4EH	02H	L1D_PREFETCH.MISS	Counts number of hardware prefetch requests that miss the L1D. There are two prefetchers in the L1D. A streamer, which predicts lines sequentially after this one should be fetched, and the IP prefetcher that remembers access patterns for the current instruction. The streamer prefetcher stops on an L1D hit, while the IP prefetcher does not.	
4EH	04H	L1D_PREFETCH.TRIGGERS	Counts number of prefetch requests triggered by the Finite State Machine and pushed into the prefetch FIFO. Some of the prefetch requests are dropped due to overwrites or competition between the IP index prefetcher and streamer prefetcher. The prefetch FIFO contains 4 entries.	
51H	01H	L1D.REPL	Counts the number of lines brought into the L1 data cache.	Counter 0, 1 only
51H	02H	L1D.M_REPL	Counts the number of modified lines brought into the L1 data cache.	Counter 0, 1 only
51H	04H	L1D.M_EVICT	Counts the number of modified lines evicted from the L1 data cache due to replacement.	Counter 0, 1 only
51H	08H	L1D.M_SNOOP_EVICT	Counts the number of modified lines evicted from the L1 data cache due to snoop HITM intervention.	Counter 0, 1 only
52H	01H	L1D_CACHE_PREFETCH_LOCK_FB_HIT	Counts the number of cacheable load lock speculated instructions accepted into the fill buffer.	
53H	01H	L1D_CACHE_LOCK_FB_HIT	Counts the number of cacheable load lock speculated or retired instructions accepted into the fill buffer.	
63H	01H	CACHE_LOCK_CYCLES.L1D_L2	Cycle count during which the L1D and L2 are locked. A lock is asserted when there is a locked memory access, due to uncacheable memory, a locked operation that spans two cache lines, or a page walk from an uncacheable page table.	Counter 0, 1 only. L1D and L2 locks have a very high performance penalty and it is highly recommended to avoid such accesses.
63H	02H	CACHE_LOCK_CYCLES.L1D	Counts the number of cycles that cacheline in the L1 data cache unit is locked.	Counter 0, 1 only.

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
6CH	01H	IO_TRANSACTIONS	Counts the number of completed I/O transactions.	
80H	01H	L1I.HITS	Counts all instruction fetches that hit the L1 instruction cache.	
80H	02H	L1I.MISSES	Counts all instruction fetches that miss the L1I cache. This includes instruction cache misses, streaming buffer misses, victim cache misses and uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding.	
80H	03H	L1I.READS	Counts all instruction fetches, including uncacheable fetches that bypass the L1I.	
80H	04H	L1I.CYCLES_STALLED	Cycle counts for which an instruction fetch stalls due to a L1I cache miss, ITLB miss or ITLB fault.	
82H	01H	LARGE_ITLB.HIT	Counts number of large ITLB hits.	
85H	01H	ITLB_MISSES.ANY	Counts the number of misses in all levels of the ITLB which causes a page walk.	
85H	02H	ITLB_MISSES.WALK_COMPLETED	Counts number of misses in all levels of the ITLB which resulted in a completed page walk.	
87H	01H	ILD_STALL.LCP	Cycles Instruction Length Decoder stalls due to length changing prefixes: 66, 67 or REX.W (for EM64T) instructions which change the length of the decoded instruction.	
87H	02H	ILD_STALL.MRU	Instruction Length Decoder stall cycles due to Branch Prediction Unit (PBU) Most Recently Used (MRU) bypass.	
87H	04H	ILD_STALL.IQ_FULL	Stall cycles due to a full instruction queue.	
87H	08H	ILD_STALL.REGEN	Counts the number of regen stalls.	
87H	0FH	ILD_STALL.ANY	Counts any cycles the Instruction Length Decoder is stalled.	
88H	01H	BR_INST_EXEC.COND	Counts the number of conditional near branch instructions executed, but not necessarily retired.	
88H	02H	BR_INST_EXEC.DIRECT	Counts all unconditional near branch instructions excluding calls and indirect branches.	
88H	04H	BR_INST_EXEC.INDIRECT_NON_CALL	Counts the number of executed indirect near branch instructions that are not calls.	
88H	07H	BR_INST_EXEC.NON_CALLS	Counts all non call near branch instructions executed, but not necessarily retired.	
88H	08H	BR_INST_EXEC.RETURN_NEAR	Counts indirect near branches that have a return mnemonic.	
88H	10H	BR_INST_EXEC.DIRECT_NEAR_CALL	Counts unconditional near call branch instructions, excluding non call branch, executed.	
88H	20H	BR_INST_EXEC.INDIRECT_NEAR_CALL	Counts indirect near calls, including both register and memory indirect, executed.	
88H	30H	BR_INST_EXEC.NEAR_CALLS	Counts all near call branches executed, but not necessarily retired.	

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
88H	40H	BR_INST_EXEC.TAKEN	Counts taken near branches executed, but not necessarily retired.	
88H	7FH	BR_INST_EXEC.ANY	Counts all near executed branches (not necessarily retired). This includes only instructions and not micro-op branches. Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem.	
89H	01H	BR_MISP_EXEC.COND	Counts the number of mispredicted conditional near branch instructions executed, but not necessarily retired.	
89H	02H	BR_MISP_EXEC.DIRECT	Counts mispredicted macro unconditional near branch instructions, excluding calls and indirect branches (should always be 0).	
89H	04H	BR_MISP_EXEC.INDIRECT_NO_N_CALL	Counts the number of executed mispredicted indirect near branch instructions that are not calls.	
89H	07H	BR_MISP_EXEC.NON_CALLS	Counts mispredicted non call near branches executed, but not necessarily retired.	
89H	08H	BR_MISP_EXEC.RETURN_NEAR	Counts mispredicted indirect branches that have a rear return mnemonic.	
89H	10H	BR_MISP_EXEC.DIRECT_NEAR_CALL	Counts mispredicted non-indirect near calls executed, (should always be 0).	
89H	20H	BR_MISP_EXEC.INDIRECT_NEAR_CALL	Counts mispredicted indirect near calls executed, including both register and memory indirect.	
89H	30H	BR_MISP_EXEC.NEAR_CALLS	Counts all mispredicted near call branches executed, but not necessarily retired.	
89H	40H	BR_MISP_EXEC.TAKEN	Counts executed mispredicted near branches that are taken, but not necessarily retired.	
89H	7FH	BR_MISP_EXEC.ANY	Counts the number of mispredicted near branch instructions that were executed, but not necessarily retired.	
A2H	01H	RESOURCE_STALLS.ANY	Counts the number of Allocator resource related stalls. Includes register renaming buffer entries, memory buffer entries. In addition to resource related stalls, this event counts some other events. Includes stalls arising during branch misprediction recovery, such as if retirement of the mispredicted branch is delayed and stalls arising while store buffer is draining from synchronizing operations.	Does not include stalls due to SuperQ (off core) queue full, too many cache misses, etc.
A2H	02H	RESOURCE_STALLS.LOAD	Counts the cycles of stall due to lack of load buffer for load operation.	
A2H	04H	RESOURCE_STALLS.RS_FULL	This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle. A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, or instructions dependent upon instructions further down the pipeline that have yet to retire.	When RS is full, new instructions can not enter the reservation station and start execution.

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
A2H	08H	RESOURCE_STALLS.STORE	This event counts the number of cycles that a resource related stall will occur due to the number of store instructions reaching the limit of the pipeline, (i.e. all store buffers are used). The stall ends when a store instruction commits its data to the cache or memory.	
A2H	10H	RESOURCE_STALLS.ROB_FULL	Counts the cycles of stall due to re-order buffer full.	
A2H	20H	RESOURCE_STALLS.FPCW	Counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word.	
A2H	40H	RESOURCE_STALLS.MXCSR	Stalls due to the MXCSR register rename occurring to close to a previous MXCSR rename. The MXCSR provides control and status for the MMX registers.	
A2H	80H	RESOURCE_STALLS.OTHER	Counts the number of cycles while execution was stalled due to other resource issues.	
A6H	01H	MACRO_INSTS.FUSIONS_DECODED	Counts the number of instructions decoded that are macro-fused but not necessarily executed or retired.	
A7H	01H	BACLEAR_FORCE_IQ	Counts number of times a BACLEAR was forced by the Instruction Queue. The IQ is also responsible for providing conditional branch prediction direction based on a static scheme and dynamic data provided by the L2 Branch Prediction Unit. If the conditional branch target is not found in the Target Array and the IQ predicts that the branch is taken, then the IQ will force the Branch Address Calculator to issue a BACLEAR. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline.	
A8H	01H	LSD.UOPS	Counts the number of micro-ops delivered by loop stream detector.	Use cmask=1 and invert to count cycles
AEH	01H	ITLB_FLUSH	Counts the number of ITLB flushes.	
B0H	40H	OFFCORE_REQUESTS.L1D_WRITEBACK	Counts number of L1D writebacks to the uncore.	
B1H	01H	UOPS_EXECUTED.PORT0	Counts number of Uops executed that were issued on port 0. Port 0 handles integer arithmetic, SIMD and FP add Uops.	
B1H	02H	UOPS_EXECUTED.PORT1	Counts number of Uops executed that were issued on port 1. Port 1 handles integer arithmetic, SIMD, integer shift, FP multiply and FP divide Uops.	
B1H	04H	UOPS_EXECUTED.PORT2_CORE	Counts number of Uops executed that were issued on port 2. Port 2 handles the load Uops. This is a core count only and can not be collected per thread.	
B1H	08H	UOPS_EXECUTED.PORT3_CORE	Counts number of Uops executed that were issued on port 3. Port 3 handles store Uops. This is a core count only and can not be collected per thread.	

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
B1H	10H	UOPS_EXECUTED.PORT4_COR E	Counts number of Uops executed that where issued on port 4. Port 4 handles the value to be stored for the store Uops issued on port 3. This is a core count only and can not be collected per thread.	
B1H	1FH	UOPS_EXECUTED.CORE_ACTIV E_CYCLES_NO_PORT5	Counts cycles when the Uops executed were issued from any ports except port 5. Use Cmask=1 for active cycles; Cmask=0 for weighted cycles; Use CMask=1, Invert=1 to count P0-4 stalled cycles Use Cmask=1, Edge=1, Invert=1 to count P0-4 stalls.	
B1H	20H	UOPS_EXECUTED.PORT5	Counts number of Uops executed that where issued on port 5.	
B1H	3FH	UOPS_EXECUTED.CORE_ACTIV E_CYCLES	Counts cycles when the Uops are executing . Use Cmask=1 for active cycles; Cmask=0 for weighted cycles; Use CMask=1, Invert=1 to count P0-4 stalled cycles Use Cmask=1, Edge=1, Invert=1 to count P0-4 stalls.	
B1H	40H	UOPS_EXECUTED.PORT015	Counts number of Uops executed that where issued on port 0, 1, or 5.	use cmask=1, invert=1 to count stall cycles
B1H	80H	UOPS_EXECUTED.PORT234	Counts number of Uops executed that where issued on port 2, 3, or 4.	
B2H	01H	OFFCORE_REQUESTS_SQ_FUL L	Counts number of cycles the SQ is full to handle off-core requests.	
B7H	01H	OFF_CORE_RESPONSE_0	see Section 18.7.1.3, "Off-core Response Performance Monitoring in the Processor Core".	Requires programming MSR 01A6H
B8H	01H	SNOOP_RESPONSE.HIT	Counts HIT snoop response sent by this thread in response to a snoop request.	
B8H	02H	SNOOP_RESPONSE.HITE	Counts HIT E snoop response sent by this thread in response to a snoop request.	
B8H	04H	SNOOP_RESPONSE.HITM	Counts HIT M snoop response sent by this thread in response to a snoop request.	
BBH	01H	OFF_CORE_RESPONSE_1	See Section 18.8, "Performance Monitoring for Processors Based on Intel® Microarchitecture Code Name Westmere".	Requires programming MSR 01A7H
COH	00H	INST_RETIRED.ANY_P	See Table 19-1 Notes: INST_RETIRED.ANY is counted by a designated fixed counter. INST_RETIRED.ANY_P is counted by a programmable counter and is an architectural performance event. Event is supported if CPUID.A.EBX[1] = 0.	Counting: Faulting executions of GETSEC/VM entry/VM Exit/MWait will not count as retired instructions.
COH	02H	INST_RETIRED.X87	Counts the number of MMX instructions retired.	
COH	04H	INST_RETIRED.MMX	Counts the number of floating point computational operations retired: floating point computational operations executed by the assist handler and sub-operations of complex floating point instructions like transcendental instructions.	

