Arm® A32/T32 Instruction Set Architecture

Armv8, for Armv8-A architecture profile

DDI 0597 (ID092421)

Arm A32/T32 Instruction Set Architecture
Armv8, for Armv8-A architecture profile

Release Information

For information on the change history and known issues for this release, see the **Release Notes** in the **A32/T32 ISA XML for Armv8.8 (2021-09)**.

Arm Limited. Company 02557590 registered in England.
110 Fulbourn Road, Cambridge, England CB1 9NJ.

(LES-PRE-20349 version 21.0)

Confidentiality Status

This document is Non-Confidential. The right to use, copy and disclose this document may be subject to license restrictions in accordance with the terms of the agreement entered into by Arm and the party that Arm delivered this document to.

Product Status

This release covers multiple versions of the architecture. The content relating to different versions is given different quality ratings.

The information related to the 2021 Architecture Extensions is at Alpha quality. Alpha quality means that most major features of the specification are described in the manual, some features and details might be missing.

The information related to the remaining Armv8-A features which was also published in previous releases, is at Beta quality. Beta quality means that all major features of the specification are described, some details might be missing.

Progressive Terminology Commitment

Arm values inclusive communities. Arm recognizes that we and our industry have used terms that can be offensive. Arm strives to lead the industry and create change.

Previous issues of this document included terms that can be offensive. We have replaced these terms. If you find offensive terms in this document, please contact `terms@arm.com`.

AArch32 -- Base Instructions (alphabetic order)

LDMIB, LDMED: Load Multiple Increment Before (Empty Descending).

LDR (immediate): Load Register (immediate).

LDR (literal): Load Register (literal).

LDR (register): Load Register (register).

LDRB (immediate): Load Register Byte (immediate).

LDRB (literal): Load Register Byte (literal).

LDRB (register): Load Register Byte (register).

LDRBT: Load Register Byte Unprivileged.

LDRD (immediate): Load Register Dual (immediate).

LDRD (literal): Load Register Dual (literal).

LDRD (register): Load Register Dual (register).

LDREX: Load Register Exclusive.

LDREXB: Load Register Exclusive Byte.

LDREXD: Load Register Exclusive Doubleword.

LDREXH: Load Register Exclusive Halfword.

LDRH (immediate): Load Register Halfword (immediate).

LDRH (literal): Load Register Halfword (literal).

LDRH (register): Load Register Halfword (register).

LDRHT: Load Register Halfword Unprivileged.

LDRSB (immediate): Load Register Signed Byte (immediate).

LDRSB (literal): Load Register Signed Byte (literal).

LDRSB (register): Load Register Signed Byte (register).

LDRSBT: Load Register Signed Byte Unprivileged.

LDRSH (immediate): Load Register Signed Halfword (immediate).

LDRSH (literal): Load Register Signed Halfword (literal).

LDRSH (register): Load Register Signed Halfword (register).

LDRSHT: Load Register Signed Halfword Unprivileged.

LDRT: Load Register Unprivileged.

LSL (immediate): Logical Shift Left (immediate): an alias of MOV, MOVS (register).

LSL (register): Logical Shift Left (register): an alias of MOV, MOVS (register-shifted register).

LSLS (immediate): Logical Shift Left, setting flags (immediate): an alias of MOV, MOVS (register).

LSLS (register): Logical Shift Left, setting flags (register): an alias of MOV, MOVS (register-shifted register).

LSR (immediate): Logical Shift Right (immediate): an alias of MOV, MOVS (register).

LSR (register): Logical Shift Right (register): an alias of MOV, MOVS (register-shifted register).

LSRS (immediate): Logical Shift Right, setting flags (immediate): an alias of MOV, MOVS (register).

LSRS (register): Logical Shift Right, setting flags (register): an alias of MOV, MOVS (register-shifted register).

SSUB8: Signed Subtract 8.

STC: Store data to System register.

STL: Store-Release Word.

STLB: Store-Release Byte.

STLEX: Store-Release Exclusive Word.

STLEXB: Store-Release Exclusive Byte.

STLEXD: Store-Release Exclusive Doubleword.

STLEXH: Store-Release Exclusive Halfword.

STLH: Store-Release Halfword.

STM (User registers): Store Multiple (User registers).

STM, STMIA, STMEA: Store Multiple (Increment After, Empty Ascending).

STMDA, STMED: Store Multiple Decrement After (Empty Descending).

STMDB, STMFD: Store Multiple Decrement Before (Full Descending).

STMIB, STMFA: Store Multiple Increment Before (Full Ascending).

STR (immediate): Store Register (immediate).

STR (register): Store Register (register).

STRB (immediate): Store Register Byte (immediate).

STRB (register): Store Register Byte (register).

STRBT: Store Register Byte Unprivileged.

STRD (immediate): Store Register Dual (immediate).

STRD (register): Store Register Dual (register).

STREX: Store Register Exclusive.

STREXB: Store Register Exclusive Byte.

STREXD: Store Register Exclusive Doubleword.

STREXH: Store Register Exclusive Halfword.

STRH (immediate): Store Register Halfword (immediate).

STRH (register): Store Register Halfword (register).

STRHT: Store Register Halfword Unprivileged.

STRT: Store Register Unprivileged.

SUB (immediate, from PC): Subtract from PC: an alias of ADR.

SUB, SUBS (immediate): Subtract (immediate).

SUB, SUBS (register): Subtract (register).

SUB, SUBS (register-shifted register): Subtract (register-shifted register).

SUB, SUBS (SP minus immediate): Subtract from SP (immediate).

SUB, SUBS (SP minus register): Subtract from SP (register).

SVC: Supervisor Call.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

ADC, ADCS (immediate)

Add with Carry (immediate) adds an immediate value and the Carry flag value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0 0 1 0	1 0 1	S	Rn	Rd	imm12
cond						

ADC (S == 0)

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ADCS (S == 1)

```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = A32ExpandImm(imm12);
```

T1

15 14 13 12 11	10	9	8 7 6 5	4	3 2 1 0	15	14 13 12	11 10 9 8	7 6 5 4 3 2 1 0
1 1 1 1 0	i	0	1 0 1 0	S	Rn	0	imm3	Rd	imm8

ADC (S == 0)

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ADCS (S == 1)

```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 || n == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ADCS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], imm32, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

ADC, ADCS (register)

Add with Carry (register) adds a register value, the Carry flag value, and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ADCS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0

ADCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm3:imm2);
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ADCS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ADCS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADCS <Rd>, <Rn> had been written.
- Inside an IT block, if ADC<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ADC<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

ADC, ADCS (register-shifted register)

Add with Carry (register-shifted register) adds a register value, the Carry flag value, and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

31	30	29	28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
!= 1111				0	0	0	0	1	0	1	S	Rn	Rd	Rs	0	stype	1	Rm
cond																		

Flag setting (S == 1)

```
ADCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting (S == 0)

```
ADC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

ADD (immediate, to PC)

Add to PC adds an immediate value to the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias

This is a pseudo-instruction of ADR. This means:

- The encodings in this description are named to match the encodings of ADR.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of ADR gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T3) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19	18	17	16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	0	1	0	1	0	0	0	1	1	1	1	Rd	imm12
cond														

A1

```
ADD{<c>}{<q>} <Rd>, PC, #<const>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

T1

15	14	13	12	11	10 9 8	7 6 5 4 3 2 1 0
1	0	1	0	0	Rd	imm8

T1

```
ADD{<c>}{<q>} <Rd>, PC, #<imm8>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

T3

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14 13 12	11 10 9 8	7 6 5 4 3 2 1 0
1	1	1	1	0	i	1	0	0	0	0	0	1	1	1	1	0	imm3	Rd	imm8

T3

```
ADDW{<c>}{<q>} <Rd>, PC, #<imm12> // (<Rd>, <imm12> can be represented in T1)
```

```
ADD{<c>}{<q>} <Rd>, PC, #<imm12>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

For encoding T1 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<label> For encoding A1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the `ADR` instruction to this label.

If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset.

If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions*.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the `ADR` instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the `ADR` instruction to this label.

If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.

If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are 0-4095.

<imm8> Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> An immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

Operation

The description of ADR gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

ADD, ADDS (immediate)

Add (immediate) adds an immediate value to a register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 , T3 and T4) .

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rdn>	Is the general-purpose source and destination register, encoded in the "Rdn" field.
<imm8>	Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ADDS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>. Arm deprecates use of this instruction.

For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see *ADD (SP plus immediate)*. If the PC is used, see *ADR*.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see *ADD (SP plus immediate)*.

<imm3> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T3: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

When multiple encodings of the same length are available for an instruction, encoding T3 is preferred to encoding T4 (if encoding T4 is required, use the `ADDW` syntax). Encoding T1 is preferred to encoding T2 if <Rd> is specified and encoding T2 is preferred to encoding T1 if <Rd> is omitted.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        (result, nzcv) = AddWithCarry(R[n], imm32, '0');
        if d == 15 then          // Can only occur for A32 encoding
            if setflags then
                ALUExceptionReturn(result);
            else
                ALUWritePC(result);
        else
            R[d] = result;
            if setflags then
                PSTATE.<N,Z,C,V> = nzcv;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        (result, nzcv) = AddWithCarry(R[n], imm32, '0');
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

ADD, ADDS (register)

Add (register) adds a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 and T3) .

// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rdn> Is the general-purpose source and destination register, encoded in the "DN:Rdn" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

The assembler language allows <Rdn> to be specified once or twice in the assembler syntax. When used inside an IT block, and <Rdn> and <Rm> are in the range R0 to R7, <Rdn> must be specified once so that encoding T2 is preferred to encoding T1. In all other cases there is no difference in behavior when <Rdn> is specified once or twice.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ADDS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>. Arm deprecates use of this instruction.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

When used inside an IT block, <Rd> must be specified. When used outside an IT block, <Rd> is optional, and:

- If omitted, this register is the same as <Rn>.
- If present, encoding T1 is preferred to encoding T2.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used. If the SP is used, see *ADD (SP plus register)*.

For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see *ADD (SP plus register)*.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T3: is the second general-purpose source register, encoded in the "Rm" field.

For encoding T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Inside an IT block, if ADD<c> <Rd>, <Rn>, <Rd> cannot be assembled using encoding T1, it is assembled using encoding T2 as though ADD<c> <Rd>, <Rn> had been written. To prevent this happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

ADD, ADDS (register-shifted register)

Add (register-shifted register) adds a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
!= 1111	0	0	0	0	1	0	0	S	Rn	Rd	Rs	0	stype	1	Rm
cond															

Flag setting (S == 1)

```
ADDS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting (S == 0)

```
ADD{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

ADD, ADDS (SP plus immediate)

Add to SP (immediate) adds an immediate value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ADDS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 , T3 and T4) .

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

SP, — Is the stack pointer.

<imm7> — Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.

<Rd> — For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ADDS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

For encoding T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm8> — Is an unsigned immediate, a multiple of 4, in the range 0 to 1020, encoded in the "imm8" field as <imm8>/4.

<imm12> — Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> — For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T3: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, imm32, '0');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

ADD, ADDS (SP plus register)

Add to SP (register) adds an optionally-shifted register value to the SP value, and writes the result to the destination register.

If the destination register is not the PC, the ADDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The ADD variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ADDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 and T3) .

A1

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

SP, — Is the stack pointer.

<Rdm> — Is the general-purpose destination and second source register, encoded in the "Rdm" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is a simple branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

<Rd> — For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ADD variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

- For the ADDS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<Rm> For encoding A1 and T2: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, shifted, '0');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

ADR

Form PC-relative address adds an immediate value to the PC value to form a PC-relative address, and writes the result to the destination register.

This instruction is used by the alias SUB (immediate, from PC).

This instruction is used by the pseudo-instruction ADD (immediate, to PC).

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 , T2 and T3) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19	18	17	16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	0	1	0	1	0	0	0	1	1	1	1	Rd	imm12
cond

```
ADR{<c>}{<q>} <Rd>, <label>
```

```
d = UInt(Rd);  imm32 = ZeroExtend(i:imm3:imm8, 32);  add = TRUE;
if d == 15 then UNPREDICTABLE;   // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1 and A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

For encoding T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<label> For encoding A1 and A2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.
If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset.
If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32.
Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions*.

For encoding T1: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label. Permitted values of the size of the offset are multiples of 4 in the range 0 to 1020.

For encoding T2 and T3: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the ADR instruction to this label.
If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.
If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.
Permitted values of the size of the offset are 0-4095.

The instruction aliases permit the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Alias Conditions

Alias	Of variant	Is preferred when
ADD (immediate, to PC)		`Never`
SUB (immediate, from PC)	T2	`i:imm3:imm8 == '000000000000'`
SUB (immediate, from PC)	A2	`imm12 == '000000000000'`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if d == 15 then          // Can only occur for A32 encodings
        ALUWritePC(result);
    else
        R[d] = result;
```

AND, ANDS (immediate)

Bitwise AND (immediate) performs a bitwise AND of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	0	1	0	0	0	0	S	Rn	Rd	imm12

```

ANDS (S == 1 && Rd != 1111)

```
ANDS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
if Rd == '1111' && S == '1' then SEE "TST (immediate)";
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if (d == 15 && !setflags) || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ANDS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND imm32;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

AND, ANDS (register)

Bitwise AND (register) performs a bitwise AND of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the ANDS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The AND variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ANDS variant of the instruction performs an exception return without the use of the stack. In this case:
    - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
    - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
    - The instruction is UNDEFINED in Hyp mode.
    - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the AND variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ANDS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ANDS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ANDS <Rd>, <Rn> had been written.
- Inside an IT block, if AND<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though AND<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

AND, ANDS (register-shifted register)

Bitwise AND (register-shifted register) performs a bitwise AND of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0

if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Assembler Symbols

<c> For encoding A1, T2 and T4: see *Standard assembler syntax fields*.

For encoding T1: see *Standard assembler syntax fields*. Must not be AL or omitted.

For encoding T3: see *Standard assembler syntax fields*. <c> must not be AL or omitted.

<q> See *Standard assembler syntax fields*.

<label> For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset.
Permitted offsets are multiples of 4 in the range –33554432 to 33554428.

For encoding T1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –256 to 254.

For encoding T2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset. Permitted offsets are even numbers in the range –2048 to 2046.

For encoding T3: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset.
Permitted offsets are even numbers in the range –1048576 to 1048574.

For encoding T4: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the B instruction to this label, then selects an encoding that sets imm32 to that offset.
Permitted offsets are even numbers in the range –16777216 to 16777214.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BranchWritePC(PC + imm32, BranchType_DIR);
```

BFC

Bit Field Clear clears any number of adjacent bits at any position in a register, without affecting the other bits in the register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31–28	27	26	25	24	23	22	21	20–16	15–12	11–7	6	5	4	3	2	1	0
!= 1111	0	1	1	1	1	1	0	msb	Rd	lsb	0	0	1	1	1	1	1
cond																	

A1

```
BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>
```

```
d = UInt(Rd);  msbit = UInt(msb);  lsbit = UInt(lsb);
if d == 15 then UNPREDICTABLE;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14–12	11–8	7–6	5	4–0
1	1	1	1	0	(0)	1	1	0	1	1	0	1	1	1	1	0	imm3	Rd	imm2	(0)	msb

T1

```
BFC{<c>}{<q>} <Rd>, #<lsb>, #<width>
```

```
d = UInt(Rd);  msbit = UInt(msb);  lsbit = UInt(imm3:imm2);
if d == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rd> — Is the general-purpose destination register, encoded in the "Rd" field.

<lsb> — For encoding A1: is the least significant bit to be cleared, in the range 0 to 31, encoded in the "lsb" field.

For encoding T1: is the least significant bit that is to be cleared, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width> — Is the number of bits to be cleared, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+<width>-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = Replicate('0', msbit-lsbit+1);
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rd> — Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> — Is the general-purpose source register, encoded in the "Rn" field.

<lsb> — For encoding A1: is the least significant destination bit, in the range 0 to 31, encoded in the "lsb" field.

For encoding T1: is the least significant destination bit, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width> — Is the number of bits to be copied, in the range 1 to 32-<lsb>, encoded in the "msb" field as <lsb>+<width>-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if msbit >= lsbit then
        R[d]<msbit:lsbit> = R[n]<(msbit-lsbit):0>;
        // Other bits of R[d] are unchanged
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit < lsbit`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

BIC, BICS (immediate)

Bitwise Bit Clear (immediate) performs a bitwise AND of a register value and the complement of an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the BICS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The BIC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The BICS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	0	1	1	1	1	0	S	Rn	Rd	imm12
cond											

BIC (S == 0)

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

BICS (S == 1)

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2 1 0	15	14 13 12	11 10 9 8	7 6 5 4 3 2 1 0

BIC (S == 0)

```
BIC{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

BICS (S == 1)

```
BICS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 || n == 15 then UNPREDICTABLE;  // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the BIC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the BICS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] AND NOT(imm32);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] AND NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

BKPT

Breakpoint causes a Breakpoint Instruction exception.
Breakpoint is always unconditional, even when inside an IT block.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16 15 14 13 12 11 10 9 8	7	6	5	4	3 2 1 0
!= 1111	0	0	0	1	0	0	1	0	imm12	0	1	1	1	imm4
cond														

A1

```
BKPT{<q>} {#}<imm>
```

```
imm16 = imm12:imm4;
if cond != '1110' then UNPREDICTABLE;  // BKPT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

15	14	13	12	11	10	9	8	7 6 5 4 3 2 1 0
1	0	1	1	1	1	1	0	imm8

T1

```
BKPT{<q>} {#}<imm>
```

```
imm16 = ZeroExtend(imm8, 16);
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<q> — See *Standard assembler syntax fields*. An `BKPT` instruction must be unconditional.

<imm> — For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value:

- Is recorded in the Comment field of ESR_ELx.ISS if the Software Breakpoint Instruction exception is taken to an exception level that is using AArch64.
- Is ignored otherwise.

Operation

```
EncodingSpecificOperations();
AArch32.SoftwareBreakpoint(imm16);
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

BL, BLX (immediate)

Branch with Link calls a subroutine at a PC-relative address, and setting LR to the return address.

Branch with Link and Exchange Instruction Sets (immediate) calls a subroutine at a PC-relative address, setting LR to the return address, and changes the instruction set from A32 to T32, or from T32 to A32.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25	24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For encoding A1, T1 and T2: see *Standard assembler syntax fields*.

For encoding A2: see *Standard assembler syntax fields*. <c> must be AL or omitted.

<q> See *Standard assembler syntax fields*.

<label> For encoding A1: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding that sets imm32 to that offset.
Permitted offsets are multiples of 4 in the range –33554432 to 33554428.

For encoding A2: the label of the instruction that is to be branched to. The assembler calculates the required value of the offset from the PC value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.
Permitted offsets are even numbers in the range –33554432 to 33554430.

For encoding T1: the label of the instruction that is to be branched to.
The assembler calculates the required value of the offset from the PC value of the BL instruction to this label, then selects an encoding with imm32 set to that offset.
Permitted offsets are even numbers in the range –16777216 to 16777214.

For encoding T2: the label of the instruction that is to be branched to.
The assembler calculates the required value of the offset from the Align(PC, 4) value of the BLX instruction to this label, then selects an encoding with imm32 set to that offset.
Permitted offsets are multiples of 4 in the range –16777216 to 16777212.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if CurrentInstrSet() == InstrSet_A32 then
        LR = PC - 4;
    else
        LR = PC<31:1> : '1';
    if targetInstrSet == InstrSet_A32 then
        targetAddress = Align(PC,4) + imm32;
    else
        targetAddress = PC + imm32;
    SelectInstrSet(targetInstrSet);
    BranchWritePC(targetAddress, BranchType_DIRCALL);
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

BLX (register)

Branch with Link and Exchange (register) calls a subroutine at an address specified in the register, and if necessary changes to the instruction set indicated by bit[0] of the register value. If the value in bit[0] is 0, the instruction set after the branch will be A32. If the value in bit[0] is 1, the instruction set after the branch will be T32.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3 2 1 0
!= 1111	0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	1	Rm
cond																									

A1

```
BLX{<c>}{<q>} <Rm>
```

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
```

T1

15	14	13	12	11	10	9	8	7	6 5 4 3	2	1	0
0	1	0	0	0	1	1	1	1	Rm	(0)	(0)	(0)

T1

```
BLX{<c>}{<q>} <Rm>
```

```
m = UInt(Rm);
if m == 15 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rm> Is the general-purpose register holding the address to be branched to, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    target = R[m];
    if CurrentInstrSet() == InstrSet_A32 then
        next_instr_addr = PC - 4;
        LR = next_instr_addr;
    else
        next_instr_addr = PC - 2;
        LR = next_instr_addr<31:1> : '1';
    BXWritePC(target, BranchType_INDCALL);
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

BX

Branch and Exchange causes a branch to an address and instruction set specified by a register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	0	1	Rm			
cond																															

A1

```
BX{<c>}{<q>} <Rm>
```

```
m = UInt(Rm);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	1	1	1	0	Rm				(0)	(0)	(0)

T1

```
BX{<c>}{<q>} <Rm>
```

```
m = UInt(Rm);
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rm> For encoding A1: is the general-purpose register holding the address to be branched to, encoded in the "Rm" field. The PC can be used.

For encoding T1: is the general-purpose register holding the address to be branched to, encoded in the "Rm" field. The PC can be used.
If <Rm> is the PC at a non word-aligned address, it results in UNPREDICTABLE behavior because the address passed to the BXWritePC() pseudocode function has bits<1:0> = '10'.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    BXWritePC(R[m], BranchType_INDIR);
```

BXJ

Branch and Exchange, previously Branch and Exchange Jazelle.

In Armv8, BXJ behaves as a BX instruction, see *BX*. This means it causes a branch to an address and instruction set specified by a register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	0	0	1	0	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	0	0	1	0	Rm

T1

```
CLZ{<c>}{<q>} <Rd>, <Rm>
```

```
d = UInt(Rd);  m = UInt(Rm);  n = UInt(Rn);
if m != n || d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `m != n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes with the additional decode: m = UInt(Rn);.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	For encoding A1: is the general-purpose source register, encoded in the "Rm" field.
	For encoding T1: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = CountLeadingZeroBits(R[m]);
    R[d] = result<31:0>;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

CMN (immediate)

Compare Negative (immediate) adds a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15	14	13	12	11 10 9 8 7 6 5 4 3 2 1 0

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], shifted, '0');
    PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

CPS, CPSID, CPSIE

Change PE State changes one or more of the *PSTATE*.{A, I, F} interrupt mask bits and, optionally, the *PSTATE*.M mode field, without changing any other *PSTATE* bits.

CPS is treated as NOP if executed in User mode unless it is defined as being CONSTRAINED UNPREDICTABLE elsewhere in this section.

The PE checks whether the value being written to PSTATE.M is legal. See *Illegal changes to PSTATE.M*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19 18	17	16	15	14	13	12	11	10	9	8	7	6	5	4 3 2 1 0
1	1	1	1	0	0	0	1	0	0	0	0	imod	M	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	A	I	F	0	mode

Change mode (imod == 00 && M == 1)

```
CPS{<q>} #<mode> // (Cannot be conditional)

CONSTRAINED UNPREDICTABLE behavior

If `imod == '01'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode != '00000' && M == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: changemode = TRUE.
- The instruction executes as described, and the value specified by mode is ignored. There are no additional side-effects.

If `imod<1> == '1' && A:I:F == '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if imod<1> == '0'.
- The instruction behaves as if A:I:F has an UNKNOWN nonzero value.

If `imod<1> == '0' && A:I:F != '000'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction behaves as if imod<1> == '1'.
- The instruction behaves as if A:I:F == '000'.

Hint instructions: In encoding T2, if the imod field is 00 and the M bit is 0, a hint instruction is encoded. To determine which hint instruction, see *Branches and miscellaneous control*.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<q> See *Standard assembler syntax fields*.

<iflags> Is a sequence of one or more of the following, specifying which interrupt mask bits are affected:

a
: Sets the A bit in the instruction, causing the specified effect on *PSTATE*.A, the SError interrupt mask bit.

i
: Sets the I bit in the instruction, causing the specified effect on *PSTATE*.I, the IRQ interrupt mask bit.

f
: Sets the F bit in the instruction, causing the specified effect on *PSTATE*.F, the FIQ interrupt mask bit.

<mode> Is the number of the mode to change to, in the range 0 to 31, encoded in the "mode" field.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then

            AArch32.WriteModeByInstr(mode);
```

CRC32

CRC32 performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x04C11DB7 is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it.

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27	26	25	24	23	22-21	20	19-16	15-12	11	10	9	8	7	6	5	4	3-0

if size == 64 then UNPREDICTABLE;
if cond != '1110' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: size = 32;.

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if size == 64 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == 64`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: size = 32;.

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<q>	See *Standard assembler syntax fields*. An `CRC32` instruction must be unconditional.
<Rd>	Is the general-purpose accumulator output register, encoded in the "Rd" field.
<Rn>	Is the general-purpose accumulator input register, encoded in the "Rn" field.
<Rm>	Is the general-purpose data source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    acc = R[n];             // accumulator
    val = R[m]<size-1:0>;   // input value
    poly = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;
    tempacc = BitReverse(acc):Zeros(size);
    tempval = BitReverse(val):Zeros(32);
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

CRC32C

CRC32C performs a cyclic redundancy check (CRC) calculation on a value held in a general-purpose register. It takes an input CRC value in the first source operand, performs a CRC on the input value in the second source operand, and returns the output CRC value. The second source operand can be 8, 16, or 32 bits. To align with common usage, the bit order of the values is reversed as part of the operation, and the polynomial 0x1EDC6F41 is used for the CRC calculation.

In Armv8-A, this is an OPTIONAL instruction, and in Armv8.1 it is mandatory for all implementations to implement it.

ID_ISAR5.CRC32 indicates whether this instruction is supported in the T32 and A32 instruction sets.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

    tempval = BitReverse(val):Zeros(32);
    // Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
    R[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

CSDB

Consumption of Speculative Data Barrier is a memory barrier that controls speculative execution and data value prediction.

No instruction other than branch instructions and instructions that write to the PC appearing in program order after the CSDB can be speculatively executed using the results of any:

- Data value predictions of any instructions.
- PSTATE.{N,Z,C,V} predictions of any instructions other than conditional branch instructions and conditional instructions that write to the PC appearing in program order before the CSDB that have not been architecturally resolved.

For purposes of the definition of CSDB, PSTATE.{N,Z,C,V} is not considered a data value. This definition permits:

- Control flow speculation before and after the CSDB.
- Speculative execution of conditional data processing instructions after the CSDB, unless they use the results of data value or PSTATE.{N,Z,C,V} predictions of instructions appearing in program order before the CSDB that have not been architecturally resolved.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCPS1

Debug Change PE State to EL1 allows the debugger to move the PE into EL1 from EL0 or to a specific mode at the current Exception level.

`DCPS1` is UNDEFINED if any of:

- The PE is in Non-debug state.
- EL2 is implemented, EL2 is implemented and enabled in the current Security state, and any of:
  - EL2 is using AArch32 and HCR.TGE is set to 1.
  - EL2 is using AArch64 and HCR_EL2.TGE is set to 1.

When the PE executes `DCPS1` at EL0, EL1 or EL3:

- If EL3 or EL1 is using AArch32, the PE enters SVC mode and LR_svc, SPSR_svc, DLR, and DSPSR become UNKNOWN. If `DCPS1` is executed in Monitor mode, SCR.NS is cleared to 0.
- If EL1 is using AArch64, the PE enters EL1 using AArch64, selects SP_EL1, and ELR_EL1, ESR_EL1, SPSR_EL1, DLR_EL0 and DSPSR_EL0 become UNKNOWN.

When the PE executes `DCPS1` at EL2 the PE does not change mode, and ELR_hyp, HSR, SPSR_hyp, DLR and DSPSR become UNKNOWN.

For more information on the operation of this instruction, see *DCPS*.

T1

```

DMB

Data Memory Barrier is a memory barrier that ensures the ordering of observations of memory accesses, see *Data Memory Barrier (DMB)*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	1	0	1	option			

A1

```
DMB{<c>}{<q>} {<option>}
```

```
// No additional decoding required
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	1	0	1	option			

T1

```
DMB{<c>}{<q>} {<option>}
```

```
// No additional decoding required
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. Must be AL or omitted.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<option> Specifies an optional limitation on the barrier operation. Values are:

SY

Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Can be omitted. This option is referred to as the full system barrier. Encoded as option = 0b1111.

ST

Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. SYST is a synonym for ST. Encoded as option = 0b1110.

LD

Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1101.

ISH

Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b1011.

ISHST

Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b1010.

ISHLD
: Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1001.

NSH
: Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as option = 0b0111.

NSHST
: Non-shareable is the required shareability domain, writes are the required access type both before and after the barrier instruction. Encoded as option = 0b0110.

NSHLD
: Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0101.

OSH
: Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b0011.

OSHST
: Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b0010.

OSHLD
: Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0001.

For more information on whether an access is before or after a barrier instruction, see *Data Memory Barrier (DMB)*. All other encodings of option are reserved. All unsupported and reserved options must execute as a full system DMB operation, but software must not rely on this behavior.

The instruction supports the following alternative <option> values, but Arm recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST as an alias for NSHST.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    case option of
        when '0001'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Reads;
        when '0010'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Writes;
        when '0011'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_All;
        when '0101'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Reads;
        when '0110'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_Writes;
        when '0111'  domain = MBReqDomain_Nonshareable;    types = MBReqTypes_All;
        when '1001'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Reads;
        when '1010'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_Writes;
        when '1011'  domain = MBReqDomain_InnerShareable;  types = MBReqTypes_All;
        when '1101'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Reads;
        when '1110'  domain = MBReqDomain_FullSystem;      types = MBReqTypes_Writes;
        otherwise    domain = MBReqDomain_FullSystem;      types = MBReqTypes_All;

    if PSTATE.EL IN {EL0, EL1} && EL2Enabled() then
        if HCR.BSU == '11' then
            domain = MBReqDomain_FullSystem;
        if HCR.BSU == '10' && domain != MBReqDomain_FullSystem then
            domain = MBReqDomain_OuterShareable;
        if HCR.BSU == '01' && domain == MBReqDomain_Nonshareable then
            domain = MBReqDomain_InnerShareable;

    DataMemoryBarrier(domain, types);
```

DSB

Data Synchronization Barrier is a memory barrier that ensures the completion of memory accesses, see *Data Synchronization Barrier (DSB)*.

An AArch32 DSB instruction does not require the completion of any AArch64 TLB maintenance instructions, regardless of the nXS qualifier, appearing in program order before the AArch32 DSB.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	1	0	1	1	1	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	1	0	0	!= 0x00			
																												option			

A1

```
DSB{<c>}{<q>} {<option>}
```

```
// No additional decoding required
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	0	1	1	(1)	(1)	(1)	(1)	1	0	(0)	0	(1)	(1)	(1)	(1)	0	1	0	0	!= 0x00			
																												option			

T1

```
DSB{<c>}{<q>} {<option>}
```

```
// No additional decoding required
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. Must be AL or omitted.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<option> Specifies an optional limitation on the barrier operation. Values are:

SY

Full system is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Can be omitted. This option is referred to as the full system barrier. Encoded as option = 0b1111.

ST

Full system is the required shareability domain, writes are the required access type, both before and after the barrier instruction. SYST is a synonym for ST. Encoded as option = 0b1110.

LD

Full system is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1101.

ISH

Inner Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b1011.

ISHST
: Inner Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b1010.

ISHLD
: Inner Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b1001.

NSH
: Non-shareable is the required shareability domain, reads and writes are the required access, both before and after the barrier instruction. Encoded as option = 0b0111.

NSHST
: Non-shareable is the required shareability domain, writes are the required access type both before and after the barrier instruction. Encoded as option = 0b0110.

NSHLD
: Non-shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0101.

OSH
: Outer Shareable is the required shareability domain, reads and writes are the required access types, both before and after the barrier instruction. Encoded as option = 0b0011.

OSHST
: Outer Shareable is the required shareability domain, writes are the required access type, both before and after the barrier instruction. Encoded as option = 0b0010.

OSHLD
: Outer Shareable is the required shareability domain, reads are the required access type before the barrier instruction, and reads and writes are the required access types after the barrier instruction. Encoded as option = 0b0001.

For more information on whether an access is before or after a barrier instruction, see *Data Synchronization Barrier (DSB)*. All other encodings of option are reserved, other than the values 0b0000 and 0b0100. All unsupported and reserved options must execute as a full system DSB operation, but software must not rely on this behavior.

The value 0b0000 is used to encode SSBB and the value 0b0100 is used to encode PSSBB.

The instruction supports the following alternative <option> values, but Arm recommends that software does not use these alternative values:

- SH as an alias for ISH.
- SHST as an alias for ISHST.
- UN as an alias for NSH.
- UNST as an alias for NSHST.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if HaveFeatXS() && HaveFeatHCX() then
        nXS = (PSTATE.EL IN {EL0, EL1} && !ELUsingAArch32(EL2) &&
            IsHCRXEL2Enabled() && HCRX_EL2.FnXS == '1');
    else
        nXS = FALSE;
    case option of
        when '0001'  domain = MBReqDomain_OuterShareable;  types = MBReqTypes_Reads;

        if HCR.BSU == '01' && domain == MBReqDomain_Nonshareable then
            domain = MBReqDomain_InnerShareable;

    DataSynchronizationBarrier(domain, types, nXS);
```

EOR, EORS (immediate)

Bitwise Exclusive OR (immediate) performs a bitwise Exclusive OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27	26	25	24	23	22	21	20	19-16	15-12	11-0
!= 1111	0	0	1	0	0	0	1	S	Rn	Rd	imm12
cond											

EOR (S == 0)

```
EOR{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

EORS (S == 1)

```
EORS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3-0	15	14-12	11-8	7-0
1	1	1	1	0	i	0	0	1	0	0	S	Rn	0	imm3	Rd	imm8

EOR (S == 0)

```
EOR{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

EORS (S == 1 && Rd != 1111)

```
EORS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
if Rd == '1111' && S == '1' then SEE "TEQ (immediate)";
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if (d == 15 && !setflags) || n == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the EORS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

EOR, EORS (register)

Bitwise Exclusive OR (register) performs a bitwise Exclusive OR of a register value and an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the EORS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The EOR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The EORS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the EOR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the EORS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if EORS <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EORS <Rd>, <Rn> had been written
- Inside an IT block, if EOR<c> <Rd>, <Rn>, <Rd> has <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though EOR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

EOR, EORS (register-shifted register)

Bitwise Exclusive OR (register-shifted register) performs a bitwise Exclusive OR of a register value and a register-shifted register value. It writes the result to the destination register, and can optionally update the condition flags based on the result.

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0

```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] EOR shifted;
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

ERET

Exception Return.

The PE branches to the address held in the register holding the preferred return address, and restores *PSTATE* from SPSR_<current_mode>.

The register holding the preferred return address is:

- *ELR_hyp*, when executing in Hyp mode.
- LR, when executing in a mode other than Hyp mode, User mode, or System mode.

The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.

Exception Return is CONSTRAINED UNPREDICTABLE in User mode and System mode.

In Debug state, the T1 encoding of ERET executes the DRPS operation.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

            PSTATE.<N,Z,C,V,Q,GE,SS,A,I,F> = bits(13) UNKNOWN;
            // In AArch32 Debug state, all instructions are T32 and unconditional.
            PSTATE.IT = '00000000';  PSTATE.T = '1';        // PSTATE.J is RES0
            DLR = bits(32) UNKNOWN;  DSPSR = bits(32) UNKNOWN;
            UpdateEDSCRFields();                  // Update EDSCR PE state flags
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User,M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

ESB

Error Synchronization Barrier is an error synchronization event that might also update DISR and VDISR. This instruction can be used at all Exception levels and in Debug state.

In Debug state, this instruction behaves as if SError interrupts are masked at all Exception levels. See Error Synchronization Barrier in the ARM(R) Reliability, Availability, and Serviceability (RAS) Specification, Armv8, for Armv8-A architecture profile.

If the RAS Extension is not implemented, this instruction executes as a NOP.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1
(FEAT_RAS)

31–28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if cond != '1110' then UNPREDICTABLE; // HLT must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1

15	14	13	12	11	10	9	8	7	6	5 4 3 2 1 0
1	0	1	1	1	0	1	0	1	0	imm6

T1

```
HLT{<q>} {#}<imm>
```

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UNDEFINED;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<q> See *Standard assembler syntax fields*. An `HLT` instruction must be unconditional.

<imm> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

For encoding T1: is a 6-bit unsigned immediate, in the range 0 to 63, encoded in the "imm6" field. This value is for assembly and disassembly only. It is ignored by the PE, but can be used by a debugger to store more information about the halting breakpoint.

Operation

```
EncodingSpecificOperations();
Halt(DebugHalt_HaltInstruction);
```

HVC

Hypervisor Call causes a Hypervisor Call exception. For more information, see *Hypervisor Call (HVC) exception*. Software executing at EL1 can use this instruction to call the hypervisor to request a service.

The HVC instruction is UNDEFINED:

- When EL3 is implemented and using AArch64, and *SCR_EL3*.HCE is set to 0.
- In Non-secure EL1 modes when EL3 is implemented and using AArch32, and *SCR*.HCE is set to 0.
- When EL3 is not implemented and either *HCR_EL2*.HCD is set to 1 or *HCR*.HCD is set to 1.
- When EL2 is not implemented.
- In Secure state, if EL2 is not enabled in the current Security state.
- In User mode.

The HVC instruction is CONSTRAINED UNPREDICTABLE in Hyp mode when EL3 is implemented and using AArch32, and *SCR*.HCE is set to 0.

On executing an HVC instruction, the *HSR, Hyp Syndrome Register* reports the exception as a Hypervisor Call exception, using the EC value 0x12, and captures the value of the immediate argument, see *Use of the HSR*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

```

```
imm16 = imm4:imm12;
if InITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<q> See *Standard assembler syntax fields*. An HVC instruction must be unconditional.

<imm16> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. This value is for assembly and disassembly only. It is reported in the HSR but

otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

For encoding T1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. This value is for assembly and disassembly only. It is reported in the HSR but otherwise is ignored by hardware. An HVC handler might interpret imm16, for example to determine the required service.

Operation

```
EncodingSpecificOperations();
if !HaveEL(EL2) || PSTATE.EL == EL0 || (IsSecure() && !IsSecureEL2Enabled()) then
    UNDEFINED;

if HaveEL(EL3) then
    if ELUsingAArch32(EL3) && SCR.HCE == '0' && PSTATE.EL == EL2 then
        UNPREDICTABLE;
    else
        hvc_enable = SCR_GEN[].HCE;
else
    hvc_enable = if ELUsingAArch32(EL2) then NOT(HCR.HCD) else NOT(HCR_EL2.HCD);

if hvc_enable == '0' then
    UNDEFINED;
else
    AArch32.CallHypervisor(imm16);
```

CONSTRAINED UNPREDICTABLE behavior

If `ELUsingAArch32(EL3) && SCR.HCE == '0' && PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

ISB

Instruction Synchronization Barrier flushes the pipeline in the PE and is a context synchronization event. For more information, see *Instruction Synchronization Barrier (ISB)*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

// No additional decoding required
```

For more information about the CONSTRAINED UNPREDICTABLE behavior, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. Must be AL or omitted.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<option> Specifies an optional limitation on the barrier operation. Values are:

SY

Full system barrier operation, encoded as option = 0b1111. Can be omitted.

All other encodings of option are reserved. The corresponding instructions execute as full system barrier operations, but must not be relied upon by software.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    InstructionSynchronizationBarrier();
```

IT

If-Then makes up to four following instructions (the IT block) conditional. The conditions for the instructions in the IT block are the same as, or the inverse of, the condition the `IT` instruction specifies for the first instruction in the block.

