10	S32
x	11	RESERVED
1	00	U8
1	01	U16
1	10	U32

<Dd>

Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm>

Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<Qd>

Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm>

Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let h : integer = elements DIV 2;

    for r = 0 to regs-1 do
        for e = 0 to h-1 do
            let op1elt : bits(esize) = D(m+r)[(2*e)*:esize];
            let op2elt : bits(esize) = D(m+r)[(2*e+1)*:esize];
            let element1 : integer = if unsigned then UInt(op1elt) else SInt(op1elt);
            let element2 : integer = if unsigned then UInt(op2elt) else SInt(op2elt);
            let result : integer = element1 + element2;
            D(d+r)[e*(2*esize)] = D(d+r)[e*(2*esize)] + result;
        end;
    end;
end;
```

Operational information

This instruction is a data-independent-time instruction as described in [About the DIT bit](#).

VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector. The operands and result are doubleword vectors. The operand and result elements are floating-point numbers. Depending on settings in the CPACR, NSACR, and HCPTR registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see Enabling Advanced SIMD and floating-point support. It has encodings from the following instruction sets: A32 (A1) and T32 (T1).

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	0	D	0	sz	Vn				Vd				1	1	0	1	N	Q	M	0	Vm			
U												opc								o1											

Encoding

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```
if Q == '1' then Undefined(); end;
if sz == '1' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	0	D	0	sz	Vn				Vd				1	1	0	1	N	Q	M	0	Vm			
U												opc								o1											

Encoding

VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>

Decode for this encoding

```
if Q == '1' then Undefined(); end;
if sz == '1' && !IsFeatureImplemented(FEAT_FP16) then Undefined(); end;
if sz == '1' && InITBlock() then UnpredictableProcedure(); end;
let esize : integer{} = 32 >> UInt(sz);
let elements : integer = 64 DIV esize;
let d : integer = UInt(D::Vd);
let n : integer = UInt(N::Vn);
let m : integer = UInt(M::Vm);
```

CONSTRAINED UNPREDICTABLE behavior

- If sz == '1' && InITBlock(), then one of the following behaviors must occur:
- The instruction is UNDEFINED.
 - The instruction executes as if it passes the Condition code check.
 - The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>	For the "A1" variant: see Standard assembler syntax fields. This encoding must be unconditional. For the "T1" variant: see Standard assembler syntax fields.						
<q>	See Standard assembler syntax fields.						
<dt>	Is the data type for the elements of the vectors, encoded in “sz”: <table><tr><th>sz</th><th><dt></th></tr><tr><td>0</td><td>F32</td></tr><tr><td>1</td><td>F16</td></tr></table>	sz	<dt>	0	F32	1	F16
sz	<dt>						
0	F32						
1	F16						
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.						
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.						
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.						

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    CheckAdvSIMDEnabled();
    let fpcr : FPCR_Type = StandardFPCR();
    var dest : bits(64);
    let h : integer = elements DIV 2;

    for e = 0 to h-1 do
        dest[e*:esize] = FPAdd{esize}( D(n)[(2*e)*:esize], D(n)[(2*e+1)*:esize], fpcr);
        dest[(e+h)*:esize] = FPAdd{esize}( D(m)[(2*e)*:esize], D(m)[(2*e+1)*:esize], fpcr);
    end;

    D(d) = dest;
end;
```