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
C2H	01H	UOPS_RETIRED.ANY	Counts the number of micro-ops retired, (macro-fused=1, micro-fused=2, others=1; maximum count of 8 per cycle). Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists.	Use cmask=1 and invert to count active cycles or stalled cycles
C2H	02H	UOPS_RETIRED.RETIRE_SLOTS	Counts the number of retirement slots used each cycle.	
C2H	04H	UOPS_RETIRED.MACRO_FUSED	Counts number of macro-fused uops retired.	
C3H	01H	MACHINE_CLEAR.CYCLES	Counts the cycles machine clear is asserted.	
C3H	02H	MACHINE_CLEAR.MEM_ORDER	Counts the number of machine clears due to memory order conflicts.	
C3H	04H	MACHINE_CLEAR.SMC	Counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel 64 and IA-32 processors. The modified cache line is written back to the L2 and L3 caches.	
C4H	00H	BR_INST_RETIRED.ALL_BRANCHES	Branch instructions at retirement	See Table 19-1
C4H	01H	BR_INST_RETIRED.CONDITIONAL	Counts the number of conditional branch instructions retired.	
C4H	02H	BR_INST_RETIRED.NEAR_CALL	Counts the number of direct & indirect near unconditional calls retired.	
C5H	00H	BR_MISP_RETIRED.ALL_BRANCHES	Mispredicted branch instructions at retirement	See Table 19-1
C5H	02H	BR_MISP_RETIRED.NEAR_CALL	Counts mispredicted direct & indirect near unconditional retired calls.	
C7H	01H	SSEX_UOPS_RETIRED.PACKED_SINGLE	Counts SIMD packed single-precision floating point Uops retired.	
C7H	02H	SSEX_UOPS_RETIRED.SCALAR_SINGLE	Counts SIMD scalar single-precision floating point Uops retired.	
C7H	04H	SSEX_UOPS_RETIRED.PACKED_DOUBLE	Counts SIMD packed double-precision floating point Uops retired.	
C7H	08H	SSEX_UOPS_RETIRED.SCALAR_DOUBLE	Counts SIMD scalar double-precision floating point Uops retired.	
C7H	10H	SSEX_UOPS_RETIRED.VECTOR_INTEGER	Counts 128-bit SIMD vector integer Uops retired.	
C8H	20H	ITLB_MISS_RETIRED	Counts the number of retired instructions that missed the ITLB when the instruction was fetched.	
CBH	01H	MEM_LOAD_RETIRED.L1D_HIT	Counts number of retired loads that hit the L1 data cache.	
CBH	02H	MEM_LOAD_RETIRED.L2_HIT	Counts number of retired loads that hit the L2 data cache.	
CBH	04H	MEM_LOAD_RETIRED.L3_UNSHARED_HIT	Counts number of retired loads that hit their own, unshared lines in the L3 cache.	

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
CBH	08H	MEM_LOAD_RETIRED.OTHER_CORE_L2_HIT_HITM	Counts number of retired loads that hit in a sibling core's L2 (on die core). Since the L3 is inclusive of all cores on the package, this is an L3 hit. This counts both clean or modified hits.	
CBH	10H	MEM_LOAD_RETIRED.L3_MISS	Counts number of retired loads that miss the L3 cache. The load was satisfied by a remote socket, local memory or an IOH.	
CBH	40H	MEM_LOAD_RETIRED.HIT_LFB	Counts number of retired loads that miss the L1D and the address is located in an allocated line fill buffer and will soon be committed to cache. This is counting secondary L1D misses.	
CBH	80H	MEM_LOAD_RETIRED.DTLB_MISS	Counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault. This event counts loads from cacheable memory only. The event does not count loads by software prefetches. Counts both primary and secondary misses to the TLB.	
CCH	01H	FP_MMX_TRANS.TO_FP	Counts the first floating-point instruction following any MMX instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.	
CCH	02H	FP_MMX_TRANS.TO_MMX	Counts the first MMX instruction following a floating-point instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.	
CCH	03H	FP_MMX_TRANS.ANY	Counts all transitions from floating point to MMX instructions and from MMX instructions to floating point instructions. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.	
D0H	01H	MACRO_INSTS.DECODED	Counts the number of instructions decoded, (but not necessarily executed or retired).	
D1H	02H	UOPS_DECODED.MS	Counts the number of Uops decoded by the Microcode Sequencer, MS. The MS delivers uops when the instruction is more than 4 uops long or a microcode assist is occurring.	
D1H	04H	UOPS_DECODED.ESP_FOLDING	Counts number of stack pointer (ESP) instructions decoded: push , pop , call , ret, etc. ESP instructions do not generate a Uop to increment or decrement ESP. Instead, they update an ESP_Offset register that keeps track of the delta to the current value of the ESP register.	
D1H	08H	UOPS_DECODED.ESP_SYNC	Counts number of stack pointer (ESP) sync operations where an ESP instruction is corrected by adding the ESP offset register to the current value of the ESP register.	

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
D2H	01H	RAT_STALLS.FLAGS	Counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall. A partial register stall may occur when two conditions are met: 1) an instruction modifies some, but not all, of the flags in the flag register and 2) the next instruction, which depends on flags, depends on flags that were not modified by this instruction.	
D2H	02H	RAT_STALLS.REGISTERS	This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction used a register that was partially written by previous instruction.	
D2H	04H	RAT_STALLS.ROB_READ_PORT	Counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline. Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read port stall is counted again.	
D2H	08H	RAT_STALLS.SCOREBOARD	Counts the cycles where we stall due to microarchitecturally required serialization. Microcode scoreboarding stalls.	
D2H	0FH	RAT_STALLS.ANY	Counts all Register Allocation Table stall cycles due to: Cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the execution pipe. Cycles when partial register stalls occurred Cycles when flag stalls occurred Cycles floating-point unit (FPU) status word stalls occurred. To count each of these conditions separately use the events: RAT_STALLS.ROB_READ_PORT, RAT_STALLS.PARTIAL, RAT_STALLS.FLAGS, and RAT_STALLS.FPSW.	
D4H	01H	SEG_RENAME_STALLS	Counts the number of stall cycles due to the lack of renaming resources for the ES, DS, FS, and GS segment registers. If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.	
D5H	01H	ES_REG_RENAMES	Counts the number of times the ES segment register is renamed.	
DBH	01H	UOP_UNFUSION	Counts unfusion events due to floating point exception to a fused uop.	
E0H	01H	BR_INST_DECODED	Counts the number of branch instructions decoded.	
E5H	01H	BPU_MISSED_CALL_RET	Counts number of times the Branch Prediction Unit missed predicting a call or return branch.	

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
E6H	01H	BACLEAR.CLEAR	Counts the number of times the front end is resteeered, mainly when the Branch Prediction Unit cannot provide a correct prediction and this is corrected by the Branch Address Calculator at the front end. This can occur if the code has many branches such that they cannot be consumed by the BPU. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. The effect on total execution time depends on the surrounding code.	
E6H	02H	BACLEAR.BAD_TARGET	Counts number of Branch Address Calculator clears (BACLEAR) asserted due to conditional branch instructions in which there was a target hit but the direction was wrong. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline.	
E8H	01H	BPU_CLEARS.EARLY	Counts early (normal) Branch Prediction Unit clears: BPU predicted a taken branch after incorrectly assuming that it was not taken.	The BPU clear leads to 2 cycle bubble in the Front End.
E8H	02H	BPU_CLEARS.LATE	Counts late Branch Prediction Unit clears due to Most Recently Used conflicts. The PBU clear leads to a 3 cycle bubble in the Front End.	
F0H	01H	L2_TRANSACTIONS.LOAD	Counts L2 load operations due to HW prefetch or demand loads.	
F0H	02H	L2_TRANSACTIONS.RFO	Counts L2 RFO operations due to HW prefetch or demand RFOs.	
F0H	04H	L2_TRANSACTIONS.IFETCH	Counts L2 instruction fetch operations due to HW prefetch or demand ifetch.	
F0H	08H	L2_TRANSACTIONS.PREFETCH	Counts L2 prefetch operations.	
F0H	10H	L2_TRANSACTIONS.L1D_WB	Counts L1D writeback operations to the L2.	
F0H	20H	L2_TRANSACTIONS.FILL	Counts L2 cache line fill operations due to load, RFO, L1D writeback or prefetch.	
F0H	40H	L2_TRANSACTIONS.WB	Counts L2 writeback operations to the L3.	
F0H	80H	L2_TRANSACTIONS.ANY	Counts all L2 cache operations.	
F1H	02H	L2_LINES_IN.S_STATE	Counts the number of cache lines allocated in the L2 cache in the S (shared) state.	
F1H	04H	L2_LINES_IN.E_STATE	Counts the number of cache lines allocated in the L2 cache in the E (exclusive) state.	
F1H	07H	L2_LINES_IN.ANY	Counts the number of cache lines allocated in the L2 cache.	
F2H	01H	L2_LINES_OUT.DEMAND_CLEAN	Counts L2 clean cache lines evicted by a demand request.	
F2H	02H	L2_LINES_OUT.DEMAND_DIRTY	Counts L2 dirty (modified) cache lines evicted by a demand request.	
F2H	04H	L2_LINES_OUT.PREFETCH_CLEAN	Counts L2 clean cache line evicted by a prefetch request.	

**Table 19-11. Non-Architectural Performance Events In the Processor Core for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
F2H	08H	L2_LINES_OUT.PREFETCH_DIRECTORY	Counts L2 modified cache line evicted by a prefetch request.	
F2H	0FH	L2_LINES_OUT.ANY	Counts all L2 cache lines evicted for any reason.	
F4H	10H	SQ_MISC.SPLIT_LOCK	Counts the number of SQ lock splits across a cache line.	
F6H	01H	SQ_FULL_STALL_CYCLES	Counts cycles the Super Queue is full. Neither of the threads on this core will be able to access the uncore.	
F7H	01H	FP_ASSIST.ALL	Counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases: SSE instructions, (Denormal input when the DAZ flag is off or Underflow result when the FTZ flag is off); x87 instructions, (NaN or denormal are loaded to a register or used as input from memory, Division by 0 or Underflow output).	
F7H	02H	FP_ASSIST.OUTPUT	Counts number of floating point micro-code assist when the output value (destination register) is invalid.	
F7H	04H	FP_ASSIST.INPUT	Counts number of floating point micro-code assist when the input value (one of the source operands to an FP instruction) is invalid.	
FDH	01H	SIMD_INT_64.PACKED_MPY	Counts number of SIMD integer 64 bit packed multiply operations.	
FDH	02H	SIMD_INT_64.PACKED_SHIFT	Counts number of SIMD integer 64 bit packed shift operations.	
FDH	04H	SIMD_INT_64.PACK	Counts number of SIMD integer 64 bit pack operations.	
FDH	08H	SIMD_INT_64.UNPACK	Counts number of SIMD integer 64 bit unpack operations.	
FDH	10H	SIMD_INT_64.PACKED_LOGICAL	Counts number of SIMD integer 64 bit logical operations.	
FDH	20H	SIMD_INT_64.PACKED_ARITH	Counts number of SIMD integer 64 bit arithmetic operations.	
FDH	40H	SIMD_INT_64.SHUFFLE_MOVE	Counts number of SIMD integer 64 bit shift or move operations.	

Non-architectural Performance monitoring events that are located in the uncore sub-system are implementation specific between different platforms using processors based on Intel microarchitecture code name Nehalem. Processors with CPUID signature of DisplayFamily\_DisplayModel 06\_1AH, 06\_1EH, and 06\_1FH support performance events listed in Table 19-12.