The `IT` instruction itself does not affect the condition flags, but the execution of the instructions in the IT block can change the condition flags.

16-bit instructions in the IT block, other than `CMP`, `CMN` and `TST`, do not set the condition flags. An `IT` instruction with the AL condition can change the behavior without conditional execution.

The architecture permits exception return to an instruction in the IT block only if the restoration of the *CPSR* restores *PSTATE*.IT to a state consistent with the conditions specified by the `IT` instruction. Any other exception return to an instruction in an IT block is UNPREDICTABLE. Any branch to a target instruction in an IT block is not permitted, and if such a branch is made it is UNPREDICTABLE what condition is used when executing that target instruction and any subsequent instruction in the IT block.

Many uses of the IT instruction are deprecated for performance reasons, and an implementation might include ITD controls that can disable those uses of IT, making them UNDEFINED.

For more information see *Conditional execution* and *Conditional instructions*. The first of these sections includes more information about the ITD controls.

T1

15	14	13	12	11	10	9	8	7 6 5 4	3 2 1 0
1	0	1	1	1	1	1	1	firstcond	!= 0000
									mask

T1

```
IT{<x>{<y>{<z>}}}{<q>} <cond>
```

```
if mask == '0000' then SEE "Related encodings";
if firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1) then UNPREDICTABLE;
if InITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `firstcond == '1111' || (firstcond == '1110' && BitCount(mask) != 1)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The '1111' condition is treated as being the same as the '1110' condition, meaning always, and the ITSTATE state machine is progressed in the same way as for any other cond_base value.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Miscellaneous 16-bit instructions*.

Assembler Symbols

<x> The condition for the second instruction in the IT block. If omitted, the "mask" field is set to 0b1000. If present it is encoded in the "mask[3]" field:

T
firstcond[0]

E
NOT firstcond[0]

<y> The condition for the third instruction in the IT block. If omitted and <x> is present, the "mask[2:0]" field is set to 0b100. If <y> is present it is encoded in the "mask[2]" field:

T
firstcond[0]

E
NOT firstcond[0]

<z> The condition for the fourth instruction in the IT block. If omitted and <y> is present, the "mask[1:0]" field is set to 0b10. If <z> is present, the "mask[0]" field is set to 1, and it is encoded in the "mask[1]" field:

T
: firstcond[0]

E
: NOT firstcond[0]

<q> See *Standard assembler syntax fields*.

<cond> The condition for the first instruction in the IT block, encoded in the "firstcond" field. See *Condition codes* for the range of conditions available, and the encodings.

The conditions specified in an IT instruction must match those specified in the syntax of the instructions in its IT block. When assembling to A32 code, assemblers check IT instruction syntax for validity but do not generate assembled instructions for them. See *Conditional instructions*.

Operation

```
EncodingSpecificOperations();
AArch32.CheckITEnabled(mask);
PSTATE.IT<7:0> = firstcond:mask;
ShouldAdvanceIT = FALSE;
```

LDA

Load-Acquire Word loads a word from memory and writes it to a register. The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

cond																															

A1

```
LDAEXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

```
t = UInt(Rt);  t2 = t + 1;  n = UInt(Rn);
if Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction is handled as described in *Using R15*.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LDAEXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

```
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The load instruction executes but the destination register takes an UNKNOWN value.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rt>	For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. <Rt> must be even-numbered and not R14. For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
<Rt2>	For encoding A1: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address, 8);
    value = MemO[address, 8];
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R[t]  = if BigEndian(AccType_ORDERED) then value<63:32> else value<31:0>;
    R[t2] = if BigEndian(AccType_ORDERED) then value<31:0>  else value<63:32>;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDAEXH

Load-Acquire Exclusive Halfword loads a halfword from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*.

LDC (immediate)

Load data to System register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to the *DBGDTRTXint* System register. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses see *Memory accesses*.

In an implementation that includes EL2, the permitted `LDC` access to *DBGDTRTXint* can be trapped to Hyp mode, meaning that an attempt to execute an `LDC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general Non-secure System register accesses to debug registers*.

For simplicity, the `LDC` pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15	14	13	12	11	10	9	8	7 6 5 4 3 2 1 0

```

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> Is the general-purpose base register, encoded in the "Rn" field. If the PC is used, see *LDC (literal)*.

<option> Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

    // System register write to DBGDTRTXint.
    AArch32.SysRegWriteM(cp, ThisInstr(), address);

    if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDC (literal)

Load data to System register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to the *DBGDTRTXint* System register. For information about memory accesses see *Memory accesses*.

In an implementation that includes EL2, the permitted LDC access to *DBGDTRTXint* can be trapped to Hyp mode, meaning that an attempt to execute an LDC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general Non-secure System register accesses to debug registers*.

For simplicity, the LDC pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]
```

```
LDC{<c>}{<q>} p14, c5, [PC], <option>
```

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
index = (P == '1');  add = (U == '1');  cp = 14;  imm32 = ZeroExtend(imm8:'00', 32);
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7 6 5 4 3 2 1 0
1	1	1	0	1	1	0	P	U	0	W	1	1	1	1	1	0	1	0	1	1	1	1	0	imm8

T1 (!(P == 0 && U == 0 && W == 0))

```
LDC{<c>}{<q>} p14, c5, <label>
```

```
LDC{<c>}{<q>} p14, c5, [PC, #{+/-}<imm>]
```

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
index = (P == '1');  add = (U == '1');  cp = 14;  imm32 = ZeroExtend(imm8:'00', 32);
if W == '1' || (P == '0' && CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `W == '1' || P == '0'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.

- The instruction executes as LDC (immediate) with writeback to the PC. The instruction is handled as described in *Using R15*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<option>	Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.
<label>	The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE (encoded as U == 1). If the offset is negative, imm32 is equal to minus the offset and add == FALSE (encoded as U == 0).
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+

<imm>	Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    address = if index then offset_addr else Align(PC,4);

    // System register write to DBGDTRTXint.
    AArch32.SysRegWriteM(cp, ThisInstr(), address);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDM (exception return)

Load Multiple (exception return) loads multiple registers from consecutive memory locations using an address from a base register. The *SPSR* of the current mode is copied to the *CPSR*. An address adjusted by the size of the data loaded can optionally be written back to the base register.

The registers loaded include the PC. The word loaded for the PC is treated as an address and a branch occurs to that address.

The PE checks the encoding that is copied to the *CPSR* for an illegal return event. See *Illegal return events from AArch32 state*.

Load Multiple (exception return) is:

- UNDEFINED in Hyp mode.
- UNPREDICTABLE in debug state, and in User mode and System mode.

cond											

A1

```
LDM{<amode>}{<c>}{<q>} <Rn>{!}, <registers_with_pc>^
```

```
n = UInt(Rn);  registers = register_list;
wback = (W == '1');  increment = (U == '1');  wordhigher = (P == U);
if n == 15 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all the loads using the specified addressing mode and the content of the register being written back is UNKNOWN. In addition, if an exception occurs during the execution of this instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<amode> is one of:

DA
Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.

FA
Full Ascending. For this instruction, a synonym for DA.

DB
Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.

EA
Empty Ascending. For this instruction, a synonym for DB.

IA
Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.

FD
Full Descending. For this instruction, a synonym for IA.

IB

Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.

ED

Empty Descending. For this instruction, a synonym for IB.

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers_with_pc> Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be loaded. The registers are loaded with the lowest-numbered register from the lowest memory address, through to the highest-numbered register from the highest memory address. The PC must be specified in the register list, and the instruction causes a branch to the address (data) loaded into the PC. See also *Encoding of lists of general-purpose registers and the PC*.

Instructions with similar syntax but without the PC included in the registers list are described in *LDM (User registers)*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;                        // UNDEFINED or NOP
    else
        length = 4*BitCount(registers) + 4;
        address = if increment then R[n] else R[n]-length;
        if wordhigher then address = address+4;

        for i = 0 to 14
            if registers<i> == '1' then
                R[i] = MemS[address,4];  address = address + 4;
        new_pc_value = MemS[address,4];

        if wback && registers<n> == '0' then R[n] = if increment then R[n]+length else R[n]-length;
        if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;

        AArch32.ExceptionReturn(new_pc_value, SPSR[]);
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User,M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDM (User registers)

In an EL1 mode other than System mode, Load Multiple (User registers) loads multiple User mode registers from consecutive memory locations using an address from a base register. The registers loaded cannot include the PC. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Load Multiple (User registers) is UNDEFINED in Hyp mode, and UNPREDICTABLE in User and System modes.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see *FEAT_LSMAOC*.

A1

LDM, LDMIA, LDMFD

Load Multiple (Increment After, Full Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the highest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see *FEAT_LSMAOC*. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*. Related system instructions are *LDM (User registers)* and *LDM (exception return)*.

This instruction is used by the alias POP (multiple registers).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

IA	Is an optional suffix for the Increment After form.
<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
!	For encoding A1 and T2: the address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0. For encoding T1: the address adjusted by the size of the data loaded is written back to the base register. It is omitted if <Rn> is included in <registers>, otherwise it must be present.
<registers>	For encoding A1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The PC can be in the list. Arm deprecates using these instructions with both the LR and the PC in the list. For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. For encoding T2: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0. If the PC is in the list: • The LR must not be in the list. • The instruction must be either outside any IT block, or the last instruction in an IT block.

Alias Conditions

Alias	Of variant	Is preferred when
POP (multiple registers)	T2	`W == '1' && Rn == '1101' && BitCount(P:M:register_list) > 1`
POP (multiple registers)	A1	`W == '1' && Rn == '1101' && BitCount(register_list) > 1`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemS[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemS[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] + 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDMDB, LDMEA

Load Multiple Decrement Before (Empty Ascending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations end just below this address, and the address of the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see *FEAT_LSMAOC*. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*. Related system instructions are *LDM (User registers)* and *LDM (exception return)*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	1	0	0	1	0	0	W	1	Rn	register_list
cond										

A1

```
LDMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

LDMEA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack)
```

```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2 1 0	15	14	13 12 11 10 9 8 7 6 5 4 3 2 1 0
1	1	1	0	1	0	0	1	0	0	W	1	Rn	P	M	register_list

T1

```
LDMDB{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```
LDMEA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack)
```

```
n = UInt(Rn);  registers = P:M:register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 || (P == '1' && M == '1') then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads a single register using the specified addressing modes.
- The instruction executes as `LDM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode, but R13 is UNKNOWN.

If `P == '1' && M == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction loads the register list and either R14 or R15, both R14 and R15, or neither of these registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers> For encoding A1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.
The PC can be in the list.
Arm deprecates using these instructions with both the LR and the PC in the list.

For encoding T1: is a list of one or more registers to be loaded, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = MemS[address,4];  address = address + 4;
    if registers<15> == '1' then
        LoadWritePC(MemS[address,4]);
    if wback && registers<n> == '0' then R[n] = R[n] - 4*BitCount(registers);
    if wback && registers<n> == '1' then R[n] = bits(32) UNKNOWN;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDMIB, LDMED

Load Multiple Increment Before (Empty Descending) loads multiple registers from consecutive memory locations using an address from a base register. The consecutive memory locations start just above this address, and the address of the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

Armv8.2 permits the deprecation of some Load Multiple ordering behaviors in AArch32 state, for more information see *FEAT_LSMAOC*. The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*. Related system instructions are *LDM (User registers)* and *LDM (exception return)*.

LDR (immediate)

Load Register (immediate) calculates an address from a base register value and an immediate offset, loads a word from memory, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.

This instruction is used by the alias POP (single register).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 , T3 and T4) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

For encoding T1 and T2: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T3 and T4: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

<Rn> For encoding A1, T3 and T4: is the general-purpose base register, encoded in the "Rn" field. For PC use see *LDR (literal)*.

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.

For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.

For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T4: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Alias Conditions

Alias	Of variant	Is preferred when
POP (single register)	A1 (post-indexed)	`P == '0' && U == '1' && W == '0' && Rn == '1101' && imm12 == '000000000100'`
POP (single register)	T4 (post-indexed)	`Rn == '1101' && P == '0' && U == '1' && W == '1' && imm8 == '00000100'`

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        data = MemU[address,4];
        if wback then R[n] = offset_addr;
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
        else
            R[t] = data;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        data = MemU[address,4];
        if wback then R[n] = offset_addr;
        if t == 15 then
            if address<1:0> == '00' then

            else
                UNPREDICTABLE;
        else
            R[t] = data;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDR (literal)

Load Register (literal) calculates an address from the PC value and an immediate offset, loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19	18	17	16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	1	0	P	U	0	W	1	1	1	1	1	Rt	imm12
cond														

A1 (!(P == 0 && W == 1))

```
LDR{<c>}{<q>} <Rt>, <label> // (Normal form)

LDR{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

```
if P == '0' && W == '1' then SEE "LDRT";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in *LDR (immediate)*. The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15*.

T1

15	14	13	12	11	10 9 8	7 6 5 4 3 2 1 0
0	1	0	0	1	Rt	imm8

T1

```
LDR{<c>}{<q>} <Rt>, <label> // (Normal form)
```

```
t = UInt(Rt);  imm32 = ZeroExtend(imm8:'00', 32);  add = TRUE;
```

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
1	1	1	1	1	0	0	0	U	1	0	1	1	1	1	1	Rt	imm12

T2

```
LDR{<c>}.W <Rt>, <label> // (Preferred syntax, and <Rt>, <label> can be represented in T1)

LDR{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDR{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

```
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The SP can be used. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

<label> For encoding A1 and T2: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are Multiples of four in the range 0 to 1020.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T2: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,4];
    if t == 15 then
        if address<1:0> == '00' then
            LoadWritePC(data);
        else
            UNPREDICTABLE;
    else
        R[t] = data;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDR (register)

Load Register (register) calculates an address from a base register value and an offset register value, loads a word from memory, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses, see *Memory accesses*.

The T32 form of LDR (register) does not support register writeback.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0
!= 1111	0 1 1	P	U	0	W	1	Rn	Rt	imm5	stype	0	Rm
cond												

Offset (P == 1 && W == 0)

```
LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]
```

Post-indexed (P == 0 && W == 0)

```
LDR{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>{, <shift>}
```

Pre-indexed (P == 1 && W == 1)

```
LDR{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>{, <shift>}]!
```

```
if P == '0' && W == '1' then SEE "LDRT";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
if m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if t == 15 && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used. If the PC is used, the instruction branches to the address (data) loaded to the PC. This branch is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

For encoding T2: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, provided the instruction is either outside an IT block or the last instruction of an IT block. If the PC is used, the instruction branches to the address (data) loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

\+ Specifies the index register is added to the base register.

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see *Shifts applied to a register*.

<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
        offset_addr = if add then (R[n] + offset) else (R[n] - offset);
        address = if index then offset_addr else R[n];
        data = MemU[address,4];
        if wback then R[n] = offset_addr;
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
        else
            R[t] = data;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
        offset_addr = (R[n] + offset);
        address = offset_addr;
        data = MemU[address,4];
        if t == 15 then
            if address<1:0> == '00' then
                LoadWritePC(data);
            else
                UNPREDICTABLE;
        else
            R[t] = data;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDRB (immediate)

Load Register Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 and T3) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rt> — Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> — For encoding A1, T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see *LDRB (literal)*.

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 5-bit unsigned immediate byte offset, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        R[t] = ZeroExtend(MemU[address,1], 32);
        if wback then R[n] = offset_addr;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        R[t] = ZeroExtend(MemU[address,1], 32);
        if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDRB (literal)

Load Register Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0 1 0	P	U	1	W	1	1 1 1 1	Rt	imm12
cond									

A1 (!(P == 0 && W == 1))

```
LDRB{<c>}{<q>} <Rt>, <label> // (Normal form)

LDRB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

```
if P == '0' && W == '1' then SEE "LDRBT";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in *LDRB (immediate)*. The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15*.

T1

15 14 13 12 11 10 9 8	7	6 5	4	3 2 1 0	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 1 0 0 0	U	0 0	1	1 1 1 1	!= 1111	imm12
					Rt	

T1

```
LDRB{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDRB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

```
if Rt == '1111' then SEE "PLD";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<label> The label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = ZeroExtend(MemU[address,1], 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRB (register)

Load Register Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can optionally be shifted. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rt> — Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> — For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

+/- — Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+

+ — Specifies the index register is added to the base register.

<Rm> — Is the general-purpose index register, encoded in the "Rm" field.

<shift> — The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see *Shifts applied to a register*.

<imm> — If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    R[t] = ZeroExtend(MemU[address,1],32);
    if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRBT

Load Register Byte Unprivileged loads a byte from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

`LDRBT` is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0

```
LDRBT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For encoding A2 and T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see *Shifts applied to a register*.

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = ZeroExtend(MemU_unpriv[address,1],32);
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDRB` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDRD (immediate)

Load Register Dual (immediate) calculates an address from a base register value and an immediate offset, loads two words from memory, and writes them to two registers. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0

Post-indexed (P == 0 && W == 0)

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #{+/-}<imm>
```

Pre-indexed (P == 1 && W == 1)

```
LDRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #{+/-}<imm>]!
```

```
if Rn == '1111' then SEE "LDRD (literal)";
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as an `LDRD` using one of offset, post-indexed, or pre-indexed addressing.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when Rt == '1111'.

T1

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rt> — For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.

For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

<Rt2> — For encoding A1: is the second general-purpose register to be transferred. This register must be <R(t+1)>.

For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field. For PC use see *LDRD (literal)*.

+/- — Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 if omitted, and encoded in the "imm8" field as <imm>/4.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian(AccType_ATOMIC)  then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
    if wback then R[n] = offset_addr;
```

Operational information

if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if W == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The load instruction executes but the destination register takes an UNKNOWN value.

If `W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15*.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Load/Store dual, Load/Store-Exclusive, Load-Acquire/Store-Release, table branch*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. This register must be even-numbered and not R14.

For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

<Rt2> For encoding A1: is the second general-purpose register to be transferred. This register must be <R(t+1)>.

For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

<label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are multiples of 4 in the range -1020 to 1020.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    if address == Align(address, 8) then
        data = MemA[address,8];
        if BigEndian(AccType_ATOMIC) then
            R[t] = data<63:32>;
            R[t2] = data<31:0>;
        else
            R[t] = data<31:0>;
            R[t2] = data<63:32>;
    else
        R[t] = MemA[address,4];
        R[t2] = MemA[address+4,4];
```

if t == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rt> — Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field.

<imm> — For encoding A1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted.

For encoding T1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    AArch32.SetExclusiveMonitors(address,4);
    R[t] = MemA[address,4];
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDREXB

Load Register Exclusive Byte derives an address from a base register value, loads a byte from memory, zero-extends it to form a 32-bit word, writes it to a register and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

```
t = UInt(Rt);  n = UInt(Rn);
if t == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,1);
    R[t] = ZeroExtend(MemA[address,1], 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDREXD

Load Register Exclusive Doubleword derives an address from a base register value, loads a 64-bit doubleword from memory, writes it to two registers and:

- If the address has the Shared Memory attribute, marks the physical address as exclusive access for the executing PE in a global monitor.
- Causes the executing PE to indicate an active exclusive access in the local monitor.

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

cond																															

A1

```
LDREXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

```
t = UInt(Rt);  t2 = t + 1;  n = UInt(Rn);
if Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction is handled as described in *Using R15*.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

T1

```
LDREXD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>]
```

```
t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if t == 15 || t2 == 15 || t == t2 || n == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The load instruction executes but the destination register takes an UNKNOWN value.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rt>	For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. <Rt> must be even-numbered and not R14. For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.
<Rt2>	For encoding A1: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>. For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,8);
    value = MemA[address,8];
    // Extract words from 64-bit loaded value such that R[t] is
    // loaded from address and R[t2] from address+4.
    R[t]  = if BigEndian(AccType_ATOMIC) then value<63:32> else value<31:0>;
    R[t2] = if BigEndian(AccType_ATOMIC) then value<31:0> else value<63:32>;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    AArch32.SetExclusiveMonitors(address,2);
    R[t] = ZeroExtend(MemA[address,2], 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRH (immediate)

Load Register Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 and T3) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
!= 1111	0 0 0	P	U	1	W	1	!= 1111	Rt	imm4H	1	0 1	1	imm4L
cond							Rn						

Offset (P == 1 && W == 0)

```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1, T2 and T3: is the general-purpose base register, encoded in the "Rn" field. For PC use see *LDRH (literal)*.

For encoding T1: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        data = MemU[address,2];
        if wback then R[n] = offset_addr;
        R[t] = ZeroExtend(data, 32);
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        data = MemU[address,2];
        if wback then R[n] = offset_addr;
        R[t] = ZeroExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDRH (literal)

Load Register Halfword (literal) calculates an address from the PC value and an immediate offset, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
!= 1111	0 0 0	P	U	1	W	1	1 1 1 1	Rt	imm4H	1	0 1	1	imm4L
cond													

A1 (!(P == 0 && W == 1))

```
LDRH{<c>}{<q>} <Rt>, <label> // (Normal form)

LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

```
if P == '0' && W == '1' then SEE "LDRHT";
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in *LDRH (immediate)*. The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15*.

T1

15 14 13 12 11 10 9 8	7	6 5	4	3 2 1 0	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 1 1 0 0 0	U	0 1	1	1 1 1 1	!= 1111	imm12
					Rt	

T1

```
LDRH{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDRH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

```
if Rt == '1111' then SEE "PLD (literal)";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = ZeroExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRH (register)

Load Register Halfword (register) calculates an address from a base register value and an offset register value, loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

\+ Specifies the index register is added to the base register.

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<imm> If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRHT

Load Register Halfword Unprivileged loads a halfword from memory, zero-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

`LDRHT` is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1) .

A1

31-28	27	26	25	24	23	22	21	20	19-16	15-12	11-8	7	6	5	4	3-0
!= 1111	0	0	0	0	U	1	1	1	Rn	Rt	imm4H	1	0	1	1	imm4L
cond																

A1

```
LDRHT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

31-28	27	26	25	24	23	22	21	20	19-16	15-12	11	10	9	8	7	6	5	4	3-0

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rt> — Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field.

+/- — For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm> — Is the general-purpose index register, encoded in the "Rm" field.

\+ — Specifies the offset is added to the base register.

<imm> — For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    R[t] = ZeroExtend(data, 32);
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDRH` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDRSB (immediate)

Load Register Signed Byte (immediate) calculates an address from a base register value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0

// Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rt> — Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field. For PC use see *LDRSB (literal)*.

+/- — Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

\+ — Specifies the offset is added to the base register.

<imm> — For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    R[t] = SignExtend(MemU[address,1], 32);
    if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDRSB (literal)

Load Register Signed Byte (literal) calculates an address from the PC value and an immediate offset, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
!= 1111	0 0 0	P	U	1	W	1	1 1 1 1	Rt	imm4H	1	1 0	1	imm4L
cond													

A1 (!(P == 0 && W == 1))

```
LDRSB{<c>}{<q>} <Rt>, <label> // (Normal form)

LDRSB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative form)
```

```
if P == '0' && W == '1' then SEE "LDRSBT";
t = UInt(Rt);  imm32 = ZeroExtend(imm4H:imm4L, 32);
add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 || wback then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: wback = FALSE;.
- The instruction treats bit[24] as the P bit, and bit[21] as the writeback (W) bit, and uses the same addressing mode as described in *LDRSB (immediate)*. The instruction uses post-indexed addressing when P == '0' and uses pre-indexed addressing otherwise. The instruction is handled as described in *Using R15*.

T1

15 14 13 12 11 10 9 8	7	6 5	4 3 2 1 0	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0

				Rt	

T1

```
LDRSB{<c>}{<q>} <Rt>, <label> // (Preferred syntax)

LDRSB{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

```
if Rt == '1111' then SEE "PLI";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.

<label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    R[t] = SignExtend(MemU[address,1], 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRSB (register)

Load Register Signed Byte (register) calculates an address from a base register value and an offset register value, loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. The offset register value can be shifted left by 0, 1, 2, or 3 bits. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31–28	27	26	25	24	23	22	21	20	19–16	15–12	11	10	9	8	7	6	5	4	3–0
!= 1111	0	0	0	P	U	0	W	1	Rn	Rt	(0)	(0)	(0)	(0)	1	1	0	1	Rm
cond																			

Offset (P == 1 && W == 0)

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]
```

Post-indexed (P == 0 && W == 0)

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>], {+/-}<Rm>
```

Pre-indexed (P == 1 && W == 1)

```
LDRSB{<c>}{<q>} <Rt>, [<Rn>, {+/-}<Rm>]!
```

```
if P == '0' && W == '1' then SEE "LDRSBT";
t = UInt(Rt);  n = UInt(Rn);  m = UInt(Rm);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
(shift_t, shift_n) = (SRType_LSL, 0);
if t == 15 || m == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

LDRSBT

Load Register Signed Byte Unprivileged loads a byte from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

`LDRSBT` is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
!= 1111	0 0 0	0	U	1	1	1	Rn	Rt	imm4H	1	1 0	1	imm4L
cond													

A1

```
LDRSBT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7	6 5	4	3 2 1 0

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    R[t] = SignExtend(MemU_unpriv[address,1], 32);
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDRSB` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDRSH (immediate)

Load Register Signed Halfword (immediate) calculates an address from a base register value and an immediate offset, loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rt> — Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field. For PC use see *LDRSH (literal)*.

+/- — Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

+ — Specifies the offset is added to the base register.

<imm> — For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];
    data = MemU[address,2];
    if wback then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRSH{<c>}{<q>} <Rt>, [PC, #{+/-}<imm>] // (Alternative syntax)
```

```
if Rt == '1111' then SEE "Related instructions";
t = UInt(Rt);  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.
Related instructions: *Load, signed (literal)*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rt>	Is the general-purpose register to be transferred, encoded in the "Rt" field.

<label> For encoding A1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Any value in the range -255 to 255 is permitted.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1. If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

For encoding T1: the label of the literal data item that is to be loaded into <Rt>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values of the offset are -4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE, encoded as U == 1.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE, encoded as U == 0.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = Align(PC,4);
    address = if add then (base + imm32) else (base - imm32);
    data = MemU[address,2];
    R[t] = SignExtend(data, 32);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

LDRSHT

Load Register Signed Halfword Unprivileged loads a halfword from memory, sign-extends it to form a 32-bit word, and writes it to a register. For information about memory accesses see *Memory accesses*.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

`LDRSHT` is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0
!= 1111	0	0	0	0	U	1	1	1	Rn	Rt	imm4H	1	1	1	1	imm4L
cond																

A1

```
LDRSHT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

A2

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    data = MemU_unpriv[address,2];
    if postindex then R[n] = offset_addr;
    R[t] = SignExtend(data, 32);
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `LDRSH` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LDRT

Load Register Unprivileged loads a word from memory, and writes it to a register. For information about memory accesses see *Memory accesses*.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

`LDRT` is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0 1 0	0	U	0	1	1	Rn	Rt	imm12
cond									

A1

```
LDRT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction is treated as if bit[24] == '1' and bit[21] == '0'. The instruction uses immediate offset addressing with the base register as PC, without writeback.

If `n == t && n != 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs all of the loads using the specified addressing mode and the content of the register that is written back is UNKNOWN. In addition, if an exception occurs during such as instruction, the base address might be corrupted so that the instruction cannot be repeated.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rdm>	Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	Is the first general-purpose source register, encoded in the "Rm" field.
<Rs>	Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LSLS (immediate)

Logical Shift Left, setting flags (immediate) shifts a register value left by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of MOV, MOVS (register). This means:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T2 and T3) .

LSR (immediate)

Logical Shift Right (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

This is an alias of MOV, MOVS (register). This means:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T2 and T3) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	0	1	1	0	1	0	(0)	(0)	(0)	(0)	Rd				imm5					0	1	0	Rm			
cond											S														stype						

MOV, shift or rotate by value

```
LSR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is always the preferred disassembly.

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	imm5					Rm			Rd		
			op												

T2

```
LSR<c>{<q>} {<Rd>,} <Rm>, #<imm> // (Inside IT block)
```

is equivalent to

```
MOV<c>{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is the preferred disassembly when `InITBlock()`.

T3

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	1	0	0	1	0	0	1	1	1	1	(0)	imm3			Rd				imm2		0	1	Rm			
											S															stype					

MOV, shift or rotate by value

```
LSR<c>.W {<Rd>,} <Rm>, #<imm> // (Inside IT block, and <Rd>, <Rm>, <imm> can be represented in T2)
LSR{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*. For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.
<imm>	For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as <imm> modulo 32. For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as <imm> modulo 32.

Operation

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LSR (register)

Logical Shift Right (register) shifts a register value right by a variable number of bits, shifting in zeros, and writes the result to the destination register. The variable number of bits is read from the bottom byte of a register

This is an alias of MOV, MOVS (register-shifted register). This means:

- The encodings in this description are named to match the encodings of MOV, MOVS (register-shifted register).
- The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25 24 23	22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0
!= 1111	0 0 0 1 1	0 1	0	(0) (0) (0) (0)	Rd	Rs	0	0 1	1	Rm
cond			S					stype		

Not flag setting

```
LSR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSR <Rs>
```

and is always the preferred disassembly.

T1

15 14 13 12 11 10	9 8 7 6	5 4 3	2 1 0
0 1 0 0 0 0	0 0 1 1	Rs	Rdm
	op		

Logical shift right

```
LSR<c>{<q>} {<Rdm>,} <Rdm>, <Rs> // (Inside IT block)
```

is equivalent to

```
MOV<c>{<q>} <Rdm>, <Rdm>, LSR <Rs>
```

and is the preferred disassembly when `InITBlock()`.

T2

15 14 13 12 11 10 9 8 7	6 5	4	3 2 1 0	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
1 1 1 1 1 0 1 0 0	0 1	0	Rm	1 1 1 1	Rd	0 0 0 0	Rs
	stype	S					

Not flag setting

```
LSR<c>.W {<Rd>,} <Rm>, <Rs> // (Inside IT block, and <Rd>, <Rm>, <shift>, <Rs> can be represented in T1)

LSR{<c>}{<q>} {<Rd>,} <Rm>, <Rs>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, LSR <Rs>
```

and is always the preferred disassembly.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rdm>	Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	Is the first general-purpose source register, encoded in the "Rm" field.
<Rs>	Is the second general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

LSRS (immediate)

Logical Shift Right, setting flags (immediate) shifts a register value right by an immediate number of bits, shifting in zeros, and writes the result to the destination register.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of MOV, MOVS (register). This means:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T2 and T3) .

A1

31–28	27–23	22–21	20	19–16	15–12	11–7	6–5	4	3–0
!= 1111	0 0 0 1 1	0 1	1	(0) (0) (0) (0)	Rd	imm5	0 1	0	Rm
cond			S				stype		

MOVS, shift or rotate by value

```
LSRS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is always the preferred disassembly.

T2

15–13	12–11	10–6	5–3	2–0
0 0 0	0 1	imm5	Rm	Rd
	op			

T2

```
LSRS{<q>} {<Rd>,} <Rm>, #<imm> // (Outside IT block)
```

is equivalent to

```
MOVS{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is the preferred disassembly when `!InITBlock()`.

T3

15–9	8–5	4	3–0	15	14–12	11–8	7–6	5–4	3–0
1 1 1 0 1 0 1	0 0 1 0	1	1 1 1 1	(0)	imm3	Rd	imm2	0 1	Rm
		S						stype	

MOVS, shift or rotate by value

```
LSRS.W {<Rd>,} <Rm>, #<imm> // (Outside IT block, and <Rd>, <Rm>, <imm> can be represented in T2)
```

```
LSRS{<c>}{<q>} {<Rd>,} <Rm>, #<imm>
```

is equivalent to

```
MOVS{<c>}{<q>} <Rd>, <Rm>, LSR #<imm>
```

and is always the preferred disassembly.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>. For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated. For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.
<imm>	For encoding A1 and T2: is the shift amount, in the range 1 to 32, encoded in the "imm5" field as <imm> modulo 32. For encoding T3: is the shift amount, in the range 1 to 32, encoded in the "imm3:imm2" field as <imm> modulo 32.

Operation

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

MCR

Move to System register from general-purpose register or execute a System instruction. This instruction copies the value of a general-purpose register to a System register, or executes a System instruction.

The System register and System instruction descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* and *General behavior of System registers*.

In an implementation that includes EL2, `MCR` accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an `MCR` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps*.

Because of the range of possible traps to Hyp mode, the `MCR` pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9	8	7 6 5	4	3 2 1 0
!= 1111	1 1 1 0	opc1	0	CRn	Rt	1 1 1	coproc<0>	opc2	1	CRm
cond						coproc<3:1>				

A1

```
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

```
t = UInt(Rt);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15  then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

T1

15 14 13 12 11 10 9 8	7 6 5	4	3 2 1 0	15 14 13 12	11 10 9	8	7 6 5	4	3 2 1 0
1 1 1 0 1 1 1 0	opc1	0	CRn	Rt	1 1 1	coproc<0>	opc2	1	CRm
					coproc<3:1>				

T1

```
MCR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

```
t = UInt(Rt);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15  then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<coproc> Is the System register encoding space, encoded in “coproc<0>”:

coproc<0>	<coproc>
0	p14
1	p15

<opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc1" field.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<CRn> Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.

<CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

<opc2> Is the opc2 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc2" field.

The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.SysRegWrite(cp, ThisInstr(), R[t]);
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MCRR

Move to System register from two general-purpose registers. This instruction copies the values of two general-purpose registers to a System register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* and *General behavior of System registers*.

In an implementation that includes EL2, `MCRR` accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an `MCRR` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps*.

Because of the range of possible traps to Hyp mode, the `MCRR` pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24 23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7 6 5 4	3 2 1 0
!= 1111	1 1 0 0 0	1	0	0	Rt2	Rt	1	1	1	coproc<0>	opc1	CRm
cond							coproc<3:1>					

A1

```
MCRR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

```
t = UInt(Rt);  t2 = UInt(Rt2);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

T1

15 14 13 12 11 10 9 8 7	6	5	4	3 2 1 0	15 14 13 12	11	10	9	8	7 6 5 4	3 2 1 0
1 1 1 0 1 1 0 0 0	1	0	0	Rt2	Rt	1	1	1	coproc<0>	opc1	CRm
						coproc<3:1>					

T1

```
MCRR{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

```
t = UInt(Rt);  t2 = UInt(Rt2);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<coproc> Is the System register encoding space, encoded in “coproc<0>”:

coproc<0>	<coproc>
0	p14
1	p15

<opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.

<Rt> Is the first general-purpose register that is transferred into, encoded in the "Rt" field.

<Rt2> Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.

<CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of { <coproc>, <opc1>, <CRm> } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    value = R[t2]:R[t];
    AArch32.SysRegWrite64(cp, ThisInstr(), value);
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MLA, MLAS

Multiply Accumulate multiplies two register values, and adds a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

In an A32 instruction, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
!= 1111	0 0 0 0	0 0 1	S	Rd	Ra	Rm	1 0 0 1	Rn
cond								

Flag setting (S == 1)

```
MLAS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

Not flag setting (S == 0)

```
MLA{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

T1

15 14 13 12 11 10 9 8 7	6 5 4	3 2 1 0	15 14 13 12	11 10 9 8	7 6	5 4	3 2 1 0
1 1 1 1 1 0 1 1 0	0 0 0	Rn	!= 1111	Rd	0 0	0 0	Rm
			Ra				

T1

```
MLA{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

```
if Ra == '1111' then SEE "MUL";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  setflags = FALSE;
if d == 15 || n == 15 || m  == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

<Ra> Is the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = operand1 * operand2 + addend;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MLS

Multiply and Subtract multiplies two register values, and subtracts the product from a third register value. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
!= 1111	0 0 0 0	0 1 1	0	Rd	Ra	Rm	1 0 0 1	Rn
cond								

A1

```
MLS{<c>}{<q>} <Rd>, <Rn>, <Rm>, <Ra>
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a == 15 then UNPREDICTABLE;
```

T1

15 14 13 12 11 10 9 8 7	6 5 4	3 2 1 0	15 14 13 12	11 10 9 8	7 6	5 4	3 2 1 0
1 1 1 1 1 0 1 1 0	0 0 0	Rn	Ra	Rd	0 0	0 1	Rm

T1

```

// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.
<Ra>	Is the third general-purpose source register holding the minuend, encoded in the "Ra" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    addend   = SInt(R[a]);  // addend   = UInt(R[a]) produces the same final results
    result = addend - operand1 * operand2;
    R[d] = result<31:0>;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

MOV, MOVS (immediate)

Move (immediate) writes an immediate value to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The MOV variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 , T2 and T3) .

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the MOVS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding A2, T1, T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<imm8> Is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

<imm16> For encoding A2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.

For encoding T3: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T2: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = imm32;
    if d == 15 then          // Can only occur for encoding A1
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

MOV, MOVS (register)

Move (register) copies a value from a register to the destination register.

If the destination register is not the PC, the MOVS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The MOV variant of the instruction is a branch. In the T32 instruction set (encoding T1) this is a simple branch, and in the A32 instruction set it is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The MOVS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This instruction is used by the aliases ASRS (immediate), ASR (immediate), LSLS (immediate), LSL (immediate), LSRS (immediate), LSR (immediate), RORS (immediate), ROR (immediate), RRXS, and RRX.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 and T3) .

A1

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used:

- For the MOV variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*. Arm deprecates use of the instruction if <Rn> is the PC.
- For the MOVS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>. Arm deprecates use of the instruction if <Rn> is not the LR, or if the optional shift or RRX argument is specified.

For encoding T1: is the general-purpose destination register, encoded in the "D:Rd" field. If the PC is used:

- The instruction causes a branch to the address moved to the PC. This is a simple branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The instruction must either be outside an IT block or the last instruction of an IT block.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used. Arm deprecates use of the instruction if <Rd> is the PC.

For encoding T2 and T3: is the general-purpose source register, encoded in the "Rm" field.