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
00H	01H	UNC_GQ_CYCLES_FULL.READ_TRACKER	Uncore cycles Global Queue read tracker is full.	
00H	02H	UNC_GQ_CYCLES_FULL.WRITE_TRACKER	Uncore cycles Global Queue write tracker is full.	
00H	04H	UNC_GQ_CYCLES_FULL.PEER_PROBE_TRACKER	Uncore cycles Global Queue peer probe tracker is full. The peer probe tracker queue tracks snoops from the IOH and remote sockets.	
01H	01H	UNC_GQ_CYCLES_NOT_EMPTY.READ_TRACKER	Uncore cycles were Global Queue read tracker has at least one valid entry.	
01H	02H	UNC_GQ_CYCLES_NOT_EMPTY.WRITE_TRACKER	Uncore cycles were Global Queue write tracker has at least one valid entry.	
01H	04H	UNC_GQ_CYCLES_NOT_EMPTY.PEER_PROBE_TRACKER	Uncore cycles were Global Queue peer probe tracker has at least one valid entry. The peer probe tracker queue tracks IOH and remote socket snoops.	
03H	01H	UNC_GQ_ALLOC.READ_TRACKER	Counts the number of read tracker allocate to deallocate entries. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency.	
03H	02H	UNC_GQ_ALLOC.RT_L3_MISS	Counts the number GQ read tracker entries for which a full cache line read has missed the L3. The GQ read tracker L3 miss to fill occupancy count is divided by this count to obtain the average cache line read L3 miss latency. The latency represents the time after which the L3 has determined that the cache line has missed. The time between a GQ read tracker allocation and the L3 determining that the cache line has missed is the average L3 hit latency. The total L3 cache line read miss latency is the hit latency + L3 miss latency.	
03H	04H	UNC_GQ_ALLOC.RT_TO_L3_RESP	Counts the number of GQ read tracker entries that are allocated in the read tracker queue that hit or miss the L3. The GQ read tracker L3 hit occupancy count is divided by this count to obtain the average L3 hit latency.	
03H	08H	UNC_GQ_ALLOC.RT_TO_RTID_ACQUIRED	Counts the number of GQ read tracker entries that are allocated in the read tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ read tracker L3 miss to RTID acquired occupancy count is divided by this count to obtain the average latency for a read L3 miss to acquire an RTID.	
03H	10H	UNC_GQ_ALLOC.WT_TO_RTID_ACQUIRED	Counts the number of GQ write tracker entries that are allocated in the write tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ write tracker L3 miss to RTID occupancy count is divided by this count to obtain the average latency for a write L3 miss to acquire an RTID.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
03H	20H	UNC_GQ_ALLOC.WRITE_TRACKER	Counts the number of GQ write tracker entries that are allocated in the write tracker queue that miss the L3. The GQ write tracker occupancy count is divided by this count to obtain the average L3 write miss latency.	
03H	40H	UNC_GQ_ALLOC.PEER_PROBE_TRACKER	Counts the number of GQ peer probe tracker (snoop) entries that are allocated in the peer probe tracker queue that miss the L3. The GQ peer probe occupancy count is divided by this count to obtain the average L3 peer probe miss latency.	
04H	01H	UNC_GQ_DATA.FROM_QPI	Cycles Global Queue Quickpath Interface input data port is busy importing data from the Quickpath Interface. Each cycle the input port can transfer 8 or 16 bytes of data.	
04H	02H	UNC_GQ_DATA.FROM_QMC	Cycles Global Queue Quickpath Memory Interface input data port is busy importing data from the Quickpath Memory Interface. Each cycle the input port can transfer 8 or 16 bytes of data.	
04H	04H	UNC_GQ_DATA.FROM_L3	Cycles GQ L3 input data port is busy importing data from the Last Level Cache. Each cycle the input port can transfer 32 bytes of data.	
04H	08H	UNC_GQ_DATA.FROM_CORES_02	Cycles GQ Core 0 and 2 input data port is busy importing data from processor cores 0 and 2. Each cycle the input port can transfer 32 bytes of data.	
04H	10H	UNC_GQ_DATA.FROM_CORES_13	Cycles GQ Core 1 and 3 input data port is busy importing data from processor cores 1 and 3. Each cycle the input port can transfer 32 bytes of data.	
05H	01H	UNC_GQ_DATA.TO_QPI_QMC	Cycles GQ QPI and QMC output data port is busy sending data to the Quickpath Interface or Quickpath Memory Interface. Each cycle the output port can transfer 32 bytes of data.	
05H	02H	UNC_GQ_DATA.TO_L3	Cycles GQ L3 output data port is busy sending data to the Last Level Cache. Each cycle the output port can transfer 32 bytes of data.	
05H	04H	UNC_GQ_DATA.TO_CORES	Cycles GQ Core output data port is busy sending data to the Cores. Each cycle the output port can transfer 32 bytes of data.	
06H	01H	UNC_SNP_RESP_TO_LOCAL_HOME.I_STATE	Number of snoop responses to the local home that L3 does not have the referenced cache line.	
06H	02H	UNC_SNP_RESP_TO_LOCAL_HOME.S_STATE	Number of snoop responses to the local home that L3 has the referenced line cached in the S state.	
06H	04H	UNC_SNP_RESP_TO_LOCAL_HOME.FWD_S_STATE	Number of responses to code or data read snoops to the local home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the local home in the S state.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
06H	08H	UNC_SNP_RESP_TO_LOCAL_HOME.FWD_I_STATE	Number of responses to read invalidate snoops to the local home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the local home in the M state.	
06H	10H	UNC_SNP_RESP_TO_LOCAL_HOME.CONFLICT	Number of conflict snoop responses sent to the local home.	
06H	20H	UNC_SNP_RESP_TO_LOCAL_HOME.WB	Number of responses to code or data read snoops to the local home that the L3 has the referenced line cached in the M state.	
07H	01H	UNC_SNP_RESP_TO_REMOTE_HOME.I_STATE	Number of snoop responses to a remote home that L3 does not have the referenced cache line.	
07H	02H	UNC_SNP_RESP_TO_REMOTE_HOME.S_STATE	Number of snoop responses to a remote home that L3 has the referenced line cached in the S state.	
07H	04H	UNC_SNP_RESP_TO_REMOTE_HOME.FWD_S_STATE	Number of responses to code or data read snoops to a remote home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the remote home in the S state.	
07H	08H	UNC_SNP_RESP_TO_REMOTE_HOME.FWD_I_STATE	Number of responses to read invalidate snoops to a remote home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the remote home in the M state.	
07H	10H	UNC_SNP_RESP_TO_REMOTE_HOME.CONFLICT	Number of conflict snoop responses sent to the local home.	
07H	20H	UNC_SNP_RESP_TO_REMOTE_HOME.WB	Number of responses to code or data read snoops to a remote home that the L3 has the referenced line cached in the M state.	
07H	24H	UNC_SNP_RESP_TO_REMOTE_HOME.HITM	Number of HITM snoop responses to a remote home	
08H	01H	UNC_L3_HITS.READ	Number of code read, data read and RFO requests that hit in the L3	
08H	02H	UNC_L3_HITS.WRITE	Number of writeback requests that hit in the L3. Writebacks from the cores will always result in L3 hits due to the inclusive property of the L3.	
08H	04H	UNC_L3_HITS.PROBE	Number of snoops from IOH or remote sockets that hit in the L3.	
08H	03H	UNC_L3_HITS.ANY	Number of reads and writes that hit the L3.	
09H	01H	UNC_L3_MISS.READ	Number of code read, data read and RFO requests that miss the L3.	
09H	02H	UNC_L3_MISS.WRITE	Number of writeback requests that miss the L3. Should always be zero as writebacks from the cores will always result in L3 hits due to the inclusive property of the L3.	
09H	04H	UNC_L3_MISS.PROBE	Number of snoops from IOH or remote sockets that miss the L3.	
09H	03H	UNC_L3_MISS.ANY	Number of reads and writes that miss the L3.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
0AH	01H	UNC_L3_LINES_IN.M_STATE	Counts the number of L3 lines allocated in M state. The only time a cache line is allocated in the M state is when the line was forwarded in M state is forwarded due to a Snoop Read Invalidate Own request.	
0AH	02H	UNC_L3_LINES_IN.E_STATE	Counts the number of L3 lines allocated in E state.	
0AH	04H	UNC_L3_LINES_IN.S_STATE	Counts the number of L3 lines allocated in S state.	
0AH	08H	UNC_L3_LINES_IN.F_STATE	Counts the number of L3 lines allocated in F state.	
0AH	0FH	UNC_L3_LINES_IN.ANY	Counts the number of L3 lines allocated in any state.	
0BH	01H	UNC_L3_LINES_OUT.M_STATE	Counts the number of L3 lines victimized that were in the M state. When the victim cache line is in M state, the line is written to its home cache agent which can be either local or remote.	
0BH	02H	UNC_L3_LINES_OUT.E_STATE	Counts the number of L3 lines victimized that were in the E state.	
0BH	04H	UNC_L3_LINES_OUT.S_STATE	Counts the number of L3 lines victimized that were in the S state.	
0BH	08H	UNC_L3_LINES_OUT.I_STATE	Counts the number of L3 lines victimized that were in the I state.	
0BH	10H	UNC_L3_LINES_OUT.F_STATE	Counts the number of L3 lines victimized that were in the F state.	
0BH	1FH	UNC_L3_LINES_OUT.ANY	Counts the number of L3 lines victimized in any state.	
20H	01H	UNC_QHL_REQUESTS.IOH_READS	Counts number of Quickpath Home Logic read requests from the IOH.	
20H	02H	UNC_QHL_REQUESTS.IOH_WRITES	Counts number of Quickpath Home Logic write requests from the IOH.	
20H	04H	UNC_QHL_REQUESTS.REMOTE_READS	Counts number of Quickpath Home Logic read requests from a remote socket.	
20H	08H	UNC_QHL_REQUESTS.REMOTE_WRITES	Counts number of Quickpath Home Logic write requests from a remote socket.	
20H	10H	UNC_QHL_REQUESTS.LOCAL_READS	Counts number of Quickpath Home Logic read requests from the local socket.	
20H	20H	UNC_QHL_REQUESTS.LOCAL_WRITES	Counts number of Quickpath Home Logic write requests from the local socket.	
21H	01H	UNC_QHL_CYCLES_FULL.IOH	Counts uclk cycles all entries in the Quickpath Home Logic IOH are full.	
21H	02H	UNC_QHL_CYCLES_FULL.REMOTE	Counts uclk cycles all entries in the Quickpath Home Logic remote tracker are full.	
21H	04H	UNC_QHL_CYCLES_FULL.LOCAL	Counts uclk cycles all entries in the Quickpath Home Logic local tracker are full.	
22H	01H	UNC_QHL_CYCLES_NOT_EMPTY.IOH	Counts uclk cycles all entries in the Quickpath Home Logic IOH is busy.	
22H	02H	UNC_QHL_CYCLES_NOT_EMPTY.REMOTE	Counts uclk cycles all entries in the Quickpath Home Logic remote tracker is busy.	
22H	04H	UNC_QHL_CYCLES_NOT_EMPTY.LOCAL	Counts uclk cycles all entries in the Quickpath Home Logic local tracker is busy.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
23H	01H	UNC_QHL_OCCUPANCY.IOH	QHL IOH tracker allocate to deallocate read occupancy.	
23H	02H	UNC_QHL_OCCUPANCY.REMOTE	QHL remote tracker allocate to deallocate read occupancy.	
23H	04H	UNC_QHL_OCCUPANCY.LOCAL	QHL local tracker allocate to deallocate read occupancy.	
24H	02H	UNC_QHL_ADDRESS_CONFLICTS.2WAY	Counts number of QHL Active Address Table (AAT) entries that saw a max of 2 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates.	
24H	04H	UNC_QHL_ADDRESS_CONFLICTS.3WAY	Counts number of QHL Active Address Table (AAT) entries that saw a max of 3 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates.	
25H	01H	UNC_QHL_CONFLICT_CYCLES.IOH	Counts cycles the Quickpath Home Logic IOH Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.	
25H	02H	UNC_QHL_CONFLICT_CYCLES.REMOTE	Counts cycles the Quickpath Home Logic Remote Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.	
25H	04H	UNC_QHL_CONFLICT_CYCLES.LOCAL	Counts cycles the Quickpath Home Logic Local Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.	
26H	01H	UNC_QHL_TO_QMC_BYPASS	Counts number or requests to the Quickpath Memory Controller that bypass the Quickpath Home Logic. All local accesses can be bypassed. For remote requests, only read requests can be bypassed.	
27H	01H	UNC_QMC_NORMAL_FULL.READ.CH0	Uncore cycles all the entries in the DRAM channel 0 medium or low priority queue are occupied with read requests.	
27H	02H	UNC_QMC_NORMAL_FULL.READ.CH1	Uncore cycles all the entries in the DRAM channel 1 medium or low priority queue are occupied with read requests.	
27H	04H	UNC_QMC_NORMAL_FULL.READ.CH2	Uncore cycles all the entries in the DRAM channel 2 medium or low priority queue are occupied with read requests.	
27H	08H	UNC_QMC_NORMAL_FULL.WRITE.CH0	Uncore cycles all the entries in the DRAM channel 0 medium or low priority queue are occupied with write requests.	
27H	10H	UNC_QMC_NORMAL_FULL.WRITE.CH1	Counts cycles all the entries in the DRAM channel 1 medium or low priority queue are occupied with write requests.	
27H	20H	UNC_QMC_NORMAL_FULL.WRITE.CH2	Uncore cycles all the entries in the DRAM channel 2 medium or low priority queue are occupied with write requests.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
28H	01H	UNC_QMC_ISOC_FULL.READ.C H0	Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous read requests.	
28H	02H	UNC_QMC_ISOC_FULL.READ.C H1	Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous read requests.	
28H	04H	UNC_QMC_ISOC_FULL.READ.C H2	Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous read requests.	
28H	08H	UNC_QMC_ISOC_FULL.WRITE.C H0	Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous write requests.	
28H	10H	UNC_QMC_ISOC_FULL.WRITE.C H1	Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous write requests.	
28H	20H	UNC_QMC_ISOC_FULL.WRITE.C H2	Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous write requests.	
29H	01H	UNC_QMC_BUSY.READ.CHO	Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 0.	
29H	02H	UNC_QMC_BUSY.READ.CH1	Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 1.	
29H	04H	UNC_QMC_BUSY.READ.CH2	Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 2.	
29H	08H	UNC_QMC_BUSY.WRITE.CHO	Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 0.	
29H	10H	UNC_QMC_BUSY.WRITE.CH1	Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 1.	
29H	20H	UNC_QMC_BUSY.WRITE.CH2	Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 2.	
2AH	01H	UNC_QMC_OCCUPANCY.CHO	IMC channel 0 normal read request occupancy.	
2AH	02H	UNC_QMC_OCCUPANCY.CH1	IMC channel 1 normal read request occupancy.	
2AH	04H	UNC_QMC_OCCUPANCY.CH2	IMC channel 2 normal read request occupancy.	
2BH	01H	UNC_QMC_ISSOC_OCCUPANCY.CHO	IMC channel 0 issoc read request occupancy.	
2BH	02H	UNC_QMC_ISSOC_OCCUPANCY.CH1	IMC channel 1 issoc read request occupancy.	
2BH	04H	UNC_QMC_ISSOC_OCCUPANCY.CH2	IMC channel 2 issoc read request occupancy.	
2BH	07H	UNC_QMC_ISSOC_READS.ANY	IMC issoc read request occupancy.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
2CH	01H	UNC_QMC_NORMAL_READS.CH0	Counts the number of Quickpath Memory Controller channel 0 medium and low priority read requests. The QMC channel 0 normal read occupancy divided by this count provides the average QMC channel 0 read latency.	
2CH	02H	UNC_QMC_NORMAL_READS.CH1	Counts the number of Quickpath Memory Controller channel 1 medium and low priority read requests. The QMC channel 1 normal read occupancy divided by this count provides the average QMC channel 1 read latency.	
2CH	04H	UNC_QMC_NORMAL_READS.CH2	Counts the number of Quickpath Memory Controller channel 2 medium and low priority read requests. The QMC channel 2 normal read occupancy divided by this count provides the average QMC channel 2 read latency.	
2CH	07H	UNC_QMC_NORMAL_READS.ANY	Counts the number of Quickpath Memory Controller medium and low priority read requests. The QMC normal read occupancy divided by this count provides the average QMC read latency.	
2DH	01H	UNC_QMC_HIGH_PRIORITY_READS.CH0	Counts the number of Quickpath Memory Controller channel 0 high priority isochronous read requests.	
2DH	02H	UNC_QMC_HIGH_PRIORITY_READS.CH1	Counts the number of Quickpath Memory Controller channel 1 high priority isochronous read requests.	
2DH	04H	UNC_QMC_HIGH_PRIORITY_READS.CH2	Counts the number of Quickpath Memory Controller channel 2 high priority isochronous read requests.	
2DH	07H	UNC_QMC_HIGH_PRIORITY_READS.ANY	Counts the number of Quickpath Memory Controller high priority isochronous read requests.	
2EH	01H	UNC_QMC_CRITICAL_PRIORITY_READS.CH0	Counts the number of Quickpath Memory Controller channel 0 critical priority isochronous read requests.	
2EH	02H	UNC_QMC_CRITICAL_PRIORITY_READS.CH1	Counts the number of Quickpath Memory Controller channel 1 critical priority isochronous read requests.	
2EH	04H	UNC_QMC_CRITICAL_PRIORITY_READS.CH2	Counts the number of Quickpath Memory Controller channel 2 critical priority isochronous read requests.	
2EH	07H	UNC_QMC_CRITICAL_PRIORITY_READS.ANY	Counts the number of Quickpath Memory Controller critical priority isochronous read requests.	
2FH	01H	UNC_QMC_WRITES.FULL.CH0	Counts number of full cache line writes to DRAM channel 0.	
2FH	02H	UNC_QMC_WRITES.FULL.CH1	Counts number of full cache line writes to DRAM channel 1.	
2FH	04H	UNC_QMC_WRITES.FULL.CH2	Counts number of full cache line writes to DRAM channel 2.	
2FH	07H	UNC_QMC_WRITES.FULL.ANY	Counts number of full cache line writes to DRAM.	
2FH	08H	UNC_QMC_WRITES.PARTIAL.CH0	Counts number of partial cache line writes to DRAM channel 0.	
2FH	10H	UNC_QMC_WRITES.PARTIAL.CH1	Counts number of partial cache line writes to DRAM channel 1.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
2FH	20H	UNC_QMC_WRITES.PARTIAL.CH2	Counts number of partial cache line writes to DRAM channel 2.	
2FH	38H	UNC_QMC_WRITES.PARTIAL.ANY	Counts number of partial cache line writes to DRAM.	
30H	01H	UNC_QMC_CANCEL.CH0	Counts number of DRAM channel 0 cancel requests.	
30H	02H	UNC_QMC_CANCEL.CH1	Counts number of DRAM channel 1 cancel requests.	
30H	04H	UNC_QMC_CANCEL.CH2	Counts number of DRAM channel 2 cancel requests.	
30H	07H	UNC_QMC_CANCEL.ANY	Counts number of DRAM cancel requests.	
31H	01H	UNC_QMC_PRIORITY_UPDATE.S.CH0	Counts number of DRAM channel 0 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.	
31H	02H	UNC_QMC_PRIORITY_UPDATE.S.CH1	Counts number of DRAM channel 1 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.	
31H	04H	UNC_QMC_PRIORITY_UPDATE.S.CH2	Counts number of DRAM channel 2 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.	
31H	07H	UNC_QMC_PRIORITY_UPDATE.S.ANY	Counts number of DRAM priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.	
33H	04H	UNC_QHL_FRC_ACK_CNFLTS.LOCAL	Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the local home.	
40H	01H	UNC_QPI_TX_STALLED_SINGLE_FLIT.HOME.LINK_0	Counts cycles the Quickpath outbound link 0 HOME virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	02H	UNC_QPI_TX_STALLED_SINGLE_FLIT.SNOOP.LINK_0	Counts cycles the Quickpath outbound link 0 SNOOP virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
40H	04H	UNC_QPI_TX_STALLED_SINGLE_FLIT.NDR.LINK_0	Counts cycles the Quickpath outbound link 0 non-data response virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	08H	UNC_QPI_TX_STALLED_SINGLE_FLIT.HOME.LINK_1	Counts cycles the Quickpath outbound link 1 HOME virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	10H	UNC_QPI_TX_STALLED_SINGLE_FLIT.SNOOP.LINK_1	Counts cycles the Quickpath outbound link 1 SNOOP virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	20H	UNC_QPI_TX_STALLED_SINGLE_FLIT.NDR.LINK_1	Counts cycles the Quickpath outbound link 1 non-data response virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	07H	UNC_QPI_TX_STALLED_SINGLE_FLIT.LINK_0	Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	38H	UNC_QPI_TX_STALLED_SINGLE_FLIT.LINK_1	Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	01H	UNC_QPI_TX_STALLED_MULTIFLIT.DRS.LINK_0	Counts cycles the Quickpath outbound link 0 Data ResponSe virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	02H	UNC_QPI_TX_STALLED_MULTIFLIT.NCB.LINK_0	Counts cycles the Quickpath outbound link 0 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	04H	UNC_QPI_TX_STALLED_MULTIFLIT.NCS.LINK_0	Counts cycles the Quickpath outbound link 0 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
41H	08H	UNC_QPI_TX_STALLED_MULTIFLIT.DRS.LINK_1	Counts cycles the Quickpath outbound link 1 Data ResponSe virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	10H	UNC_QPI_TX_STALLED_MULTIFLIT.NCB.LINK_1	Counts cycles the Quickpath outbound link 1 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	20H	UNC_QPI_TX_STALLED_MULTIFLIT.NCS.LINK_1	Counts cycles the Quickpath outbound link 1 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	07H	UNC_QPI_TX_STALLED_MULTIFLIT.LINK_0	Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	38H	UNC_QPI_TX_STALLED_MULTIFLIT.LINK_1	Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
42H	02H	UNC_QPI_TX_HEADER.BUSY.LINK_0	Number of cycles that the header buffer in the Quickpath Interface outbound link 0 is busy.	
42H	08H	UNC_QPI_TX_HEADER.BUSY.LINK_1	Number of cycles that the header buffer in the Quickpath Interface outbound link 1 is busy.	
43H	01H	UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_0	Number of cycles that snoop packets incoming to the Quickpath Interface link 0 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries.	
43H	02H	UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_1	Number of cycles that snoop packets incoming to the Quickpath Interface link 1 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries.	
60H	01H	UNC_DRAM_OPEN.CH0	Counts number of DRAM Channel 0 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.	
60H	02H	UNC_DRAM_OPEN.CH1	Counts number of DRAM Channel 1 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.	
60H	04H	UNC_DRAM_OPEN.CH2	Counts number of DRAM Channel 2 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
61H	01H	UNC_DRAM_PAGE_CLOSE.CH0	DRAM channel 0 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.	
61H	02H	UNC_DRAM_PAGE_CLOSE.CH1	DRAM channel 1 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.	
61H	04H	UNC_DRAM_PAGE_CLOSE.CH2	DRAM channel 2 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.	
62H	01H	UNC_DRAM_PAGE_MISS.CH0	Counts the number of precharges (PRE) that were issued to DRAM channel 0 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge.	
62H	02H	UNC_DRAM_PAGE_MISS.CH1	Counts the number of precharges (PRE) that were issued to DRAM channel 1 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge.	
62H	04H	UNC_DRAM_PAGE_MISS.CH2	Counts the number of precharges (PRE) that were issued to DRAM channel 2 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge.	
63H	01H	UNC_DRAM_READ_CAS.CH0	Counts the number of times a read CAS command was issued on DRAM channel 0.	
63H	02H	UNC_DRAM_READ_CAS.AUTO PRE_CH0	Counts the number of times a read CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode.	
63H	04H	UNC_DRAM_READ_CAS.CH1	Counts the number of times a read CAS command was issued on DRAM channel 1.	
63H	08H	UNC_DRAM_READ_CAS.AUTO PRE_CH1	Counts the number of times a read CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode.	
63H	10H	UNC_DRAM_READ_CAS.CH2	Counts the number of times a read CAS command was issued on DRAM channel 2.	
63H	20H	UNC_DRAM_READ_CAS.AUTO PRE_CH2	Counts the number of times a read CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode.	
64H	01H	UNC_DRAM_WRITE_CAS.CH0	Counts the number of times a write CAS command was issued on DRAM channel 0.	