<shift> For encoding A1 and T3: is the type of shift to be applied to the source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

For encoding T2: is the type of shift to be applied to the source register, encoded in “op”:

op	<shift>
00	LSL
01	LSR
10	ASR

<amount> For encoding A1: is the shift amount, in the range 0 to 31 (when <shift> = LSL), or 1 to 31 (when <shift> = ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T3: is the shift amount, in the range 0 to 31 (when <shift> = LSL) or 1 to 31 (when <shift> = ROR), or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Alias Conditions

Alias	Of variant	Is preferred when
ASRS (immediate)	T3 (MOVS, shift or rotate by value), A1 (MOVS, shift or rotate by value)	`S == '1' && stype == '10'`

```

Related encodings: In encoding T1, for an op field value that is not described above, see *Data-processing (two low registers)*.
For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rdm>	Is the general-purpose source register and the destination register, encoded in the "Rdm" field.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	Is the general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Alias Conditions

Alias	Of variant	Is preferred when

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (result, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:

    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

MOVT{<c>}{<q>} <Rd>, #<imm16>
```

```
d = UInt(Rd);  imm16 = imm4:i:imm3:imm8;
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<imm16> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field.

For encoding T1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:i:imm3:imm8" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    R[d]<31:16> = imm16;
    // R[d]<15:0> unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

MRC

Move to general-purpose register from System register. This instruction copies the value of a System register to a general-purpose register.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* and *General behavior of System registers*.

In an implementation that includes EL2, `MRC` accesses to system control registers can be trapped to Hyp mode, meaning that an attempt to execute an `MRC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps*.

Because of the range of possible traps to Hyp mode, the `MRC` pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11	10	9	8	7 6 5	4	3 2 1 0
!= 1111	1 1 1 0	opc1	1	CRn	Rt	1	1	1	coproc<0>	opc2	1	CRm
cond						coproc<3:1>						

A1

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

```
t = UInt(Rt);  cp = if coproc<0> == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
```

T1

15 14 13 12 11 10 9 8	7 6 5 4	3 2 1 0	15 14 13 12	11	10	9	8	7 6 5	4	3 2 1 0
1 1 1 0 1 1 1 0	opc1 1	CRn	Rt	1	1	1	coproc<0>	opc2	1	CRm
				coproc<3:1>						

T1

```
MRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <CRn>, <CRm>{, {#}<opc2>}
```

```
t = UInt(Rt);  cp = if coproc<0> == '0' then 14 else 15;
// Armv8-A removes UNPREDICTABLE for R13
```

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<coproc> Is the System register encoding space, encoded in “coproc<0>”:

coproc<0>	<coproc>
0	p14
1	p15

<opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc1" field.

<Rt> Is the general-purpose register to be transferred or APSR_nzcv (encoded as 0b1111), encoded in the "Rt" field. If APSR_nzcv is used, bits [31:28] of the transferred value are written to the *PSTATE* condition flags.

<CRn> Is the CRn parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRn" field.

<CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

<opc2> Is the opc2 parameter within the System register encoding space, in the range 0 to7, encoded in the "opc2" field.

The possible values of { <coproc>, <opc1>, <CRn>, <CRm>, <opc2> } encode the entire System register and System instruction encoding space. Not all of this space is allocated, and the System register and System instruction descriptions identify the allocated encodings.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) value = AArch32.SysRegRead(cp, ThisInstr());
    if t != 15 then
        R[t] = value;
    elsif AArch32.SysRegReadCanWriteAPSR(cp, ThisInstr()) then
        PSTATE.<N,Z,C,V> = value<31:28>;
        // value<27:0> are not used.
    else
        UNPREDICTABLE;
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MRRC

Move to two general-purpose registers from System register. This instruction copies the value of a System register to two general-purpose registers.

The System register descriptions identify valid encodings for this instruction. Other encodings are UNDEFINED. For more information see *About the AArch32 System register interface* and *General behavior of System registers*.

In an implementation that includes EL2, `MRRC` accesses to System registers can be trapped to Hyp mode, meaning that an attempt to execute an `MRRC` instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *EL2 configurable instruction enables, disables, and traps*.

Because of the range of possible traps to Hyp mode, the `MRRC` pseudocode does not show these possible traps.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24 23	22	21	20	19 18 17 16	15 14 13 12	11 10 9	8	7 6 5 4	3 2 1 0
!= 1111	1 1 0 0 0	1	0	1	Rt2	Rt	1 1 1	coproc<0>	opc1	CRm
cond							coproc<3:1>			

A1

```
MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

```
t = UInt(Rt);  t2 = UInt(Rt2);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

T1

15 14 13 12 11 10 9 8 7	6	5	4	3 2 1 0	15 14 13 12	11 10 9	8	7 6 5 4	3 2 1 0
1 1 1 0 1 1 0 0 0	1	0	1	Rt2	Rt	1 1 1	coproc<0>	opc1	CRm
						coproc<3:1>			

T1

```
MRRC{<c>}{<q>} <coproc>, {#}<opc1>, <Rt>, <Rt2>, <CRm>
```

```
t = UInt(Rt);  t2 = UInt(Rt2);  cp = if coproc<0> == '0' then 14 else 15;
if t == 15 || t2 == 15 || t == t2 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<coproc> Is the System register encoding space, encoded in “coproc<0>”:

coproc<0>	<coproc>
0	p14
1	p15

<opc1> Is the opc1 parameter within the System register encoding space, in the range 0 to 15, encoded in the "opc1" field.

<Rt> Is the first general-purpose register that is transferred into, encoded in the "Rt" field.

<Rt2> Is the second general-purpose register that is transferred into, encoded in the "Rt2" field.

<CRm> Is the CRm parameter within the System register encoding space, in the range c0 to c15, encoded in the "CRm" field.

The possible values of { <coproc>, <opc1>, <CRm> } encode the entire System register encoding space. Not all of this space is allocated, and the System register descriptions identify the allocated encodings.

For the permitted uses of these instructions, as described in this manual, <Rt2> transfers bits[63:32] of the selected System register, while <Rt> transfers bits[31:0].

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    value = AArch32.SysRegRead64(cp, ThisInstr());
    R[t] = value<31:0>;
    R[t2] = value<63:32>;
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MRS

Move Special register to general-purpose register moves the value of the *APSR*, *CPSR*, or *SPSR*_<current_mode> into a general-purpose register.

Arm recommends the APSR form when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *APSR*.

An MRS that accesses the *SPSRs* is UNPREDICTABLE if executed in User mode or System mode.

An MRS that is executed in User mode and accesses the *CPSR* returns an UNKNOWN value for the *CPSR*.{E, A, I, F, M} fields.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

1	1	1	1	0	0	1	1	1	1	1	R	(1)	(1)	(1)	(1)	1	0	(0)	0	Rd				(0)	(0)	0	(0)	(0)	(0)	(0)	(0)

T1

```
MRS{<c>}{<q>} <Rd>, <spec_reg>
```

```
d = UInt(Rd);  read_spsr = (R == '1');
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<spec_reg> Is the special register to be accessed, encoded in “R”:

R	<spec_reg>
0	CPSR|APSR
1	SPSR

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if read_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;
        else
            R[d] = SPSR[];
    else
        // CPSR has same bit assignments as SPSR, but with the IT, J, SS, IL, and T bits masked out.
        bits(32) mask = '11111000 11101111 00000011 11011111';
        psr_val = GetPSRFromPSTATE(AArch32_NonDebugState) AND mask;
        if PSTATE.EL == EL0 then
            // If accessed from User mode return UNKNOWN values for E, A, I, F bits, bits<9:6>,
            // and for the M field, bits<4:0>
            psr_val<22> = bits(1) UNKNOWN;
            psr_val<9:6> = bits(4) UNKNOWN;
            psr_val<4:0> = bits(5) UNKNOWN;
        R[d] = psr_val;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User, M32_System} && read_spsr`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MRS (Banked register)

Move to Register from Banked or Special register moves the value from the Banked general-purpose register or *Saved Program Status Registers (SPSRs)* of the specified mode, or the value of *ELR_hyp*, to a general-purpose register.

MRS (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MRS (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an MRS (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

                when '11111'                       // Access SP_hyp register
                    R[d] = Rmode[13,M32_Hyp];
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MSR (Banked register)

Move to Banked or Special register from general-purpose register moves the value of a general-purpose register to the Banked general-purpose register or *Saved Program Status Registers (SPSRs)* of the specified mode, or to *ELR_hyp*.

`MSR` (Banked register) is UNPREDICTABLE if executed in User mode.

When EL3 is using AArch64, if an MSR (Banked register) instruction that is executed in a Secure EL1 mode would access SPSR_mon, SP_mon, or LR_mon, it is trapped to EL3.

The effect of using an `MSR` (Banked register) instruction with a register argument that is not valid for the current mode is UNPREDICTABLE. For more information see *Usage restrictions on the Banked register transfer instructions*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31–28	27	26	25	24	23	22	21	20	19–16	15	14	13	12	11	10	9	8	7	6	5	4	3–0

                    Rmode[13,M32_Hyp] = R[n];
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MSR (immediate)

Move immediate value to Special register moves selected bits of an immediate value to the corresponding bits in the *APSR*, *CPSR*, or *SPSR*_<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, the immediate form of `MSR` is normally only useful at the Application level for writing to APSR_nzcvq (CPSR_f).

If an `MSR` (immediate) moves selected bits of an immediate value to the *CPSR*, the PE checks whether the value being written to *PSTATE*.M is legal. See *Illegal changes to PSTATE.M*.

An `MSR` (immediate) executed in User mode:

- Is CONSTRAINED UNPREDICTABLE if it attempts to update the *SPSR*.
- Otherwise, does not update any *CPSR* field that is accessible only at EL1 or higher,

An `MSR` (immediate) executed in System mode is CONSTRAINED UNPREDICTABLE if it attempts to update the *SPSR*.

The *CPSR*.E bit is writable from any mode using an `MSR` instruction. Arm deprecates using this to change its value.

A1 (!(R == 0 && mask == 0000))

```
MSR{<c>}{<q>} <spec_reg>, #<imm>
```

```
if mask == '0000' && R == '0' then SEE "Related encodings";
imm32 = A32ExpandImm(imm12);  write_spsr = (R == '1');
if mask == '0000' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `mask == '0000' && R == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: *Move Special Register and Hints (immediate)*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<spec_reg> Is one of:

- APSR_<bits>.
- CPSR_<fields>.
- SPSR_<fields>.

For CPSR and SPSR, <fields> is a sequence of one or more of the following:

c

mask<0> = '1' to enable writing of bits<7:0> of the destination PSR.

x

mask<1> = '1' to enable writing of bits<15:8> of the destination PSR.

s

mask<2> = '1' to enable writing of bits<23:16> of the destination PSR.

f

mask<3> = '1' to enable writing of bits<31:24> of the destination PSR.

For APSR, <bits> is one of nzcvq, g, or nzcvqg. These map to the following CPSR_<fields> values:

- APSR_nzcvq is the same as CPSR_f (mask== '1000').

- APSR_g is the same as CPSR_s (mask == '0100').
- APSR_nzcvqg is the same as CPSR_fs (mask == '1100').

Arm recommends the APSR_<bits> forms when only the N, Z, C, V, Q, and GE[3:0] bits are being written. For more information, see *The Application Program Status Register, APSR*.

<imm> Is an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if write_spsr then
        if PSTATE.M IN {M32_User,M32_System} then
            UNPREDICTABLE;
        else
            SPSRWriteByInstr(imm32, mask);
    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(imm32, mask);
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User,M32_System} && write_spsr`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MSR (register)

Move general-purpose register to Special register moves selected bits of a general-purpose register to the *APSR*, *CPSR* or *SPSR*_<current_mode>.

Because of the Do-Not-Modify nature of its reserved bits, a read-modify-write sequence is normally required when the `MSR` instruction is being used at Application level and its destination is not APSR_nzcvq (CPSR_f).

If an `MSR` (register) moves selected bits of an immediate value to the *CPSR*, the PE checks whether the value being written to *PSTATE*.M is legal. See *Illegal changes to PSTATE.M*.

An `MSR` (register) executed in User mode:

- Is UNPREDICTABLE if it attempts to update the *SPSR*.
- Otherwise, does not update any *CPSR* field that is accessible only at EL1 or higher.

An `MSR` (register) executed in System mode is UNPREDICTABLE if it attempts to update the *SPSR*.

The *CPSR*.E bit is writable from any mode using an `MSR` instruction. Arm deprecates using this to change its value.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27	26	25	24	23	22	21	20	19-16	15	14	13	12	11	10	9	8	7	6	5	4	3-0

    else
        // Attempts to change to an illegal mode will invoke the Illegal Execution state mechanism
        CPSRWriteByInstr(R[n], mask);
```

CONSTRAINED UNPREDICTABLE behavior

If `write_spsr && PSTATE.M IN {M32_User,M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MUL, MULS

Multiply multiplies two register values. The least significant 32 bits of the result are written to the destination register. These 32 bits do not depend on whether the source register values are considered to be signed values or unsigned values.

Optionally, it can update the condition flags based on the result. In the T32 instruction set, this option is limited to only a few forms of the instruction. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
!= 1111	0 0 0 0	0 0 0	S	Rd	(0) (0) (0) (0)	Rm	1 0 0 1	Rn
cond								

Flag setting (S == 1)

```
MULS{<c>}{<q>} <Rd>, <Rn>{, <Rm>}
```

Not flag setting (S == 0)

```
MUL{<c>}{<q>} <Rd>, <Rn>{, <Rm>}
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE;
```

T1

15 14 13 12 11 10	9 8 7 6	5 4 3	2 1 0
0 1 0 0 0 0	1 1 0 1	Rn	Rdm

T1

```
MUL<c>{<q>} <Rdm>, <Rn>{, <Rdm>} // (Inside IT block)
```

```
MULS{<q>} <Rdm>, <Rn>{, <Rdm>} // (Outside IT block)
```

```
d = UInt(Rdm);  n = UInt(Rn);  m = UInt(Rdm);  setflags = !InITBlock();
```

T2

15 14 13 12 11 10 9 8 7	6 5 4	3 2 1 0	15 14 13 12	11 10 9 8	7 6	5 4	3 2 1 0
1 1 1 1 1 0 1 1 0	0 0 0	Rn	1 1 1 1	Rd	0 0	0 0	Rm

T2

```
MUL<c>.W <Rd>, <Rn>{, <Rm>} // (Inside IT block, and <Rd>, <Rn>, <Rm> can be represented in T1)
```

```
MUL{<c>}{<q>} <Rd>, <Rn>{, <Rm>}
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q>	See *Standard assembler syntax fields*.
<Rdm>	Is the second general-purpose source register holding the multiplier and the destination register, encoded in the "Rdm" field.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field. If omitted, <Rd> is used.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = SInt(R[n]);  // operand1 = UInt(R[n]) produces the same final results
    operand2 = SInt(R[m]);  // operand2 = UInt(R[m]) produces the same final results
    result = operand1 * operand2;
    R[d] = result<31:0>;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result<31:0>);
        // PSTATE.C, PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

MVN, MVNS (immediate)

Bitwise NOT (immediate) writes the bitwise inverse of an immediate value to the destination register.

If the destination register is not the PC, the MVNS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The MVN variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The MVNS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27	26	25	24	23	22	21	20	19	18	17	16	15-12	11-0

cond														

MVN (S == 0)

```
MVN{<c>}{<q>} <Rd>, #<const>
```

MVNS (S == 1)

```
MVNS{<c>}{<q>} <Rd>, #<const>
```

```
d = UInt(Rd);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14-12	11-8	7-0
1	1	1	1	0	i	0	0	0	1	1	S	1	1	1	1	0	imm3	Rd	imm8

MVN (S == 0)

```
MVN{<c>}{<q>} <Rd>, #<const>
```

MVNS (S == 1)

```
MVNS{<c>}{<q>} <Rd>, #<const>
```

```
d = UInt(Rd);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the MVNS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = NOT(imm32);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the MVN variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the MVNS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1 and T2: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = NOT(shifted);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

MVN, MVNS (register-shifted register)

Bitwise NOT (register-shifted register) writes the bitwise inverse of a register-shifted register value to the destination register. It can optionally update the condition flags based on the result.

A1

31 30 29 28	27 26 25 24 23	22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> Is the general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

NOP

No Operation does nothing. This instruction can be used for instruction alignment purposes.

The timing effects of including a `NOP` instruction in a program are not guaranteed. It can increase execution time, leave it unchanged, or even reduce it. Therefore, `NOP` instructions are not suitable for timing loops.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] OR NOT(shifted);
    R[d] = result;
    if setflags then
        PSTATE.N = result<31>;
        PSTATE.Z = IsZeroBit(result);
        PSTATE.C = carry;
        // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

ORR, ORRS (immediate)

Bitwise OR (immediate) performs a bitwise (inclusive) OR of a register value and an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the ORRS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The ORR variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The ORRS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	0	1	1	1	0	0	S	Rn	Rd	imm12
cond											

ORR (S == 0)

```
ORR{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ORRS (S == 1)

```
ORRS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = A32ExpandImm_C(imm12, PSTATE.C);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2 1 0	15	14 13 12	11 10 9 8	7 6 5 4 3 2 1 0

												Rn				

ORR (S == 0)

```
ORR{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

ORRS (S == 1)

```
ORRS{<c>}{<q>} {<Rd>,} <Rn>, #<const>
```

```
if Rn == '1111' then SEE "MOV (immediate)";
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if d == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ORRS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] OR imm32;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Operational information

if d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.
Related encodings: *Data-processing (shifted register)*

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the ORR variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the ORRS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

In T32 assembly:

- Outside an IT block, if ORRS <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORRS <Rd>, <Rn> had been written.
- Inside an IT block, if ORR<c> <Rd>, <Rn>, <Rd> is written with <Rd> and <Rn> both in the range R0-R7, it is assembled using encoding T1 as though ORR<c> <Rd>, <Rn> had been written.

To prevent either of these happening, use the .W qualifier.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (shifted, carry) = Shift_C(R[m], shift_t, shift_n, PSTATE.C);
    result = R[n] OR shifted;
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.N = result<31>;
            PSTATE.Z = IsZeroBit(result);
            PSTATE.C = carry;
            // PSTATE.V unchanged
```

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rd> — Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> — Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> — Is the second general-purpose source register, encoded in the "Rm" field.

<imm> — For encoding A1: the shift to apply to the value read from <Rm>, encoded in the "imm5" field.
For PKHBT, it is one of:

omitted
No shift, encoded as 0b00000.

1-31
: Left shift by specified number of bits, encoded as a binary number.

For PKHTB, it is one of:

omitted
: Instruction is a pseudo-instruction and is assembled as though `PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn>` had been written.

1-32
: Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

For encoding T1: the shift to apply to the value read from <Rm>, encoded in the "imm3:imm2" field.

For PKHBT, it is one of:

omitted
: No shift, encoded as 0b00000.

1-31
: Left shift by specified number of bits, encoded as a binary number.

For PKHTB, it is one of:

omitted
: Instruction is a pseudo-instruction and is assembled as though `PKHBT{<c>}{<q>} <Rd>, <Rm>, <Rn>` had been written.

1-32
: Arithmetic right shift by specified number of bits. A shift by 32 bits is encoded as 0b00000. Other shift amounts are encoded as binary numbers.

An assembler can permit <imm> = 0 to mean the same thing as omitting the shift, but this is not standard UAL and must not be used for disassembly.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = Shift(R[m], shift_t, shift_n, PSTATE.C);  // PSTATE.C ignored
    R[d]<15:0>  = if tbform then operand2<15:0> else R[n]<15:0>;
    R[d]<31:16> = if tbform then R[n]<31:16>    else operand2<31:16>;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

PLD (literal)

Preload Data (literal) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The effect of a PLD instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. Must be AL or omitted.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<label> The label of the literal data item that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range –4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

For encoding T1: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = if add then (Align(PC,4) + imm32) else (Align(PC,4) - imm32);
    Hint_PreloadData(address);
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

PLD, PLDW (immediate)

Preload Data (immediate) signals the memory system that data memory accesses from a specified address are likely in the near future. The memory system can respond by taking actions that are expected to speed up the memory accesses when they do occur, such as preloading the cache line containing the specified address into the data cache.

The `PLD` instruction signals that the likely memory access is a read, and the `PLDW` instruction signals that it is a write.

The effect of a `PLD` or `PLDW` instruction is IMPLEMENTATION DEFINED. For more information, see *Preloading caches*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19-16	15	14	13	12	11-0

1	1	1	1	1	0	0	1	1	0	0	1	!= 1111	1	1	1	1	imm12
												Rn					

T1

```
PLI{<c>}{<q>} [<Rn> {, #{+}<imm>}]
```

```
if Rn == '1111' then SEE "encoding T3";
n = UInt(Rn);  imm32 = ZeroExtend(imm12, 32);  add = TRUE;
```

T2

15	14	13	12	11	10	9	8	7	6	5	4	3-0	15	14	13	12	11	10	9	8	7-0
1	1	1	1	1	0	0	1	0	0	0	1	!= 1111	1	1	1	1	1	1	0	0	imm8
												Rn									

T2

```
PLI{<c>}{<q>} [<Rn> {, #-<imm>}]
```

```
if Rn == '1111' then SEE "encoding T3";
n = UInt(Rn);  imm32 = ZeroExtend(imm8, 32);  add = FALSE;
```

T3

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11-0
1	1	1	1	1	0	0	1	U	0	0	1	1	1	1	1	1	1	1	1	imm12

T3

```
PLI{<c>}{<q>} <label> // (Preferred syntax)
```

```
PLI{<c>}{<q>} [PC, #{+/-}<imm>] // (Alternative syntax)
```

```
n = 15;  imm32 = ZeroExtend(imm12, 32);  add = (U == '1');
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. Must be AL or omitted.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<label> The label of the instruction that is likely to be accessed in the near future. The assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. The offset must be in the range –4095 to 4095.

If the offset is zero or positive, imm32 is equal to the offset and add == TRUE.

If the offset is negative, imm32 is equal to minus the offset and add == FALSE.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T1: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T2: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

For encoding T3: is a 12-bit unsigned immediate byte offset, in the range 0 to 4095, encoded in the "imm12" field.

For the literal forms of the instruction, encoding T3 is used, or Rn is encoded as 0b1111 in encoding A1, to indicate that the PC is the base register.

The alternative literal syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    Hint_PreloadInstr(address);
```

												Rn												

T1

```
PLI{<c>}{<q>} [<Rn>, {+}<Rm> {, LSL #<amount>}]
```

```
if Rn == '1111' then SEE "PLI (immediate, literal)";
n = UInt(Rn);  m = UInt(Rm);  add = TRUE;
(shift_t, shift_n) = (SRType_LSL, UInt(imm2));
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. <c> must be AL or omitted.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

+	Specifies the index register is added to the base register.
<Rm>	Is the general-purpose index register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the index register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the shift amount, in the range 0 to 3, defaulting to 0 and encoded in the "imm2" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    address = if add then (R[n] + offset) else (R[n] - offset);
    Hint_PreloadInstr(address);
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

POP

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

The registers loaded can include the PC, causing a branch to a loaded address. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	1	1	0	P	register_list							

T1

```
POP{<c>}{<q>} <registers> // (Preferred syntax)
```

```
LDM{<c>}{<q>} SP!, <registers> // (Alternate syntax)
```

```
registers = P:'0000000':register_list;   UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
if registers<15> == '1' && InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<registers> Is a list of one or more registers to be loaded, separated by commas and surrounded by { and }.

The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the PC. If the PC is in the list, the "P" field is set to 1, otherwise this field defaults to 0.

If the PC is in the list, the instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = SP;
    for i = 0 to 14
        if registers<i> == '1' then
            R[i] = if UnalignedAllowed then MemU[address,4] else MemA[address,4];
            address = address + 4;
    if registers<15> == '1' then
        if UnalignedAllowed then
            if address<1:0> == '00' then
                LoadWritePC(MemU[address,4]);
            else
                UNPREDICTABLE;
        else
            LoadWritePC(MemA[address,4]);
    if registers<13> == '0' then SP = SP + 4*BitCount(registers);
    if registers<13> == '1' then SP = bits(32) UNKNOWN;
```

POP (multiple registers)

Pop Multiple Registers from Stack loads multiple general-purpose registers from the stack, loading from consecutive memory locations starting at the address in SP, and updates SP to point just above the loaded data

This is an alias of LDM, LDMIA, LDMFD. This means:

- The encodings in this description are named to match the encodings of LDM, LDMIA, LDMFD.
- The description of LDM, LDMIA, LDMFD gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T2) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	1	0	0	0	1	0	1	1	1 1 0 1	register_list
cond							W		Rn	

A1

`POP{<c>}{<q>} <registers>`

is equivalent to

`LDM{<c>}{<q>} SP!, <registers>`

and is the preferred disassembly when `BitCount(register_list) > 1`.

T2

15 14 13 12 11 10 9	8 7	6	5	4	3 2 1 0	15	14	13 12 11 10 9 8 7 6 5 4 3 2 1 0
1 1 1 0 1 0 0	0 1	0	1	1	1 1 0 1	P	M	register_list
			W		Rn			

T2

`POP{<c>}.W <registers> // (All registers in R0-R7, PC)`

`POP{<c>}{<q>} <registers>`

is equivalent to

`LDM{<c>}{<q>} SP!, <registers>`

and is the preferred disassembly when `BitCount(P:M:register_list) > 1`.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<registers> For encoding A1: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

If the SP is in the list, the value of the SP after such an instruction is UNKNOWN.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

Arm deprecates the use of this instruction with both the LR and the PC in the list.

For encoding T2: is a list of two or more registers to be loaded, separated by commas and surrounded by { and }. The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain one of the LR or the PC. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0. If the PC is in the list, the "P" field is set to 1, otherwise it defaults to 0.

The PC can be in the list. If it is, the instruction branches to the address loaded to the PC. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*. If the PC is in the list:

- The LR must not be in the list.
- The instruction must be either outside any IT block, or the last instruction in an IT block.

Operation

The description of LDM, LDMIA, LDMFD gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

POP (single register)

Pop Single Register from Stack loads a single general-purpose register from the stack, loading from the address in SP, and updates SP to point just above the loaded data

This is an alias of LDR (immediate). This means:

- The encodings in this description are named to match the encodings of LDR (immediate).
- The description of LDR (immediate) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T4) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0

PSSBB

Physical Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same physical address.

The semantics of the Physical Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the PSSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order before the PSSBB.
- When a load to a location appears in program order before the PSSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
  - The store is to the same location as the load.
  - The store appears in program order after the PSSBB.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PUSH

Push Multiple Registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data.

The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	1	1	0	1	0	M	register_list							

T1

```
PUSH{<c>}{<q>} <registers> // (Preferred syntax)
```

```
STMDB{<c>}{<q>} SP!, <registers> // (Alternate syntax)
```

```
registers = '0':M:'000000':register_list;  UnalignedAllowed = FALSE;
if BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction targets an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers loaded.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<registers> Is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field, and can optionally include the LR. If the LR is in the list, the "M" field is set to 1, otherwise this field defaults to 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = SP - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == 13 && i != LowestSetBit(registers) then  // Only possible for encoding A1
                MemA[address,4] = bits(32) UNKNOWN;
            else
                if UnalignedAllowed then
                    MemU[address,4] = R[i];
                else
                    MemA[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1 or A2
        if UnalignedAllowed then
            MemU[address,4] = PCStoreValue();
        else
            MemA[address,4] = PCStoreValue();
    SP = SP - 4*BitCount(registers);
```

PUSH (multiple registers)

Push multiple registers to Stack stores multiple general-purpose registers to the stack, storing to consecutive memory locations ending just below the address in SP, and updates SP to point to the start of the stored data

This is an alias of STMDB, STMFD. This means:

- The encodings in this description are named to match the encodings of STMDB, STMFD.
- The description of STMDB, STMFD gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19	18	17	16	15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	1	0	0	1	0	0	1	0	1	1	0	1	register_list
cond							W			Rn			

A1

```
PUSH{<c>}{<q>} <registers>
```

is equivalent to

```
STMDB{<c>}{<q>} SP!, <registers>
```

and is the preferred disassembly when `BitCount(register_list) > 1`.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13 12 11 10 9 8 7 6 5 4 3 2 1 0

										W			Rn			P		

T1

```
PUSH{<c>}.W <registers> // (All registers in R0-R7, LR)
```

```
PUSH{<c>}{<q>} <registers>
```

is equivalent to

```
STMDB{<c>}{<q>} SP!, <registers>
```

and is the preferred disassembly when `BitCount(M:register_list) > 1`.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<registers> For encoding A1: is a list of two or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

The SP and PC can be in the list. However:

- Arm deprecates the use of instructions that include the PC in the list.
- If the SP is in the list, and it is not the lowest-numbered register in the list, the instruction stores an UNKNOWN value for the SP.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The lowest-numbered register is stored to the lowest memory address, through to the

highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.
The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation

The description of STMDB, STMFD gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

PUSH (single register)

Push Single Register to Stack stores a single general-purpose register to the stack, storing to the 32-bit word below the address in SP, and updates SP to point to the start of the stored data

This is an alias of STR (immediate). This means:

- The encodings in this description are named to match the encodings of STR (immediate).
- The description of STR (immediate) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T4) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0

QDADD

Saturating Double and Add adds a doubled register value to another register value, and writes the result to the destination register. Both the doubling and the addition have their results saturated to the 32-bit signed integer range $-2^{31} <= x <= 2^{31} - 1$. If saturation occurs in either operation, it sets *PSTATE*.Q to 1.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

RBIT

Reverse Bits reverses the bit order in a 32-bit register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24 23	22	21 20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5 4	3 2 1 0
!= 1111	0 1 1 0 1	1	1 1	(1) (1) (1) (1)	Rd	(1) (1) (1) (1)	0	0 1 1	Rm
cond									

A1

```
RBIT{<c>}{<q>} <Rd>, <Rm>
```

```
d = UInt(Rd);  m = UInt(Rm);
if d == 15 || m == 15 then UNPREDICTABLE;
```

T1

15 14 13 12 11 10 9 8 7	6 5 4	3 2 1 0	15 14 13 12	11 10 9 8	7 6	5 4	3 2 1 0
1 1 1 1 1 0 1 0 1	0 0 1	Rn	1 1 1 1	Rd	1 0	1 0	Rm

T1

```
RBIT{<c>}{<q>} <Rd>, <Rm>
```

```
d = UInt(Rd);  m = UInt(Rm);  n = UInt(Rn);
if m != n || d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `m != n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: m = UInt(Rn);.
- The instruction executes with the additional decode: m = UInt(Rm);.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rd> — Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> — For encoding A1: is the general-purpose source register, encoded in the "Rm" field.

For encoding T1: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    for i = 0 to 31
        result<31-i> = R[m]<i>;
    R[d] = result;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

1 1 1 1 1 0 1 0 1	0 0 1	Rn	1 1 1 1	Rd	1 0	0 1	Rm

T2

```
REV16{<c>}.W <Rd>, <Rm> // (<Rd>, <Rm> can be represented in T1)
```

```
REV16{<c>}{<q>} <Rd>, <Rm>
```

```
d = UInt(Rd);  m = UInt(Rm);  n = UInt(Rn);
if m != n || d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `m != n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: m = UInt(Rn);.
- The instruction executes with the additional decode: m = UInt(Rm);.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1 and T1: is the general-purpose source register, encoded in the "Rm" field.

For encoding T2: is the general-purpose source register, encoded in the "Rm" field. It must be encoded with an identical value in the "Rn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    bits(32) result;
    result<31:24> = R[m]<23:16>;
    result<23:16> = R[m]<31:24>;
    result<15:8>  = R[m]<7:0>;
    result<7:0>   = R[m]<15:8>;
    R[d] = result;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

RFE, RFEDA, RFEDB, RFEIA, RFEIB

Return From Exception loads two consecutive memory locations using an address in a base register:

- The word loaded from the lower address is treated as an instruction address. The PE branches to it.
- The word loaded from the higher address is used to restore *PSTATE*. This word must be in the format of an SPSR.

An address adjusted by the size of the data loaded can optionally be written back to the base register.

The PE checks the value of the word loaded from the higher address for an illegal return event. See *Illegal return events from AArch32 state*.

RFE is UNDEFINED in Hyp mode and CONSTRAINED UNPREDICTABLE in User mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

IA — For encoding A1: is an optional suffix to indicate the Increment After variant.

For encoding T2: is an optional suffix for the Increment After form.

<c> — For encoding A1: see *Standard assembler syntax fields*. <c> must be AL or omitted.

For encoding T1 and T2: see *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field.

! — The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

RFEFA, RFEEA, RFEFD, and RFEED are pseudo-instructions for RFEDA, RFEDB, RFEIA, and RFEIB respectively, referring to their use for popping data from Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.EL == EL0 then
        UNPREDICTABLE;                        // UNDEFINED or NOP
    else
        address = if increment then R[n] else R[n]-8;
        if wordhigher then address = address+4;
        new_pc_value = MemA[address,4];
        spsr = MemA[address+4,4];
        if wback then R[n] = if increment then R[n]+8 else R[n]-8;
        AArch32.ExceptionReturn(new_pc_value, spsr);
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rdm>	Is the first general-purpose source register and the destination register, encoded in the "Rdm" field.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rm>	Is the first general-purpose source register, encoded in the "Rm" field.
<Rs>	Is the second general-purpose source register holding a rotate amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

The description of MOV, MOVS (register-shifted register) gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

RORS (immediate)

Rotate Right, setting flags (immediate) provides the value of the contents of a register rotated by a constant value. The bits that are rotated off the right end are inserted into the vacated bit positions on the left.

If the destination register is not the PC, this instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of MOV, MOVS (register). This means:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T3) .

A1

		S			imm3		imm2	stype	

MOV, rotate right with extend

```
RRX{<c>}{<q>} {<Rd>,} <Rm>
```

is equivalent to

```
MOV{<c>}{<q>} <Rd>, <Rm>, RRX
```

and is always the preferred disassembly.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the general-purpose source register, encoded in the "Rm" field.

Operation

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

RRXS

Rotate Right with Extend, setting flags provides the value of the contents of a register shifted right by one place, with the Carry flag shifted into bit[31].

If the destination register is not the PC, this instruction updates the condition flags based on the result, and bit[0] is shifted into the Carry flag.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. Arm deprecates any use of these encodings. However, when the destination register is the PC:

- The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
- The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
- The instruction is UNDEFINED in Hyp mode.
- The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

This is an alias of MOV, MOVS (register). This means:

- The encodings in this description are named to match the encodings of MOV, MOVS (register).
- The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T3) .

MOVS{<c>}{<q>} <Rd>, <Rm>, RRX
```

and is always the preferred disassembly.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. Arm deprecates using the PC as the destination register, but if the PC is used, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T3: is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T3: is the general-purpose source register, encoded in the "Rm" field.

Operation

The description of MOV, MOVS (register) gives the operational pseudocode for this instruction.

RSB, RSBS (immediate)

Reverse Subtract (immediate) subtracts a register value from an immediate value, and writes the result to the destination register.

If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0

```
d = UInt(Rd);  n = UInt(Rn);  setflags = (S == '1');  imm32 = T32ExpandImm(i:imm3:imm8);
if d == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the RSB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the RSBS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1 and T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T2: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(NOT(R[n]), imm32, '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

RSB, RSBS (register)

Reverse Subtract (register) subtracts a register value from an optionally-shifted register value, and writes the result to the destination register.

If the destination register is not the PC, the RSBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The RSB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The RSBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

RSCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, RRX
```

RSCS, shift or rotate by value (S == 1 && !(imm5 == 00000 && stype == 11))

```
RSCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, <shift> #<amount>}
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
(shift_t, shift_n) = DecodeImmShift(stype, imm5);
```

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the RSC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the RSCS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> Is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, PSTATE.C);
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

RSC, RSCS (register-shifted register)

Reverse Subtract (register-shifted register) subtracts a register value and the value of NOT (Carry flag) from a register-shifted register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0

setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(NOT(R[n]), shifted, PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

SB

Speculation Barrier is a barrier that controls speculation.

The semantics of the Speculation Barrier are that the execution, until the barrier completes, of any instruction that appears later in the program order than the barrier:

- Cannot be performed speculatively to the extent that such speculation can be observed through side-channels as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception.

In particular, any instruction that appears later in the program order than the barrier cannot cause a speculative allocation into any caching structure where the allocation of that entry could be indicative of any data value present in memory or in the registers.

The SB instruction:

- Cannot be speculatively executed as a result of control flow speculation or data value speculation.
- Can be speculatively executed as a result of predicting that a potentially exception generating instruction has not generated an exception. The potentially exception generating instruction can complete once it is known not to be speculative, and all data values generated by instructions appearing in program order before the SB instruction have their predicted values confirmed.

When the prediction of the instruction stream is not informed by data taken from the register outputs of the speculative execution of instructions appearing in program order after an uncompleted SB instruction, the SB instruction has no effect on the use of prediction resources to predict the instruction stream that is being fetched.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

SBC, SBCS (immediate)

Subtract with Carry (immediate) subtracts an immediate value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SBCS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. ARM deprecates any use of these encodings. However, when the destination register is the PC:

- The SBC variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The SBCS variant of the instruction performs an exception return without the use of the stack. In this case:
    - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
    - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
    - The instruction is UNDEFINED in Hyp mode.
    - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the SBCS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], NOT(imm32), PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rdn> Is the first general-purpose source register and the destination register, encoded in the "Rdn" field.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SBC variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the SBCS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

SBC, SBCS (register-shifted register)

Subtract with Carry (register-shifted register) subtracts a register-shifted register value and the value of NOT (Carry flag) from a register value, and writes the result to the destination register. It can optionally update the condition flags based on the result.

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6 5	4	3 2 1 0

cond															

Flag setting (S == 1)

```
SBCS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting (S == 0)

```
SBC{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), PSTATE.C);
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

cond								

A1

```
SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>
```

```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(lsb);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

T1

15 14 13 12 11	10	9 8	7 6	5	4	3 2 1 0	15	14 13 12	11 10 9 8	7 6	5	4 3 2 1 0
1 1 1 1 0	(0)	1 1	0 1	0	0	Rn	0	imm3	Rd	imm2	(0)	widthm1

T1

```
SBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>
```

```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(imm3:imm2);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rd> — Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> — Is the general-purpose source register, encoded in the "Rn" field.

<lsb> — For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.

For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width> — Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = SignExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

SDIV

Signed Divide divides a 32-bit signed integer register value by a 32-bit signed integer register value, and writes the result to the destination register. The condition flags are not affected.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24 23	22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5	4	3 2 1 0
!= 1111	0 1 1 1 0	0 0 1	Rd	(1) (1) (1) (1)	Rm	0 0 0	1	Rn
cond				Ra				

A1

```
SDIV{<c>}{<q>} {<Rd>,} <Rn>, <Rm>
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `Ra != '1111'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes as described, and the register specified by Ra becomes UNKNOWN.

T1

15 14 13 12 11 10 9 8 7	6 5 4	3 2 1 0	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
1 1 1 1 1 0 1 1 1	0 0 1	Rn	(1) (1) (1) (1)	Rd	1 1 1 1	Rm
			Ra			

T1

```
SDIV{<c>}{<q>} {<Rd>,} <Rn>, <Rm>
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `Ra != '1111'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction executes as described, and the register specified by Ra becomes UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

Overflow

If the signed integer division 0x80000000 / 0xFFFFFFFF is performed, the pseudocode produces the intermediate integer result $+2^{31}$, that overflows the 32-bit signed integer range. No indication of this overflow case is produced, and the 32-bit result written to <Rd> must be the bottom 32 bits of the binary representation of $+2^{31}$. So the result of the division is 0x80000000.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if SInt(R[m]) == 0 then
        result = 0;
    else
        result = RoundTowardsZero(Real(SInt(R[n])) / Real(SInt(R[m])));
    R[d] = result<31:0>;
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

SEL

Select Bytes selects each byte of its result from either its first operand or its second operand, according to the values of the *PSTATE*.GE flags.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    SendEvent();
```

SEVL

Send Event Local is a hint instruction that causes an event to be signaled locally without requiring the event to be signaled to other PEs in the multiprocessor system. It can prime a wait-loop which starts with a `WFE` instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    sum1 = SInt(R[n]<15:0>) + SInt(R[m]<15:0>);
    sum2 = SInt(R[n]<31:16>) + SInt(R[m]<31:16>);
    R[d]<15:0>  = sum1<16:1>;
    R[d]<31:16> = sum2<16:1>;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

SMC

Secure Monitor Call causes a Secure Monitor Call exception. For more information see *Secure Monitor Call (SMC) exception*.

SMC is available only for software executing at EL1 or higher. It is UNDEFINED in User mode.

If the values of *HCR*.TSC and *SCR*.SCD are both 0, execution of an SMC instruction at EL1 or higher generates a Secure Monitor Call exception that is taken to EL3. When EL3 is using AArch32 this exception is taken to Monitor mode. When EL3 is using AArch64, it is the *SCR_EL3*.SMD bit, rather than the *SCR*.SCD bit, that can change the effect of executing an SMC instruction.

If the value of *HCR*.TSC is 1, execution of an SMC instruction in a Non-secure EL1 mode generates an exception that is taken to EL2, regardless of the value of *SCR*.SCD. When EL2 is using AArch32, this is a Hyp Trap exception that is taken to Hyp mode. For more information see *Traps to Hyp mode of Non-secure EL1 execution of SMC instructions*.

If the value of *HCR*.TSC is 0 and the value of *SCR*.SCD is 1, the SMC instruction is:

- UNDEFINED in Non-secure state.
- CONSTRAINED UNPREDICTABLE if executed in Secure state at EL1 or higher.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3-0
!= 1111	0	0	0	1	0	1	1	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	0	1	1	1	imm4
cond																									

A1

```
SMC{<c>}{<q>} {#}<imm4>
```

```
// imm4 is for assembly/disassembly only and is ignored by hardware
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3-0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	1	1	1	1	1	1	imm4	1	0	0	0	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)	(0)

T1

```
SMC{<c>}{<q>} {#}<imm4>
```

```
// imm4 is for assembly/disassembly only and is ignored by hardware
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<imm4> Is a 4-bit unsigned immediate value, in the range 0 to 15, encoded in the "imm4" field. This is ignored by the PE. The Secure Monitor Call exception handler (Secure Monitor code) can use this value to determine what service is being requested, but Arm does not recommend this.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();

    AArch32.CheckForSMCUndefOrTrap();

    if !ELUsingAArch32(EL3) then
        if SCR_EL3.SMD == '1' then
            // SMC disabled.
            UNDEFINED;
    else
        if SCR.SCD == '1' then
            // SMC disabled
            if IsSecure() then
                // Executes either as a NOP or UNALLOCATED.
                c = ConstrainUnpredictable(Unpredictable_SMD);
                assert c IN {Constraint_NOP, Constraint_UNDEF};
                if c == Constraint_NOP then EndOfInstruction();
            UNDEFINED;

    if !ELUsingAArch32(EL3) then
        AArch64.CallSecureMonitor(Zeros(16));
    else
        AArch32.TakeSMCException();
```

CONSTRAINED UNPREDICTABLE behavior

If `SCR.SCD == '1' && IsSecure()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

SMLABB, SMLABT, SMLATB, SMLATT

Signed Multiply Accumulate (halfwords) performs a signed multiply accumulate operation. The multiply acts on two signed 16-bit quantities, taken from either the bottom or the top half of their respective source registers. The other halves of these source registers are ignored. The 32-bit product is added to a 32-bit accumulate value and the result is written to the destination register.

If overflow occurs during the addition of the accumulate value, the instruction sets *PSTATE*.Q to 1. It is not possible for overflow to occur during the multiplication.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

SMLAL, SMLALS

Signed Multiply Accumulate Long multiplies two signed 32-bit values to produce a 64-bit value, and accumulates this with a 64-bit value.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
!= 1111	0 0 0 0	1 1 1	S	RdHi	RdLo	Rm	1 0 0 1	Rn
cond								

Flag setting (S == 1)

```
SMLALS{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>
```

Not flag setting (S == 0)

```
SMLAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>
```

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

T1

15 14 13 12 11 10 9 8 7	6 5 4	3 2 1 0	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
1 1 1 1 1 0 1 1 1	1 0 0	Rn	RdLo	RdHi	0 0 0 0	Rm

T1

```
SMLAL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>
```

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<RdLo>	Is the general-purpose source register holding the lower 32 bits of the addend, and the destination register for the lower 32 bits of the result, encoded in the "RdLo" field.
<RdHi>	Is the general-purpose source register holding the upper 32 bits of the addend, and the destination register for the upper 32 bits of the result, encoded in the "RdHi" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]) + SInt(R[dHi]:R[dLo]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

SMLAWB, SMLAWT

Signed Multiply Accumulate (word by halfword) performs a signed multiply accumulate operation. The multiply acts on a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are added to a 32-bit accumulate value and the result is written to the destination register. The bottom 16 bits of the 48-bit product are ignored.

If overflow occurs during the addition of the accumulate value, the instruction sets *PSTATE*.Q to 1. No overflow can occur during the multiplication.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);  m_high = (M == '1');
if d == 15 || n == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the "Rm" field.

<Ra> Is the third general-purpose source register holding the addend, encoded in the "Ra" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(R[n]) * SInt(operand2) + (SInt(R[a]) << 16);
    R[d] = result<47:16>;
    if (result >> 16) != SInt(R[d]) then  // Signed overflow
        PSTATE.Q = '1';
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

SMLSD, SMLSDX

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It adds the difference of the products to a 32-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

This instruction sets *PSTATE*.Q to 1 if the accumulate operation overflows. Overflow cannot occur during the multiplications or subtraction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

SMLSLD, SMLSLDX

Signed Multiply Subtract Long Dual performs two signed 16 x 16-bit multiplications. It adds the difference of the products to a 64-bit accumulate operand.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow is possible during this instruction, but only as a result of the 64-bit addition. This overflow is not detected if it occurs. Instead, the result wraps around modulo 2^{64}.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<Rn>	Is the first general-purpose source register holding the multiplicand in the bottom or top half (selected by <x>), encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier in the bottom or top half (selected by <y>), encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand1 = if n_high then R[n]<31:16> else R[n]<15:0>;
    operand2 = if m_high then R[m]<31:16> else R[m]<15:0>;
    result = SInt(operand1) * SInt(operand2);
    R[d] = result<31:0>;
    // Signed overflow cannot occur
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

SMULL, SMULLS

Signed Multiply Long multiplies two 32-bit signed values to produce a 64-bit result.

In A32 instructions, the condition flags can optionally be updated based on the result. Use of this option adversely affects performance on many implementations.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
!= 1111	0 0 0 0	1 1 0	S	RdHi	RdLo	Rm	1 0 0 1	Rn
cond								

Flag setting (S == 1)

```
SMULLS{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>
```

Not flag setting (S == 0)

```
SMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>
```

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = (S == '1');
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

T1

15 14 13 12 11 10 9 8 7	6 5 4	3 2 1 0	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1 0
1 1 1 1 1 0 1 1 1	0 0 0	Rn	RdLo	RdHi	0 0 0 0	Rm

T1

```
SMULL{<c>}{<q>} <RdLo>, <RdHi>, <Rn>, <Rm>
```

```
dLo = UInt(RdLo);  dHi = UInt(RdHi);  n = UInt(Rn);  m = UInt(Rm);  setflags = FALSE;
if dLo == 15 || dHi == 15 || n == 15 || m == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
if dHi == dLo then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `dHi == dLo`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<RdLo>	Is the general-purpose destination register for the lower 32 bits of the result, encoded in the "RdLo" field.
<RdHi>	Is the general-purpose destination register for the upper 32 bits of the result, encoded in the "RdHi" field.
<Rn>	Is the first general-purpose source register holding the multiplicand, encoded in the "Rn" field.
<Rm>	Is the second general-purpose source register holding the multiplier, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = SInt(R[n]) * SInt(R[m]);
    R[dHi] = result<63:32>;
    R[dLo] = result<31:0>;
    if setflags then
        PSTATE.N = result<63>;
        PSTATE.Z = IsZeroBit(result<63:0>);
        // PSTATE.C, PSTATE.V unchanged
```

Operational information

SMULWB, SMULWT

Signed Multiply (word by halfword) multiplies a signed 32-bit quantity and a signed 16-bit quantity. The signed 16-bit quantity is taken from either the bottom or the top half of its source register. The other half of the second source register is ignored. The top 32 bits of the 48-bit product are written to the destination register. The bottom 16 bits of the 48-bit product are ignored. No overflow is possible during this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24 23	22 21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0

SMUSD, SMUSDX

Signed Multiply Subtract Dual performs two signed 16 x 16-bit multiplications. It subtracts one of the products from the other, and writes the result to the destination register.

Optionally, the instruction can exchange the halfwords of the second operand before performing the arithmetic. This produces top x bottom and bottom x top multiplication.

Overflow cannot occur.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24 23	22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6	5	4	3 2 1 0

SRS, SRSDA, SRSDB, SRSIA, SRSIB

Store Return State stores the LR_<current_mode> and *SPSR*_<current_mode> to the stack of a specified mode. For information about memory accesses see *Memory accesses*.

SRS is UNDEFINED in Hyp mode.

SRS is CONSTRAINED UNPREDICTABLE if it is executed in User or System mode, or if the specified mode is any of the following:

- Not implemented.
- A mode that *Table G1-5* does not show.
- Hyp mode.
- Monitor mode, if the SRS instruction is executed in Non-secure state.

If EL3 is using AArch64 and an SRS instruction that is executed in a Secure EL1 mode specifies Monitor mode, it is trapped to EL3.

See *Traps to EL3 of Secure monitor functionality from Secure EL1 using AArch32*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

IA	For encoding A1: is an optional suffix to indicate the Increment After variant. For encoding T2: is an optional suffix for the Increment After form.
<c>	For encoding A1: see *Standard assembler syntax fields*. <c> must be AL or omitted. For encoding T1 and T2: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
!	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<mode>	Is the number of the mode whose Banked SP is used as the base register, encoded in the "mode" field. For details of PE modes and their numbers see *AArch32 PE mode descriptions*.

`SRSFA`, `SRSEA`, `SRSFD`, and `SRSED` are pseudo-instructions for `SRSIB`, `SRSIA`, `SRSDB`, and `SRSDA` respectively, referring to their use for pushing data onto Full Ascending, Empty Ascending, Full Descending, and Empty Descending stacks.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then

```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User,M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode == M32_Hyp`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

If `mode == M32_Monitor && (!HaveEL(EL3) || !IsSecure())`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

If `BadMode(mode)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction stores to the stack of the mode in which it is executed.
- The instruction stores to an UNKNOWN address, and if the instruction specifies writeback then any general-purpose register that can be accessed from the current Exception level without a privilege violation becomes UNKNOWN.

SSAT

Signed Saturate saturates an optionally-shifted signed value to a selectable signed range.
This instruction sets *PSTATE*.Q to 1 if the operation saturates.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.
<imm>	Is the bit position for saturation, in the range 1 to 32, encoded in the "sat_imm" field as <imm>-1.
<Rn>	Is the general-purpose source register, encoded in the "Rn" field.
<amount>	For encoding A1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.
	For encoding A1: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

For encoding T1: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, PSTATE.C);  // PSTATE.C ignored
    (result, sat) = SignedSatQ(SInt(operand), saturate_to);
    R[d] = SignExtend(result, 32);
    if sat then
        PSTATE.Q = '1';
```

SSAT16

Signed Saturate 16 saturates two signed 16-bit values to a selected signed range.
This instruction sets *PSTATE*.Q to 1 if the operation saturates.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27-23	22	21-20	19-16	15-12	11	10	9	8	7-4	3-0

SSBB

Speculative Store Bypass Barrier is a memory barrier which prevents speculative loads from bypassing earlier stores to the same virtual address under certain conditions.

The semantics of the Speculative Store Bypass Barrier are:

- When a load to a location appears in program order after the SSBB, then the load does not speculatively read an entry earlier in the coherence order for that location than the entry generated by the latest store satisfying all of the following conditions:
    - The store is to the same location as the load.
    - The store uses the same virtual address as the load.
    - The store appears in program order before the SSBB.
- When a load to a location appears in program order before the SSBB, then the load does not speculatively read data from any store satisfying all of the following conditions:
    - The store is to the same location as the load.
    - The store uses the same virtual address as the load.
    - The store appears in program order after the SSBB.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

STC

Store data to System register calculates an address from a base register value and an immediate offset, and stores a word from the *DBGDTRRXint* System register to memory. It can use offset, post-indexed, pre-indexed, or unindexed addressing. For information about memory accesses, see *Memory accesses*.

In an implementation that includes EL2, the permitted STC access to *DBGDTRRXint* can be trapped to Hyp mode, meaning that an attempt to execute an STC instruction in a Non-secure mode other than Hyp mode, that would be permitted in the absence of the Hyp trap controls, generates a Hyp Trap exception. For more information, see *Trapping general Non-secure System register accesses to debug registers*.

For simplicity, the STC pseudocode does not show this possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15	14	13	12	11	10	9	8	7 6 5 4 3 2 1 0
!= 1111	1	1	0	P	U	0	W	0	Rn	0	1	0	1	1	1	1	0	imm8
cond																		

Offset (P == 1 && W == 0)

```
STC{<c>}{<q>} p14, c5, [<Rn>{, #{+/-}<imm>}]
```

Post-indexed (P == 0 && W == 1)

```
STC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>
```

Pre-indexed (P == 1 && W == 1)

```
STC{<c>}{<q>} p14, c5, [<Rn>, #{+/-}<imm>]!
```

Unindexed (P == 0 && U == 1 && W == 0)

```
STC{<c>}{<q>} p14, c5, [<Rn>], <option>
```

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
n = UInt(Rn);  cp = 14;
imm32 = ZeroExtend(imm8:'00', 32);  index = (P == '1');  add = (U == '1');  wback = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in *Using R15*.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2 1 0	15	14	13	12	11	10	9	8	7 6 5 4 3 2 1 0

Offset (P == 1 && W == 0)

```
STC{<c>}{<q>} p14, c5, [<Rn>{, #{+/-}<imm>}]
```

Post-indexed (P == 0 && W == 1)

```
STC{<c>}{<q>} p14, c5, [<Rn>], #{+/-}<imm>
```

Pre-indexed (P == 1 && W == 1)

```
STC{<c>}{<q>} p14, c5, [<Rn>, #{+/-}<imm>]!
```

Unindexed (P == 0 && U == 1 && W == 0)

```
STC{<c>}{<q>} p14, c5, [<Rn>], <option>
```

```
if P == '0' && U == '0' && W == '0' then UNDEFINED;
n = UInt(Rn);  cp = 14;
imm32 = ZeroExtend(imm8:'00', 32);  index = (P == '1');  add = (U == '1');  wback = (W == '1');
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in *Using R15*.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> For the offset or unindexed variant: is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For the offset, post-indexed or pre-indexed variant: is the general-purpose base register, encoded in the "Rn" field.

<option> Is an 8-bit immediate, in the range 0 to 255 enclosed in { }, encoded in the "imm8" field. The value of this field is ignored when executing this instruction.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> Is the immediate offset used for forming the address, a multiple of 4 in the range 0-1020, defaulting to 0 and encoded in the "imm8" field, as <imm>/4.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
    address = if index then offset_addr else R[n];

    // System register read from DBGDTRRXint.
    MemA[address,4] = AArch32.SysRegRead(cp, ThisInstr());
    if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

- The instruction executes as `NOP`.

- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:

0
: If the operation updates memory.

1
: If the operation fails to update memory.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemO[address, 4] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

STLEXB

Store-Release Exclusive Byte stores a byte from a register to memory if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

The instruction also has memory ordering semantics as described in *Load-Acquire, Store-Release*.

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

STM (User registers)

In an EL1 mode other than System mode, Store Multiple (User registers) stores multiple User mode registers to consecutive memory locations using an address from a base register. The PE reads the base register value normally, using the current mode to determine the correct Banked version of the register. This instruction cannot writeback to the base register.

Store Multiple (User registers) is UNDEFINED in Hyp mode, and CONSTRAINED UNPREDICTABLE in User or System modes.

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see *FEAT_LSMAOC*.

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	1	0	0	P	U	1	(0)	0	Rn	register_list
cond										

A1

```
STM{<amode>}{<c>}{<q>} <Rn>, <registers>^
```

```
n = UInt(Rn);  registers = register_list;  increment = (U == '1');  wordhigher = (P == U);
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<amode> is one of:

DA
: Decrement After. The consecutive memory addresses end at the address in the base register. Encoded as P = 0, U = 0.

ED
: Empty Descending. For this instruction, a synonym for DA.

DB
: Decrement Before. The consecutive memory addresses end one word below the address in the base register. Encoded as P = 1, U = 0.

FD
: Full Descending. For this instruction, a synonym for DB.

IA
: Increment After. The consecutive memory addresses start at the address in the base register. This is the default. Encoded as P = 0, U = 1.

EA
: Empty Ascending. For this instruction, a synonym for IA.

IB
: Increment Before. The consecutive memory addresses start one word above the address in the base register. Encoded as P = 1, U = 1.

FA

Full Ascending. For this instruction, a synonym for IB.

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<registers> Is a list of one or more registers, separated by commas and surrounded by { and }. It specifies the set of registers to be stored by the STM instruction. The registers are stored with the lowest-numbered register to the lowest memory address, through to the highest-numbered register to the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if PSTATE.EL == EL2 then
        UNDEFINED;
    elsif PSTATE.M IN {M32_User,M32_System} then
        UNPREDICTABLE;
    else

```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.M IN {M32_User,M32_System}`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STM, STMIA, STMEA

Store Multiple (Increment After, Empty Ascending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations start at this address, and the address just above the last of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see *FEAT_LSMAOC*. For details of related system instructions see *STM (User registers)*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	1	0	0	0	1	0	W	0	Rn	register_list
cond										

A1

```
STM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)
```

```

```

```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in *Using R15*.

T1

STM{IA}{<c>}.W <Rn>{!}, <registers> // (Preferred syntax, if <Rn>, '!' and <registers> can be represented

STMEA{<c>}.W <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack, if <Rn>, '!' and <register

STM{IA}{<c>}{<q>} <Rn>{!}, <registers> // (Preferred syntax)

STMEA{<c>}{<q>} <Rn>{!}, <registers> // (Alternate syntax, Empty Ascending stack)
```

```
n = UInt(Rn);  registers = P:M:register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored for the base register is UNKNOWN.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If `registers<15> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as `NOP`.
- The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction executes with writeback to the PC. The instruction is handled as described in *Using R15*.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

IA	Is an optional suffix for the Increment After form.
<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field.
!	The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.
<registers>	For encoding A1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list. If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register. For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R7, encoded in the "register_list" field. If the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register. For encoding T2: is a list of one or more registers to be stored, separated by commas and surrounded by { and }. The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS[address,4] = bits(32) UNKNOWN;  // Only possible for encodings T1 and A1
            else
                MemS[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1
        MemS[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

STMDA, STMED

Store Multiple Decrement After (Empty Descending) stores multiple registers to consecutive memory locations using an address from a base register. The consecutive memory locations end at this address, and the address just below the lowest of those locations can optionally be written back to the base register.

The lowest-numbered register is loaded from the lowest memory address, through to the highest-numbered register from the highest memory address. See also *Encoding of lists of general-purpose registers and the PC*.

Armv8.2 permits the deprecation of some Store Multiple ordering behaviors in AArch32 state, for more information see *FEAT_LSMAOC*. For details of related system instructions see *STM (User registers)*.

```
n = UInt(Rn);  registers = P:M:register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 2 then UNPREDICTABLE;
if wback && registers<n> == '1' then UNPREDICTABLE;
if registers<13> == '1' then UNPREDICTABLE;
if registers<15> == '1' then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `wback && registers<n> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored for the base register is UNKNOWN.

If `BitCount(registers) == 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction operates as an STM with the same addressing mode but targeting an unspecified set of registers. These registers might include R15.

If `registers<13> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The store instruction performs all of the stores using the specified addressing mode but the value of R13 is UNKNOWN.

If `registers<15> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs all of the stores using the specified addressing mode but the value of R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

! The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers> For encoding A1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.
The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list.
If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

For encoding T1: is a list of one or more registers to be stored, separated by commas and surrounded by { and }.
The registers in the list must be in the range R0-R12, encoded in the "register_list" field, and can optionally contain the LR. If the LR is in the list, the "M" field is set to 1, otherwise it defaults to 0.

Alias Conditions

Alias	Of variant	Is preferred when
PUSH (multiple registers)	T1	`W == '1' && Rn == '1101' && BitCount(M:register_list) > 1`
PUSH (multiple registers)	A1	`W == '1' && Rn == '1101' && BitCount(register_list) > 1`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] - 4*BitCount(registers);
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS[address,4] = bits(32) UNKNOWN;  // Only possible for encoding A1
            else
                MemS[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then  // Only possible for encoding A1
        MemS[address,4] = PCStoreValue();
    if wback then R[n] = R[n] - 4*BitCount(registers);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

```
n = UInt(Rn);  registers = register_list;  wback = (W == '1');
if n == 15 || BitCount(registers) < 1 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `BitCount(registers) < 1`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as an `STM` with the same addressing mode but targeting an unspecified set of registers. These registers might include R15. If the instruction specifies writeback, the modification to the base address on writeback might differ from the number of registers stored.

If `n == 15 && wback`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field.

! — The address adjusted by the size of the data loaded is written back to the base register. If specified, it is encoded in the "W" field as 1, otherwise this field defaults to 0.

<registers> — Is a list of one or more registers to be stored, separated by commas and surrounded by { and }.

The PC can be in the list. However, Arm deprecates the use of instructions that include the PC in the list.

If base register writeback is specified, and the base register is not the lowest-numbered register in the list, such an instruction stores an UNKNOWN value for the base register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + 4;
    for i = 0 to 14
        if registers<i> == '1' then
            if i == n && wback && i != LowestSetBit(registers) then
                MemS[address,4] = bits(32) UNKNOWN;
            else
                MemS[address,4] = R[i];
            address = address + 4;
    if registers<15> == '1' then
        MemS[address,4] = PCStoreValue();
    if wback then R[n] = R[n] + 4*BitCount(registers);
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For encoding T1, T2, T3 and T4: is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.

For encoding T1, T3 and T4: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 124, defaulting to 0 and encoded in the "imm5" field as <imm>/4.

For encoding T2: is the optional positive unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0 and encoded in the "imm8" field as <imm>/4.

For encoding T3: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T4: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Alias Conditions

Alias	Of variant	Is preferred when
PUSH (single register)	A1 (pre-indexed)	`P == '1' && U == '0' && W == '1' && Rn == '1101' && imm12 == '000000000100'`
PUSH (single register)	T4 (pre-indexed)	`Rn == '1101' && P == '1' && U == '0' && W == '1' && imm8 == '00000100'`

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        MemU[address,4] = if t == 15 then PCStoreValue() else R[t];
        if wback then R[n] = offset_addr;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        MemU[address,4] = R[t];
        if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STRBT

Store Register Byte Unprivileged stores a byte from a register to memory. For information about memory accesses see *Memory accesses*.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRBT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	1	0	0	U	1	1	0	Rn	Rt	imm12
cond											

A1

```
STRBT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

A2

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0

```

```
if Rn == '1111' then UNDEFINED;
t = UInt(Rt);  n = UInt(Rn);  postindex = FALSE;  add = TRUE;
register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> For encoding A1: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For encoding A2 and T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in "U":

U	+/-
0	-
1	+

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see *Shifts applied to a register*.

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    MemU_unpriv[address,1] = R[t]<7:0>;
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `STRB` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

STRD (immediate)

Store Register Dual (immediate) calculates an address from a base register value and an immediate offset, and stores two words from two registers to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0
!= 1111	0	0	0	P	U	1	W	0	Rn	Rt	imm4H	1	1	1	1	imm4L
cond																

Offset (P == 1 && W == 0)

```
STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed (P == 0 && W == 0)

```
STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>], #{+/-}<imm>
```

Pre-indexed (P == 1 && W == 1)

```
STRD{<c>}{<q>} <Rt>, <Rt2>, [<Rn>, #{+/-}<imm>]!
```

```
if Rt<0> == '1' then UNPREDICTABLE;
t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if P == '0' && W == '1' then UNPREDICTABLE;
if wback && (n == 15 || n == t || n == t2) then UNPREDICTABLE;
if t2 == 15 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15 || t2 == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && (n == t || n == t2)`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes with the additional decode: t<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side-effects. This does not apply when Rt == '1111'.

If `P == '0' && W == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as an `LDRD` using one of offset, post-indexed, or pre-indexed addressing.

T1

cond																			

A1

```
STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, {#}<imm>}]
```

```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);  imm32 = Zeros(32); // Zero offset
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs the store to an UNKNOWN address.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2 1 0	15 14 13 12	11 10 9 8	7 6 5 4 3 2 1 0
1	1	1	0	1	0	0	0	0	1	0	0	Rn	Rt	Rd	imm8

T1

```
STREX{<c>}{<q>} <Rd>, <Rt>, [<Rn> {, #<imm>}]
```

```
d = UInt(Rd);  t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:

0
If the operation updates memory.

1
If the operation fails to update memory.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<imm> For encoding A1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can only be 0 or omitted.

For encoding T1: the immediate offset added to the value of <Rn> to calculate the address. <imm> can be omitted, meaning an offset of 0. Values are multiples of 4 in the range 0-1020.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non word-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n] + imm32;
    if AArch32.ExclusiveMonitorsPass(address,4) then
        MemA[address,4] = R[t];
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

STREXB

Store Register Exclusive Byte derives an address from a base register value, stores a byte from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

if d == 15 || t == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs the store to an UNKNOWN address.

T1

if d == 15 || t == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if d == n || d == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:

0
If the operation updates memory.

1
If the operation fails to update memory.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

Aborts

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    if AArch32.ExclusiveMonitorsPass(address,1) then
        MemA[address,1] = R[t]<7:0>;
        R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

STREXD

Store Register Exclusive Doubleword derives an address from a base register value, stores a 64-bit doubleword from two registers to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27	26	25	24	23	22	21	20	19-16	15-12	11	10	9	8	7	6	5	4	3-0

cond																			

A1

```
STREXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]
```

```
d = UInt(Rd);  t = UInt(Rt);  t2 = t+1;  n = UInt(Rn);
if d == 15 || Rt<0> == '1' || t2 == 15 || n == 15 then UNPREDICTABLE;
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs the store to an UNKNOWN address.

If `Rt<0> == '1'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes with the additional decode: Rt<0> = '0'.
- The instruction executes with the additional decode: t2 = t.
- The instruction executes as described, with no change to its behavior and no additional side effects.

If `Rt == '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction is handled as described in *Using R15*.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3-0	15-12	11-8	7	6	5	4	3-0
1	1	1	0	1	0	0	0	1	1	0	0	Rn	Rt	Rt2	0	1	1	1	Rd

T1

```
STREXD{<c>}{<q>} <Rd>, <Rt>, <Rt2>, [<Rn>]
```

```
d = UInt(Rd);  t = UInt(Rt);  t2 = UInt(Rt2);  n = UInt(Rn);
if d == 15 || t == 15 || t2 == 15 || n == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
if d == n || d == t || d == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `d == n`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction performs the store to an UNKNOWN address.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the destination general-purpose register into which the status result of the store exclusive is written, encoded in the "Rd" field. The value returned is:

0
If the operation updates memory.

1
If the operation fails to update memory.

<Rd> must not be the same as <Rn>, <Rt>, or <Rt2>.

<Rt> For encoding A1: is the first general-purpose register to be transferred, encoded in the "Rt" field. <Rt> must be even-numbered and not R14.

For encoding T1: is the first general-purpose register to be transferred, encoded in the "Rt" field.

<Rt2> For encoding A1: is the second general-purpose register to be transferred. <Rt2> must be <R(t+1)>.

For encoding T1: is the second general-purpose register to be transferred, encoded in the "Rt2" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

Aborts and alignment

If a synchronous Data Abort exception is generated by the execution of this instruction:

- Memory is not updated.
- <Rd> is not updated.

A non doubleword-aligned memory address causes an Alignment fault Data Abort exception to be generated, subject to the following rules:

- If AArch32.ExclusiveMonitorsPass() returns TRUE, the exception is generated.
- Otherwise, it is IMPLEMENTATION DEFINED whether the exception is generated.

If AArch32.ExclusiveMonitorsPass() returns FALSE and the memory address, if accessed, would generate a synchronous Data Abort exception, it is IMPLEMENTATION DEFINED whether the exception is generated.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    address = R[n];
    // Create doubleword to store such that R[t] will be stored at address and R[t2] at address+4.
    value = if BigEndian(AccType_ATOMIC) then R[t]:R[t2] else R[t2]:R[t];
    if AArch32.ExclusiveMonitorsPass(address,8) then
        MemA[address,8] = value;  R[d] = ZeroExtend('0');
    else
        R[d] = ZeroExtend('1');
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

STREXH

Store Register Exclusive Halfword derives an address from a base register value, stores a halfword from a register to the derived address if the executing PE has exclusive access to the memory at that address, and returns a status value of 0 if the store was successful, or of 1 if no store was performed.

For more information about support for shared memory see *Synchronization and semaphores*. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

STRH (immediate)

Store Register Halfword (immediate) calculates an address from a base register value and an immediate offset, and stores a halfword from a register to memory. It can use offset, post-indexed, or pre-indexed addressing. For information about memory accesses see *Memory accesses*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 and T3) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0
!= 1111	0	0	0	P	U	1	W	0	Rn	Rt	imm4H	1	0	1	1	imm4L
cond																

Offset (P == 1 && W == 0)

```
STRH{<c>}{<q>} <Rt>, [<Rn> {, #{+/-}<imm>}]
```

Post-indexed (P == 0 && W == 0)

```
STRH{<c>}{<q>} <Rt>, [<Rn>], #{+/-}<imm>
```

Pre-indexed (P == 1 && W == 1)

```
STRH{<c>}{<q>} <Rt>, [<Rn>, #{+/-}<imm>]!
```

```
if P == '0' && W == '1' then SEE "STRHT";
t = UInt(Rt);  n = UInt(Rn);  imm32 = ZeroExtend(imm4H:imm4L, 32);
index = (P == '1');  add = (U == '1');  wback = (P == '0') || (W == '1');
if t == 15 then UNPREDICTABLE;
if wback && (n == 15 || n == t) then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `wback && n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes without writeback of the base address.
- The instruction uses the addressing mode described in the equivalent immediate offset instruction.

```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.

- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `wback && n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.

For encoding A1, T1, T2, T3: is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is the optional positive unsigned immediate byte offset, a multiple of 2, in the range 0 to 62, defaulting to 0 and encoded in the "imm5" field as <imm>/2.

For encoding T2: is an optional 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the "imm12" field.

For encoding T3: is an 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm8" field.

Operation

```
if CurrentInstrSet() == InstrSet_A32 then
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        MemU[address,2] = R[t]<15:0>;
        if wback then R[n] = offset_addr;
else
    if ConditionPassed() then
        EncodingSpecificOperations();
        offset_addr = if add then (R[n] + imm32) else (R[n] - imm32);
        address = if index then offset_addr else R[n];
        MemU[address,2] = R[t]<15:0>;
        if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rt> — Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> — For encoding A1: is the general-purpose base register, encoded in the "Rn" field. The PC can be used in the offset variant, but this is deprecated.

For encoding T1 and T2: is the general-purpose base register, encoded in the "Rn" field.

+/- — Specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

\+ — Specifies the index register is added to the base register.

<Rm> — Is the general-purpose index register, encoded in the "Rm" field.

<imm> — If present, the size of the left shift to apply to the value from <Rm>, in the range 1-3. <imm> is encoded in imm2. If absent, no shift is specified and imm2 is encoded as 0b00.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    offset = Shift(R[m], shift_t, shift_n, PSTATE.C);
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if index then offset_addr else R[n];
    MemU[address,2] = R[t]<15:0>;
    if wback then R[n] = offset_addr;
```

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

STRHT

Store Register Halfword Unprivileged stores a halfword from a register to memory. For information about memory accesses see *Memory accesses*.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

`STRHT` is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or a register value.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0
!= 1111	0	0	0	0	U	1	1	0	Rn	Rt	imm4H	1	0	1	1	imm4L
cond																

A1

```
STRHT{<c>}{<q>} <Rt>, [<Rn>] {, #{+/-}<imm>}
```

```
t = UInt(Rt);  n = UInt(Rn);  postindex = TRUE;  add = (U == '1');
register_form = FALSE;  imm32 = ZeroExtend(imm4H:imm4L, 32);
if t == 15 || n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

If `n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction executes but the value stored is UNKNOWN.

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 if omitted, and encoded in the "imm4H:imm4L" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;              // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then R[m] else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    MemU_unpriv[address,2] = R[t]<15:0>;
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as `STRH` (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

STRT

Store Register Unprivileged stores a word from a register to memory. For information about memory accesses see *Memory accesses*.

The memory access is restricted as if the PE were running in User mode. This makes no difference if the PE is actually running in User mode.

STRT is UNPREDICTABLE in Hyp mode.

The T32 instruction uses an offset addressing mode, that calculates the address used for the memory access from a base register value and an immediate offset, and leaves the base register unchanged.

The A32 instruction uses a post-indexed addressing mode, that uses a base register value as the address for the memory access, and calculates a new address from a base register value and an offset and writes it back to the base register. The offset can be an immediate value or an optionally-shifted register value.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0 1 0	0	U	0	1	0	Rn	Rt	imm12
cond									

A1

```

register_form = FALSE;  imm32 = ZeroExtend(imm12, 32);
if n == 15 || n == t then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n == t`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The store instruction executes but the value stored is UNKNOWN.

If `n == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction uses post-indexed addressing with the base register as PC. This is handled as described in *Using R15*.
- The instruction is treated as if bit[24] == 1 and bit[21] == 0. The instruction uses immediate offset addressing with the base register as PC, without writeback.

A2

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0

register_form = FALSE;  imm32 = ZeroExtend(imm8, 32);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `t == 15`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The store instruction performs the store using the specified addressing mode but the value corresponding to R15 is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> For encoding A1 and A2: is the general-purpose register to be transferred, encoded in the "Rt" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose register to be transferred, encoded in the "Rt" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- For encoding A1: specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

For encoding A2: specifies the index register is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<Rm> Is the general-purpose index register, encoded in the "Rm" field.

<shift> The shift to apply to the value read from <Rm>. If absent, no shift is applied. Otherwise, see *Shifts applied to a register*.

\+ Specifies the offset is added to the base register.

<imm> For encoding A1: is the 12-bit unsigned immediate byte offset, in the range 0 to 4095, defaulting to 0 if omitted, and encoded in the "imm12" field.

For encoding T1: is an optional 8-bit unsigned immediate byte offset, in the range 0 to 255, defaulting to 0 and encoded in the "imm8" field.

Operation

```
if ConditionPassed() then
    if PSTATE.EL == EL2 then UNPREDICTABLE;               // Hyp mode
    EncodingSpecificOperations();
    offset = if register_form then Shift(R[m], shift_t, shift_n, PSTATE.C) else imm32;
    offset_addr = if add then (R[n] + offset) else (R[n] - offset);
    address = if postindex then R[n] else offset_addr;
    if t == 15 then  // Only possible for encodings A1 and A2
        data = PCStoreValue();
    else
        data = R[t];
    MemU_unpriv[address,4] = data;
    if postindex then R[n] = offset_addr;
```

CONSTRAINED UNPREDICTABLE behavior

If `PSTATE.EL == EL2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction executes as STR (immediate).

Operational information

If CPSR.DIT is 1, the timing of this instruction is insensitive to the value of the data being loaded or stored.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

SUB (immediate, from PC)

Subtract from PC subtracts an immediate value from the Align(PC, 4) value to form a PC-relative address, and writes the result to the destination register. Arm recommends that, where possible, software avoids using this alias

This is an alias of ADR. This means:

- The encodings in this description are named to match the encodings of ADR.
- The description of ADR gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A2) and T32 (T2) .

A2

31 30 29 28	27	26	25	24	23	22	21	20	19	18	17	16	15 14 13 12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	0	1	0	0	1	0	0	1	1	1	1	Rd	imm12
cond														

A2

```
SUB{<c>}{<q>} <Rd>, PC, #<const>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

and is the preferred disassembly when `imm12 == '000000000000'`.

T2

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14 13 12	11 10 9 8	7 6 5 4 3 2 1 0
1	1	1	1	0	i	1	0	1	0	1	0	1	1	1	1	0	imm3	Rd	imm8

T2

```
SUB{<c>}{<q>} <Rd>, PC, #<imm12>
```

is equivalent to

```
ADR{<c>}{<q>} <Rd>, <label>
```

and is the preferred disassembly when `i:imm3:imm8 == '000000000000'`.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A2: is the general-purpose destination register, encoded in the "Rd" field. If the PC is used, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.

For encoding T2: is the general-purpose destination register, encoded in the "Rd" field.

<label> For encoding A2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the `ADR` instruction to this label.

If the offset is zero or positive, encoding A1 is used, with imm32 equal to the offset.

If the offset is negative, encoding A2 is used, with imm32 equal to the size of the offset. That is, the use of encoding A2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are any of the constants described in *Modified immediate constants in A32 instructions*.

For encoding T2: the label of an instruction or literal data item whose address is to be loaded into <Rd>. The assembler calculates the required value of the offset from the Align(PC, 4) value of the `ADR` instruction to this label.

If the offset is zero or positive, encoding T3 is used, with imm32 equal to the offset.

If the offset is negative, encoding T2 is used, with imm32 equal to the size of the offset. That is, the use of encoding T2 indicates that the required offset is minus the value of imm32.

Permitted values of the size of the offset are 0-4095.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> An immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

Operation

The description of ADR gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

SUB, SUBS (immediate)

Subtract (immediate) subtracts an immediate value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. If the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The SUBS variant of the instruction performs an exception return without the use of the stack. In this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode, except for encoding T5 with <imm8> set to zero, which is the encoding for the ERET instruction, see *ERET*.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 , T2 , T3 , T4 and T5) .

```
SUBS{<c>}{<q>} PC, LR, #<imm8>
```

```
if Rn == '1110' && IsZero(imm8) then SEE "ERET";
d = 15;  n = UInt(Rn);  setflags = TRUE;  imm32 = ZeroExtend(imm8, 32);
if n != 14 then UNPREDICTABLE;
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *SUBS PC. LR and related instructions (A32)* and *SUBS PC, LR and related instructions (T32)*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rdn> Is the general-purpose source and destination register, encoded in the "Rdn" field.

<imm8> For encoding T2: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field.

For encoding T5: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. If <Rn> is the LR, and zero is used, see *ERET*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. If the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the SUBS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>. Arm deprecates use of this instruction unless <Rn> is the LR.

For encoding T1, T3 and T4: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> For encoding A1 and T4: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see *SUB (SP minus immediate)*. If the PC is used, see *ADR*.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

For encoding T3: is the general-purpose source register, encoded in the "Rn" field. If the SP is used, see *SUB (SP minus immediate)*.

<imm3> Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the "imm3" field.

<imm12> Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T3: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

In the T32 instruction set, MOVS{<c>}{<q>} PC, LR is a pseudo-instruction for SUBS{<c>}{<q>} PC, LR, #0.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(R[n], NOT(imm32), '1');
    if d == 15 then
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

SUB, SUBS (register)

Subtract (register) subtracts an optionally-shifted register value from a register value, and writes the result to the destination register.