**Table 19-12. Non-Architectural Performance Events In the Processor Uncore for Intel® Core™ i7 Processor and Intel® Xeon® Processor 5500 Series (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
64H	02H	UNC_DRAM_WRITE_CAS.AUTO PRE_CH0	Counts the number of times a write CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode.	
64H	04H	UNC_DRAM_WRITE_CAS.CH1	Counts the number of times a write CAS command was issued on DRAM channel 1.	
64H	08H	UNC_DRAM_WRITE_CAS.AUTO PRE_CH1	Counts the number of times a write CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode.	
64H	10H	UNC_DRAM_WRITE_CAS.CH2	Counts the number of times a write CAS command was issued on DRAM channel 2.	
64H	20H	UNC_DRAM_WRITE_CAS.AUTO PRE_CH2	Counts the number of times a write CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode.	
65H	01H	UNC_DRAM_REFRESH.CH0	Counts number of DRAM channel 0 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.	
65H	02H	UNC_DRAM_REFRESH.CH1	Counts number of DRAM channel 1 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.	
65H	04H	UNC_DRAM_REFRESH.CH2	Counts number of DRAM channel 2 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.	
66H	01H	UNC_DRAM_PRE_ALL.CH0	Counts number of DRAM Channel 0 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode.	
66H	02H	UNC_DRAM_PRE_ALL.CH1	Counts number of DRAM Channel 1 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode.	
66H	04H	UNC_DRAM_PRE_ALL.CH2	Counts number of DRAM Channel 2 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode.	

Intel Xeon processors with CPUID signature of DisplayFamily\_DisplayModel 06\_2EH have a distinct uncore subsystem that is significantly different from the uncore found in processors with CPUID signature 06\_1AH, 06\_1EH, and 06\_1FH. Non-architectural Performance monitoring events for its uncore will be available in future documentation.

## 19.6 PERFORMANCE MONITORING EVENTS FOR PROCESSORS BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE

Intel 64 processors based on Intel® microarchitecture code name Westmere support the architectural and non-architectural performance-monitoring events listed in Table 19-1 and Table 19-13. Table 19-13 applies to processors with CPUID signature of DisplayFamily\_DisplayModel encoding with the following values: 06\_25H, 06\_2CH. In addition, these processors (CPUID signature of DisplayFamily\_DisplayModel 06\_25H, 06\_2CH) also support the following non-architectural, product-specific uncore performance-monitoring events listed in Table 19-14. Fixed counters support the architecture events defined in Table 19-16.

**Table 19-13. Non-Architectural Performance Events in the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
03H	02H	LOAD_BLOCK.OVERLAP_STORE	Loads that partially overlap an earlier store.	
04H	07H	SB_DRAIN.ANY	All Store buffer stall cycles.	
05H	02H	MISALIGN_MEMORY.STORE	All store referenced with misaligned address.	
06H	04H	STORE_BLOCKS.AT_RET	Counts number of loads delayed with at-Retirement block code. The following loads need to be executed at retirement and wait for all senior stores on the same thread to be drained: load splitting across 4K boundary (page split), load accessing uncacheable (UC or USWC) memory, load lock, and load with page table in UC or USWC memory region.	
06H	08H	STORE_BLOCKS.L1D_BLOCK	Cacheable loads delayed with L1D block code.	
07H	01H	PARTIAL_ADDRESS_ALIAS	Counts false dependency due to partial address aliasing.	
08H	01H	DTLB_LOAD_MISSES.ANY	Counts all load misses that cause a page walk.	
08H	02H	DTLB_LOAD_MISSES.WALK_COMPLETED	Counts number of completed page walks due to load miss in the STLB.	
08H	04H	DTLB_LOAD_MISSES.WALK_CYCLES	Cycles PMH is busy with a page walk due to a load miss in the STLB.	
08H	10H	DTLB_LOAD_MISSES.STLB_HIT	Number of cache load STLB hits.	
08H	20H	DTLB_LOAD_MISSES.PDE_MISSES	Number of DTLB cache load misses where the low part of the linear to physical address translation was missed.	
0BH	01H	MEM_INST_RETIRED.LOADS	Counts the number of instructions with an architecturally-visible load retired on the architected path.	
0BH	02H	MEM_INST_RETIRED.STORES	Counts the number of instructions with an architecturally-visible store retired on the architected path.	
0BH	10H	MEM_INST_RETIRED.LATENCY_ABOVE_THRESHOLD	Counts the number of instructions exceeding the latency specified with Id_lat facility.	In conjunction with Id_lat facility
0CH	01H	MEM_STORE_RETIRED.DTLB_MISS	The event counts the number of retired stores that missed the DTLB. The DTLB miss is not counted if the store operation causes a fault. Does not counter prefetches. Counts both primary and secondary misses to the TLB.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
0EH	01H	UOPS_ISSUED.ANY	Counts the number of Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end.	
0EH	01H	UOPS_ISSUED.STALLED_CYCLES	Counts the number of cycles no Uops issued by the Register Allocation Table to the Reservation Station, i.e. the UOPs issued from the front end to the back end.	set "invert=1, cmask = 1"
0EH	02H	UOPS_ISSUED.FUSED	Counts the number of fused Uops that were issued from the Register Allocation Table to the Reservation Station.	
0FH	01H	MEM_UNCORE_RETIRED.UNKNOWNSOURCE	Load instructions retired with unknown LLC miss (Precise Event).	Applicable to one and two sockets
0FH	02H	MEM_UNCORE_RETIRED.OTHER_CORE_L2_HIT	Load instructions retired that HIT modified data in sibling core (Precise Event).	Applicable to one and two sockets
0FH	04H	MEM_UNCORE_RETIRED.REMOTE_HITM	Load instructions retired that HIT modified data in remote socket (Precise Event).	Applicable to two sockets only
0FH	08H	MEM_UNCORE_RETIRED.LOCAL_DRAM_AND_REMOTE_CACHE_HIT	Load instructions retired local dram and remote cache HIT data sources (Precise Event).	Applicable to one and two sockets
0FH	10H	MEM_UNCORE_RETIRED.REMOTE_DRAM	Load instructions retired remote DRAM and remote home-remote cache HITM (Precise Event).	Applicable to two sockets only
0FH	20H	MEM_UNCORE_RETIRED.OTHER_LLC_MISS	Load instructions retired other LLC miss (Precise Event).	Applicable to two sockets only
0FH	80H	MEM_UNCORE_RETIRED.UNCACHEABLE	Load instructions retired I/O (Precise Event).	Applicable to one and two sockets
10H	01H	FP_COMP_OPS_EXE.X87	Counts the number of FP Computational Uops Executed. The number of FADD, FSUB, FCOM, FMULs, integer MULs and IMULs, FDIVs, FPREMs, FSQRTS, integer DIVs, and IDIVs. This event does not distinguish an FADD used in the middle of a transcendental flow from a separate FADD instruction.	
10H	02H	FP_COMP_OPS_EXE.MMX	Counts number of MMX Uops executed.	
10H	04H	FP_COMP_OPS_EXE.SSE_FP	Counts number of SSE and SSE2 FP uops executed.	
10H	08H	FP_COMP_OPS_EXE.SSE2_INTEGER	Counts number of SSE2 integer uops executed.	
10H	10H	FP_COMP_OPS_EXE.SSE_FP_PACKED	Counts number of SSE FP packed uops executed.	
10H	20H	FP_COMP_OPS_EXE.SSE_FP_SCALAR	Counts number of SSE FP scalar uops executed.	
10H	40H	FP_COMP_OPS_EXE.SSE_SINGLE_PRECISION	Counts number of SSE* FP single precision uops executed.	
10H	80H	FP_COMP_OPS_EXE.SSE_DOUBLE_PRECISION	Counts number of SSE* FP double precision uops executed.	
12H	01H	SIMD_INT_128.PACKED_MPY	Counts number of 128 bit SIMD integer multiply operations.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
12H	02H	SIMD_INT_128.PACKED_SHIFT	Counts number of 128 bit SIMD integer shift operations.	
12H	04H	SIMD_INT_128.PACK	Counts number of 128 bit SIMD integer pack operations.	
12H	08H	SIMD_INT_128.UNPACK	Counts number of 128 bit SIMD integer unpack operations.	
12H	10H	SIMD_INT_128.PACKED_LOGICAL	Counts number of 128 bit SIMD integer logical operations.	
12H	20H	SIMD_INT_128.PACKED_ARITH	Counts number of 128 bit SIMD integer arithmetic operations.	
12H	40H	SIMD_INT_128.SHUFFLE_MOVE	Counts number of 128 bit SIMD integer shuffle and move operations.	
13H	01H	LOAD_DISPATCH.RS	Counts number of loads dispatched from the Reservation Station that bypass the Memory Order Buffer.	
13H	02H	LOAD_DISPATCH.RS_DELAYED	Counts the number of delayed RS dispatches at the stage latch. If an RS dispatch can not bypass to LB, it has another chance to dispatch from the one-cycle delayed staging latch before it is written into the LB.	
13H	04H	LOAD_DISPATCH.MOB	Counts the number of loads dispatched from the Reservation Station to the Memory Order Buffer.	
13H	07H	LOAD_DISPATCH.ANY	Counts all loads dispatched from the Reservation Station.	
14H	01H	ARITH.CYCLES_DIV_BUSY	Counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE.  Set 'edge =1, invert=1, cmask=1' to count the number of divides.	Count may be incorrect When SMT is on
14H	02H	ARITH.MUL	Counts the number of multiply operations executed. This includes integer as well as floating point multiply operations but excludes DPPS mul and MPSAD.	Count may be incorrect When SMT is on
17H	01H	INST_QUEUE_WRITES	Counts the number of instructions written into the instruction queue every cycle.	
18H	01H	INST_DECODED.DECO	Counts number of instructions that require decoder 0 to be decoded. Usually, this means that the instruction maps to more than 1 uop.	
19H	01H	TWO_UOP_INSTS_DECODED	An instruction that generates two uops was decoded.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
1EH	01H	INST_QUEUE_WRITE_CYCLES	This event counts the number of cycles during which instructions are written to the instruction queue. Dividing this counter by the number of instructions written to the instruction queue (INST_QUEUE_WRITES) yields the average number of instructions decoded each cycle. If this number is less than four and the pipe stalls, this indicates that the decoder is failing to decode enough instructions per cycle to sustain the 4-wide pipeline.	If SSE* instructions that are 6 bytes or longer arrive one after another, then front end throughput may limit execution speed.
20H	01H	LSD_OVERFLOW	Number of loops that can not stream from the instruction queue.	
24H	01H	L2_RQSTS.LD_HIT	Counts number of loads that hit the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches. L2 loads can be rejected for various reasons. Only non rejected loads are counted.	
24H	02H	L2_RQSTS.LD_MISS	Counts the number of loads that miss the L2 cache. L2 loads include both L1D demand misses as well as L1D prefetches.	
24H	03H	L2_RQSTS.LOADS	Counts all L2 load requests. L2 loads include both L1D demand misses as well as L1D prefetches.	
24H	04H	L2_RQSTS.RFO_HIT	Counts the number of store RFO requests that hit the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches. Count includes WC memory requests, where the data is not fetched but the permission to write the line is required.	
24H	08H	L2_RQSTS.RFO_MISS	Counts the number of store RFO requests that miss the L2 cache. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches.	
24H	0CH	L2_RQSTS.RFOS	Counts all L2 store RFO requests. L2 RFO requests include both L1D demand RFO misses as well as L1D RFO prefetches..	
24H	10H	L2_RQSTS.IFETCH_HIT	Counts number of instruction fetches that hit the L2 cache. L2 instruction fetches include both L11 demand misses as well as L11 instruction prefetches.	
24H	20H	L2_RQSTS.IFETCH_MISS	Counts number of instruction fetches that miss the L2 cache. L2 instruction fetches include both L11 demand misses as well as L11 instruction prefetches.	
24H	30H	L2_RQSTS.IFETCHES	Counts all instruction fetches. L2 instruction fetches include both L11 demand misses as well as L11 instruction prefetches.	
24H	40H	L2_RQSTS.PREFETCH_HIT	Counts L2 prefetch hits for both code and data.	
24H	80H	L2_RQSTS.PREFETCH_MISS	Counts L2 prefetch misses for both code and data.	
24H	COH	L2_RQSTS.PREFETCHES	Counts all L2 prefetches for both code and data.	
24H	AAH	L2_RQSTS.MISS	Counts all L2 misses for both code and data.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
24H	FFH	L2_RQSTS.REFERENCES	Counts all L2 requests for both code and data.	
26H	01H	L2_DATA_RQSTS.DEMAND.I_STATE	Counts number of L2 data demand loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. L2 demand loads are both L1D demand misses and L1D prefetches.	
26H	02H	L2_DATA_RQSTS.DEMAND.S_STATE	Counts number of L2 data demand loads where the cache line to be loaded is in the S (shared) state. L2 demand loads are both L1D demand misses and L1D prefetches.	
26H	04H	L2_DATA_RQSTS.DEMAND.E_STATE	Counts number of L2 data demand loads where the cache line to be loaded is in the E (exclusive) state. L2 demand loads are both L1D demand misses and L1D prefetches.	
26H	08H	L2_DATA_RQSTS.DEMAND.M_STATE	Counts number of L2 data demand loads where the cache line to be loaded is in the M (modified) state. L2 demand loads are both L1D demand misses and L1D prefetches.	
26H	0FH	L2_DATA_RQSTS.DEMAND.MESI	Counts all L2 data demand requests. L2 demand loads are both L1D demand misses and L1D prefetches.	
26H	10H	L2_DATA_RQSTS.PREFETCH.I_STATE	Counts number of L2 prefetch data loads where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss.	
26H	20H	L2_DATA_RQSTS.PREFETCH.S_STATE	Counts number of L2 prefetch data loads where the cache line to be loaded is in the S (shared) state. A prefetch RFO will miss on an S state line, while a prefetch read will hit on an S state line.	
26H	40H	L2_DATA_RQSTS.PREFETCH.E_STATE	Counts number of L2 prefetch data loads where the cache line to be loaded is in the E (exclusive) state.	
26H	80H	L2_DATA_RQSTS.PREFETCH.M_STATE	Counts number of L2 prefetch data loads where the cache line to be loaded is in the M (modified) state.	
26H	F0H	L2_DATA_RQSTS.PREFETCH.MESI	Counts all L2 prefetch requests.	
26H	FFH	L2_DATA_RQSTS.ANY	Counts all L2 data requests.	
27H	01H	L2_WRITE.RFO.I_STATE	Counts number of L2 demand store RFO requests where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss. The L1D prefetcher does not issue a RFO prefetch.	This is a demand RFO request
27H	02H	L2_WRITE.RFO.S_STATE	Counts number of L2 store RFO requests where the cache line to be loaded is in the S (shared) state. The L1D prefetcher does not issue a RFO prefetch.	This is a demand RFO request
27H	08H	L2_WRITE.RFO.M_STATE	Counts number of L2 store RFO requests where the cache line to be loaded is in the M (modified) state. The L1D prefetcher does not issue a RFO prefetch.	This is a demand RFO request
27H	0EH	L2_WRITE.RFO.HIT	Counts number of L2 store RFO requests where the cache line to be loaded is in either the S, E or M states. The L1D prefetcher does not issue a RFO prefetch.	This is a demand RFO request