If the destination register is not the PC, the SUBS variant of the instruction updates the condition flags based on the result.

The field descriptions for <Rd> identify the encodings where the PC is permitted as the destination register. However, when the destination register is the PC:

- The SUB variant of the instruction is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- The SUBS variant of the instruction performs an exception return without the use of the stack. Arm deprecates use of this instruction. However, in this case:
  - The PE branches to the address written to the PC, and restores *PSTATE* from SPSR_<current_mode>.
  - The PE checks SPSR_<current_mode> for an illegal return event. See *Illegal return events from AArch32 state*.
  - The instruction is UNDEFINED in Hyp mode.
  - The instruction is CONSTRAINED UNPREDICTABLE in User mode and System mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25 24	23 22 21	20	19 18 17 16	15 14 13 12	11 10 9 8 7	6 5	4	3 2 1 0

if (d == 15 && !setflags) || n == 15 || m == 15 then UNPREDICTABLE;
// Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Rd> — For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the SUBS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1 and T2: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the same as <Rn>.

<Rn> — For encoding A1: is the first general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated. If the SP is used, see *SUB (SP minus register)*.

For encoding T1: is the first general-purpose source register, encoded in the "Rn" field.

For encoding T2: is the first general-purpose source register, encoded in the "Rn" field. If the SP is used, see *SUB (SP minus register)*.

<Rm> — For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1 and T2: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in "stype":

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T2: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1 and this instruction does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

cond															

Flag setting (S == 1)

```
SUBS{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

Not flag setting (S == 0)

```
SUB{<c>}{<q>} {<Rd>,} <Rn>, <Rm>, <shift> <Rs>
```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  s = UInt(Rs);
setflags = (S == '1');  shift_t = DecodeRegShift(stype);
if d == 15 || n == 15 || m == 15 || s == 15 then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<Rs> Is the third general-purpose source register holding a shift amount in its bottom 8 bits, encoded in the "Rs" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shift_n = UInt(R[s]<7:0>);
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(R[n], NOT(shifted), '1');
    R[d] = result;
    if setflags then
        PSTATE.<N,Z,C,V> = nzcv;
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

SP, — Is the stack pointer.

<imm7> — Is the unsigned immediate, a multiple of 4, in the range 0 to 508, encoded in the "imm7" field as <imm7>/4.

<Rd> — For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. If the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the SUBS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>. Arm deprecates use of this instruction unless <Rn> is the LR.

For encoding T2 and T3: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<imm12> — Is a 12-bit unsigned immediate, in the range 0 to 4095, encoded in the "i:imm3:imm8" field.

<const> — For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T2: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    (result, nzcv) = AddWithCarry(SP, NOT(imm32), '1');
    if d == 15 then          // Can only occur for A32 encoding

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> For encoding A1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP. Arm deprecates using the PC as the destination register, but if the PC is used:

- For the SUB variant, the instruction is a branch to the address calculated by the operation. This is an interworking branch, see *Pseudocode description of operations on the AArch32 general-purpose registers and the PC*.
- For the SUBS variant, the instruction performs an exception return, that restores *PSTATE* from SPSR_<current_mode>.

For encoding T1: is the general-purpose destination register, encoded in the "Rd" field. If omitted, this register is the SP.

<Rm> For encoding A1: is the second general-purpose source register, encoded in the "Rm" field. The PC can be used, but this is deprecated.

For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.

<shift> Is the type of shift to be applied to the second source register, encoded in “stype”:

stype	<shift>
00	LSL
01	LSR
10	ASR
11	ROR

<amount> For encoding A1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR) encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the shift amount, in the range 1 to 31 (when <shift> = LSL or ROR) or 1 to 32 (when <shift> = LSR or ASR), encoded in the "imm3:imm2" field as <amount> modulo 32.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    shifted = Shift(R[m], shift_t, shift_n, PSTATE.C);
    (result, nzcv) = AddWithCarry(SP, NOT(shifted), '1');
    if d == 15 then          // Can only occur for A32 encoding
        if setflags then
            ALUExceptionReturn(result);
        else
            ALUWritePC(result);
    else
        R[d] = result;
        if setflags then
            PSTATE.<N,Z,C,V> = nzcv;
```

SVC

Supervisor Call causes a Supervisor Call exception. For more information, see *Supervisor Call (SVC) exception*.

SVC was previously called SWI, Software Interrupt, and this name is still found in some documentation.

Software can use this instruction as a call to an operating system to provide a service.

In the following cases, the Supervisor Call exception generated by the SVC instruction is taken to Hyp mode:

- If the SVC is executed in Hyp mode.
- If *HCR*.TGE is set to 1, and the SVC is executed in Non-secure User mode. For more information, see *Supervisor Call exception, when HCR.TGE is set to 1*

In these cases, the *HSR, Hyp Syndrome Register* identifies that the exception entry was caused by a Supervisor Call exception, EC value 0x11, see *Use of the HSR*. The immediate field in the *HSR*:

- If the SVC is unconditional:
  - For the T32 instruction, is the zero-extended value of the imm8 field.
  - For the A32 instruction, is the least-significant 16 bits the imm24 field.
- If the SVC is conditional, is UNKNOWN.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	1	1	1	1	imm24
cond					

A1

```
SVC{<c>}{<q>} {#}<imm>
```

```
imm32 = ZeroExtend(imm24, 32);
```

T1

15	14	13	12	11	10	9	8	7 6 5 4 3 2 1 0
1	1	0	1	1	1	1	1	imm8

T1

```
SVC{<c>}{<q>} {#}<imm>
```

```
imm32 = ZeroExtend(imm8, 32);
```

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<imm> For encoding A1: is a 24-bit unsigned immediate, in the range 0 to 16777215, encoded in the "imm24" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm24 in software, for example to determine the required service.

For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. This value is for assembly and disassembly only. SVC handlers in some systems interpret imm8 in software, for example to determine the required service.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    AArch32.CheckForSVCTrap(imm32<15:0>);
    AArch32.CallSupervisor(imm32<15:0>);
```

SXTAB

Signed Extend and Add Byte extracts an 8-bit value from a register, sign-extends it to 32 bits, adds the result to the value in another register, and writes the final result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27-23	22	21-20	19-16	15-12	11-10	9	8	7-4	3-0

d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

T1

15-7	6-5	4	3-0	15-12	11-8	7	6	5-4	3-0
1 1 1 1 1 0 1 0 0	1 0	0	!= 1111	1 1 1 1	Rd	1	(0)	rotate	Rm
			Rn						

T1

```
SXTAB{<c>}{<q>} {<Rd>,} <Rn>, <Rm> {, ROR #<amount>}
```

```
if Rn == '1111' then SEE "SXTB";
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register, encoded in the "Rm" field.

<amount> Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	(omitted)
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = R[n] + SignExtend(rotated<7:0>, 32);
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

TBB, TBH

Table Branch Byte or Halfword causes a PC-relative forward branch using a table of single byte or halfword offsets. A base register provides a pointer to the table, and a second register supplies an index into the table. The branch length is twice the value returned from the table.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	0	1	0	0	0	1	1	0	1	Rn				(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	H	Rm			

Byte (H == 0)

```
TBB{<c>}{<q>} [<Rn>, <Rm>] // (Outside or last in IT block)
```

Halfword (H == 1)

```
TBH{<c>}{<q>} [<Rn>, <Rm>, LSL #1] // (Outside or last in IT block)
```

```
n = UInt(Rn);  m = UInt(Rm);  is_tbh = (H == '1');
if m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
if InITBlock() && !LastInITBlock() then UNPREDICTABLE;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> Is the general-purpose base register holding the address of the table of branch lengths, encoded in the "Rn" field. The PC can be used. If it is, the table immediately follows this instruction.

<Rm> For the byte variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a single byte in the table. The offset in the table is the value of the index.

For the halfword variant: is the general-purpose index register, encoded in the "Rm" field. This register contains an integer pointing to a halfword in the table. The offset in the table is twice the value of the index.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if is_tbh then
        halfwords = UInt(MemU[R[n]+LSL(R[m],1), 2]);
    else
        halfwords = UInt(MemU[R[n]+R[m], 1]);
    BranchWritePC(PC + 2*halfwords, BranchType_INDIR);
```

TEQ (immediate)

Test Equivalence (immediate) performs a bitwise exclusive OR operation on a register value and an immediate value. It updates the condition flags based on the result, and discards the result.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15	14	13	12	11 10 9 8 7 6 5 4 3 2 1 0
!= 1111	0	0	1	1	0	0	1	1	Rn	(0)	(0)	(0)	(0)	imm12
cond														

A1

```

```
n = UInt(Rn);
(imm32, carry) = T32ExpandImm_C(i:imm3:imm8, PSTATE.C);
if n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rn> For encoding A1: is the general-purpose source register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

For encoding T1: is the general-purpose source register, encoded in the "Rn" field.

<const> For encoding A1: an immediate value. See *Modified immediate constants in A32 instructions* for the range of values.

For encoding T1: an immediate value. See *Modified immediate constants in T32 instructions* for the range of values.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    result = R[n] EOR imm32;
    PSTATE.N = result<31>;
    PSTATE.Z = IsZeroBit(result);
    PSTATE.C = carry;
    // PSTATE.V unchanged
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

TSB CSYNC

Trace Synchronization Barrier. This instruction is a barrier that synchronizes the trace operations of instructions. If *FEAT_TRF* is not implemented, this instruction executes as a `NOP`.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1
(FEAT_TRF)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	0	1	1	0	0	1	0	0	0	0	0	(1)	(1)	(1)	(1)	(0)	(0)	(0)	(0)	0	0	0	1	0	0	1	0
cond																															

A1

```
TSB{<c>}{<q>} CSYNC
```

```
if !HaveSelfHostedTrace() then EndOfInstruction(); // Instruction executes as NOP
if cond != '1110' then UNPREDICTABLE;              // ESB must be encoded with AL condition
```

CONSTRAINED UNPREDICTABLE behavior

If `cond != '1110'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes unconditionally.
- The instruction executes conditionally.

T1
(FEAT_TRF)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

UBFX

Unsigned Bit Field Extract extracts any number of adjacent bits at any position from a register, zero-extends them to 32 bits, and writes the result to the destination register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31–28	27	26	25	24	23	22	21	20–16	15–12	11–7	6	5	4	3–0
!= 1111	0	1	1	1	1	1	1	widthm1	Rd	lsb	1	0	1	Rn
cond														

A1

```
UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>
```

```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(lsb);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3–0	15	14–12	11–8	7–6	5	4–0
1	1	1	1	0	(0)	1	1	1	1	0	0	Rn	0	imm3	Rd	imm2	(0)	widthm1

T1

```
UBFX{<c>}{<q>} <Rd>, <Rn>, #<lsb>, #<width>
```

```
d = UInt(Rd);  n = UInt(Rn);
lsbit = UInt(imm3:imm2);  widthminus1 = UInt(widthm1);
if d == 15 || n == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the general-purpose source register, encoded in the "Rn" field.

<lsb> For encoding A1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "lsb" field.

For encoding T1: is the bit number of the least significant bit in the field, in the range 0 to 31, encoded in the "imm3:imm2" field.

<width> Is the width of the field, in the range 1 to 32-<lsb>, encoded in the "widthm1" field as <width>-1.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    msbit = lsbit + widthminus1;
    if msbit <= 31 then
        R[d] = ZeroExtend(R[n]<msbit:lsbit>, 32);
    else
        UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `msbit > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

UDF

Permanently Undefined generates an Undefined Instruction exception.

The encodings for `UDF` used in this section are defined as permanently UNDEFINED in the Armv8-A architecture. However:

- With the T32 instruction set, Arm deprecates using the `UDF` instruction in an IT block.
- In the A32 instruction set, `UDF` is not conditional.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25 24 23 22 21 20	19 18 17 16 15 14 13 12 11 10 9 8	7 6 5 4	3 2 1 0

T2

```
UDF{<c>}.W {#}<imm> // (<imm> can be represented in T1)

UDF{<c>}{<q>} {#}<imm>
```

```
imm32 = ZeroExtend(imm4:imm12, 32);
// imm32 is for assembly and disassembly only, and is ignored by hardware.
```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. <c> must be AL or omitted.

For encoding T1 and T2: see *Standard assembler syntax fields*. Arm deprecates using any <c> value other than AL.

<q> See *Standard assembler syntax fields*.

<imm> For encoding A1: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm12:imm4" field. The PE ignores the value of this constant.

For encoding T1: is a 8-bit unsigned immediate, in the range 0 to 255, encoded in the "imm8" field. The PE ignores the value of this constant.

For encoding T2: is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the "imm4:imm12" field. The PE ignores the value of this constant.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    UNDEFINED;
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

UDIV

Unsigned Divide divides a 32-bit unsigned integer register value by a 32-bit unsigned integer register value, and writes the result to the destination register. The condition flags are not affected.

See *Divide instructions* for more information about this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

```
d = UInt(Rd);  n = UInt(Rn);  m = UInt(Rm);  a = UInt(Ra);
if d == 15 || n == 15 || m == 15 || a != 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `Ra != '1111'`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction executes as described, with no change to its behavior and no additional side effects.
- The instruction performs a divide and the register specified by Ra becomes UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rd>	Is the general-purpose destination register, encoded in the "Rd" field.

<Rn> Is the first general-purpose source register holding the dividend, encoded in the "Rn" field.

<Rm> Is the second general-purpose source register holding the divisor, encoded in the "Rm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if UInt(R[m]) == 0 then
        result = 0;
    else
        result = RoundTowardsZero(Real(UInt(R[n])) / Real(UInt(R[m])));
    R[d] = result<31:0>;
```

UHADD16

Unsigned Halving Add 16 performs two unsigned 16-bit integer additions, halves the results, and writes the results to the destination register.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27 26 25 24 23	22 21 20	19 18 17 16	15 14 13 12	11	10	9	8	7	6 5	4	3 2 1 0

```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<imm> Is the bit position for saturation, in the range 0 to 31, encoded in the "sat_imm" field.

<Rn> Is the general-purpose source register, encoded in the "Rn" field.

<amount> For encoding A1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm5" field.

For encoding A1: is the shift amount, in the range 1 to 32 encoded in the "imm5" field as <amount> modulo 32.

For encoding T1: is the optional shift amount, in the range 0 to 31, defaulting to 0 and encoded in the "imm3:imm2" field.

For encoding T1: is the shift amount, in the range 1 to 31 encoded in the "imm3:imm2" field as <amount>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    operand = Shift(R[n], shift_t, shift_n, PSTATE.C);  // PSTATE.C ignored
    (result, sat) = UnsignedSatQ(SInt(operand), saturate_to);
    R[d] = ZeroExtend(result, 32);
    if sat then
        PSTATE.Q = '1';
```

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

USAT16

Unsigned Saturate 16 saturates two signed 16-bit values to a selected unsigned range.
This instruction sets *PSTATE*.Q to 1 if the operation saturates.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

UXTB

Unsigned Extend Byte extracts an 8-bit value from a register, zero-extends it to 32 bits, and writes the result to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit value.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25 24 23	22	21 20	19 18 17 16	15 14 13 12	11 10	9	8	7 6 5 4	3 2 1 0
!= 1111	0 1 1 0 1	1	1 0	1 1 1 1	Rd	rotate	(0)	(0)	0 1 1 1	Rm
cond										

A1

```
UXTB{<c>}{<q>} {<Rd>,} <Rm> {, ROR #<amount>}
```

```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

T1

15 14 13 12 11 10 9 8	7	6	5 4 3	2 1 0
1 0 1 1 0 0 1 0	1	1	Rm	Rd

T1

```
UXTB{<c>}{<q>} {<Rd>,} <Rm>
```

```
d = UInt(Rd);  m = UInt(Rm);  rotation = 0;
```

T2

15 14 13 12 11 10 9 8 7	6 5	4	3 2 1 0	15 14 13 12	11 10 9 8	7	6	5 4	3 2 1 0
1 1 1 1 1 0 1 0 0	1 0	1	1 1 1 1	1 1 1 1	Rd	1	(0)	rotate	Rm

T2

```
UXTB{<c>}.W {<Rd>,} <Rm> // (<Rd>, <Rm> can be represented in T1)
```

```
UXTB{<c>}{<q>} {<Rd>,} <Rm> {, ROR #<amount>}
```

```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> Is the general-purpose source register, encoded in the "Rm" field.

<amount> Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	(omitted)
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d] = ZeroExtend(rotated<7:0>, 32);
```

Operational information

If CPSR.DIT is 1, this instruction has passed its condition execution check, and does not use R15 as either its source or destination:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

UXTB16

Unsigned Extend Byte 16 extracts two 8-bit values from a register, zero-extends them to 16 bits each, and writes the results to the destination register. The instruction can specify a rotation by 0, 8, 16, or 24 bits before extracting the 8-bit values.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
!= 1111				0	1	1	0	1	1	0	0	1	1	1	1	Rd				rotate		(0)	(0)	0	1	1	1	Rm			
cond																															

A1

```
UXTB16{<c>}{<q>} {<Rd>,} <Rm> {, ROR #<amount>}
```

```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	0	1	0	0	0	1	1	1	1	1	1	1	1	1	1	Rd				1	(0)	rotate		Rm			

T1

```
UXTB16{<c>}{<q>} {<Rd>,} <Rm> {, ROR #<amount>}
```

```
d = UInt(Rd);  m = UInt(Rm);  rotation = UInt(rotate:'000');
if d == 15 || m == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rd> Is the general-purpose destination register, encoded in the "Rd" field.

<Rm> For encoding A1: is the general-purpose source register, encoded in the "Rm" field.

For encoding T1: is the second general-purpose source register, encoded in the "Rm" field.

<amount> Is the rotate amount, encoded in “rotate”:

rotate	<amount>
00	(omitted)
01	8
10	16
11	24

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    rotated = ROR(R[m], rotation);
    R[d]<15:0>  = ZeroExtend(rotated<7:0>, 16);
    R[d]<31:16> = ZeroExtend(rotated<23:16>, 16);
```

WFE

Wait For Event is a hint instruction that indicates that the PE can enter a low-power state and remain there until a wakeup event occurs. Wakeup events include the event signaled as a result of executing the SEV instruction on any PE in the multiprocessor system. For more information, see *Wait For Event and Send Event*.

As described in *Wait For Event and Send Event*, the execution of a WFE instruction that would otherwise cause entry to a low-power state can be trapped to a higher Exception level, see:

- *Traps to Undefined mode of PL0 execution of WFE and WFI instructions*.
- *Traps to Hyp mode of Non-secure EL0 and EL1 execution of WFE and WFI instructions*.
- *Traps to Monitor mode of the execution of WFE and WFI instructions in modes other than Monitor mode*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

YIELD

YIELD is a hint instruction. Software with a multithreading capability can use a YIELD instruction to indicate to the PE that it is performing a task, for example a spin-lock, that could be swapped out to improve overall system performance. The PE can use this hint to suspend and resume multiple software threads if it supports the capability.

For more information about the recommended use of this instruction see *The Yield instruction*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1 and T2) .

A1

31-28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

AArch32 -- SIMD&FP Instructions (alphabetic order)

VBIC (register): Vector Bitwise Bit Clear (register).

VBIF: Vector Bitwise Insert if False.

VBIT: Vector Bitwise Insert if True.

VBSL: Vector Bitwise Select.

VCADD: Vector Complex Add.

VCEQ (immediate #0): Vector Compare Equal to Zero.

VCEQ (register): Vector Compare Equal.

VCGE (immediate #0): Vector Compare Greater Than or Equal to Zero.

VCGE (register): Vector Compare Greater Than or Equal.

VCGT (immediate #0): Vector Compare Greater Than Zero.

VCGT (register): Vector Compare Greater Than.

VCLE (immediate #0): Vector Compare Less Than or Equal to Zero.

VCLE (register): Vector Compare Less Than or Equal: an alias of VCGE (register).

VCLS: Vector Count Leading Sign Bits.

VCLT (immediate #0): Vector Compare Less Than Zero.

VCLT (register): Vector Compare Less Than: an alias of VCGT (register).

VCLZ: Vector Count Leading Zeros.

VCMLA: Vector Complex Multiply Accumulate.

VCMLA (by element): Vector Complex Multiply Accumulate (by element).

VCMP: Vector Compare.

VCMPE: Vector Compare, raising Invalid Operation on NaN.

VCNT: Vector Count Set Bits.

VCVT (between double-precision and single-precision): Convert between double-precision and single-precision.

VCVT (between floating-point and fixed-point, Advanced SIMD): Vector Convert between floating-point and fixed-point.

VCVT (between floating-point and fixed-point, floating-point): Convert between floating-point and fixed-point.

VCVT (between floating-point and integer, Advanced SIMD): Vector Convert between floating-point and integer.

VCVT (between half-precision and single-precision, Advanced SIMD): Vector Convert between half-precision and single-precision.

VCVT (floating-point to integer, floating-point): Convert floating-point to integer with Round towards Zero.

VCVT (from single-precision to BFloat16, Advanced SIMD): Vector Convert from single-precision to BFloat16.

VCVT (integer to floating-point, floating-point): Convert integer to floating-point.

VCVTA (Advanced SIMD): Vector Convert floating-point to integer with Round to Nearest with Ties to Away.

VCVTA (floating-point): Convert floating-point to integer with Round to Nearest with Ties to Away.

VCVTB: Convert to or from a half-precision value in the bottom half of a single-precision register.

VCVTB (BFloat16): Converts from a single-precision value to a BFloat16 value in the bottom half of a single-precision register.

VCVTM (Advanced SIMD): Vector Convert floating-point to integer with Round towards -Infinity.

VMOV (register): Copy between FP registers.

VMOV (register, SIMD): Copy between SIMD registers: an alias of VORR (register).

VMOV (scalar to general-purpose register): Copy a vector element to a general-purpose register with sign or zero extension.

VMOVL: Vector Move Long.

VMOVN: Vector Move and Narrow.

VMOVX: Vector Move extraction.

VMRS: Move SIMD&FP Special register to general-purpose register.

VMSR: Move general-purpose register to SIMD&FP Special register.

VMUL (by scalar): Vector Multiply (by scalar).

VMUL (floating-point): Vector Multiply (floating-point).

VMUL (integer and polynomial): Vector Multiply (integer and polynomial).

VMULL (by scalar): Vector Multiply Long (by scalar).

VMULL (integer and polynomial): Vector Multiply Long (integer and polynomial).

VMVN (immediate): Vector Bitwise NOT (immediate).

VMVN (register): Vector Bitwise NOT (register).

VNEG: Vector Negate.

VNMLA: Vector Negate Multiply Accumulate.

VNMLS: Vector Negate Multiply Subtract.

VNMUL: Vector Negate Multiply.

VORN (immediate): Vector Bitwise OR NOT (immediate): an alias of VORR (immediate).

VORN (register): Vector bitwise OR NOT (register).

VORR (immediate): Vector Bitwise OR (immediate).

VORR (register): Vector bitwise OR (register).

VPADAL: Vector Pairwise Add and Accumulate Long.

VPADD (floating-point): Vector Pairwise Add (floating-point).

VPADD (integer): Vector Pairwise Add (integer).

VPADDL: Vector Pairwise Add Long.

VPMAX (floating-point): Vector Pairwise Maximum (floating-point).

VPMAX (integer): Vector Pairwise Maximum (integer).

VPMIN (floating-point): Vector Pairwise Minimum (floating-point).

VPMIN (integer): Vector Pairwise Minimum (integer).

VPOP: Pop SIMD&FP registers from Stack: an alias of VLDM, VLDMDB, VLDMIA.

VPUSH: Push SIMD&FP registers to Stack: an alias of VSTM, VSTMDB, VSTMIA.

VQABS: Vector Saturating Absolute.

VQADD: Vector Saturating Add.

VQDMLAL: Vector Saturating Doubling Multiply Accumulate Long.

FLDM*X (FLDMDBX, FLDMIAX)

FLDMDBX is the Decrement Before variant of this instruction, and FLDMIAX is the Increment After variant. FLDM*X loads multiple SIMD&FP registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Arm deprecates use of FLDMDBX and FLDMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7 6 5 4 3 2 1	0
!= 1111	1	1	0	P	U	D	W	1	Rn	Vd	1	0	1	1	imm8<7:1>	1
cond																imm8<0>

Decrement Before (P == 1 && U == 0 && W == 1)

```
FLDMDBX{<c>}{<q>} <Rn>!, <dreglist>
```

Increment After (P == 0 && U == 1)

```
FLDMIAX{<c>}{<q>} <Rn>{!}, <dreglist>
```

```
if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE "VLDR";
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE;  add = (U == '1');  wback = (W == '1');
d = UInt(D:Vd);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2;  // If UInt(imm8) is odd, see "FLDM*X".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as a `VLDM` with the same addressing mode but loads no registers.

If `regs > 16 || (d+regs) > 16`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2 1 0	15 14 13 12	11	10	9	8	7 6 5 4 3 2 1	0

if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VLDM with the same addressing mode but loads no registers.

If `regs > 16 || (d+regs) > 16`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: See *Advanced SIMD and floating-point 64-bit move* for the T32 instruction set, or *Advanced SIMD and floating-point 64-bit move* for the A32 instruction set.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.
!	Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
<dreglist>	Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list plus one. The list must contain at least one register, all registers must be in the range D0-D15, and must not contain more than 16 registers.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4];  address = address+4;
        else
            word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian(AccType_ATOMIC) then word1:word2 else word2:word1;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

FSTMDBX, FSTMIAX

FSTMX stores multiple SIMD&FP registers from the Advanced SIMD and floating-point register file to consecutive locations in using an address from a general-purpose register.

Arm deprecates use of FSTMDBX and FSTMIAX, except for disassembly purposes, and reassembly of disassembled code.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VABA

Vector Absolute Difference and Accumulate subtracts the elements of one vector from the corresponding elements of another vector, and accumulates the absolute values of the results into the elements of the destination vector.

Operand and result elements are all integers of the same length.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

64-bit SIMD vector (Q == 0)

```
VABD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VABD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	0	D	1	sz	Vn				Vd				1	1	0	1	N	Q	M	0	Vm			

64-bit SIMD vector (Q == 0)

```
VABD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VABD{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
if sz == '1' && InITBlock() then UNPREDICTABLE;
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];
            op2 = Elem[Din[m+r],e,esize];
            absdiff = Abs(Int(op1,unsigned) - Int(op2,unsigned));
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = absdiff<2*esize-1:0>;
            else
                Elem[D[d+r],e,esize] = absdiff<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VABS

Vector Absolute takes the absolute value of each element in a vector, and places the results in a second vector. The floating-point version only clears the sign bit.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VACGE

Vector Absolute Compare Greater Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is greater than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operands and result can be quadword or doubleword vectors. They must all be the same size.

The operand vector elements are floating-point numbers. The result vector elements are the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the pseudo-instruction VACLE.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```

VACLE

Vector Absolute Compare Less Than or Equal takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of VACGE. This means:

- The encodings in this description are named to match the encodings of VACGE.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VACGE gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

Assembler Symbols

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<c>	For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional. For encoding T1: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Operation

The description of VACGE gives the operational pseudocode for this instruction.

Operational information

The description of *VACGE* gives the operational pseudocode for this instruction.

VACLT

Vector Absolute Compare Less Than takes the absolute value of each element in a vector, and compares it with the absolute value of the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of VACGT. This means:

- The encodings in this description are named to match the encodings of VACGT.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VACGT gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VACGT{<c>}{<q>}.<dt> <Qd>, <Qm>, <Qn>
```

Assembler Symbols

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Operation

The description of VACGT gives the operational pseudocode for this instruction.

Operational information

The description of *VACGT* gives the operational pseudocode for this instruction.

VADD (floating-point)

Vector Add (floating-point) adds corresponding elements in two vectors, and places the results in the destination vector.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = Elem[D[n+r],e,esize] + Elem[D[m+r],e,esize];
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VADDHN

Vector Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are truncated. For rounded results, see *VRADDHN*.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VAND (immediate)

Vector Bitwise AND (immediate) performs a bitwise AND between a register value and an immediate value, and returns the result into the destination vector

This is a pseudo-instruction of VBIC (immediate). This means:

- The encodings in this description are named to match the encodings of VBIC (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VBIC (immediate) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

Assembler Symbols

<c> — For encoding A1 and A2: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1 and T2: see *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<Qd> — Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> — Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<imm> — Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions*.

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] AND NOT(imm64);
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.

    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Assembler Symbols

<c>	For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.
	For encoding T1: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<dt>	An optional data type. It is ignored by assemblers, and does not affect the encoding.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] AND NOT(D[m+r]);
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VBIF

Vector Bitwise Insert if False inserts each bit from the first source register into the destination register if the corresponding bit of the second source register is 0, otherwise leaves the bit in the destination register unchanged.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28 27 26 25	24	23	22	21 20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3 2 1 0

VCADD

Vector Complex Add.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 90 or 270 degrees.
- The rotated complex number is added to the complex number from the first source register.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VCEQ (immediate #0)

Vector Compare Equal to Zero takes each element in a vector, and compares it with zero. If it is equal to zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in "F:size":

F	size	<dt>
0	00	I8
0	01	I16
0	10	I32
1	01	F16
1	10	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                bits(esize) zero = FPZero('0');
                test_passed = FPCompareEQ(Elem[D[m+r],e,esize], zero, StandardFPSCRValue());
            else
                test_passed = (Elem[D[m+r],e,esize] == Zeros(esize));
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

VCEQ (register)

Vector Compare Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If they are equal, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VCGT (immediate #0)

Vector Compare Greater Than Zero takes each element in a vector, and compares it with zero. If it is greater than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```
VCGT{<c>}{<q>}.<dt> {<Dd>,} <Dm>, #0
```

128-bit SIMD vector (Q == 1)

```
VCGT{<c>}{<q>}.<dt> {<Qd>,} <Qm>, #0
```

```
if size == '11' then UNDEFINED;
if F == '1' && ((size == '01' && !HaveFP16Ext()) || size == '00') then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
floating_point = (F == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	1	1	size		0	1	Vd				0	F	0	0	0	Q	M	0	Vm			

64-bit SIMD vector (Q == 0)

```
VCGT{<c>}{<q>}.<dt> {<Dd>,} <Dm>, #0
```

128-bit SIMD vector (Q == 1)

```
VCGT{<c>}{<q>}.<dt> {<Qd>,} <Qm>, #0
```

```
if size == '11' then UNDEFINED;
if F == '1' && ((size == '01' && !HaveFP16Ext()) || size == '00') then UNDEFINED;
if F == '1' && size == '01' && InITBlock() then UNPREDICTABLE;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
floating_point = (F == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in “F:size”:

F	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	01	F16
1	10	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                bits(esize) zero = FPZero('0');
                test_passed = FPCompareGT(Elem[D[m+r],e,esize], zero, StandardFPSCRValue());
            else
                test_passed = (SInt(Elem[D[m+r],e,esize]) > 0);
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

VCLE (register)

Vector Compare Less Than or Equal takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than or equal to the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of VCGE (register). This means:

- The encodings in this description are named to match the encodings of VCGE (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VCGE (register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler Symbols

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<c> For encoding A1 and A2: see *Standard assembler syntax fields*. This encoding must be unconditional.
For encoding T1 and T2: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> For encoding A1 and T1: is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

For encoding A2 and T2: is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

Operation

The description of VCGE (register) gives the operational pseudocode for this instruction.

Operational information

The description of *VCGE_r* gives the operational pseudocode for this instruction.

VCLS

Vector Count Leading Sign Bits counts the number of consecutive bits following the topmost bit, that are the same as the topmost bit, in each element in a vector, and places the results in a second vector. The count does not include the topmost bit itself.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit signed integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = CountLeadingSignBits(Elem[D[m+r],e,esize])<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VCLT (immediate #0)

Vector Compare Less Than Zero takes each element in a vector, and compares it with zero. If it is less than zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements are the same type, and are signed integers or floating-point numbers. The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19 18	17	16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

64-bit SIMD vector (Q == 0)

```
VCLT{<c>}{<q>}.<dt> {<Dd>,} <Dm>, #0
```

128-bit SIMD vector (Q == 1)

```
VCLT{<c>}{<q>}.<dt> {<Qd>,} <Qm>, #0
```

```
if size == '11' then UNDEFINED;
if F == '1' && ((size == '01' && !HaveFP16Ext()) || size == '00') then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
floating_point = (F == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2	1	0	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	1	1	1	1	1	1	D	1	1	size	0	1	Vd	0	F	1	0	0	Q	M	0	Vm

64-bit SIMD vector (Q == 0)

```
VCLT{<c>}{<q>}.<dt> {<Dd>,} <Dm>, #0
```

128-bit SIMD vector (Q == 1)

```
VCLT{<c>}{<q>}.<dt> {<Qd>,} <Qm>, #0
```

```
if size == '11' then UNDEFINED;
if F == '1' && ((size == '01' && !HaveFP16Ext()) || size == '00') then UNDEFINED;
if F == '1' && size == '01' && InITBlock() then UNPREDICTABLE;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
floating_point = (F == '1');
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in "F:size":

F	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	01	F16
1	10	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                bits(esize) zero = FPZero('0');
                test_passed = FPCompareGT(zero, Elem[D[m+r],e,esize], StandardFPSCRValue());
            else
                test_passed = (SInt(Elem[D[m+r],e,esize]) < 0);
            Elem[D[d+r],e,esize] = if test_passed then Ones(esize) else Zeros(esize);
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VCLT (register)

Vector Compare Less Than takes each element in a vector, and compares it with the corresponding element of a second vector. If the first is less than the second, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

This is a pseudo-instruction of VCGT (register). This means:

- The encodings in this description are named to match the encodings of VCGT (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VCGT (register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VCLZ

Vector Count Leading Zeros counts the number of consecutive zeros, starting from the most significant bit, in each element in a vector, and places the results in a second vector.

The operand vector elements can be any one of 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The result vector elements are the same data type as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19 18	17	16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = CountLeadingZeroBits(Elem[D[m+r],e,esize])<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

VCMLA

Vector Complex Multiply Accumulate.

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on the corresponding complex number element pairs from the two source registers and the destination register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VCMLA (by element)

Vector Complex Multiply Accumulate (by element).

This instruction operates on complex numbers that are represented in SIMD&FP registers as pairs of elements, with the more significant element holding the imaginary part of the number and the less significant element holding the real part of the number. Each element holds a floating-point value. It performs the following computation on complex numbers from the first source register and the destination register with the specified complex number from the second source register:

- Considering the complex number from the second source register on an Argand diagram, the number is rotated counterclockwise by 0, 90, 180, or 270 degrees.
- The two elements of the transformed complex number are multiplied by:
  - The real element of the complex number from the first source register, if the transformation was a rotation by 0 or 180 degrees.
  - The imaginary element of the complex number from the first source register, if the transformation was a rotation by 90 or 270 degrees.
- The complex number resulting from that multiplication is added to the complex number from the destination register.

The multiplication and addition operations are performed as a fused multiply-add, without any intermediate rounding.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VCMP

Vector Compare compares two floating-point registers, or one floating-point register and zero. It writes the result to the *FPSCR* flags. These are normally transferred to the *PSTATE*.{N, Z, C, V} Condition flags by a subsequent VMRS instruction.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is a signaling NaN.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19	18	17	16	15 14 13 12	11	10	9 8	7	6	5	4	3 2 1 0

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    bits(4) nzcv;
    case esize of
        when 16
            bits(16) op16 = if with_zero then FPZero('0') else S[m]<15:0>;
            nzcv = FPCompare(S[d]<15:0>, op16, quiet_nan_exc, FPSCR[]);
        when 32
            bits(32) op32 = if with_zero then FPZero('0') else S[m];
            nzcv = FPCompare(S[d], op32, quiet_nan_exc, FPSCR[]);
        when 64
            bits(64) op64 = if with_zero then FPZero('0') else D[m];
            nzcv = FPCompare(D[d], op64, quiet_nan_exc, FPSCR[]);

    FPSCR<31:28> = nzcv; // FPSCR.<N,Z,C,V> set to nzcv
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the *FPSCR* condition flags to N=0, Z=0, C=1, and V=1.

VCMPE

Vector Compare, raising Invalid Operation on NaN compares two floating-point registers, or one floating-point register and zero. It writes the result to the *FPSCR* flags. These are normally transferred to the *PSTATE*.{N, Z, C, V} Condition flags by a subsequent VMRS instruction.

This instruction raises an Invalid Operation floating-point exception if either or both of the operands is any type of NaN.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    bits(4) nzcv;
    case esize of
        when 16
            bits(16) op16 = if with_zero then FPZero('0') else S[m]<15:0>;
            nzcv = FPCompare(S[d]<15:0>, op16, quiet_nan_exc, FPSCR[]);
        when 32
            bits(32) op32 = if with_zero then FPZero('0') else S[m];
            nzcv = FPCompare(S[d], op32, quiet_nan_exc, FPSCR[]);
        when 64
            bits(64) op64 = if with_zero then FPZero('0') else D[m];
            nzcv = FPCompare(D[d], op64, quiet_nan_exc, FPSCR[]);

    FPSCR<31:28> = nzcv; // FPSCR.<N,Z,C,V> set to nzcv
```

Operational information

The IEEE 754 standard specifies that the result of a comparison is precisely one of <, ==, > or unordered. If either or both of the operands is a NaN, they are unordered, and all three of (Operand1 < Operand2), (Operand1 == Operand2) and (Operand1 > Operand2) are false. An unordered comparison sets the *FPSCR* condition flags to N=0, Z=0, C=1, and V=1.

        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = BitCount(Elem[D[m+r],e,esize])<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VCVT (between double-precision and single-precision)

Convert between double-precision and single-precision does one of the following:

- Converts the value in a double-precision register to single-precision and writes the result to a single-precision register.
- Converts the value in a single-precision register to double-precision and writes the result to a double-precision register.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

VCVT (between floating-point and fixed-point, Advanced SIMD)

Vector Convert between floating-point and fixed-point converts each element in a vector from floating-point to fixed-point, or from fixed-point to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt1> Is the data type for the elements of the destination vector, encoded in “op:U”:

op	U	<dt1>
00	x	F16
01	0	S16
01	1	U16
10	x	F32
11	0	S32
11	1	U32

<dt2> Is the data type for the elements of the source vector, encoded in “op:U”:

op	U	<dt2>
00	0	S16
00	1	U16
01	x	F16
10	0	S32
10	1	U32
11	x	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<fbits> The number of fraction bits in the fixed point number, in the range 1 to 32 for 32-bit elements, or in the range 1 to 16 for 16-bit elements:

- (64 - <fbits>) is encoded in imm6.