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
27H	0FH	L2_WRITE.RFO.MESI	Counts all L2 store RFO requests. The L1D prefetcher does not issue a RFO prefetch.	This is a demand RFO request
27H	10H	L2_WRITE.LOCK.I_STATE	Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the I (invalid) state, i.e. a cache miss.	
27H	20H	L2_WRITE.LOCK.S_STATE	Counts number of L2 lock RFO requests where the cache line to be loaded is in the S (shared) state.	
27H	40H	L2_WRITE.LOCK.E_STATE	Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the E (exclusive) state.	
27H	80H	L2_WRITE.LOCK.M_STATE	Counts number of L2 demand lock RFO requests where the cache line to be loaded is in the M (modified) state.	
27H	E0H	L2_WRITE.LOCK.HIT	Counts number of L2 demand lock RFO requests where the cache line to be loaded is in either the S, E, or M state.	
27H	F0H	L2_WRITE.LOCK.MESI	Counts all L2 demand lock RFO requests.	
28H	01H	L1D_WB_L2.I_STATE	Counts number of L1 writebacks to the L2 where the cache line to be written is in the I (invalid) state, i.e. a cache miss.	
28H	02H	L1D_WB_L2.S_STATE	Counts number of L1 writebacks to the L2 where the cache line to be written is in the S state.	
28H	04H	L1D_WB_L2.E_STATE	Counts number of L1 writebacks to the L2 where the cache line to be written is in the E (exclusive) state.	
28H	08H	L1D_WB_L2.M_STATE	Counts number of L1 writebacks to the L2 where the cache line to be written is in the M (modified) state.	
28H	0FH	L1D_WB_L2.MESI	Counts all L1 writebacks to the L2 .	
2EH	41H	L3_LAT_CACHE.MISS	Counts uncore Last Level Cache misses. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended.	see Table 19-1
2EH	4FH	L3_LAT_CACHE.REFERENCE	Counts uncore Last Level Cache references. Because cache hierarchy, cache sizes and other implementation-specific characteristics; value comparison to estimate performance differences is not recommended.	see Table 19-1
3CH	00H	CPU_CLK_UNHALTED.THREAD_P	Counts the number of thread cycles while the thread is not in a halt state. The thread enters the halt state when it is running the HLT instruction. The core frequency may change from time to time due to power or thermal throttling.	see Table 19-1
3CH	01H	CPU_CLK_UNHALTED.REF_P	Increments at the frequency of TSC when not halted.	see Table 19-1
49H	01H	DTLB_MISSES.ANY	Counts the number of misses in the STLB which causes a page walk.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
49H	02H	DTLB_MISSES.WALK_COMPLETED	Counts number of misses in the STLB which resulted in a completed page walk.	
49H	04H	DTLB_MISSES.WALK_CYCLES	Counts cycles of page walk due to misses in the STLB.	
49H	10H	DTLB_MISSES.STLB_HIT	Counts the number of DTLB first level misses that hit in the second level TLB. This event is only relevant if the core contains multiple DTLB levels.	
49H	20H	DTLB_MISSES.PDE_MISS	Number of DTLB misses caused by low part of address, includes references to 2M pages because 2M pages do not use the PDE.	
49H	80H	DTLB_MISSES.LARGE_WALK_COMPLETED	Counts number of completed large page walks due to misses in the STLB.	
4CH	01H	LOAD_HIT_PRE	Counts load operations sent to the L1 data cache while a previous SSE prefetch instruction to the same cache line has started prefetching but has not yet finished.	Counter 0, 1 only
4EH	01H	L1D_PREFETCH.REQUESTS	Counts number of hardware prefetch requests dispatched out of the prefetch FIFO.	Counter 0, 1 only
4EH	02H	L1D_PREFETCH.MISS	Counts number of hardware prefetch requests that miss the L1D. There are two prefetchers in the L1D. A streamer, which predicts lines sequentially after this one should be fetched, and the IP prefetcher that remembers access patterns for the current instruction. The streamer prefetcher stops on an L1D hit, while the IP prefetcher does not.	Counter 0, 1 only
4EH	04H	L1D_PREFETCH.TRIGGERS	Counts number of prefetch requests triggered by the Finite State Machine and pushed into the prefetch FIFO. Some of the prefetch requests are dropped due to overwrites or competition between the IP index prefetcher and streamer prefetcher. The prefetch FIFO contains 4 entries.	Counter 0, 1 only
4FH	10H	EPT.WALK_CYCLES	Counts Extended Page walk cycles.	
51H	01H	L1D.REPL	Counts the number of lines brought into the L1 data cache.	Counter 0, 1 only
51H	02H	L1D.M_REPL	Counts the number of modified lines brought into the L1 data cache.	Counter 0, 1 only
51H	04H	L1D.M_EVICT	Counts the number of modified lines evicted from the L1 data cache due to replacement.	Counter 0, 1 only
51H	08H	L1D.M_SNOOP_EVICT	Counts the number of modified lines evicted from the L1 data cache due to snoop HITM intervention.	Counter 0, 1 only
52H	01H	L1D_CACHE_PREFETCH_LOCK_FB_HIT	Counts the number of cacheable load lock speculated instructions accepted into the fill buffer.	
60H	01H	OFFCORE_REQUESTS_OUTSTANDING.DEMAND.READ_DATA	Counts weighted cycles of offcore demand data read requests. Does not include L2 prefetch requests.	counter 0
60H	02H	OFFCORE_REQUESTS_OUTSTANDING.DEMAND.READ_CODE	Counts weighted cycles of offcore demand code read requests. Does not include L2 prefetch requests.	counter 0

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
60H	04H	OFFCORE_REQUESTS_OUTSTANDING.DEMAND.RFO	Counts weighted cycles of offcore demand RFO requests. Does not include L2 prefetch requests.	counter 0
60H	08H	OFFCORE_REQUESTS_OUTSTANDING.ANY.READ	Counts weighted cycles of offcore read requests of any kind. Include L2 prefetch requests.	counter 0
63H	01H	CACHE_LOCK_CYCLES.L1D_L2	Cycle count during which the L1D and L2 are locked. A lock is asserted when there is a locked memory access, due to uncacheable memory, a locked operation that spans two cache lines, or a page walk from an uncacheable page table. This event does not cause locks, it merely detects them.	Counter 0, 1 only. L1D and L2 locks have a very high performance penalty and it is highly recommended to avoid such accesses.
63H	02H	CACHE_LOCK_CYCLES.L1D	Counts the number of cycles that cacheline in the L1 data cache unit is locked.	Counter 0, 1 only.
6CH	01H	IO_TRANSACTIONS	Counts the number of completed I/O transactions.	
80H	01H	L1I.HITS	Counts all instruction fetches that hit the L1 instruction cache.	
80H	02H	L1I.MISSES	Counts all instruction fetches that miss the L1I cache. This includes instruction cache misses, streaming buffer misses, victim cache misses and uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding.	
80H	03H	L1I.READS	Counts all instruction fetches, including uncacheable fetches that bypass the L1I.	
80H	04H	L1I.CYCLES_STALLED	Cycle counts for which an instruction fetch stalls due to a L1I cache miss, ITLB miss or ITLB fault.	
82H	01H	LARGE_ITLB.HIT	Counts number of large ITLB hits.	
85H	01H	ITLB_MISSES.ANY	Counts the number of misses in all levels of the ITLB which causes a page walk.	
85H	02H	ITLB_MISSES.WALK_COMPLETED	Counts number of misses in all levels of the ITLB which resulted in a completed page walk.	
85H	04H	ITLB_MISSES.WALK_CYCLES	Counts ITLB miss page walk cycles.	
85H	10H	ITLB_MISSES.STLB_HIT	Counts number of ITLB first level miss but second level hits	
85H	80H	ITLB_MISSES.LARGE_WALK_COMPLETED	Counts number of completed large page walks due to misses in the STLB.	
87H	01H	ILD_STALL.LCP	Cycles Instruction Length Decoder stalls due to length changing prefixes: 66, 67 or REX.W (for EM64T) instructions which change the length of the decoded instruction.	
87H	02H	ILD_STALL.MRU	Instruction Length Decoder stall cycles due to Branch Prediction Unit (PBU) Most Recently Used (MRU) bypass.	
87H	04H	ILD_STALL.IQ_FULL	Stall cycles due to a full instruction queue.	
87H	08H	ILD_STALL.REGEN	Counts the number of regen stalls.	
87H	0FH	ILD_STALL.ANY	Counts any cycles the Instruction Length Decoder is stalled.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
88H	01H	BR_INST_EXEC.COND	Counts the number of conditional near branch instructions executed, but not necessarily retired.	
88H	02H	BR_INST_EXEC.DIRECT	Counts all unconditional near branch instructions excluding calls and indirect branches.	
88H	04H	BR_INST_EXEC.INDIRECT_NO_N_CALL	Counts the number of executed indirect near branch instructions that are not calls.	
88H	07H	BR_INST_EXEC.NON_CALLS	Counts all non call near branch instructions executed, but not necessarily retired.	
88H	08H	BR_INST_EXEC.RETURN_NEAR	Counts indirect near branches that have a return mnemonic.	
88H	10H	BR_INST_EXEC.DIRECT_NEAR_CALL	Counts unconditional near call branch instructions, excluding non call branch, executed.	
88H	20H	BR_INST_EXEC.INDIRECT_NEAR_CALL	Counts indirect near calls, including both register and memory indirect, executed.	
88H	30H	BR_INST_EXEC.NEAR_CALLS	Counts all near call branches executed, but not necessarily retired.	
88H	40H	BR_INST_EXEC.TAKEN	Counts taken near branches executed, but not necessarily retired.	
88H	7FH	BR_INST_EXEC.ANY	Counts all near executed branches (not necessarily retired). This includes only instructions and not micro-op branches. Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem.	
89H	01H	BR_MISP_EXEC.COND	Counts the number of mispredicted conditional near branch instructions executed, but not necessarily retired.	
89H	02H	BR_MISP_EXEC.DIRECT	Counts mispredicted macro unconditional near branch instructions, excluding calls and indirect branches (should always be 0).	
89H	04H	BR_MISP_EXEC.INDIRECT_NO_N_CALL	Counts the number of executed mispredicted indirect near branch instructions that are not calls.	
89H	07H	BR_MISP_EXEC.NON_CALLS	Counts mispredicted non call near branches executed, but not necessarily retired.	
89H	08H	BR_MISP_EXEC.RETURN_NEAR	Counts mispredicted indirect branches that have a near return mnemonic.	
89H	10H	BR_MISP_EXEC.DIRECT_NEAR_CALL	Counts mispredicted non-indirect near calls executed, (should always be 0).	
89H	20H	BR_MISP_EXEC.INDIRECT_NEAR_CALL	Counts mispredicted indirect near calls executed, including both register and memory indirect.	
89H	30H	BR_MISP_EXEC.NEAR_CALLS	Counts all mispredicted near call branches executed, but not necessarily retired.	
89H	40H	BR_MISP_EXEC.TAKEN	Counts executed mispredicted near branches that are taken, but not necessarily retired.	
89H	7FH	BR_MISP_EXEC.ANY	Counts the number of mispredicted near branch instructions that were executed, but not necessarily retired.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
A2H	01H	RESOURCE_STALLS.ANY	Counts the number of Allocator resource related stalls. Includes register renaming buffer entries, memory buffer entries. In addition to resource related stalls, this event counts some other events. Includes stalls arising during branch misprediction recovery, such as if retirement of the mispredicted branch is delayed and stalls arising while store buffer is draining from synchronizing operations.	Does not include stalls due to SuperQ (off core) queue full, too many cache misses, etc.
A2H	02H	RESOURCE_STALLS.LOAD	Counts the cycles of stall due to lack of load buffer for load operation.	
A2H	04H	RESOURCE_STALLS.RS_FULL	This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle. A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, or instructions dependent upon instructions further down the pipeline that have yet to retire.	When RS is full, new instructions can not enter the reservation station and start execution.
A2H	08H	RESOURCE_STALLS.STORE	This event counts the number of cycles that a resource related stall will occur due to the number of store instructions reaching the limit of the pipeline, (i.e. all store buffers are used). The stall ends when a store instruction commits its data to the cache or memory.	
A2H	10H	RESOURCE_STALLS.ROB_FULL	Counts the cycles of stall due to re-order buffer full.	
A2H	20H	RESOURCE_STALLS.FPCW	Counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word.	
A2H	40H	RESOURCE_STALLS.MXCSR	Stalls due to the MXCSR register rename occurring to close to a previous MXCSR rename. The MXCSR provides control and status for the MMX registers.	
A2H	80H	RESOURCE_STALLS.OTHER	Counts the number of cycles while execution was stalled due to other resource issues.	
A6H	01H	MACRO_INSTS.FUSIONS_DECODED	Counts the number of instructions decoded that are macro-fused but not necessarily executed or retired.	
A7H	01H	BACLEAR_FORCE_IQ	Counts number of times a BACLEAR was forced by the Instruction Queue. The IQ is also responsible for providing conditional branch prediction direction based on a static scheme and dynamic data provided by the L2 Branch Prediction Unit. If the conditional branch target is not found in the Target Array and the IQ predicts that the branch is taken, then the IQ will force the Branch Address Calculator to issue a BACLEAR. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline.	
A8H	01H	LSD.UOPS	Counts the number of micro-ops delivered by loop stream detector.	Use cmask=1 and invert to count cycles
AEH	01H	ITLB_FLUSH	Counts the number of ITLB flushes.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
B0H	01H	OFFCORE_REQUESTS.DEMAND.READ_DATA	Counts number of offcore demand data read requests. Does not count L2 prefetch requests.	
B0H	02H	OFFCORE_REQUESTS.DEMAND.READ_CODE	Counts number of offcore demand code read requests. Does not count L2 prefetch requests.	
B0H	04H	OFFCORE_REQUESTS.DEMAND.RFO	Counts number of offcore demand RFO requests. Does not count L2 prefetch requests.	
B0H	08H	OFFCORE_REQUESTS.ANY.READ	Counts number of offcore read requests. Includes L2 prefetch requests.	
B0H	10H	OFFCORE_REQUESTS.ANY.RFO	Counts number of offcore RFO requests. Includes L2 prefetch requests.	
B0H	40H	OFFCORE_REQUESTS.L1D_WRITEBACK	Counts number of L1D writebacks to the uncore.	
B0H	80H	OFFCORE_REQUESTS.ANY	Counts all offcore requests.	
B1H	01H	UOPS_EXECUTED.PORT0	Counts number of Uops executed that were issued on port 0. Port 0 handles integer arithmetic, SIMD and FP add Uops.	
B1H	02H	UOPS_EXECUTED.PORT1	Counts number of Uops executed that were issued on port 1. Port 1 handles integer arithmetic, SIMD, integer shift, FP multiply and FP divide Uops.	
B1H	04H	UOPS_EXECUTED.PORT2_CORE	Counts number of Uops executed that were issued on port 2. Port 2 handles the load Uops. This is a core count only and can not be collected per thread.	
B1H	08H	UOPS_EXECUTED.PORT3_CORE	Counts number of Uops executed that were issued on port 3. Port 3 handles store Uops. This is a core count only and can not be collected per thread.	
B1H	10H	UOPS_EXECUTED.PORT4_CORE	Counts number of Uops executed that where issued on port 4. Port 4 handles the value to be stored for the store Uops issued on port 3. This is a core count only and can not be collected per thread.	
B1H	1FH	UOPS_EXECUTED.CORE_ACTIVE_CYCLES_NO_PORT5	Counts number of cycles there are one or more uops being executed and were issued on ports 0-4. This is a core count only and can not be collected per thread.	
B1H	20H	UOPS_EXECUTED.PORT5	Counts number of Uops executed that where issued on port 5.	
B1H	3FH	UOPS_EXECUTED.CORE_ACTIVE_CYCLES	Counts number of cycles there are one or more uops being executed on any ports. This is a core count only and can not be collected per thread.	
B1H	40H	UOPS_EXECUTED.PORT015	Counts number of Uops executed that where issued on port 0, 1, or 5.	use cmask=1, invert=1 to count stall cycles
B1H	80H	UOPS_EXECUTED.PORT234	Counts number of Uops executed that where issued on port 2, 3, or 4.	
B2H	01H	OFFCORE_REQUESTS_SQ_FULL	Counts number of cycles the SQ is full to handle offcore requests.	
B3H	01H	SNOOPQ_REQUESTS_OUTSTANDING.DATA	Counts weighted cycles of snoopq requests for data. Counter 0 only.	Use cmask=1 to count cycles not empty.