An assembler can permit an <fbits> value of 0. This is encoded as floating-point to integer or integer to floating-point instruction, see *VCVT (between floating-point and integer, Advanced SIMD)*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_fixed then
                result = FPToFixed(op1, frac_bits, unsigned, StandardFPSCRValue(),
                                   FPRounding_ZERO);
            else
                result = FixedToFP(op1, frac_bits, unsigned, StandardFPSCRValue(),
                                   FPRounding_TIEEVEN);
            Elem[D[d+r],e,esize] = result;
```

VCVT (between floating-point and fixed-point, floating-point)

Convert between floating-point and fixed-point converts a value in a register from floating-point to fixed-point, or from fixed-point to floating-point. Software can specify the fixed-point value as either signed or unsigned.

The fixed-point value can be 16-bit or 32-bit. Conversions from fixed-point values take their operand from the low-order bits of the source register and ignore any remaining bits. Signed conversions to fixed-point values sign-extend the result value to the destination register width. Unsigned conversions to fixed-point values zero-extend the result value to the destination register width.

The floating-point to fixed-point operation uses the Round towards Zero rounding mode. The fixed-point to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

    when '11' fp_size = 64; d = UInt(D:Vd);

if frac_bits < 0 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `frac_bits < 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VCVT (between floating-point and fixed-point)*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the fixed-point number, encoded in “U:sx”:

U	sx	<dt>
0	0	S16
0	1	S32
1	0	U16
1	1	U32

<Sdm> Is the 32-bit name of the SIMD&FP destination and source register, encoded in the "Vd:D" field.

<Ddm> Is the 64-bit name of the SIMD&FP destination and source register, encoded in the "D:Vd" field.

<fbits> The number of fraction bits in the fixed-point number:

- If <dt> is S16 or U16, <fbits> must be in the range 0-16. (16 - <fbits>) is encoded in [imm4, i]
- If <dt> is S32 or U32, <fbits> must be in the range 1-32. (32 - <fbits>) is encoded in [imm4, i].

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_fixed then
        bits(size) result;
        case fp_size of
            when 16

VCVT (between floating-point and integer, Advanced SIMD)

Vector Convert between floating-point and integer converts each element in a vector from floating-point to integer, or from integer to floating-point, and places the results in a second vector.

The vector elements are the same type, and are floating-point numbers or integers. Signed and unsigned integers are distinct.

The floating-point to integer operation uses the Round towards Zero rounding mode. The integer to floating-point operation uses the Round to Nearest rounding mode.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VCVT{<c>}{<q>}.<dt1>.<dt2> <Dd>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VCVT{<c>}{<q>}.<dt1>.<dt2> <Qd>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && !HaveFP16Ext()) || size IN {'00', '11'} then UNDEFINED;
to_integer = (op<1> == '1');  unsigned = (op<0> == '1');
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	1	1	size		1	1	Vd				0	1	1	op		Q	M	0	Vm			

64-bit SIMD vector (Q == 0)

```
VCVT{<c>}{<q>}.<dt1>.<dt2> <Dd>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VCVT{<c>}{<q>}.<dt1>.<dt2> <Qd>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && !HaveFP16Ext()) || size IN {'00', '11'} then UNDEFINED;
if size == '01' && InITBlock()  then UNPREDICTABLE;
to_integer = (op<1> == '1');  unsigned = (op<0> == '1');
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt1> Is the data type for the elements of the destination vector, encoded in “size:op”:

size	op	<dt1>
01	0x	F16
01	10	S16
01	11	U16
10	0x	F32
10	10	S32
10	11	U32

<dt2> Is the data type for the elements of the source vector, encoded in “size:op”:

size	op	<dt2>
01	00	S16
01	01	U16
01	1x	F16
10	00	S32
10	01	U32
10	1x	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(esize) result;
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[m+r],e,esize];
            if to_integer then
                result = FPToFixed(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_ZERO);
            else
                result = FixedToFP(op1, 0, unsigned, StandardFPSCRValue(), FPRounding_TIEEVEN);
            Elem[D[d+r],e,esize] = result;
```

VCVT (floating-point to integer, floating-point)

Convert floating-point to integer with Round towards Zero converts a value in a register from floating-point to a 32-bit integer, using the Round towards Zero rounding mode, and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```

VCVT (from single-precision to BFloat16, Advanced SIMD)

Vector Convert from single-precision to BFloat16 converts each 32-bit element in a vector from single-precision floating-point to BFloat16 format, and writes the result into a second vector. The result vector elements are half the width of the source vector elements.

Unlike the BFloat16 multiplication instructions, this instruction uses the Round to Nearest rounding mode, and can generate a floating-point exception that causes cumulative exception bits in the *FPSCR* to be set.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VCVT (integer to floating-point, floating-point)

Convert integer to floating-point converts a 32-bit integer to floating-point using the rounding mode specified by the *FPSCR*, and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19	18	17	16	15 14 13 12	11	10	9 8	7	6	5	4	3 2 1 0

VCVTA (Advanced SIMD)

Vector Convert floating-point to integer with Round to Nearest with Ties to Away converts each element in a vector from floating-point to integer using the Round to Nearest with Ties to Away rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are integers, and the same size as the operand vector elements. Signed and unsigned integers are distinct.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VCVTB

Convert to or from a half-precision value in the bottom half of a single-precision register does one of the following:

- Converts the half-precision value in the bottom half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the bottom half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the bottom half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

```

VCVTB (BFloat16)

Converts the single-precision value in a single-precision register to BFloat16 format and writes the result into the bottom half of a single precision register, preserving the top 16 bits of the destination register.

Unlike the BFloat16 multiplication instructions, this instruction honors all the control bits in the *FPSCR* that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception which causes a cumulative exception bit in the *FPSCR* to be set, or a synchronous exception to be taken, depending on the enable bits in the *FPSCR*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VCVTM (Advanced SIMD)

Vector Convert floating-point to integer with Round towards -Infinity converts each element in a vector from floating-point to integer using the Round towards -Infinity rounding mode, and places the results in a second vector.

The operand vector elements are floating-point numbers.

The result vector elements are integers, and the same size as the operand vector elements. Signed and unsigned integers are distinct.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VCVTP (floating-point)

Convert floating-point to integer with Round towards +Infinity converts a value in a register from floating-point to a 32-bit integer using the Round towards +Infinity rounding mode, and places the result in a second register.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15-12	11	10	9-8	7	6	5	4	3-0

    when '10' esize = 32; m = UInt(Vm:M);
    when '11' esize = 64; m = UInt(M:Vm);
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the destination, encoded in “op”:

op	<dt>
0	U32
1	S32

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
EncodingSpecificOperations(); CheckVFPEnabled(TRUE);
case esize of
    when 16
        S[d] = FPToFixed(S[m]<15:0>, 0, unsigned, FPSCR[], rounding);
    when 32
        S[d] = FPToFixed(S[m], 0, unsigned, FPSCR[], rounding);
    when 64
        S[d] = FPToFixed(D[m], 0, unsigned, FPSCR[], rounding);
```

VCVTR

Convert floating-point to integer converts a value in a register from floating-point to a 32-bit integer, using the rounding mode specified by the *FPSCR* and places the result in a second register.

VCVT (between floating-point and fixed-point, floating-point) describes conversions between floating-point and 16-bit integers.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```

VCVTT

Convert to or from a half-precision value in the top half of a single-precision register does one of the following:

- Converts the half-precision value in the top half of a single-precision register to single-precision and writes the result to a single-precision register.
- Converts the half-precision value in the top half of a single-precision register to double-precision and writes the result to a double-precision register.
- Converts the single-precision value in a single-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.
- Converts the double-precision value in a double-precision register to half-precision and writes the result into the top half of a single-precision register, preserving the other half of the destination register.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. ```

VCVTT (BFloat16)

Converts the single-precision value in a single-precision register to BFloat16 format and writes the result in the top half of a single-precision register, preserving the bottom 16 bits of the register.

Unlike the BFloat16 multiplication instructions, this instruction honors all the control bits in the *FPSCR* that apply to single-precision arithmetic, including the rounding mode. This instruction can generate a floating-point exception which causes a cumulative exception bit in the *FPSCR* to be set, or a synchronous exception to be taken, depending on the enable bits in the *FPSCR*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

<q>	See *Standard assembler syntax fields*.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    case esize of
        when 16
            S[d] = Zeros(16) : FPDiv(S[n]<15:0>, S[m]<15:0>, FPSCR[]);
        when 32
            S[d] = FPDiv(S[n], S[m], FPSCR[]);
        when 64
            D[d] = FPDiv(D[n], D[m], FPSCR[]);
```

VDOT (by element)

BFloat16 floating-point indexed dot product (vector, by element). This instruction delimits the source vectors into pairs of 16-bit BF16 elements. Each pair of elements in the first source vector is multiplied by the indexed pair of elements in the second source vector. The resulting single-precision products are then summed and added destructively to the single-precision element in the destination vector which aligns with the pair of BFloat16 values in the first source vector. The instruction does not update the *FPSCR* exception status.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VDUP (general-purpose register)

Duplicate general-purpose register to vector duplicates an element from a general-purpose register into every element of the destination vector.

The destination vector elements can be 8-bit, 16-bit, or 32-bit fields. The source element is the least significant 8, 16, or 32 bits of the general-purpose register. There is no distinction between data types.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31-28	27	26	25	24	23	22	21	20	19-16	15-12	11	10	9	8	7	6	5	4	3	2	1	0

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*. Arm strongly recommends that any VDUP instruction is unconditional, see *Conditional execution*.

<q> — See *Standard assembler syntax fields*.

<size> The data size for the elements of the destination vector. It must be one of:

8
: Encoded as [b, e] = 0b10.

16
: Encoded as [b, e] = 0b01.

32
: Encoded as [b, e] = 0b00.

<Qd> The destination vector for a quadword operation.

<Dd> The destination vector for a doubleword operation.

<Rt> The Arm source register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    scalar = R[t]<esize-1:0>;
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VDUP (scalar)

Duplicate vector element to vector duplicates a single element of a vector into every element of the destination vector.

The scalar, and the destination vector elements, can be any one of 8-bit, 16-bit, or 32-bit fields. There is no distinction between data types.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> The data size. It must be one of:

8

Encoded as imm4<0> = '1'. imm4<3:1> encodes the index[x] of the scalar.

16

Encoded as imm4<1:0> = '10'. imm4<3:2> encodes the index [x] of the scalar.

32

Encoded as imm4<2:0> = '100'. imm4<3> encodes the index [x] of the scalar.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm[x]> The scalar. For details of how [x] is encoded, see the description of <size>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    scalar = Elem[D[m],index,esize];
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = scalar;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

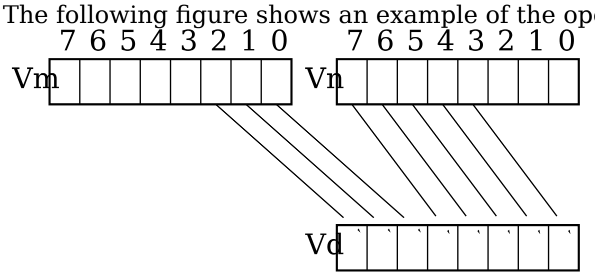
VEXT (byte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector.

The elements of the vectors are treated as being 8-bit fields. There is no distinction between data types.

The following figure shows an example of the operation of VEXT doubleword operation for imm = 3.



Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the pseudo-instruction VEXT (multibyte elements).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

<c>	For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional. For encoding T1: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<imm>	For the 64-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 7, encoded in the "imm4" field. For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to 15, encoded in the "imm4" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if quadword_operation then
        Q[d>>1] = (Q[m>>1]:Q[n>>1])<position+127:position>;
    else
        D[d] = (D[m]:D[n])<position+63:position>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VEXT (multibyte elements)

Vector Extract extracts elements from the bottom end of the second operand vector and the top end of the first, concatenates them and places the result in the destination vector

This is a pseudo-instruction of VEXT (byte elements). This means:

- The encodings in this description are named to match the encodings of VEXT (byte elements).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VEXT (byte elements) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	0	1	D	1	1	Vn				Vd				imm4				N	Q	M	0	Vm			

64-bit SIMD vector (Q == 0)

```
VEXT{<c>}{<q>}.<size> {<Dd>,} <Dn>, <Dm>, #<imm>
```

is equivalent to

```
VEXT{<c>}{<q>}.8 {<Dd>,} <Dn>, <Dm>, #<imm*(size/8)>
```

128-bit SIMD vector (Q == 1)

```
VEXT{<c>}{<q>}.<size> {<Qd>,} <Qn>, <Qm>, #<imm>
```

is equivalent to

```
VEXT{<c>}{<q>}.8 {<Qd>,} <Qn>, <Qm>, #<imm*(size/8)>
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<imm>	For the 64-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to (128/<size>)-1. For the 128-bit SIMD vector variant: is the location of the extracted result in the concatenation of the operands, as a number of bytes from the least significant end, in the range 0 to (64/<size>)-1.

Operation

The description of VEXT (byte elements) gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

VFMA

Vector Fused Multiply Accumulate multiplies corresponding elements of two vectors, and accumulates the results into the elements of the destination vector. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19-16	15-12	11	10	9	8	7	6	5	4	3-0

VFMAB, VFMAT (BFloat16, by scalar)

The BFloat16 floating-point widening multiply-add long instruction widens the even-numbered (bottom) or odd-numbered (top) 16-bit elements in the first source vector, and an indexed element in the second source vector from Bfloat16 to single-precision format. The instruction then multiplies and adds these values to the overlapping single-precision elements of the destination vector.

Unlike other BFloat16 multiplication instructions, this performs a fused multiply-add, without intermediate rounding that uses the Round to Nearest rounding mode and can generate a floating-point exception that causes cumulative exception bits in the *FPSCR* to be set.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VFMAL (by scalar)

Vector Floating-point Multiply-Add Long to accumulator (by scalar). This instruction multiplies the vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID_ISAR6.FHM indicates whether this instruction is supported.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VFMSL (by scalar)

Vector Floating-point Multiply-Subtract Long from accumulator (by scalar). This instruction multiplies the negated vector elements in the first source SIMD&FP register by the specified value in the second source SIMD&FP register, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID_ISAR6.FHM indicates whether this instruction is supported.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```

Assembler Symbols

<q> — See *Standard assembler syntax fields*.

<Qd> — Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dn> — Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> — Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field.

<Dd> — Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Sn> — Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.

<Sm> — Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>:M" field.

<index> — For the 64-bit SIMD vector variant: is the element index in the range 0 to 1, encoded in the "Vm<3>" field.

For the 128-bit SIMD vector variant: is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field.

Operation

```
CheckAdvSIMDEnabled();
bits(datasize) operand1 ;
bits(datasize) operand2 ;
bits(64) operand3;
bits(64) result;
bits(esize DIV 2) element1;
bits(esize DIV 2) element2;

if Q=='0' then
    operand1 = S[n]<datasize-1:0>;
    operand2 = S[m]<datasize-1:0>;
else
    operand1 = D[n]<datasize-1:0>;
    operand2 = D[m]<datasize-1:0>;
element2 = Elem[operand2, index, esize DIV 2];
for r = 0 to regs-1
    operand3 = D[d+r];
    for e = 0 to 1
        element1 = Elem[operand1, 2*r+e, esize DIV 2];
        if sub_op then element1 = FPNeg(element1);
        Elem[result, e, esize] = FPMulAddH(Elem[operand3, e, esize], element1, element2, StandardFPSCRVal
    D[d+r] = result;
```

VFMSL (vector)

Vector Floating-point Multiply-Subtract Long from accumulator (vector). This instruction negates the values in the vector of one SIMD&FP register, multiplies these with the corresponding values in another vector, and accumulates the product to the corresponding vector element of the destination SIMD&FP register. The instruction does not round the result of the multiply before the accumulation.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID_ISAR6.FHM indicates whether this instruction is supported.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in "U:size":

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);
            op2 = Int(Elem[D[m+r],e,esize], unsigned);
            result = if add then op1+op2 else op1-op2;
            Elem[D[d+r],e,esize] = result<esize:1>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VHSUB

Vector Halving Subtract subtracts the elements of the second operand from the corresponding elements of the first operand, shifts each result right one bit, and places the final results in the destination vector. The results of the halving operations are truncated. There is no rounding version.

The operand and result elements are all the same type, and can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21 20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	00	U8
1	01	U16
1	10	U32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Int(Elem[D[n+r],e,esize], unsigned);
            op2 = Int(Elem[D[m+r],e,esize], unsigned);
            result = if add then op1+op2 else op1-op2;
            Elem[D[d+r],e,esize] = result<esize:1>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

VINS

Vector move Insertion. This instruction copies the lower 16 bits of the 32-bit source SIMD&FP register into the upper 16 bits of the 32-bit destination SIMD&FP register, while preserving the values in the remaining bits.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1
(FEAT_FP16)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	1	1	1	1	0	1	D	1	1	0	0	0	0	Vd	1	0	1	0	1	1	M	0	Vm

A1

```
VINS{<q>}.F16 <Sd>, <Sm>
```

```
if !HaveFP16Ext() then UNDEFINED;
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
d = UInt(Vd:D); m = UInt(Vm:M);
```

T1
(FEAT_FP16)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	1	1	1	1	0	1	D	1	1	0	0	0	0	Vd	1	0	1	0	1	1	M	0	Vm

T1

```
VINS{<q>}.F16 <Sd>, <Sm>
```

```
if InITBlock() then UNPREDICTABLE;
if !HaveFP16Ext() then UNDEFINED;
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
d = UInt(Vd:D); m = UInt(Vm:M);
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q>	See *Standard assembler syntax fields*.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    S[d] = S[m]<15:0> : S[d]<15:0>;
```

VJCVT

Javascript Convert to signed fixed-point, rounding toward Zero. This instruction converts the double-precision floating-point value in the SIMD&FP source register to a 32-bit signed integer using the Round towards Zero rounding mode, and writes the result to the SIMD&FP destination register. If the result is too large to be accommodated as a signed 32-bit integer, then the result is the integer modulo 2^{32}, as held in a 32-bit signed integer.

This instruction can generate a floating-point exception. Depending on the settings in *FPSCR*, the exception results in either a flag being set or a synchronous exception being generated. For more information, see *Floating-point exceptions and exception traps*.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD1 (multiple single elements)*.

Related encodings: See *Advanced SIMD element or structure load/store* for the T32 instruction set, or *Advanced SIMD element or structure load/store* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1, A2, A3 and A4: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2, T3 and T4: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	64

<list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd> }
Single register. Selects the A1 and T1 encodings of the instruction.

{ <Dd>, <Dd+1> }
Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.

{ <Dd>, <Dd+1>, <Dd+2> }
Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.

{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the permitted values are:

64
: 64-bit alignment, encoded in the "align" field as 0b01.

128
: 128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.

256
: 256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1
            bits(ebytes*8) data;
            if ebytes != 8 then
                data = MemU[address,ebytes];
            else
                - = AArch32.CheckAlignment(address, ebytes, AccType_NORMAL, iswrite);
                data<31:0> = if BigEndian(AccType_NORMAL) then MemU[address+4,4] else MemU[address,4];
                data<63:32> = if BigEndian(AccType_NORMAL) then MemU[address,4] else MemU[address+4,4];
            Elem[D[d+r],e] = data;
            address = address + ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 8*regs;
```

VLD1 (single element to all lanes)

Load single 1-element structure and replicate to all lanes of one register loads one element from memory into every element of one or two vectors. For details of the addressing mode see *Advanced SIMD addressing mode*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	1	0	0	1	D	1	0	Rn				Vd				1	1	0	0	size		T	a	Rm			

Offset (Rm == 1111)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Post-indexed (Rm == 1101)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Post-indexed (Rm != 11x1)

```
VLD1{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}],<Rm>
```

```
if size == '11' || (size == '00' && a == '1') then UNDEFINED;
ebytes = 1 << UInt(size);  regs = if T == '0' then 1 else 2;
alignment = if a == '0' then 1 else ebytes;
d = UInt(D:Vd);  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d+regs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

d = UInt(D:Vd);  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d+regs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD1 (single element to all lanes)*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	RESERVED

<list> Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

{ <Dd>[] }
Encoded in the "T" field as 0.

{ <Dd>[], <Dd+1>[] }
Encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "a" field as 0.
Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16
<align> is 16, meaning 16-bit alignment, encoded in the "a" field as 1.

<size> == 32

<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    bits(64) replicated_element = Replicate(MemU[address,ebytes]);
    for r = 0 to regs-1
        D[d+r] = replicated_element;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

Assembler Symbols

<c> For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list> Is a list containing the single 64-bit name of the SIMD&FP register holding the element.
The list must be { <Dd>[<index>] }.
The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:

<size> == 8
<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and the encoding depends on <size>:

<size> == 8
Encoded in the "index_align<0>" field as 0.

<size> == 16
Encoded in the "index_align<1:0>" field as 0b00.

<size> == 32
Encoded in the "index_align<2:0>" field as 0b000.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16
<align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

<size> == 32
<align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then

```

CONSTRAINED UNPREDICTABLE behavior

If `d2+pairs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD2 (multiple 2-element structures)*.

Related encodings: See *Advanced SIMD element or structure load/store* for the T32 instruction set, or *Advanced SIMD element or structure load/store* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1 and A2: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1 and T2: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32
11	RESERVED

<list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd>, <Dd+1> }

Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "itype" field as 0b1000.

{ <Dd>, <Dd+2> }
Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "itype" field as 0b1001.

{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the permitted values are:

64
64-bit alignment, encoded in the "align" field as 0b01.

128
128-bit alignment, encoded in the "align" field as 0b10.

256
256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to pairs-1
        for e = 0 to elements-1
            Elem[D[d+r], e] = MemU[address,ebytes];
            Elem[D[d2+r],e] = MemU[address+ebytes,ebytes];
            address = address + 2*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 16*pairs;
```

Assembler Symbols

<c> For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32

<list> Is a list containing the 64-bit names of the two SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>] }
: Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>] }
: Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 16
: "spacing" is encoded in the "index_align<1>" field.

<size> == 32
: "spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8
: <index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
: <index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
: <index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and the encoding depends on <size>:

<size> == 8
: Encoded in the "index_align<0>" field as 0.

<size> == 16
: Encoded in the "index_align<0>" field as 0.

<size> == 32
: Encoded in the "index_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8
: <align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.

<size> == 16
: <align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.

<size> == 32
: <align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
```

VLD3 (multiple 3-element structures)

Load multiple 3-element structures to three registers loads multiple 3-element structures from memory into three registers, with de-interleaving. For more information, see *Element and structure load/store instructions*. Every element of each register is loaded. For details of the addressing mode see *Advanced SIMD addressing mode*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19-16	15-12	11	10	9	8	7-6	5-4	3-0
1	1	1	1	0	1	0	0	0	D	1	0	Rn	Vd	0	1	0	x	size	align	Rm
														itype						

Offset (Rm == 1111)

```
VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Post-indexed (Rm == 1101)

```
VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Post-indexed (Rm != 11x1)

```
VLD3{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

```
case itype of
    when '0100'
        inc = 1;
    when '0101'
        inc = 2;
    otherwise
        SEE "Related encodings";
if size == '11' || align<1> == '1' then UNDEFINED;
alignment = if align<0> == '0' then 1 else 8;
ebytes = 1 << UInt(size);  elements = 8 DIV ebytes;
d = UInt(D:Vd);  d2 = d + inc;  d3 = d2 + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d3 > 31 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d3 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

T1

if n == 15 || d3 > 31 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d3 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD3 (multiple 3-element structures)*.

Related encodings: See *Advanced SIMD element or structure load/store* for the T32 instruction set, or *Advanced SIMD element or structure load/store* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	RESERVED

<list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd>, <Dd+1>, <Dd+2> }
Single-spaced registers, encoded in the "itype" field as 0b0100.

{ <Dd>, <Dd+2>, <Dd+4> }
Double-spaced registers, encoded in the "itype" field as 0b0101.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the only permitted values is 64, meaning 64-bit alignment, encoded in the "align" field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about <Rn>, !, and <Rm>, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        Elem[D[d], e] = MemU[address,ebytes];
        Elem[D[d2],e] = MemU[address+ebytes,ebytes];
        Elem[D[d3],e] = MemU[address+2*ebytes,ebytes];
        address = address + 3*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 24;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD3 (single 3-element structure to one lane)*.

Assembler Symbols

<c> — For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<size> — Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32

<list> — Is a list containing the 64-bit names of the three SIMD&FP registers holding the element.
The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] }
Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] }
Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 8
"spacing" is encoded in the "index_align<0>" field.

<size> == 16
"spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0.

<size> == 32
"spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8
<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Alignment

Standard alignment rules apply, see *Alignment support*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];

VLD4 (multiple 4-element structures)

Load multiple 4-element structures to four registers loads multiple 4-element structures from memory into four registers, with de-interleaving. For more information, see *Element and structure load/store instructions*. Every element of each register is loaded. For details of the addressing mode see *Advanced SIMD addressing mode*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7 6	5 4	3 2 1 0
1	1	1	1	0	1	0	0	0	D	1	0	Rn	Vd	0	0	0	x	size	align	Rm
														itype						

Offset (Rm == 1111)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]
```

Post-indexed (Rm == 1101)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}]!
```

Post-indexed (Rm != 11x1)

```
VLD4{<c>}{<q>}.<size> <list>, [<Rn>{:<align>}], <Rm>
```

```
case itype of
    when '0000'

if n == 15 || d4 > 31 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d4 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD4 (multiple 4-element structures)*.

Related encodings: See *Advanced SIMD element or structure load/store* for the T32 instruction set, or *Advanced SIMD element or structure load/store* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	RESERVED

<list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
Single-spaced registers, encoded in the "itype" field as 0b0000.

{ <Dd>, <Dd+2>, <Dd+4>, <Dd+6> }
Double-spaced registers, encoded in the "itype" field as 0b0001.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the permitted values are:

64
: 64-bit alignment, encoded in the "align" field as 0b01.

128
: 128-bit alignment, encoded in the "align" field as 0b10.

256
: 256-bit alignment, encoded in the "align" field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        Elem[D[d], e] = MemU[address,ebytes];
        Elem[D[d2],e] = MemU[address+ebytes,ebytes];
        Elem[D[d3],e] = MemU[address+2*ebytes,ebytes];
        Elem[D[d4],e] = MemU[address+3*ebytes,ebytes];
        address = address + 4*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 32;
```

wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d4 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD4 (single 4-element structure to all lanes)*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
1x	32

<list> Is a list containing the 64-bit names of four SIMD&FP registers.
The list must be one of:

{ <Dd>[], <Dd+1>[], <Dd+2>[], <Dd+3>[] }
Single-spaced registers, encoded in the "T" field as 0.

{ <Dd>[], <Dd+2>[], <Dd+4>[], <Dd+6>[] }
Double-spaced registers, encoded in the "T" field as 1.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "a" field as 0.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8

<align> is 32, meaning 32-bit alignment, encoded in the "a" field as 1.

<size> == 16

<align> is 64, meaning 64-bit alignment, encoded in the "a" field as 1.

<size> == 32

<align> can be 64 or 128. 64-bit alignment is encoded in the "a:size<0>" field as 0b10, and 128-bit alignment is encoded in the "a:size<0>" field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    D[d] = Replicate(MemU[address,ebytes]);
    D[d2] = Replicate(MemU[address+ebytes,ebytes]);
    D[d3] = Replicate(MemU[address+2*ebytes,ebytes]);
    D[d4] = Replicate(MemU[address+3*ebytes,ebytes]);
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
```

```
if size == '11' then SEE "VLD4 (single 4-element structure to all lanes)";
if index_align<1:0> == '11' then UNDEFINED;
ebytes = 4;  index = UInt(index_align<3>);
inc = if index_align<2> == '0' then 1 else 2;
alignment = if index_align<1:0> == '00' then 1 else 4 << UInt(index_align<1:0>);
d = UInt(D:Vd);  d2 = d + inc;  d3 = d2 + inc;  d4 = d3 + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d4 > 31 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d4 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLD4 (single 4-element structure to one lane)*.

Assembler Symbols

<c> — For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<size> — Is the data size, encoded in "size":

size	<size>
00	8
01	16
10	32

<list> — Is a list containing the 64-bit names of the four SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] }
Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] }
Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 16
"spacing" is encoded in the "index_align<1>" field.

<size> == 32
"spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8
<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and the encoding depends on <size>:

<size> == 8
Encoded in the "index_align<0>" field as 0.

<size> == 16
Encoded in the "index_align<0>" field as 0.

<size> == 32
Encoded in the "index_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8
<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.

<size> == 16
<align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.

<size> == 32
<align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = FALSE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    Elem[D[d], index] = MemU[address,ebytes];
    Elem[D[d2],index] = MemU[address+ebytes,ebytes];
    Elem[D[d3],index] = MemU[address+2*ebytes,ebytes];
    Elem[D[d4],index] = MemU[address+3*ebytes,ebytes];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
```

VLDM, VLDMDB, VLDMIA

Load Multiple SIMD&FP registers loads multiple registers from consecutive locations in the Advanced SIMD and floating-point register file using an address from a general-purpose register.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the alias VPOP.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31 30 29 28	27 26 25	24	23	22	21	20	19 18 17 16	15 14 13 12	11 10	9 8	7 6 5 4 3 2 1	0

- One or more of the SIMD and floating-point registers are UNKNOWN. If the instruction specifies writeback, the base register becomes UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VLDM*.

Related encodings: See *Advanced SIMD and floating-point 64-bit move* for the T32 instruction set, or *Advanced SIMD and floating-point 64-bit move* for the A32 instruction set.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<size> — An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used.

! — Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.

<sreglist> Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.

<dreglist> Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

Alias Conditions

Alias	Is preferred when
VPOP	`P == '0' && U == '1' && W == '1' && Rn == '1101'`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            S[d+r] = MemA[address,4];  address = address+4;
        else
            word1 = MemA[address,4];  word2 = MemA[address+4,4];  address = address+8;
            // Combine the word-aligned words in the correct order for current endianness.
            D[d+r] = if BigEndian(AccType_ATOMIC) then word1:word2 else word2:word1;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

.64 Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

.32 Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

+/- Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For the single-precision scalar or double-precision scalar variants: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.

For the half-precision scalar variant: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    case esize of
        when 16
            S[d] = Zeros(16) : MemA[address,2];
        when 32
            S[d] = MemA[address,4];
        when 64
            word1 = MemA[address,4];  word2 = MemA[address+4,4];
            // Combine the word-aligned words in the correct order for current endianness.
            D[d] = if BigEndian(AccType_ATOMIC) then word1:word2 else word2:word1;
```

VLDR (literal)

Load SIMD&FP register (literal) loads a single register from the Advanced SIMD and floating-point register file, using an address from the PC value and an immediate offset.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
.64	Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
.32	Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<label>	The label of the literal data item to be loaded. For the single-precision scalar or double-precision scalar variants: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 4 in the range -1020 to 1020. For the half-precision scalar variant: the assembler calculates the required value of the offset from the Align(PC, 4) value of the instruction to this label. Permitted values are multiples of 2 in the range -510 to 510. If the offset is zero or positive, imm32 is equal to the offset and add == TRUE. If the offset is negative, imm32 is equal to minus the offset and add == FALSE.
+/-	Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> For the single-precision scalar or double-precision scalar variants: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.

For the half-precision scalar variant: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.

The alternative syntax permits the addition or subtraction of the offset and the immediate offset to be specified separately, including permitting a subtraction of 0 that cannot be specified using the normal syntax. For more information, see *Use of labels in UAL instruction syntax*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    base = if n == 15 then Align(PC,4) else R[n];
    address = if add then (base + imm32) else (base - imm32);
    case esize of
        when 16
            S[d] = Zeros(16) : MemA[address,2];
        when 32
            S[d] = MemA[address,4];
        when 64
            word1 = MemA[address,4];  word2 = MemA[address+4,4];
            // Combine the word-aligned words in the correct order for current endianness.
            D[d] = if BigEndian(AccType_ATOMIC) then word1:word2 else word2:word1;
```

VMAX (integer)

Vector Maximum compares corresponding elements in two vectors, and copies the larger of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

            result = if maximum then Max(op1,op2) else Min(op1,op2);
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

VMAXNM

This instruction determines the floating-point maximum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point VMAX.

This instruction is not conditional.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Floating-point minimum

- min(+0.0, -0.0) = -0.0
- If any input is a NaN, the corresponding result element is the default NaN.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[D[n+r],e,esize];  op2 = Elem[D[m+r],e,esize];
            if maximum then
                Elem[D[d+r],e,esize] = FPMax(op1, op2, StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = FPMin(op1, op2, StandardFPSCRValue());
```

VMIN (integer)

Vector Minimum compares corresponding elements in two vectors, and copies the smaller of each pair into the corresponding element in the destination vector.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.

The result vector elements are the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

VMINNM

This instruction determines the floating point minimum number.

It handles NaNs in consistence with the IEEE754-2008 specification. It returns the numerical operand when one operand is numerical and the other is a quiet NaN, but otherwise the result is identical to floating-point `VMIN`.

This instruction is not conditional.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VMLA (floating-point)

Vector Multiply Accumulate multiplies corresponding elements in two vectors, and accumulates the results into the elements of the destination vector.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19-16	15-12	11	10	9	8	7	6	5	4	3-0

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            product = Int(Elem[Din[n+r],e,esize],unsigned) * Int(Elem[Din[m+r],e,esize],unsigned);
            addend = if add then product else -product;
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
            else
                Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VMLS (by scalar)

Vector Multiply Subtract multiplies elements of a vector by a scalar, and either subtracts the products from corresponding elements of the destination vector.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21 20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

if size == '10' then esize = 32;  elements = 2;  m = UInt(Vm);  index = UInt(M);
```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See *Advanced SIMD data-processing* for the T32 instruction set, or *Advanced SIMD data-processing* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the scalar and the elements of the operand vector, encoded in “F:size”:

F	size	<dt>
0	01	I16
0	10	I32
1	01	F16
1	10	F32

<Qd> Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Dd> Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm[x]> Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is I16 or F16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is I32 or F32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            if floating_point then
                fp_addend = if add then FPMul(op1,op2,StandardFPSCRValue()) else FPNeg(FPMul(op1,op2,Star
                Elem[D[d+r],e,esize] = FPAdd(Elem[Din[d+r],e,esize], fp_addend, StandardFPSCRValue());
            else
                addend = if add then op1val*op2val else -op1val*op2val;
                if long_destination then
                    Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
                else
                    Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VMLS (floating-point)

Vector Multiply Subtract multiplies corresponding elements in two vectors, subtracts the products from corresponding elements of the destination vector, and places the results in the destination vector.

Arm recommends that software does not use the `VMLS` instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the scalar and the elements of the operand vector, encoded in “U:size”:

U	size	<dt>
0	01	S16
0	10	S32
1	01	U16
1	10	U32

<Qd> Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm[x]> Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16 or U16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is S32 or U32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            if floating_point then
                fp_addend = if add then FPMul(op1,op2,StandardFPSCRValue()) else FPNeg(FPMul(op1,op2,Star
                Elem[D[d+r],e,esize] = FPAdd(Elem[Din[d+r],e,esize], fp_addend, StandardFPSCRValue());
            else
                addend = if add then op1val*op2val else -op1val*op2val;
                if long_destination then
                    Elem[Q[d>>1],e,2*esize] = Elem[Qin[d>>1],e,2*esize] + addend;
                else
                    Elem[D[d+r],e,esize] = Elem[Din[d+r],e,esize] + addend;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VMLSL (integer)

Vector Multiply Subtract Long multiplies corresponding elements in two vectors, and subtract the products from the corresponding elements of the destination vector. The destination vector element is twice as long as the elements that are multiplied.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VMMLA

BFloat16 floating-point matrix multiply-accumulate. This instruction multiplies the 2x4 matrix of BF16 values in the first 128-bit source vector by the 4x2 BF16 matrix in the second 128-bit source vector. The resulting 2x2 single-precision matrix product is then added destructively to the 2x2 single-precision matrix in the 128-bit destination vector. This is equivalent to performing a 4-way dot product per destination element. The instruction does not update the *FPSCR* exception status.

Arm expects that the VMMLA instruction will deliver a peak BF16 multiply throughput that is at least as high as can be achieved using two VDOT instructions, with a goal that it should have significantly higher throughput.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VMOV (between two general-purpose registers and two single-precision registers)

Copy two general-purpose registers to a pair of 32-bit SIMD&FP registers transfers the contents of two consecutively numbered single-precision Floating-point registers to two general-purpose registers, or the contents of two general-purpose registers to a pair of single-precision Floating-point registers. The general-purpose registers do not have to be contiguous.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
!= 1111	1	1	0	0	0	1	0	op	Rt2	Rt	1	0	1	0	0	0	M	1	Vm
cond																			

From general-purpose registers (op == 0)

```
VMOV{<c>}{<q>} <Sm>, <Sm1>, <Rt>, <Rt2>
```

To general-purpose registers (op == 1)

```
VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sm1>
```

```
to_arm_registers = (op == '1');  t = UInt(Rt);  t2 = UInt(Rt2);  m = UInt(Vm:M);
if t == 15 || t2 == 15 || m == 31 then UNPREDICTABLE;
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `to_arm_registers && t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

If `m == 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2 1 0	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	0	1	1	0	0	0	1	0	op	Rt2	Rt	1	0	1	0	0	0	M	1	Vm

From general-purpose registers (op == 0)

```
VMOV{<c>}{<q>} <Sm>, <Sm1>, <Rt>, <Rt2>
```

To general-purpose registers (op == 1)

```
VMOV{<c>}{<q>} <Rt>, <Rt2>, <Sm>, <Sm1>
```

```
to_arm_registers = (op == '1');  t = UInt(Rt);  t2 = UInt(Rt2);  m = UInt(Vm:M);
if t == 15 || t2 == 15 || m == 31 then UNPREDICTABLE;
if to_arm_registers && t == t2 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `to_arm_registers && t == t2`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The value in the destination register is UNKNOWN.

If `m == 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- One or more of the single-precision registers become UNKNOWN for a move to the single-precision register. The general-purpose registers listed in the instruction become UNKNOWN for a move from the single-precision registers. This behavior does not affect any other general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VMOV (between two general-purpose registers and two single-precision registers)*.

Assembler Symbols

<Rt2>	Is the second general-purpose register that <Sm1> will be transferred to or from, encoded in the "Rt2" field.
<Rt>	Is the first general-purpose register that <Sm> will be transferred to or from, encoded in the "Rt" field.
<Sm1>	Is the 32-bit name of the second SIMD&FP register to be transferred. This is the next SIMD&FP register after <Sm>.
<Sm>	Is the 32-bit name of the first SIMD&FP register to be transferred, encoded in the "Vm:M" field.
<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    if to_arm_registers then
        R[t] = S[m];
        R[t2] = S[m+1];
    else
        S[m] = R[t];
        S[m+1] = R[t2];
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VMOV (general-purpose register to scalar)

Copy a general-purpose register to a vector element copies a byte, halfword, or word from a general-purpose register into an Advanced SIMD scalar.

On a Floating-point-only system, this instruction transfers one word to the upper or lower half of a double-precision floating-point register from a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22 21	20	19 18 17 16	15 14 13 12	11	10	9	8	7	6 5	4	3	2	1	0

T1

```
VMOV{<c>}{<q>}{.<size>} <Dd[x]>, <Rt>
```

```
case opc1:opc2 of
    when '1xxx'  advsimd = TRUE;  esize = 8;  index = UInt(opc1<0>:opc2);
    when '0xx1'  advsimd = TRUE;  esize = 16;  index = UInt(opc1<0>:opc2<1>);
    when '0x00'  advsimd = FALSE;  esize = 32;  index = UInt(opc1<0>);
    when '0x10'  UNDEFINED;
d = UInt(D:Vd);  t = UInt(Rt);
if t == 15 then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> The data size. It must be one of:

8

Encoded as opc1<1> = 1. [x] is encoded in opc1<0>, opc2.

16

Encoded as opc1<1> = 0, opc2<0> = 1. [x] is encoded in opc1<0>, opc2<1>.

32

Encoded as opc1<1> = 0, opc2 = 0b00. [x] is encoded in opc1<0>.

omitted

Equivalent to 32.

<Dd[x]> The scalar. The register <Dd> is encoded in D:Vd. For details of how [x] is encoded, see the description of <size>.

<Rt> The source general-purpose register.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    Elem[D[d],index,esize] = R[t]<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Assembler Symbols

<c> For encoding A1, A3, A4 and A5: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding A2, T1, T2, T3, T4 and T5: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> The data type, encoded in “cmode”:

cmode	<dt>
110x	I32
1110	I8
1111	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<imm> For encoding A1, A3, A4, A5, T1, T3, T4 and T5: is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions*.

For encoding A2 and T2: is a signed floating-point constant with 3-bit exponent and normalized 4 bits of precision, encoded in "imm4H:imm4L". For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 floating-point instructions*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    if single_register then
        S[d] = imm32;
    else
        for r = 0 to regs-1
            D[d+r] = imm64;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VMOV (register)

Copy between FP registers copies the contents of one FP register to another.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A2) and T32 (T2) .

A2

31-28	27	26	25	24	23	22	21	20	19	18	17	16	15-12	11	10	9	8	7	6	5	4	3-0

```

is equivalent to

```
VORR{<c>}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>
```

and is the preferred disassembly when `N:Vn == M:Vm`.

128-bit SIMD vector (Q == 1)

```
VMOV{<c>}{<q>}{.<dt>} <Qd>, <Qm>
```

is equivalent to

```
VORR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>
```

and is the preferred disassembly when `N:Vn == M:Vm`.

Assembler Symbols

<c>	For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional. For encoding T1: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<dt>	An optional data type. <dt> must not be F64, but it is otherwise ignored.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "N:Vn" and "M:Vm" field.

Operation

The description of VORR (register) gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

VMOV (scalar to general-purpose register)

Copy a vector element to a general-purpose register with sign or zero extension copies a byte, halfword, or word from an Advanced SIMD scalar to a general-purpose register. Bytes and halfwords can be either zero-extended or sign-extended.

On a Floating-point-only system, this instruction transfers one word from the upper or lower half of a double-precision floating-point register to a general-purpose register. This is an identical operation to the Advanced SIMD single word transfer.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

VMOVN

Vector Move and Narrow copies the least significant half of each element of a quadword vector into the corresponding elements of a doubleword vector.

The operand vector elements can be any one of 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the pseudo-instructions VRSHRN (zero), and VSHRN (zero).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

if InITBlock() then UNPREDICTABLE;
if !HaveFP16Ext() then UNDEFINED;
if FPSCR.Len != '000' || FPSCR.Stride != '00' then UNDEFINED;
d = UInt(Vd:D); m = UInt(Vm:M);
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<q>	See *Standard assembler syntax fields*.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sm>	Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    S[d] = Zeros(16) : S[m]<31:16>;
```

VMRS

Move SIMD&FP Special register to general-purpose register moves the value of an Advanced SIMD and floating-point System register to a general-purpose register. When the specified System register is the *FPSCR*, a form of the instruction transfers the *FPSCR*.{N, Z, C, V} condition flags to the *APSR*.{N, Z, C, V} condition flags.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

When these settings permit the execution of Advanced SIMD and floating-point instructions, if the specified floating-point System register is not the *FPSCR*, the instruction is UNDEFINED if executed in User mode.

In an implementation that includes EL2, when *HCR*.TID0 is set to 1, any `VMRS` access to *FPSID* from a Non-secure EL1 mode that would be permitted if *HCR*.TID0 was set to 0 generates a Hyp Trap exception. For more information, see *ID group 0, Primary device identification registers*.

For simplicity, the `VMRS` pseudocode does not show the possible trap to Hyp mode.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3	2	1	0

VMRS{<c>}{<q>} <Rt>, <spec_reg>
```

```
t = UInt(Rt);
if !(reg IN {'000x', '0101', '011x', '1000'}) then UNPREDICTABLE;
if t == 15 && reg != '0001' then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `!(reg IN {'000x', '0101', '011x', '1000'})`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the *APSR*.{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

T1

if t == 15 && reg != '0001' then UNPREDICTABLE; // Armv8-A removes UNPREDICTABLE for R13
```

CONSTRAINED UNPREDICTABLE behavior

If `!(reg IN {'000x', '0101', '011x', '1000'})`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

- The instruction transfers an UNKNOWN value to the specified target register. When the Rt field holds the value 0b1111, the specified target register is the *APSR*.{N, Z, C, V} bits, and these bits become UNKNOWN. Otherwise, the specified target register is the register specified by the Rt field, R0 - R14.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> See *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Rt> Is the general-purpose destination register, encoded in the "Rt" field. Is one of:

R0-R14
General-purpose register.

APSR_nzcv
Permitted only when <spec_reg> is FPSCR. Encoded as 0b1111. The instruction transfers the *FPSCR*.{N, Z, C, V} condition flags to the *APSR*.{N, Z, C, V} condition flags.

<spec_reg> Is the source Advanced SIMD and floating-point System register, encoded in “reg”:

reg	<spec_reg>
0000	FPSID
0001	FPSCR
001x	UNPREDICTABLE
0100	UNPREDICTABLE
0101	MVFR2
0110	MVFR1
0111	MVFR0
1000	FPEXC
1001	UNPREDICTABLE
101x	UNPREDICTABLE
11xx	UNPREDICTABLE

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();
    if reg == '0001' then                 // FPSCR
        CheckVFPEnabled(TRUE);
        if t == 15 then
            PSTATE.<N,Z,C,V> = FPSR.<N,Z,C,V>;
        else
            R[t] = FPSCR;
    elsif PSTATE.EL == EL0 then
        UNDEFINED;                        // Non-FPSCR registers accessible only at PL1 or above
    else
        CheckVFPEnabled(FALSE);           // Non-FPSCR registers are not affected by FPEXC.EN
        AArch32.CheckAdvSIMDOrFPRegisterTraps(reg);
        case reg of
            when '0000'  R[t] = FPSID;

            when '0110'  R[t] = MVFR1;
            when '0111'  R[t] = MVFR0;
            when '1000'  R[t] = FPEXC;
            otherwise    Unreachable();   // Dealt with above or in encoding-specific pseudocode
```

VMSR

Move general-purpose register to SIMD&FP Special register moves the value of a general-purpose register to a floating-point System register.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

When these settings permit the execution of Advanced SIMD and floating-point instructions:

- If the specified floating-point System register is *FPSID* or *FPEXC*, the instruction is UNDEFINED if executed in User mode.
- If the specified floating-point System register is the *FPSID* and the instruction is executed in a mode other than User mode, the instruction is ignored.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31–28	27	26	25	24	23	22	21	20	19–16	15–12	11	10	9	8	7	6	5	4	3	2	1	0

        case reg of
            when '0000'                   // VMSR access to FPSID is ignored
            when '1000'  FPEXC = R[t];
            otherwise    Unreachable();   // Dealt with above or in encoding-specific pseudocode
```

VMUL (by scalar)

Vector Multiply multiplies each element in a vector by a scalar, and places the results in a second vector.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28 27 26 25	24	23	22	21 20	19 18 17 16	15 14 13 12	11 10 9	8	7	6	5	4	3 2 1 0

```

CONSTRAINED UNPREDICTABLE behavior

If `F == '1' && size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Related encodings: See *Advanced SIMD data-processing* for the T32 instruction set, or *Advanced SIMD data-processing* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the scalar and the elements of the operand vector, encoded in “F:size”:

F	size	<dt>
0	01	I16
0	10	I32
1	01	F16
1	10	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register. When <dt> is I16 or F16, this is encoded in the "Vm<2:0>" field. Otherwise it is encoded in the "Vm" field.

<index> Is the element index. When <dt> is I16 or F16, this is in the range 0 to 3 and is encoded in the "M:Vm<3>" field. Otherwise it is in the range 0 to 1 and is encoded in the "M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            if floating_point then
                Elem[D[d+r],e,esize] = FPMul(op1, op2, StandardFPSCRValue());
            else
                if long_destination then
                    Elem[Q[d>>1],e,2*esize] = (op1val*op2val)<2*esize-1:0>;
                else
                    Elem[D[d+r],e,esize] = (op1val*op2val)<esize-1:0>;
```

VMUL (integer and polynomial)

Vector Multiply multiplies corresponding elements in two vectors.

For information about multiplying polynomials, see *Polynomial arithmetic over {0, 1}*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information, see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21-20	19-16	15-12	11	10	9	8	7	6	5	4	3-0
1	1	1	1	0	0	1	op	0	D	size	Vn	Vd	1	0	0	1	N	Q	M	1	Vm

64-bit SIMD vector (Q == 0)

```
VMUL{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VMUL{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>
```

```
if size == '11' || (op == '1' && size != '00') then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
unsigned = FALSE;  // "Don't care" value: TRUE produces same functionality
polynomial = (op == '1');  long_destination = FALSE;
esize = 8 << UInt(size);  elements = 64 DIV esize;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

T1

```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in “op:size”:

op	size	<dt>
0	00	I8
0	01	I16
0	10	I32
1	00	P8

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            op2 = Elem[Din[m+r],e,esize];  op2val = Int(op2, unsigned);
            if polynomial then
                product = PolynomialMult(op1,op2);
            else
                product = (op1val*op2val)<2*esize-1:0>;
            if long_destination then
                Elem[Q[d>>1],e,2*esize] = product;
            else
                Elem[D[d+r],e,esize] = product<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VMULL (by scalar)

Vector Multiply Long multiplies each element in a vector by a scalar, and places the results in a second vector. The destination vector elements are twice as long as the elements that are multiplied.

For more information about scalars see *Advanced SIMD scalars*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21 20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	1	0	0	1	U	1	D	!= 11	Vn	Vd	1	0	1	0	N	1	M	0	Vm
										size											

A1

```
VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]
```

```
if size == '11' then SEE "Related encodings";
if size == '00' || Vd<0> == '1' then UNDEFINED;
unsigned = (U == '1');  long_destination = TRUE;  floating_point = FALSE;
d = UInt(D:Vd);  n = UInt(N:Vn);  regs = 1;
if size == '01' then esize = 16;  elements = 4;  m = UInt(Vm<2:0>);  index = UInt(M:Vm<3>);
if size == '10' then esize = 32;  elements = 2;  m = UInt(Vm);  index = UInt(M);
```

T1

15	14	13	12	11	10	9	8	7	6	5 4	3 2 1 0	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	U	1	1	1	1	1	D	!= 11	Vn	Vd	1	0	1	0	N	1	M	0	Vm
										size											

T1

```
VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>[<index>]
```

```
if size == '11' then SEE "Related encodings";
if size == '00' || Vd<0> == '1' then UNDEFINED;
unsigned = (U == '1');  long_destination = TRUE;  floating_point = FALSE;
d = UInt(D:Vd);  n = UInt(N:Vn);  regs = 1;
if size == '01' then esize = 16;  elements = 4;  m = UInt(Vm<2:0>);  index = UInt(M:Vm<3>);
if size == '10' then esize = 32;  elements = 2;  m = UInt(Vm);  index = UInt(M);
```

Related encodings: See *Advanced SIMD data-processing* for the T32 instruction set, or *Advanced SIMD data-processing* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the scalar and the elements of the operand vector, encoded in “U:size”:

U	size	<dt>
0	01	S16
0	10	S32
1	01	U16
1	10	U32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "Vm<2:0>" field when <dt> is S16 or U16, otherwise the "Vm" field.

<index> Is the element index in the range 0 to 3, encoded in the "M:Vm<3>" field when <dt> is S16 or U16, otherwise in range 0 to 1, encoded in the "M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    op2 = Elem[Din[m],index,esize];  op2val = Int(op2, unsigned);
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            if floating_point then
                Elem[D[d+r],e,esize] = FPMul(op1, op2, StandardFPSCRValue());
            else

VMULL (integer and polynomial)

Vector Multiply Long multiplies corresponding elements in two vectors. The destination vector elements are twice as long as the elements that are multiplied.

For information about multiplying polynomials see *Polynomial arithmetic over {0, 1}*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21 20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	1	0	0	1	U	1	D	!= 11	Vn	Vd	1	1	op	0	N	0	M	0	Vm
										size											

A1

```
VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>
```

```
if size == '11' then SEE "Related encodings";
unsigned = (U == '1'); polynomial = (op == '1'); long_destination = TRUE;
esize = 8 << UInt(size); elements = 64 DIV esize;
if polynomial then
    if U == '1' || size == '01' then UNDEFINED;
    if size == '10' then    // .p64
        if !HaveBit128PMULLExt() then UNDEFINED;
        esize = 64; elements = 1;
if Vd<0> == '1' then UNDEFINED;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = 1;
```

T1

15	14	13	12	11	10	9	8	7	6	5 4	3 2 1 0	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	U	1	1	1	1	1	D	!= 11	Vn	Vd	1	1	op	0	N	0	M	0	Vm
										size											

T1

```
VMULL{<c>}{<q>}.<dt> <Qd>, <Dn>, <Dm>
```

```
if size == '11' then SEE "Related encodings";
unsigned = (U == '1'); polynomial = (op == '1'); long_destination = TRUE;
esize = 8 << UInt(size); elements = 64 DIV esize;
if polynomial then
    if U == '1' || size == '01' then UNDEFINED;
    if size == '10' then    // .p64
        if InITBlock() then UNPREDICTABLE;
        if !HaveBit128PMULLExt() then UNDEFINED;
        esize = 64; elements = 1;
if Vd<0> == '1' then UNDEFINED;
d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm); regs = 1;
```

CONSTRAINED UNPREDICTABLE behavior

If `op == '1' && size == '10' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Related encodings: See *Advanced SIMD data-processing* for the T32 instruction set, or *Advanced SIMD data-processing* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in "op:U:size":

op	U	size	<dt>
0	0	00	S8
0	0	01	S16
0	0	10	S32
0	1	00	U8
0	1	01	U16
0	1	10	U32
1	0	00	P8
1	0	10	P64

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            op1 = Elem[Din[n+r],e,esize];  op1val = Int(op1, unsigned);
            op2 = Elem[Din[m+r],e,esize];  op2val = Int(op2, unsigned);
            if polynomial then
                product = PolynomialMult(op1,op2);
            else

<c>	For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional. For encoding T1, T2 and T3: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<imm>	Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(imm64);
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VMVN (register)

Vector Bitwise NOT (register) takes a value from a register, inverts the value of each bit, and places the result in the destination register. The registers can be either doubleword or quadword.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

128-bit SIMD vector (Q == 1)

```
VMVN{<c>}{<q>}{.<dt>} <Qd>, <Qm>
```

```
if size != '00' then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>	For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional. For encoding T1: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<dt>	An optional data type. It is ignored by assemblers, and does not affect the encoding.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qm>	Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = NOT(D[m+r]);
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding A2, T1 and T2: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “F:size”:

F	size	<dt>
0	00	S8
0	01	S16
0	10	S32
1	01	F16
1	10	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<Sd> Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

<Sm> Is the 32-bit name of the SIMD&FP source register, encoded in the "Vm:M" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDOrVFPEnabled(TRUE, advsimd);
    if advsimd then  // Advanced SIMD instruction
        for r = 0 to regs-1
            for e = 0 to elements-1
                if floating_point then
                    Elem[D[d+r],e,esize] = FPNeg(Elem[D[m+r],e,esize]);
                else
                    result = -SInt(Elem[D[m+r],e,esize]);
                    Elem[D[d+r],e,esize] = result<esize-1:0>;
    else             // VFP instruction
        case esize of
            when 16 S[d] = Zeros(16) : FPNeg(S[m]<15:0>);
            when 32 S[d] = FPNeg(S[m]);
            when 64 D[d] = FPNeg(D[m]);
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check and is operating only on integer vector elements, then the following apply:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VNMLA

Vector Negate Multiply Accumulate multiplies together two floating-point register values, adds the negation of the floating-point value in the destination register to the negation of the product, and writes the result back to the destination register.

Arm recommends that software does not use the `VNMLA` instruction in the Round towards Plus Infinity and Round towards Minus Infinity rounding modes, because the rounding of the product and of the sum can change the result of the instruction in opposite directions, defeating the purpose of these rounding modes.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

    when '01' esize = 16; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the "Vn:N" field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the "Vm:M" field.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    case esize of

VNMUL

Vector Negate Multiply multiplies together two floating-point register values, and writes the negation of the result to the destination register.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VORN (immediate)

Vector Bitwise OR NOT (immediate) performs a bitwise OR between a register value and the complement of an immediate value, and returns the result into the destination vector

This is a pseudo-instruction of VORR (immediate). This means:

- The encodings in this description are named to match the encodings of VORR (immediate).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (immediate) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Assembler Symbols

<c>	For encoding A1 and A2: see *Standard assembler syntax fields*. This encoding must be unconditional. For encoding T1 and T2: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<imm>	Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions*.

Operation

The description of VORR (immediate) gives the operational pseudocode for this instruction.

VORN (register)

Vector bitwise OR NOT (register) performs a bitwise OR NOT operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c>	For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.
	For encoding T1: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<dt>	An optional data type. It is ignored by assemblers, and does not affect the encoding.
<Qd>	Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.
<Qn>	Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.
<Qm>	Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR NOT(D[m+r]);
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.

Assembler Symbols

<c> For encoding A1 and A2: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1 and T2: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<imm> Is a constant of the specified type that is replicated to fill the destination register. For details of the range of constants available and the encoding of <imm>, see *Modified immediate constants in T32 and A32 Advanced SIMD instructions*.

The I8, I64, and F32 data types are permitted as pseudo-instructions, if the immediate can be represented by this instruction, and are encoded using a permitted encoding of the I16 or I32 data type.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[d+r] OR imm64;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
    - The values of the data supplied in any of its registers.
    - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
    - The values of the data supplied in any of its registers.

- The values of the NZCV flags.

VORR (register)

Vector bitwise OR (register) performs a bitwise OR operation between two registers, and places the result in the destination register. The operand and result registers can be quadword or doubleword. They must all be the same size.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the alias VMOV (register, SIMD).

This instruction is used by the pseudo-instructions VRSHR (zero), and VSHR (zero).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

64-bit SIMD vector (Q == 0)

```
VORR{<c>}{<q>}{.<dt>} {<Dd>,} <Dn>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VORR{<c>}{<q>}{.<dt>} {<Qd>,} <Qn>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

Assembler Symbols

<c> — For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<dt> — An optional data type. It is ignored by assemblers, and does not affect the encoding.

<Qd> — Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> — Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> — Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> — Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Alias Conditions

Alias	Is preferred when
VMOV (register, SIMD)	`N:Vn == M:Vm`
VRSHR (zero)	`Never`
VSHR (zero)	`Never`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        D[d+r] = D[n+r] OR D[m+r];
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

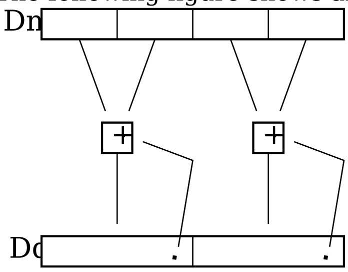
VPADAL

Vector Pairwise Add and Accumulate Long adds adjacent pairs of elements of a vector, and accumulates the results into the elements of the destination vector.

The vectors can be doubleword or quadword. The operand elements can be 8-bit, 16-bit, or 32-bit integers. The result elements are twice the length of the operand elements.

The following figure shows an example of the operation of VPADAL doubleword operation for data type S16.



Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VPADD (floating-point)

Vector Pairwise Add (floating-point) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements are floating-point numbers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	0	D	0	sz	Vn				Vd				1	1	0	1	N	Q	M	0	Vm			

A1

```
VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

```
if Q == '1' then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	0	D	0	sz	Vn				Vd				1	1	0	1	N	Q	M	0	Vm			

T1

```
VPADD{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

```
if Q == '1' then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
if sz == '1' && InITBlock() then UNPREDICTABLE;
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        Elem[dest,e,esize]   = FPAdd(Elem[D[n],2*e,esize], Elem[D[n],2*e+1,esize], StandardFPSCRValue());
        Elem[dest,e+h,esize] = FPAdd(Elem[D[m],2*e,esize], Elem[D[m],2*e+1,esize], StandardFPSCRValue());

    D[d] = dest;
```

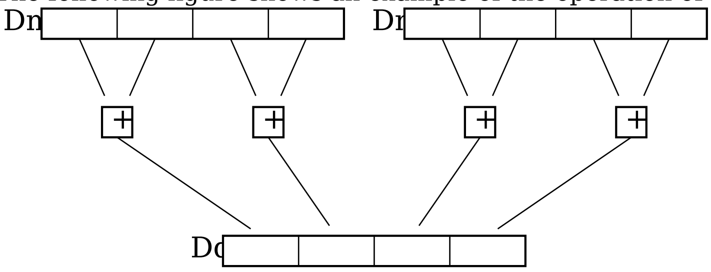
VPADD (integer)

Vector Pairwise Add (integer) adds adjacent pairs of elements of two vectors, and places the results in the destination vector.

The operands and result are doubleword vectors.

The operand and result elements must all be the same type, and can be 8-bit, 16-bit, or 32-bit integers. There is no distinction between signed and unsigned integers.

The following figure shows an example of the operation of VPADD doubleword operation for data type I16.



Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
```

CONSTRAINED UNPREDICTABLE behavior

If `sz == '1' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

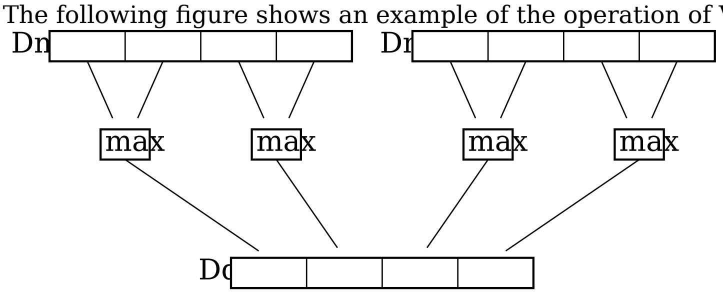
    for e = 0 to h-1
        op1 = Elem[D[n],2*e,esize];  op2 = Elem[D[n],2*e+1,esize];
        Elem[dest,e,esize] = if maximum then FPMax(op1,op2,StandardFPSCRValue()) else FPMin(op1,op2,Stanc
        op1 = Elem[D[m],2*e,esize];  op2 = Elem[D[m],2*e+1,esize];
        Elem[dest,e+h,esize] = if maximum then FPMax(op1,op2,StandardFPSCRValue()) else FPMin(op1,op2,Sta

    D[d] = dest;
```

VPMAX (integer)

Vector Pairwise Maximum compares adjacent pairs of elements in two doubleword vectors, and copies the larger of each pair into the corresponding element in the destination doubleword vector.

The following figure shows an example of the operation of VPMAX doubleword operation for data type S16 or U16.



Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

1	10	U32

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    bits(64) dest;
    h = elements DIV 2;

    for e = 0 to h-1
        op1 = Int(Elem[D[n],2*e,esize], unsigned);
        op2 = Int(Elem[D[n],2*e+1,esize], unsigned);
        result = if maximum then Max(op1,op2) else Min(op1,op2);
        Elem[dest,e,esize] = result<esize-1:0>;
        op1 = Int(Elem[D[m],2*e,esize], unsigned);
        op2 = Int(Elem[D[m],2*e+1,esize], unsigned);
        result = if maximum then Max(op1,op2) else Min(op1,op2);
        Elem[dest,e+h,esize] = result<esize-1:0>;

    D[d] = dest;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VQABS

Vector Saturating Absolute takes the absolute value of each element in a vector, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	S8
01	S16
10	S32
11	RESERVED

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            result = Abs(SInt(Elem[D[m+r],e,esize]));
            (Elem[D[d+r],e,esize], sat) = SignedSatQ(result, esize);
            if sat then FPSCR.QC = '1';
```

VQADD

Vector Saturating Add adds the values of corresponding elements of two vectors, and places the results in the destination vector.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```

Related encodings: See *Advanced SIMD data-processing* for the T32 instruction set, or *Advanced SIMD data-processing* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1 and A2: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1 and T2: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operands, encoded in “size”:

size	<dt>
01	S16
10	S32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm[x]> Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is S32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if scalar_form then op2 = SInt(Elem[D[m],index,esize]);
    for r = 0 to regs-1
        for e = 0 to elements-1
            if !scalar_form then op2 = SInt(Elem[D[m+r],e,esize]);
            op1 = SInt(Elem[D[n+r],e,esize]);
            // The following only saturates if both op1 and op2 equal -(2^(esize-1))
            (result, sat) = SignedSatQ((2*op1*op2) >> esize, esize);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';
```

VQDMULL

Vector Saturating Doubling Multiply Long multiplies corresponding elements in two doubleword vectors, doubles the products, and places the results in a quadword vector.

The second operand can be a scalar instead of a vector. For more information about scalars see *Advanced SIMD scalars*.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if scalar_form then op2 = SInt(Elem[Din[m],index,esize]);
    for e = 0 to elements-1
        if !scalar_form then op2 = SInt(Elem[Din[m],e,esize]);
        op1 = SInt(Elem[Din[n],e,esize]);
        // The following only saturates if both op1 and op2 equal -(2^(esize-1))
        (product, sat) = SignedSatQ(2*op1*op2, 2*esize);
        Elem[Q[d>>1],e,2*esize] = product;
        if sat then FPSCR.QC = '1';
```

VQMOVN, VQMOVUN

Vector Saturating Move and Narrow copies each element of the operand vector to the corresponding element of the destination vector.

The operand is a quadword vector. The elements can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result is a doubleword vector. The elements are half the length of the operand vector elements. If the operand is unsigned, the results are unsigned. If the operand is signed, the results can be signed or unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the pseudo-instructions VQRSHRN (zero), VQRSHRUN (zero), VQSHRN (zero), and VQSHRUN (zero).

VQRDMLAH

Vector Saturating Rounding Doubling Multiply Accumulate Returning High Half. This instruction multiplies the vector elements of the first source SIMD&FP register with either the corresponding vector elements of the second source SIMD&FP register or the value of a vector element of the second source SIMD&FP register, without saturating the multiply results, doubles the results, and accumulates the most significant half of the final results with the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

10	S32

<Qd> Is the 128-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP register holding the accumulate vector, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm[x]> Is the 64-bit name of the second SIMD&FP source register holding the scalar. If <dt> is S16, Dm is restricted to D0-D7. Dm is encoded in "Vm<2:0>", and x is encoded in "M:Vm<3>". If <dt> is S32, Dm is restricted to D0-D15. Dm is encoded in "Vm", and x is encoded in "M".

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
EncodingSpecificOperations();  CheckAdvSIMDEnabled();
round_const = 1 << (esize-1);
if scalar_form then op2 = SInt(Elem[D[m],index,esize]);
for r = 0 to regs-1
    for e = 0 to elements-1
        op1 = SInt(Elem[D[n+r],e,esize]);
        op3 = SInt(Elem[D[d+r],e,esize]) << esize;
        if !scalar_form then op2 = SInt(Elem[D[m+r],e,esize]);
        (result, sat) = SignedSatQ((op3 + 2*(op1*op2) + round_const) >> esize, esize);
        Elem[D[d+r],e,esize] = result;
        if sat then FPSCR.QC = '1';
```

VQRDMLSH

Vector Saturating Rounding Doubling Multiply Subtract Returning High Half. This instruction multiplies the vector elements of the first source SIMD&FP register with either the corresponding vector elements of the second source SIMD&FP register or the value of a vector element of the second source SIMD&FP register, without saturating the multiply results, doubles the results, and subtracts the most significant half of the final results from the vector elements of the destination SIMD&FP register. The results are rounded.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

            Elem[D[d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';
```

VQRSHL

Vector Saturating Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

For truncated results see *VQSHL (register)*.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

            if sat then FPSCR.QC = '1';
```

VQRSHRN (zero)

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the signed rounded results in a doubleword vector

This is a pseudo-instruction of VQMOVN, VQMOVUN. This means:

- The encodings in this description are named to match the encodings of VQMOVN, VQMOVUN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operand, encoded in “op<0>:size”:

op<0>	size	<dt>
0	00	S16
0	01	S32
0	10	S64
0	11	RESERVED
1	00	U16
1	01	U32
1	10	U64
1	11	RESERVED

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

VQRSHRN, VQRSHRUN

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the rounded results in a doubleword vector.

For truncated results, see *VQSHRN and VQSHRUN*.

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21 20 19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings: See *Advanced SIMD one register and modified immediate* for the T32 instruction set, or *Advanced SIMD one register and modified immediate* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<type> For the signed result variant: is the data type for the elements of the vectors, encoded in “U”:

U	<type>
0	S
1	U

For the unsigned result variant: is the data type for the elements of the vectors, encoded in “U”:

U	<type>
1	S

<size> Is the data size for the elements of the vectors, encoded in “imm6<5:3>”:

imm6<5:3>	<size>
001	16
01x	32
1xx	64

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<imm> Is an immediate value, in the range 1 to <size>/2, encoded in the "imm6" field as <size>/2 - <imm>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount - 1);
    for e = 0 to elements-1
        operand = Int(Elem[Qin[m>>1],e,2*esize], src_unsigned);
        (result, sat) = SatQ((operand + round_const) >> shift_amount, esize, dest_unsigned);
        Elem[D[d],e,esize] = result;
        if sat then FPSCR.QC = '1';
```

VQRSHRUN (zero)

Vector Saturating Rounding Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the unsigned rounded results in a doubleword vector

This is a pseudo-instruction of VQMOVN, VQMOVUN. This means:

- The encodings in this description are named to match the encodings of VQMOVN, VQMOVUN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

```

is equivalent to

```
VQMOVUN{<c>}{<q>}.<dt> <Dd>, <Qm>
```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	S16
01	S32
10	S64
11	RESERVED

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

VQSHL (register)

Vector Saturating Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. Otherwise, it is a right shift.

The results are truncated. For rounded results, see *VQRSHL*.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is a signed integer of the same size.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
0	11	S64
1	00	U8
1	01	U16
1	10	U32
1	11	U64

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            operand = Int(Elem[D[m+r],e,esize], unsigned);
            (result,sat) = SatQ(operand << shift, esize, unsigned);
            Elem[D[d+r],e,esize] = result;
            if sat then FPSCR.QC = '1';
```

VQSHL, VQSHLU (immediate)

Vector Saturating Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in a second vector.

The operand elements must all be the same size, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are the same size as the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operand, encoded in “op<0>:size”:

op<0>	size	<dt>
0	00	S16
0	01	S32
0	10	S64
0	11	RESERVED
1	00	U16
1	01	U32
1	10	U64
1	11	RESERVED

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00

VQSHRN, VQSHRUN

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the truncated results in a doubleword vector.

For rounded results, see *VQRSHRN and VQRSHRUN*.

The operand elements must all be the same size, and can be any one of:

- 16-bit, 32-bit, or 64-bit signed integers.
- 16-bit, 32-bit, or 64-bit unsigned integers.

The result elements are half the width of the operand elements. If the operand elements are signed, the results can be either signed or unsigned. If the operand elements are unsigned, the result elements must also be unsigned.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21-16	15-12	11	10	9	8	7	6	5	4	3-0

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<type> For the signed result variant: is the data type for the elements of the vectors, encoded in “U”:

U	<type>
0	S
1	U

For the unsigned result variant: is the data type for the elements of the vectors, encoded in “U”:

U	<type>
1	S

<size> Is the data size for the elements of the vectors, encoded in “imm6<5:3>”:

imm6<5:3>	<size>
001	16
01x	32
1xx	64

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<imm> Is an immediate value, in the range 1 to <size>/2, encoded in the "imm6" field as <size>/2 - <imm>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        operand = Int(Elem[Qin[m>>1],e,2*esize], src_unsigned);
        (result, sat) = SatQ(operand >> shift_amount, esize, dest_unsigned);
        Elem[D[d],e,esize] = result;
        if sat then FPSCR.QC = '1';
```

VQSHRUN (zero)

Vector Saturating Shift Right, Narrow takes each element in a quadword vector of integers, right shifts them by an immediate value, and places the unsigned truncated results in a doubleword vector

This is a pseudo-instruction of VQMOVN, VQMOVUN. This means:

- The encodings in this description are named to match the encodings of VQMOVN, VQMOVUN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	D	1	1	size		1	0	Vd				0	0	1	0	0	1	M	0	Vm			
																								op							

Unsigned result

```
VQSHRUN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0
```

is equivalent to

```
VQMOVUN{<c>}{<q>}.<dt> <Dd>, <Qm>
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	1	1	size		1	0	Vd				0	0	1	0	0	1	M	0	Vm			
																								op							

Unsigned result

```
VQSHRUN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0
```

is equivalent to

```
VQMOVUN{<c>}{<q>}.<dt> <Dd>, <Qm>
```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	S16
01	S32
10	S64
11	RESERVED

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

The description of VQMOVN, VQMOVUN gives the operational pseudocode for this instruction.

VQSUB

Vector Saturating Subtract subtracts the elements of the second operand vector from the corresponding elements of the first operand vector, and places the results in the destination vector. Signed and unsigned operations are distinct.

The operand and result elements must all be the same type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

If any of the results overflow, they are saturated. The cumulative saturation bit, *FPSCR*.QC, is set if saturation occurs. For details see *Pseudocode details of saturation*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VRADDHN

Vector Rounding Add and Narrow, returning High Half adds corresponding elements in two quadword vectors, and places the most significant half of each result in a doubleword vector. The results are rounded. For truncated results, see *VADDHN*.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21 20	19 18 17 16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (esize-1);
    for e = 0 to elements-1
        result = Elem[Qin[n>>1],e,2*esize] + Elem[Qin[m>>1],e,2*esize] + round_const;
        Elem[D[d],e,esize] = result<2*esize-1:esize>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VRECPE

Vector Reciprocal Estimate finds an approximate reciprocal of each element in the operand vector, and places the results in the destination vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see *Floating-point reciprocal square root estimate and step*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	D	1	1	size		1	1	Vd				0	1	0	F	0	Q	M	0	Vm

```
VRECPE{<c>}{<q>}.<dt> <Dd>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VRECPE{<c>}{<q>}.<dt> <Qd>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && (!HaveFP16Ext() || F == '0')) || size IN {'00', '11'} then UNDEFINED;
if size == '01' && InITBlock()  then UNPREDICTABLE;
floating_point = (F == '1');
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.

- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

VRECPS

Vector Reciprocal Step multiplies the elements of one vector by the corresponding elements of another vector, subtracts each of the products from 2.0, and places the results into the elements of the destination vector.

The operand and result elements are floating-point numbers.

For details of the operation performed by this instruction see *Floating-point reciprocal estimate and step*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VRECPS{<c>}{<q>}.<dt> {<Dd>, }<Dn>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VRECPS{<c>}{<q>}.<dt> {<Qd>, }<Qn>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vn<0> == '1' || Vm<0> == '1') then UNDEFINED;
if sz == '1' && !HaveFP16Ext() then UNDEFINED;
if sz == '1' && InITBlock() then UNPREDICTABLE;
case sz of
    when '0' esize = 32; elements = 2;
    when '1' esize = 16; elements = 4;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “sz”:

sz	<dt>
0	F32
1	F16

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of a number, see *Floating-point reciprocal estimate and step*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = FPRecipStep(Elem[D[n+r],e,esize], Elem[D[m+r],e,esize]);
```

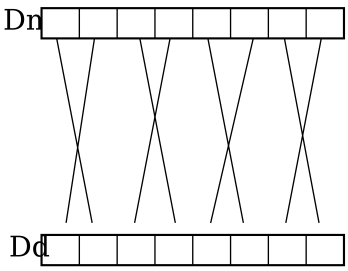
VREV16

Vector Reverse in halfwords reverses the order of 8-bit elements in each halfword of the vector, and places the result in the corresponding destination vector.

There is no distinction between data types, other than size.

The following figure shows an example of the operation of VREV16 doubleword operation.

VREV16.8, doubleword



Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

                rev_element = rev_element - 1;
        D[d+r] = result;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:

- The values of the data supplied in any of its registers.
- The values of the NZCV flags.

- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VRINTA (Advanced SIMD)

Vector Round floating-point to integer towards Nearest with Ties to Away rounds a vector of floating-point values to integral floating-point values of the same size using the Round to Nearest with Ties to Away rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

128-bit SIMD vector (Q == 1)

```
VRINTZ{<q>}.<dt> <Qd>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && !HaveFP16Ext()) || size IN {'00', '11'} then UNDEFINED;
rounding = FPRounding_ZERO;  exact = FALSE;
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
if InITBlock() then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
01	F16
10	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
EncodingSpecificOperations(); CheckAdvSIMDEnabled();
for r = 0 to regs-1
    for e = 0 to elements-1
        op1 = Elem[D[m+r],e,esize];
        result = FPRoundInt(op1, StandardFPSCRValue(), rounding, exact);
        Elem[D[d+r],e,esize] = result;
```

VRINTZ (floating-point)

Round floating-point to integer towards Zero rounds a floating-point value to an integral floating-point value of the same size, using the Round towards Zero rounding mode. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as for normal arithmetic.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VRSHL

Vector Rounding Shift Left takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a rounding right shift. For a truncating shift, see VSHL.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            round_const = 1 << (-shift-1); // 0 for left shift, 2^(n-1) for right shift
            result = (Int(Elem[D[m+r],e,esize], unsigned) + round_const) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VRSHR (zero)

Vector Rounding Shift Right copies the contents of one SIMD register to another

This is a pseudo-instruction of VORR (register). This means:

- The encodings in this description are named to match the encodings of VORR (register).
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VORR (register) gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	0	0	D	1	0	Vn				Vd				0	0	0	1	N	Q	M	1	Vm			

64-bit SIMD vector (Q == 0)

```
VRSHR{<c>}{<q>}.<dt> <Dd>, <Dm>, #0
```

is equivalent to

```
VORR{<c>}{<q>}{.<dt>} <Dd>, <Dm>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VRSHR{<c>}{<q>}.<dt> <Qd>, <Qm>, #0
```

is equivalent to

```
VORR{<c>}{<q>}{.<dt>} <Qd>, <Qm>, <Qm>
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VRSHRN

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector. For truncated results, see *VSHRN*.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers. The destination elements are half the size of the source elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings: See *Advanced SIMD one register and modified immediate* for the T32 instruction set, or *Advanced SIMD one register and modified immediate* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size for the elements of the vectors, encoded in “imm6<5:3>”:

imm6<5:3>	<size>
001	16
01x	32
1xx	64

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<imm> Is an immediate value, in the range 1 to <size>/2, encoded in the "imm6" field as <size>/2 - <imm>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    round_const = 1 << (shift_amount-1);
    for e = 0 to elements-1
        result = LSR(Elem[Qin[m>>1],e,2*esize] + round_const, shift_amount);
        Elem[D[d],e,esize] = result<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VRSHRN (zero)

Vector Rounding Shift Right and Narrow takes each element in a vector, right shifts them by an immediate value, and places the rounded results in the destination vector

This is a pseudo-instruction of VMOVN. This means:

- The encodings in this description are named to match the encodings of VMOVN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VMOVN gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	D	1	1	size		1	0	Vd				0	0	1	0	0	0	M	0	Vm			

A1

```
VRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0
```

is equivalent to

```
VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	1	1	size		1	0	Vd				0	0	1	0	0	0	M	0	Vm			

T1

```
VRSHRN{<c>}{<q>}.<dt> <Dd>, <Qm>, #0
```

is equivalent to

```
VMOVN{<c>}{<q>}.<dt> <Dd>, <Qm>
```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.
For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operand, encoded in “size”:

size	<dt>
00	I16
01	I32
10	I64
11	RESERVED

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

The description of VMOVN gives the operational pseudocode for this instruction.

VRSQRTE

Vector Reciprocal Square Root Estimate finds an approximate reciprocal square root of each element in a vector, and places the results in a second vector.

The operand and result elements are the same type, and can be floating-point numbers or unsigned integers.

For details of the operation performed by this instruction see *Floating-point reciprocal estimate and step*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

64-bit SIMD vector (Q == 0)

```
VRSQRTE{<c>}{<q>}.<dt> <Dd>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VRSQRTE{<c>}{<q>}.<dt> <Qd>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && (!HaveFP16Ext() || F == '0')) || size IN {'00', '11'} then UNDEFINED;
floating_point = (F == '1');
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	1	1	size		1	1	Vd				0	1	0	F	1	Q	M	0	Vm			

64-bit SIMD vector (Q == 0)

```
VRSQRTE{<c>}{<q>}.<dt> <Dd>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VRSQRTE{<c>}{<q>}.<dt> <Qd>, <Qm>
```

```
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
if (size == '01' && (!HaveFP16Ext() || F == '0')) || size IN {'00', '11'} then UNDEFINED;
if size == '01' && InITBlock()  then UNPREDICTABLE;
floating_point = (F == '1');
case size of
    when '01' esize = 16; elements = 4;
    when '10' esize = 32; elements = 2;
d = UInt(D:Vd);  m = UInt(M:Vm);  regs = if Q == '0' then 1 else 2;
```

CONSTRAINED UNPREDICTABLE behavior

If `size == '01' && InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.

- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “F:size”:

F	size	<dt>
0	10	U32
1	01	F16
1	10	F32

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Newton-Raphson iteration

For details of the operation performed and how it can be used in a Newton-Raphson iteration to calculate the reciprocal of the square root of a number, see *Floating-point reciprocal estimate and step*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            if floating_point then
                Elem[D[d+r],e,esize] = FPRSqrtEstimate(Elem[D[m+r],e,esize], StandardFPSCRValue());
            else
                Elem[D[d+r],e,esize] = UnsignedRSqrtEstimate(Elem[D[m+r],e,esize]);
```

VRSUBHN

Vector Rounding Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are rounded. For truncated results, see *VSUBHN*.

The operand elements can be 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VSDOT (by element)

Dot Product index form with signed integers. This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID_ISAR6.DP indicates whether this instruction is supported.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VSDOT (vector)

Dot Product vector form with signed integers. This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of the corresponding 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID_ISAR6.DP indicates whether this instruction is supported.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

```
if InITBlock() then UNPREDICTABLE;
if size == '00' || (size == '01' && !HaveFP16Ext()) then UNDEFINED;
case size of
    when '01' esize = 16; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '10' esize = 32; d = UInt(Vd:D); n = UInt(Vn:N); m = UInt(Vm:M);
    when '11' esize = 64; d = UInt(D:Vd); n = UInt(N:Vn); m = UInt(M:Vm);
cond = cc:(cc<1> EOR cc<0>):'0';
```

CONSTRAINED UNPREDICTABLE behavior

If `InITBlock()`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

Assembler Symbols

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the "Vd:D" field.

VSHL (immediate)

Vector Shift Left (immediate) takes each element in a vector of integers, left shifts them by an immediate value, and places the results in the destination vector.

Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit integers. There is no distinction between signed and unsigned integers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Related encodings: See *Advanced SIMD one register and modified immediate* for the T32 instruction set, or *Advanced SIMD one register and modified immediate* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size for the elements of the vectors, encoded in “L:imm6<5:3>”:

L	imm6<5:3>	<size>
0	001	8
0	01x	16
0	1xx	32
1	xxx	64

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = LSL(Elem[D[m+r],e,esize], shift_amount);
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VSHL (register)

Vector Shift Left (register) takes each element in a vector, shifts them by a value from the least significant byte of the corresponding element of a second vector, and places the results in the destination vector. If the shift value is positive, the operation is a left shift. If the shift value is negative, it is a truncating right shift.

For a rounding shift, see *VRSHL*.

The first operand and result elements are the same data type, and can be any one of:

- 8-bit, 16-bit, 32-bit, or 64-bit signed integers.
- 8-bit, 16-bit, 32-bit, or 64-bit unsigned integers.

The second operand is always a signed integer of the same size.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “U:size”:

U	size	<dt>
0	00	S8
0	01	S16
0	10	S32
0	11	S64
1	00	U8
1	01	U16
1	10	U32
1	11	U64

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            shift = SInt(Elem[D[n+r],e,esize]<7:0>);
            result = Int(Elem[D[m+r],e,esize], unsigned) << shift;
            Elem[D[d+r],e,esize] = result<esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VSHLL

Vector Shift Left Long takes each element in a doubleword vector, left shifts them by an immediate value, and places the results in a quadword vector.

The operand elements can be:

- 8-bit, 16-bit, or 32-bit signed integers.
- 8-bit, 16-bit, or 32-bit unsigned integers.
- 8-bit, 16-bit, or 32-bit untyped integers, maximum shift only.

The result elements are twice the length of the operand elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

d = UInt(D:Vd);  m = UInt(M:Vm);
```

Related encodings: See *Advanced SIMD one register and modified immediate* for the T32 instruction set, or *Advanced SIMD one register and modified immediate* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1 and A2: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1 and T2: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<type> The data type for the elements of the operand. It must be one of:

S

Signed. In encoding T1/A1, encoded as U = 0.

U

Unsigned. In encoding T1/A1, encoded as U = 1.

I

Untyped integer, Available only in encoding T2/A2.

<size> The data size for the elements of the operand. The following table shows the permitted values and their encodings:

<size>	Encoding T1/A1	Encoding T2/A2
8	Encoded as imm6<5:3> = 0b001	Encoded as size = 0b00
16	Encoded as imm6<5:4> = 0b01	Encoded as size = 0b01
32	Encoded as imm6<5> = 1	Encoded as size = 0b10

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> The immediate value. <imm> must lie in the range 1 to <size>, and:

- If <size> == <imm>, the encoding is T2/A2.
- Otherwise, the encoding is T1/A1, and:
  - If <size> == 8, <imm> is encoded in imm6<2:0>.
  - If <size> == 16, <imm> is encoded in imm6<3:0>.
  - If <size> == 32, <imm> is encoded in imm6<4:0>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for e = 0 to elements-1
        result = Int(Elem[Din[m],e,esize], unsigned) << shift_amount;
        Elem[Q[d>>1],e,2*esize] = result<2*esize-1:0>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the operand, encoded in "size":

size	<dt>
00	I16
01	I32
10	I64
11	RESERVED

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

Operation

The description of VMOVN gives the operational pseudocode for this instruction.

VSLI

Vector Shift Left and Insert takes each element in the operand vector, left shifts them by an immediate value, and inserts the results in the destination vector. Bits shifted out of the left of each element are lost.

The elements must all be the same size, and can be 8-bit, 16-bit, 32-bit, or 64-bit. There is no distinction between data types.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size for the elements of the vectors, encoded in “L:imm6<5:3>”:

L	imm6<5:3>	<size>
0	001	8
0	01x	16
0	1xx	32
1	xxx	64

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> Is an immediate value, in the range 0 to <size>-1, encoded in the "imm6" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    mask = LSL(Ones(esize), shift_amount);
    for r = 0 to regs-1
        for e = 0 to elements-1
            shifted_op = LSL(Elem[D[m+r],e,esize], shift_amount);
            Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VSMMLA

The widening integer matrix multiply-accumulate instruction multiplies the 2x8 matrix of signed 8-bit integer values held in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator held in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2, this is an OPTIONAL instruction. *ID_ISAR6*.I8MM indicates whether this instruction is supported in the T32 and A32 instruction sets.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size for the elements of the vectors, encoded in “L:imm6<5:3>”:

L	imm6<5:3>	<size>
0	001	8
0	01x	16
0	1xx	32
1	xxx	64

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

<imm> Is an immediate value, in the range 1 to <size>, encoded in the "imm6" field as <size> - <imm>.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    mask = LSR(Ones(esize), shift_amount);
    for r = 0 to regs-1
        for e = 0 to elements-1
            shifted_op = LSR(Elem[D[m+r],e,esize], shift_amount);
            Elem[D[d+r],e,esize] = (Elem[D[d+r],e,esize] AND NOT(mask)) OR shifted_op;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VST1 (multiple single elements)

Store multiple single elements from one, two, three, or four registers stores elements to memory from one, two, three, or four registers, without interleaving. Every element of each register is stored. For details of the addressing mode see *Advanced SIMD addressing mode*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 , A2 , A3 and A4) and T32 (T1 , T2 , T3 and T4) .

A1

if n == 15 || d+regs > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d+regs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST1 (multiple single elements)*.

Related encodings: See *Advanced SIMD element or structure load/store* for the T32 instruction set, or *Advanced SIMD element or structure load/store* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1, A2, A3 and A4: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2, T3 and T4: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	64

<list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd> }
Single register. Selects the A1 and T1 encodings of the instruction.

{ <Dd>, <Dd+1> }
Two single-spaced registers. Selects the A2 and T2 encodings of the instruction.

{ <Dd>, <Dd+1>, <Dd+2> }
Three single-spaced registers. Selects the A3 and T3 encodings of the instruction.

{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
Four single-spaced registers. Selects the A4 and T4 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the permitted values are:

64
64-bit alignment, encoded in the "align" field as 0b01.

128
128-bit alignment, encoded in the "align" field as 0b10. Available only if <list> contains two or four registers.

256
256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about <Rn>, !, and <Rm>, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to regs-1
        for e = 0 to elements-1
            if ebytes != 8 then
                MemU[address,ebytes] = Elem[D[d+r],e];
            else
                - = AArch32.CheckAlignment(address, ebytes, AccType_NORMAL, iswrite);
                bits(64) data = Elem[D[d+r],e];
                MemU[address,4] = if BigEndian(AccType_NORMAL) then data<63:32> else data<31:0>;
                MemU[address+4,4] = if BigEndian(AccType_NORMAL) then data<31:0> else data<63:32>;
            address = address + ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 8*regs;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

<size> — Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list> Is a list containing the single 64-bit name of the SIMD&FP register holding the element.
The list must be { <Dd>[<index>] }.
The register <Dd> is encoded in the "D:Vd" field.
The permitted values and encoding of <index> depend on <size>:

<size> == 8
<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> When <size> == 8, <align> must be omitted, otherwise it is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and the encoding depends on <size>:

<size> == 8
Encoded in the "index_align<0>" field as 0.

<size> == 16
Encoded in the "index_align<1:0>" field as 0b00.

<size> == 32
Encoded in the "index_align<2:0>" field as 0b000.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 16
<align> is 16, meaning 16-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

<size> == 32
<align> is 32, meaning 32-bit alignment, encoded in the "index_align<2:0>" field as 0b011.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address,ebytes] = Elem[D[d],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + ebytes;
```

VST2 (multiple 2-element structures)

Store multiple 2-element structures from two or four registers stores multiple 2-element structures from two or four registers to memory, with interleaving. For more information, see *Element and structure load/store instructions*. Every element of each register is saved. For details of the addressing mode see *Advanced SIMD addressing mode*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d2+pairs > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d2+pairs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

CONSTRAINED UNPREDICTABLE behavior

If `d2+pairs > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST2 (multiple 2-element structures)*.

Related encodings: See *Advanced SIMD element or structure load/store* for the T32 instruction set, or *Advanced SIMD element or structure load/store* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1 and A2: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1 and T2: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	RESERVED

<list> Is a list containing the 64-bit names of the SIMD&FP registers.

The list must be one of:

{ <Dd>, <Dd+1> }

Two single-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "itype" field as 0b1000.

{ <Dd>, <Dd+2> }
Two double-spaced registers. Selects the A1 and T1 encodings of the instruction, and encoded in the "itype" field as 0b1001.

{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
Three single-spaced registers. Selects the A2 and T2 encodings of the instruction.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.
Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "align" field as 0b00.
Whenever <align> is present, the permitted values are:

64
64-bit alignment, encoded in the "align" field as 0b01.

128
128-bit alignment, encoded in the "align" field as 0b10.

256
256-bit alignment, encoded in the "align" field as 0b11. Available only if <list> contains four registers.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for r = 0 to pairs-1
        for e = 0 to elements-1
            MemU[address,       ebytes] = Elem[D[d+r], e];
            MemU[address+ebytes,ebytes] = Elem[D[d2+r],e];
            address = address + 2*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 16*pairs;
```

VST2 (single 2-element structure from one lane)

Store single 2-element structure from one lane of two registers stores one 2-element structure to memory from corresponding elements of two registers. For details of the addressing mode see *Advanced SIMD addressing mode*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 , A2 and A3) and T32 (T1 , T2 and T3) .

```
if size == '11' then UNDEFINED;
if index_align<1> != '0' then UNDEFINED;
ebytes = 4;  index = UInt(index_align<3>);
inc = if index_align<2> == '0' then 1 else 2;
alignment = if index_align<0> == '0' then 1 else 8;
d = UInt(D:Vd);  d2 = d + inc;  n = UInt(Rn);  m = UInt(Rm);
wback = (m != 15);  register_index = (m != 15 && m != 13);
if n == 15 || d2 > 31 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `d2 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.

- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST2 (single 2-element structure from one lane)*.

Assembler Symbols

<c> For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list> Is a list containing the 64-bit names of the two SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>] }
Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>] }
Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 16
"spacing" is encoded in the "index_align<1>" field.

<size> == 32
"spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8
<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and the encoding depends on <size>:

<size> == 8
Encoded in the "index_align<0>" field as 0.

<size> == 16
Encoded in the "index_align<0>" field as 0.

<size> == 32
Encoded in the "index_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8
<align> is 16, meaning 16-bit alignment, encoded in the "index_align<0>" field as 1.

<size> == 16
<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.

<size> == 32
<align> is 64, meaning 64-bit alignment, encoded in the "index_align<1:0>" field as 0b01.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address,       ebytes] = Elem[D[d], index];
    MemU[address+ebytes,ebytes] = Elem[D[d2],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 2*ebytes;
```

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST3 (single 3-element structure from one lane)*.

Assembler Symbols

<c> For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list> Is a list containing the 64-bit names of the three SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>] }
Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>] }
Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 8
"spacing" is encoded in the "index_align<0>" field.

<size> == 16
"spacing" is encoded in the "index_align<1>" field, and "index_align<0>" is set to 0.

<size> == 32
"spacing" is encoded in the "index_align<2>" field, and "index_align<1:0>" is set to 0b00.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8
<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Alignment

Standard alignment rules apply, see *Alignment support*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];
    MemU[address,         ebytes] = Elem[D[d], index];
    MemU[address+ebytes,  ebytes] = Elem[D[d2],index];
    MemU[address+2*ebytes,ebytes] = Elem[D[d3],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 3*ebytes;
```

CONSTRAINED UNPREDICTABLE behavior

If `d4 > 31`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST4 (multiple 4-element structures)*.

Related encodings: See *Advanced SIMD element or structure load/store* for the T32 instruction set, or *Advanced SIMD element or structure load/store* for the A32 instruction set.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32
11	RESERVED

<list> Is a list containing the 64-bit names of the SIMD&FP registers.
The list must be one of:

{ <Dd>, <Dd+1>, <Dd+2>, <Dd+3> }
Single-spaced registers, encoded in the "itype" field as 0b0000.

{ <Dd>, <Dd+2>, <Dd+4>, <Dd+6> }
Double-spaced registers, encoded in the "itype" field as 0b0001.

The register <Dd> is encoded in the "D:Vd" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and is encoded in the "align" field as 0b00.

Whenever <align> is present, the permitted values are:

64
64-bit alignment, encoded in the "align" field as 0b01.

128
128-bit alignment, encoded in the "align" field as 0b10.

256
256-bit alignment, encoded in the "align" field as 0b11.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    for e = 0 to elements-1
        MemU[address,         ebytes] = Elem[D[d], e];
        MemU[address+ebytes,  ebytes] = Elem[D[d2],e];
        MemU[address+2*ebytes,ebytes] = Elem[D[d3],e];
        MemU[address+3*ebytes,ebytes] = Elem[D[d4],e];
        address = address + 4*ebytes;
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 32;
```

VST4 (single 4-element structure from one lane)

Store single 4-element structure from one lane of four registers stores one 4-element structure to memory from corresponding elements of four registers. For details of the addressing mode see *Advanced SIMD addressing mode*.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1 , A2 and A3) and T32 (T1 , T2 and T3) .

A1

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VST4 (single 4-element structure from one lane)*.

Assembler Symbols

<c> For encoding A1, A2 and A3: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1, T2 and T3: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<size> Is the data size, encoded in “size”:

size	<size>
00	8
01	16
10	32

<list> Is a list containing the 64-bit names of the four SIMD&FP registers holding the element.

The list must be one of:

{ <Dd>[<index>], <Dd+1>[<index>], <Dd+2>[<index>], <Dd+3>[<index>] }
Single-spaced registers, encoded as "spacing" = 0.

{ <Dd>[<index>], <Dd+2>[<index>], <Dd+4>[<index>], <Dd+6>[<index>] }
Double-spaced registers, encoded as "spacing" = 1. Not permitted when <size> == 8.

The encoding of "spacing" depends on <size>:

<size> == 16
"spacing" is encoded in the "index_align<1>" field.

<size> == 32
"spacing" is encoded in the "index_align<2>" field.

The register <Dd> is encoded in the "D:Vd" field.

The permitted values and encoding of <index> depend on <size>:

<size> == 8
<index> is in the range 0 to 7, encoded in the "index_align<3:1>" field.

<size> == 16
<index> is in the range 0 to 3, encoded in the "index_align<3:2>" field.

<size> == 32
<index> is 0 or 1, encoded in the "index_align<3>" field.

<Rn> Is the general-purpose base register, encoded in the "Rn" field.

<align> Is the optional alignment.

Whenever <align> is omitted, the standard alignment is used, see *Unaligned data access*, and the encoding depends on <size>:

<size> == 8
Encoded in the "index_align<0>" field as 0.

<size> == 16
Encoded in the "index_align<0>" field as 0.

<size> == 32
Encoded in the "index_align<1:0>" field as 0b00.

Whenever <align> is present, the permitted values and encoding depend on <size>:

<size> == 8
<align> is 32, meaning 32-bit alignment, encoded in the "index_align<0>" field as 1.

<size> == 16

<align> is 64, meaning 64-bit alignment, encoded in the "index_align<0>" field as 1.

<size> == 32

<align> can be 64 or 128. 64-bit alignment is encoded in the "index_align<1:0>" field as 0b01, and 128-bit alignment is encoded in the "index_align<1:0>" field as 0b10.

: is the preferred separator before the <align> value, but the alignment can be specified as @<align>, see *Advanced SIMD addressing mode*.

<Rm> Is the general-purpose index register containing an offset applied after the access, encoded in the "Rm" field.

For more information about the variants of this instruction, see *Advanced SIMD addressing mode*.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    address = R[n];  iswrite = TRUE;
    - = AArch32.CheckAlignment(address, alignment, AccType_VEC, iswrite);
    MemU[address,         ebytes] = Elem[D[d], index];
    MemU[address+ebytes,  ebytes] = Elem[D[d2],index];
    MemU[address+2*ebytes,ebytes] = Elem[D[d3],index];
    MemU[address+3*ebytes,ebytes] = Elem[D[d4],index];
    if wback then
        if register_index then
            R[n] = R[n] + R[m];
        else
            R[n] = R[n] + 4*ebytes;
```

VSTM, VSTMDB, VSTMIA

Store multiple SIMD&FP registers stores multiple registers from the Advanced SIMD and floating-point register file to consecutive memory locations using an address from a general-purpose register.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the alias VPUSH.

It has encodings from the following instruction sets: A32 (A1 and A2) and T32 (T1 and T2) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9	8	7 6 5 4 3 2 1	0
!= 1111	1	1	0	P	U	D	W	0	Rn	Vd	1	0	1	1	imm8<7:1>	0
cond																imm8<0>

Decrement Before (P == 1 && U == 0 && W == 1)

```
VSTMDB{<c>}{<q>}{.<size>} <Rn>!, <dreglist>
```

Increment After (P == 0 && U == 1)

```
VSTM{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>
```

```
VSTMIA{<c>}{<q>}{.<size>} <Rn>{!}, <dreglist>
```

```
if P == '0' && U == '0' && W == '0' then SEE "Related encodings";
if P == '1' && W == '0' then SEE "VSTR";
if P == U && W == '1' then UNDEFINED;
// Remaining combinations are PUW = 010 (IA without !), 011 (IA with !), 101 (DB with !)
single_regs = FALSE;  add = (U == '1');  wback = (W == '1');
d = UInt(D:Vd);  n = UInt(Rn);  imm32 = ZeroExtend(imm8:'00', 32);
regs = UInt(imm8) DIV 2;  // If UInt(imm8) is odd, see "FSTDBMX, FSTMIAX".
if n == 15 && (wback || CurrentInstrSet() != InstrSet_A32) then UNPREDICTABLE;
if regs == 0 || regs > 16 || (d+regs) > 32 then UNPREDICTABLE;
if imm8<0> == '1' && (d+regs) > 16 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The instruction operates as a `VSTM` with the same addressing mode but stores no registers.

If `regs > 16 || (d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as `NOP`.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

if regs == 0 || (d+regs) > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `regs == 0`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The instruction operates as a VSTM with the same addressing mode but stores no registers.

If `(d+regs) > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- The memory locations specified by the instruction and the number of registers specified by the instruction become UNKNOWN. If the instruction specifies writeback, then that register becomes UNKNOWN. This behavior does not affect any other memory locations.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*, and particularly *VSTM*.

Related encodings: See *Advanced SIMD and floating-point 64-bit move* for the T32 instruction set, or *Advanced SIMD and floating-point 64-bit move* for the A32 instruction set.

Assembler Symbols

<c>	See *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<size>	An optional data size specifier. If present, it must be equal to the size in bits, 32 or 64, of the registers being transferred.
<Rn>	Is the general-purpose base register, encoded in the "Rn" field. If writeback is not specified, the PC can be used. However, Arm deprecates use of the PC.

!	Specifies base register writeback. Encoded in the "W" field as 1 if present, otherwise 0.
<sreglist>	Is the list of consecutively numbered 32-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "Vd:D", and "imm8" is set to the number of registers in the list. The list must contain at least one register.
<dreglist>	Is the list of consecutively numbered 64-bit SIMD&FP registers to be transferred. The first register in the list is encoded in "D:Vd", and "imm8" is set to twice the number of registers in the list. The list must contain at least one register, and must not contain more than 16 registers.

Alias Conditions

Alias	Is preferred when
VPUSH	`P == '1' && U == '0' && W == '1' && Rn == '1101'`

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then R[n] else R[n]-imm32;
    for r = 0 to regs-1
        if single_regs then
            MemA[address,4] = S[d+r];  address = address+4;
        else
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4] = if BigEndian(AccType_ATOMIC) then D[d+r]<63:32> else D[d+r]<31:0>;
            MemA[address+4,4] = if BigEndian(AccType_ATOMIC) then D[d+r]<31:0> else D[d+r]<63:32>;
            address = address+8;
    if wback then R[n] = if add then R[n]+imm32 else R[n]-imm32;
```

VSTR

Store SIMD&FP register stores a single register from the Advanced SIMD and floating-point register file to memory, using an address from a general-purpose register, with an optional offset.

Depending on settings in the *CPACR*, *NSACR*, *HCPTR*, and *FPEXC* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31 30 29 28	27	26	25	24	23	22	21	20	19 18 17 16	15 14 13 12	11	10	9 8	7 6 5 4 3 2 1 0

- The instruction is UNDEFINED.
- The instruction executes as if it passes the Condition code check.
- The instruction executes as NOP. This means it behaves as if it fails the Condition code check.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> — See *Standard assembler syntax fields*.

<q> — See *Standard assembler syntax fields*.

.64 — Is an optional data size specifier for 64-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Dd> — Is the 64-bit name of the SIMD&FP source register, encoded in the "D:Vd" field.

.32 — Is an optional data size specifier for 32-bit memory accesses that can be used in the assembler source code, but is otherwise ignored.

<Sd> — Is the 32-bit name of the SIMD&FP source register, encoded in the "Vd:D" field.

<Rn> — Is the general-purpose base register, encoded in the "Rn" field. The PC can be used, but this is deprecated.

+/- — Specifies the offset is added to or subtracted from the base register, defaulting to + if omitted and encoded in “U”:

U	+/-
0	-
1	+

<imm> — For the single-precision scalar or double-precision scalar variants: is the optional unsigned immediate byte offset, a multiple of 4, in the range 0 to 1020, defaulting to 0, and encoded in the "imm8" field as <imm>/4.

For the half-precision scalar variant: is the optional unsigned immediate byte offset, a multiple of 2, in the range 0 to 510, defaulting to 0, and encoded in the "imm8" field as <imm>/2.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckVFPEnabled(TRUE);
    address = if add then (R[n] + imm32) else (R[n] - imm32);
    case esize of
        when 16
            MemA[address,2] = S[d]<15:0>;
        when 32
            MemA[address,4] = S[d];
        when 64
            // Store as two word-aligned words in the correct order for current endianness.
            MemA[address,4]   = if BigEndian(AccType_ATOMIC) then D[d]<63:32> else D[d]<31:0>;
            MemA[address+4,4] = if BigEndian(AccType_ATOMIC) then D[d]<31:0>  else D[d]<63:32>;
```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> Is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	I8
01	I16
10	I32
11	I64

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qn> Is the 128-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field as <Qn>*2.

<Qm> Is the 128-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dn> Is the 64-bit name of the first SIMD&FP source register, encoded in the "N:Vn" field.

<Dm> Is the 64-bit name of the second SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    for r = 0 to regs-1
        for e = 0 to elements-1
            Elem[D[d+r],e,esize] = Elem[D[n+r],e,esize] - Elem[D[m+r],e,esize];
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VSUBHN

Vector Subtract and Narrow, returning High Half subtracts the elements of one quadword vector from the corresponding elements of another quadword vector, takes the most significant half of each result, and places the final results in a doubleword vector. The results are truncated. For rounded results, see *VRSUBHN*.

There is no distinction between signed and unsigned integers.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VSUDOT (by element)

Dot Product index form with signed and unsigned integers. This instruction performs the dot product of the four signed 8-bit integer values in each 32-bit element of the first source register with the four unsigned 8-bit integer values in an indexed 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

From Armv8.2, this is an OPTIONAL instruction. *ID_ISAR6*.I8MM indicates whether this instruction is supported in the T32 and A32 instruction sets.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VTBL, VTBX

Vector Table Lookup uses byte indexes in a control vector to look up byte values in a table and generate a new vector. Indexes out of range return 0.

Vector Table Extension works in the same way, except that indexes out of range leave the destination element unchanged.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	D	1	1	Vn				Vd				1	0	len		N	op	M	0	Vm			

VTBL (op == 0)

```
VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>
```

VTBX (op == 1)

```
VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>
```

```
is_vtbl = (op == '0');  length = UInt(len)+1;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n + length > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.
- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	1	1	Vn				Vd				1	0	len		N	op	M	0	Vm			

VTBL (op == 0)

```
VTBL{<c>}{<q>}.8 <Dd>, <list>, <Dm>
```

VTBX (op == 1)

```
VTBX{<c>}{<q>}.8 <Dd>, <list>, <Dm>
```

```
is_vtbl = (op == '0');  length = UInt(len)+1;
d = UInt(D:Vd);  n = UInt(N:Vn);  m = UInt(M:Vm);
if n+length > 32 then UNPREDICTABLE;
```

CONSTRAINED UNPREDICTABLE behavior

If `n + length > 32`, then one of the following behaviors must occur:

- The instruction is UNDEFINED.

- The instruction executes as NOP.
- One or more of the SIMD and floating-point registers are UNKNOWN. This behavior does not affect any general-purpose registers.

For more information about the CONSTRAINED UNPREDICTABLE behavior of this instruction, see *Architectural Constraints on UNPREDICTABLE behaviors*.

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<list> The vectors containing the table. It must be one of:

{<Dn>}
Encoded as len = 0b00.

{<Dn>, <Dn+1>}
Encoded as len = 0b01.

{<Dn>, <Dn+1>, <Dn+2>}
Encoded as len = 0b10.

{<Dn>, <Dn+1>, <Dn+2>, <Dn+3>}
Encoded as len = 0b11.

<Dm> Is the 64-bit name of the SIMD&FP source register holding the indices, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();

    // Create 256-bit = 32-byte table variable, with zeros in entries that will not be used.
    table3 = if length == 4 then D[n+3] else Zeros(64);
    table2 = if length >= 3 then D[n+2] else Zeros(64);
    table1 = if length >= 2 then D[n+1] else Zeros(64);
    table = table3 : table2 : table1 : D[n];

    for i = 0 to 7
        index = UInt(Elem[D[m],i,8]);
        if index < 8*length then
            Elem[D[d],i,8] = Elem[table,index,8];
        else
            if is_vtbl then
                Elem[D[d],i,8] = Zeros(8);
            // else Elem[D[d],i,8] unchanged
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

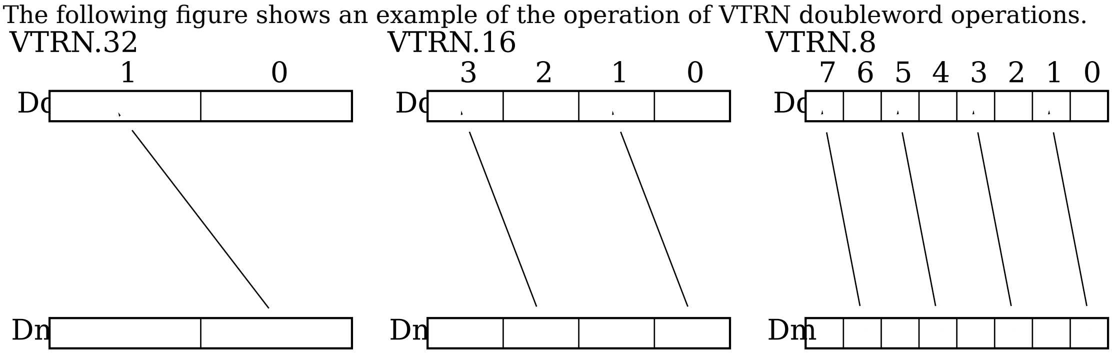
VTRN

Vector Transpose treats the elements of its operand vectors as elements of 2 x 2 matrices, and transposes the matrices.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows an example of the operation of VTRN doubleword operations.



Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

This instruction is used by the pseudo-instructions VUZP (alias), and VZIP (alias).

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

VTST

Vector Test Bits takes each element in a vector, and bitwise ANDs it with the corresponding element of a second vector. If the result is not zero, the corresponding element in the destination vector is set to all ones. Otherwise, it is set to all zeros.

The operand vector elements can be any one of:

- 8-bit, 16-bit, or 32-bit fields.

The result vector elements are fields the same size as the operand vector elements.

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VUDOT (by element)

Dot Product index form with unsigned integers. This instruction performs the dot product of the four 8-bit elements in each 32-bit element of the first source register with the four 8-bit elements of an indexed 32-bit element in the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

In Armv8.2 and Armv8.3, this is an OPTIONAL instruction. From Armv8.4 it is mandatory for all implementations to support it.

ID_ISAR6.DP indicates whether this instruction is supported.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VUMMLA

The widening integer matrix multiply-accumulate instruction multiplies the 2x8 matrix of unsigned 8-bit integer values held in the first source vector by the 8x2 matrix of unsigned 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator held in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2, this is an OPTIONAL instruction. *ID_ISAR6*.I8MM indicates whether this instruction is supported in the T32 and A32 instruction sets.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VUSDOT (by element)

Dot Product index form with unsigned and signed integers. This instruction performs the dot product of the four unsigned 8-bit integer values in each 32-bit element of the first source register with the four signed 8-bit integer values in an indexed 32-bit element of the second source register, accumulating the result into the corresponding 32-bit element of the destination register.

From Armv8.2, this is an OPTIONAL instruction. *ID_ISAR6*.I8MM indicates whether this instruction is supported in the T32 and A32 instruction sets.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

VUSMMLA

The widening integer matrix multiply-accumulate instruction multiplies the 2x8 matrix of unsigned 8-bit integer values held in the first source vector by the 8x2 matrix of signed 8-bit integer values in the second source vector. The resulting 2x2 32-bit integer matrix product is destructively added to the 32-bit integer matrix accumulator held in the destination vector. This is equivalent to performing an 8-way dot product per destination element.

From Armv8.2, this is an OPTIONAL instruction. *ID_ISAR6*.I8MM indicates whether this instruction is supported in the T32 and A32 instruction sets.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

VUZP

Vector Unzip de-interleaves the elements of two vectors.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows an example of the operation of VUZP doubleword operation for data type 8.

VUZP.8, doubleword

	Register state before opera								Register state after operation							
Dd	A7	A6	A5	A4	A3	A2	A1	A0	B6	B4	B2	B0	A6	A4	A2	A0
Dm	B7	B6	B5	B4	B3	B2	B1	B0	B7	B5	B3	B1	A7	A5	A3	A1

The following figure shows an example of the operation of VUZP quadword operation for data type 32.

VUZP.32, quadword

	Register state before opera				Register state after operation			
Qd	A3	A2	A1	A0	B2	B0	A2	A0
Qm	B3	B2	B1	B0	B3	B1	A3	A1

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VZIP

Vector Zip interleaves the elements of two vectors.

The elements of the vectors can be 8-bit, 16-bit, or 32-bit. There is no distinction between data types.

The following figure shows an example of the operation of VZIP doubleword operation for data type 8.

VZIP.8, doubleword

	Register state before operation								Register state after operation							
Dd	A7	A6	A5	A4	A3	A2	A1	A0	B3	A3	B2	A2	B1	A1	B0	A0
Dm	B7	B6	B5	B4	B3	B2	B1	B0	B7	A7	B6	A6	B5	A5	B4	A4

The following figure shows an example of the operation of VZIP quadword operation for data type 32.

VZIP.32, quadword

	Register state before operation				Register state after operation			
Qd	A3	A2	A1	A0	B1	A1	B0	A0
Qm	B3	B2	B1	B0	B3	A3	B2	A2

Depending on settings in the *CPACR*, *NSACR*, and *HCPTR* registers, and the Security state and PE mode in which the instruction is executed, an attempt to execute the instruction might be UNDEFINED, or trapped to Hyp mode. For more information see *Enabling Advanced SIMD and floating-point support*.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19 18	17	16	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	1	0	0	1	1	1	D	1	1	size	1	0	Vd	0	0	0	1	1	Q	M	0	Vm

64-bit SIMD vector (Q == 0)

```
VZIP{<c>}{<q>}.<dt> <Dd>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VZIP{<c>}{<q>}.<dt> <Qd>, <Qm>
```

```
if size == '11' || (Q == '0' && size == '10') then UNDEFINED;
if Q == '1' && (Vd<0> == '1' || Vm<0> == '1') then UNDEFINED;
quadword_operation = (Q == '1');  esize = 8 << UInt(size);
d = UInt(D:Vd);  m = UInt(M:Vm);
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3 2	1	0	15 14 13 12	11	10	9	8	7	6	5	4	3 2 1 0
1	1	1	1	1	1	1	1	1	D	1	1	size	1	0	Vd	0	0	0	1	1	Q	M	0	Vm

64-bit SIMD vector (Q == 0)

```
VZIP{<c>}{<q>}.<dt> <Dd>, <Dm>
```

128-bit SIMD vector (Q == 1)

```
VZIP{<c>}{<q>}.<dt> <Qd>, <Qm>

quadword_operation = (Q == '1');  esize = 8 << UInt(size);
d = UInt(D:Vd);  m = UInt(M:Vm);
```

Assembler Symbols

<c> For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.

For encoding T1: see *Standard assembler syntax fields*.

<q> See *Standard assembler syntax fields*.

<dt> For the 64-bit SIMD vector variant: is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	8
01	16
1x	RESERVED

For the 128-bit SIMD vector variant: is the data type for the elements of the vectors, encoded in “size”:

size	<dt>
00	8
01	16
10	32
11	RESERVED

<Qd> Is the 128-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field as <Qd>*2.

<Qm> Is the 128-bit name of the SIMD&FP source register, encoded in the "M:Vm" field as <Qm>*2.

<Dd> Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.

<Dm> Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

```
if ConditionPassed() then
    EncodingSpecificOperations();  CheckAdvSIMDEnabled();
    if quadword_operation then
        if d == m then
            Q[d>>1] = bits(128) UNKNOWN;
        else
            bits(256) zipped_q;
            for e = 0 to (128 DIV esize) - 1
                Elem[zipped_q,2*e,esize] = Elem[Q[d>>1],e,esize];
                Elem[zipped_q,2*e+1,esize] = Elem[Q[m>>1],e,esize];
            Q[d>>1] = zipped_q<127:0>;  Q[m>>1] = zipped_q<255:128>;
    else
        if d == m then
            D[d] = bits(64) UNKNOWN;
        else
            bits(128) zipped_d;
            for e = 0 to (64 DIV esize) - 1
                Elem[zipped_d,2*e,esize] = Elem[D[d],e,esize];
                Elem[zipped_d,2*e+1,esize] = Elem[D[m],e,esize];
            D[d] = zipped_d<63:0>;  D[m] = zipped_d<127:64>;
```

Operational information

If CPSR.DIT is 1 and this instruction passes its condition execution check:

- The execution time of this instruction is independent of:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.
- The response of this instruction to asynchronous exceptions does not vary based on:
  - The values of the data supplied in any of its registers.
  - The values of the NZCV flags.

VZIP (alias)

Vector Zip interleaves the elements of two vectors

This is a pseudo-instruction of VTRN. This means:

- The encodings in this description are named to match the encodings of VTRN.
- The assembler syntax is used only for assembly, and is not used on disassembly.
- The description of VTRN gives the operational pseudocode for this instruction.

It has encodings from the following instruction sets: A32 (A1) and T32 (T1) .

A1

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	0	0	1	1	1	D	1	1	size		1	0	Vd				0	0	0	0	1	0	M	0	Vm			
																									Q						

64-bit SIMD vector

```
VZIP{<c>}{<q>}.32 <Dd>, <Dm>
```

is equivalent to

```
VTRN{<c>}{<q>}.32 <Dd>, <Dm>
```

T1

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	1	1	1	1	1	1	1	D	1	1	size		1	0	Vd				0	0	0	0	1	0	M	0	Vm			
																									Q						

64-bit SIMD vector

```
VZIP{<c>}{<q>}.32 <Dd>, <Dm>
```

is equivalent to

```
VTRN{<c>}{<q>}.32 <Dd>, <Dm>
```

Assembler Symbols

<c>	For encoding A1: see *Standard assembler syntax fields*. This encoding must be unconditional.
	For encoding T1: see *Standard assembler syntax fields*.
<q>	See *Standard assembler syntax fields*.
<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the "D:Vd" field.
<Dm>	Is the 64-bit name of the SIMD&FP source register, encoded in the "M:Vm" field.

Operation

The description of VTRN gives the operational pseudocode for this instruction.

Internal version only: isa v01_26, pseudocode v2021-09_rel ; Build timestamp: 2021-09-30T19:00