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
B3H	02H	SNOOPQ_REQUESTS_OUTSTANDING.INVALIDATE	Counts weighted cycles of snoopq invalidate requests. Counter 0 only.	Use cmask=1 to count cycles not empty.
B3H	04H	SNOOPQ_REQUESTS_OUTSTANDING.CODE	Counts weighted cycles of snoopq requests for code. Counter 0 only.	Use cmask=1 to count cycles not empty.
B4H	01H	SNOOPQ_REQUESTS.CODE	Counts the number of snoop code requests.	
B4H	02H	SNOOPQ_REQUESTS.DATA	Counts the number of snoop data requests.	
B4H	04H	SNOOPQ_REQUESTS.INVALIDATE	Counts the number of snoop invalidate requests.	
B7H	01H	OFF_CORE_RESPONSE_0	see Section 18.7.1.3, "Off-core Response Performance Monitoring in the Processor Core"	Requires programming MSR 01A6H
B8H	01H	SNOOP_RESPONSE.HIT	Counts HIT snoop response sent by this thread in response to a snoop request.	
B8H	02H	SNOOP_RESPONSE.HITE	Counts HIT E snoop response sent by this thread in response to a snoop request.	
B8H	04H	SNOOP_RESPONSE.HITM	Counts HIT M snoop response sent by this thread in response to a snoop request.	
BBH	01H	OFF_CORE_RESPONSE_1	see Section 18.7.1.3, "Off-core Response Performance Monitoring in the Processor Core"	Use MSR 01A7H
COH	00H	INST_RETIRED.ANY_P	See Table 19-1 Notes: INST_RETIRED.ANY is counted by a designated fixed counter. INST_RETIRED.ANY_P is counted by a programmable counter and is an architectural performance event. Event is supported if CPUID.A.EBX[1] = 0.	Counting: Faulting executions of GETSEC/VM entry/VM Exit/MWait will not count as retired instructions.
COH	02H	INST_RETIRED.X87	Counts the number of floating point computational operations retired: floating point computational operations executed by the assist handler and sub-operations of complex floating point instructions like transcendental instructions.	
COH	04H	INST_RETIRED.MMX	Counts the number of retired: MMX instructions.	
C2H	01H	UOPS_RETIRED.ANY	Counts the number of micro-ops retired, (macro-fused=1, micro-fused=2, others=1; maximum count of 8 per cycle). Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists.	Use cmask=1 and invert to count active cycles or stalled cycles
C2H	02H	UOPS_RETIRED.RETIRE_SLOT	Counts the number of retirement slots used each cycle	
C2H	04H	UOPS_RETIRED.MACRO_FUSED	Counts number of macro-fused uops retired.	
C3H	01H	MACHINE_CLEAR.CYCLES	Counts the cycles machine clear is asserted.	
C3H	02H	MACHINE_CLEAR.MEM_ORDER	Counts the number of machine clears due to memory order conflicts.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
C3H	04H	MACHINE_CLEAR.SMC	Counts the number of times that a program writes to a code section. Self-modifying code causes a sever penalty in all Intel 64 and IA-32 processors. The modified cache line is written back to the L2 and L3caches.	
C4H	00H	BR_INST_RETIRED.ALL_BRANCHES	Branch instructions at retirement	See Table 19-1
C4H	01H	BR_INST_RETIRED.CONDITIONAL	Counts the number of conditional branch instructions retired.	
C4H	02H	BR_INST_RETIRED.NEAR_CALL	Counts the number of direct & indirect near unconditional calls retired.	
C5H	00H	BR_MISP_RETIRED.ALL_BRANCHES	Mispredicted branch instructions at retirement	See Table 19-1
C5H	01H	BR_MISP_RETIRED.CONDITIONAL	Counts mispredicted conditional retired calls.	
C5H	02H	BR_MISP_RETIRED.NEAR_CALL	Counts mispredicted direct & indirect near unconditional retired calls.	
C5H	04H	BR_MISP_RETIRED.ALL_BRANCHES	Counts all mispredicted retired calls.	
C7H	01H	SSEX_UOPS_RETIRED.PACKED_SINGLE	Counts SIMD packed single-precision floating point Uops retired.	
C7H	02H	SSEX_UOPS_RETIRED.SCALAR_SINGLE	Counts SIMD calar single-precision floating point Uops retired.	
C7H	04H	SSEX_UOPS_RETIRED.PACKED_DOUBLE	Counts SIMD packed double-precision floating point Uops retired.	
C7H	08H	SSEX_UOPS_RETIRED.SCALAR_DOUBLE	Counts SIMD scalar double-precision floating point Uops retired.	
C7H	10H	SSEX_UOPS_RETIRED.VECTOR_INTEGER	Counts 128-bit SIMD vector integer Uops retired.	
C8H	20H	ITLB_MISS_RETIRED	Counts the number of retired instructions that missed the ITLB when the instruction was fetched.	
CBH	01H	MEM_LOAD_RETIRED.L1D_HIT	Counts number of retired loads that hit the L1 data cache.	
CBH	02H	MEM_LOAD_RETIRED.L2_HIT	Counts number of retired loads that hit the L2 data cache.	
CBH	04H	MEM_LOAD_RETIRED.L3_UNSHARED_HIT	Counts number of retired loads that hit their own, unshared lines in the L3 cache.	
CBH	08H	MEM_LOAD_RETIRED.OTHER_CORE_L2_HIT_HITM	Counts number of retired loads that hit in a sibling core's L2 (on die core). Since the L3 is inclusive of all cores on the package, this is an L3 hit. This counts both clean or modified hits.	
CBH	10H	MEM_LOAD_RETIRED.L3_MISS	Counts number of retired loads that miss the L3 cache. The load was satisfied by a remote socket, local memory or an IOH.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
CBH	40H	MEM_LOAD_RETIRED.HIT_LFB	Counts number of retired loads that miss the L1D and the address is located in an allocated line fill buffer and will soon be committed to cache. This is counting secondary L1D misses.	
CBH	80H	MEM_LOAD_RETIRED.DTLB_MISSES	Counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault. This event counts loads from cacheable memory only. The event does not count loads by software prefetches. Counts both primary and secondary misses to the TLB.	
CCH	01H	FP_MMX_TRANS.TO_FP	Counts the first floating-point instruction following any MMX instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.	
CCH	02H	FP_MMX_TRANS.TO_MMX	Counts the first MMX instruction following a floating-point instruction. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.	
CCH	03H	FP_MMX_TRANS.ANY	Counts all transitions from floating point to MMX instructions and from MMX instructions to floating point instructions. You can use this event to estimate the penalties for the transitions between floating-point and MMX technology states.	
D0H	01H	MACRO_INSTS.DECODED	Counts the number of instructions decoded, (but not necessarily executed or retired).	
D1H	01H	UOPS_DECODED.STALL_CYCLE	Counts the cycles of decoder stalls. INV=1, Cmask=1	
D1H	02H	UOPS_DECODED.MS	Counts the number of Uops decoded by the Microcode Sequencer, MS. The MS delivers uops when the instruction is more than 4 uops long or a microcode assist is occurring.	
D1H	04H	UOPS_DECODED.ESP_FOLDING	Counts number of stack pointer (ESP) instructions decoded: push , pop , call , ret, etc. ESP instructions do not generate a Uop to increment or decrement ESP. Instead, they update an ESP_Offset register that keeps track of the delta to the current value of the ESP register.	
D1H	08H	UOPS_DECODED.ESP_SYNC	Counts number of stack pointer (ESP) sync operations where an ESP instruction is corrected by adding the ESP offset register to the current value of the ESP register.	
D2H	01H	RAT_STALLS.FLAGS	Counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall. A partial register stall may occur when two conditions are met: 1) an instruction modifies some, but not all, of the flags in the flag register and 2) the next instruction, which depends on flags, depends on flags that were not modified by this instruction.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
D2H	02H	RAT_STALLS.REGISTERS	This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction used a register that was partially written by previous instruction.	
D2H	04H	RAT_STALLS.ROB_READ_PORT	Counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline. Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read port stall is counted again.	
D2H	08H	RAT_STALLS.SCOREBOARD	Counts the cycles where we stall due to microarchitecturally required serialization. Microcode scoreboarding stalls.	
D2H	0FH	RAT_STALLS.ANY	Counts all Register Allocation Table stall cycles due to: Cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the execution pipe. Cycles when partial register stalls occurred Cycles when flag stalls occurred Cycles floating-point unit (FPU) status word stalls occurred. To count each of these conditions separately use the events: RAT_STALLS.ROB_READ_PORT, RAT_STALLS.PARTIAL, RAT_STALLS.FLAGS, and RAT_STALLS.FPSW.	
D4H	01H	SEG_RENAME_STALLS	Counts the number of stall cycles due to the lack of renaming resources for the ES, DS, FS, and GS segment registers. If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.	
D5H	01H	ES_REG_RENAMES	Counts the number of times the ES segment register is renamed.	
DBH	01H	UOP_UNFUSION	Counts unfusion events due to floating point exception to a fused uop.	
E0H	01H	BR_INST_DECODED	Counts the number of branch instructions decoded.	
E5H	01H	BPU_MISSED_CALL_RET	Counts number of times the Branch Prediction Unit missed predicting a call or return branch.	
E6H	01H	BACLEAR.CLEAR	Counts the number of times the front end is resteeered, mainly when the Branch Prediction Unit cannot provide a correct prediction and this is corrected by the Branch Address Calculator at the front end. This can occur if the code has many branches such that they cannot be consumed by the BPU. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline. The effect on total execution time depends on the surrounding code.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
E6H	02H	BACLEAR.BAD_TARGET	Counts number of Branch Address Calculator clears (BACLEAR) asserted due to conditional branch instructions in which there was a target hit but the direction was wrong. Each BACLEAR asserted by the BAC generates approximately an 8 cycle bubble in the instruction fetch pipeline.	
E8H	01H	BPU_CLEARS.EARLY	Counts early (normal) Branch Prediction Unit clears: BPU predicted a taken branch after incorrectly assuming that it was not taken.	The BPU clear leads to 2 cycle bubble in the Front End.
E8H	02H	BPU_CLEARS.LATE	Counts late Branch Prediction Unit clears due to Most Recently Used conflicts. The PBU clear leads to a 3 cycle bubble in the Front End.	
ECH	01H	THREAD_ACTIVE	Counts cycles threads are active.	
F0H	01H	L2_TRANSACTIONS.LOAD	Counts L2 load operations due to HW prefetch or demand loads.	
F0H	02H	L2_TRANSACTIONS.RFO	Counts L2 RFO operations due to HW prefetch or demand RFOs.	
F0H	04H	L2_TRANSACTIONS.IFETCH	Counts L2 instruction fetch operations due to HW prefetch or demand ifetch.	
F0H	08H	L2_TRANSACTIONS.PREFETCH	Counts L2 prefetch operations.	
F0H	10H	L2_TRANSACTIONS.L1D_WB	Counts L1D writeback operations to the L2.	
F0H	20H	L2_TRANSACTIONS.FILL	Counts L2 cache line fill operations due to load, RFO, L1D writeback or prefetch.	
F0H	40H	L2_TRANSACTIONS.WB	Counts L2 writeback operations to the L3.	
F0H	80H	L2_TRANSACTIONS.ANY	Counts all L2 cache operations.	
F1H	02H	L2_LINES_IN.S_STATE	Counts the number of cache lines allocated in the L2 cache in the S (shared) state.	
F1H	04H	L2_LINES_IN.E_STATE	Counts the number of cache lines allocated in the L2 cache in the E (exclusive) state.	
F1H	07H	L2_LINES_IN.ANY	Counts the number of cache lines allocated in the L2 cache.	
F2H	01H	L2_LINES_OUT.DEMAND_CLEAN	Counts L2 clean cache lines evicted by a demand request.	
F2H	02H	L2_LINES_OUT.DEMAND_DIRTY	Counts L2 dirty (modified) cache lines evicted by a demand request.	
F2H	04H	L2_LINES_OUT.PREFETCH_CLEAN	Counts L2 clean cache line evicted by a prefetch request.	
F2H	08H	L2_LINES_OUT.PREFETCH_DIRTY	Counts L2 modified cache line evicted by a prefetch request.	
F2H	0FH	L2_LINES_OUT.ANY	Counts all L2 cache lines evicted for any reason.	
F4H	04H	SQ_MISC.LRU_HINTS	Counts number of Super Queue LRU hints sent to L3.	
F4H	10H	SQ_MISC.SPLIT_LOCK	Counts the number of SQ lock splits across a cache line.	

**Table 19-13. Non-Architectural Performance Events In the Processor Core for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
F6H	01H	SQ_FULL_STALL_CYCLES	Counts cycles the Super Queue is full. Neither of the threads on this core will be able to access the uncore.	
F7H	01H	FP_ASSIST.ALL	Counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases: SSE instructions, (Denormal input when the DAZ flag is off or Underflow result when the FTZ flag is off); x87 instructions, (NaN or denormal are loaded to a register or used as input from memory, Division by 0 or Underflow output).	
F7H	02H	FP_ASSIST.OUTPUT	Counts number of floating point micro-code assist when the output value (destination register) is invalid.	
F7H	04H	FP_ASSIST.INPUT	Counts number of floating point micro-code assist when the input value (one of the source operands to an FP instruction) is invalid.	
FDH	01H	SIMD_INT_64.PACKED_MPY	Counts number of SIMD integer 64 bit packed multiply operations.	
FDH	02H	SIMD_INT_64.PACKED_SHIFT	Counts number of SIMD integer 64 bit packed shift operations.	
FDH	04H	SIMD_INT_64.PACK	Counts number of SIMD integer 64 bit pack operations.	
FDH	08H	SIMD_INT_64.UNPACK	Counts number of SIMD integer 64 bit unpack operations.	
FDH	10H	SIMD_INT_64.PACKED_LOGICAL	Counts number of SIMD integer 64 bit logical operations.	
FDH	20H	SIMD_INT_64.PACKED_ARITH	Counts number of SIMD integer 64 bit arithmetic operations.	
FDH	40H	SIMD_INT_64.SHUFFLE_MOVE	Counts number of SIMD integer 64 bit shift or move operations.	

Non-architectural Performance monitoring events of the uncore sub-system for Processors with CPUID signature of DisplayFamily\_DisplayModel 06\_25H, 06\_2CH, and 06\_1FH support performance events listed in Table 19-14.

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
00H	01H	UNC_GQ_CYCLES_FULL.READ_TRACKER	Uncore cycles Global Queue read tracker is full.	
00H	02H	UNC_GQ_CYCLES_FULL.WRITE_TRACKER	Uncore cycles Global Queue write tracker is full.	
00H	04H	UNC_GQ_CYCLES_FULL.PEER_PROBE_TRACKER	Uncore cycles Global Queue peer probe tracker is full. The peer probe tracker queue tracks snoops from the IOH and remote sockets.	
01H	01H	UNC_GQ_CYCLES_NOT_EMPTY.READ_TRACKER	Uncore cycles were Global Queue read tracker has at least one valid entry.	
01H	02H	UNC_GQ_CYCLES_NOT_EMPTY.WRITE_TRACKER	Uncore cycles were Global Queue write tracker has at least one valid entry.	
01H	04H	UNC_GQ_CYCLES_NOT_EMPTY.PEER_PROBE_TRACKER	Uncore cycles were Global Queue peer probe tracker has at least one valid entry. The peer probe tracker queue tracks IOH and remote socket snoops.	
02H	01H	UNC_GQ_OCCUPANCY.READ_TRACKER	Increments the number of queue entries (code read, data read, and RFOs) in the tread tracker. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency.	
03H	01H	UNC_GQ_ALLOC.READ_TRACKER	Counts the number of tread tracker allocate to deallocate entries. The GQ read tracker allocate to deallocate occupancy count is divided by the count to obtain the average read tracker latency.	
03H	02H	UNC_GQ_ALLOC.RT_L3_MISS	Counts the number GQ read tracker entries for which a full cache line read has missed the L3. The GQ read tracker L3 miss to fill occupancy count is divided by this count to obtain the average cache line read L3 miss latency. The latency represents the time after which the L3 has determined that the cache line has missed. The time between a GQ read tracker allocation and the L3 determining that the cache line has missed is the average L3 hit latency. The total L3 cache line read miss latency is the hit latency + L3 miss latency.	
03H	04H	UNC_GQ_ALLOC.RT_TO_L3_RESP	Counts the number of GQ read tracker entries that are allocated in the read tracker queue that hit or miss the L3. The GQ read tracker L3 hit occupancy count is divided by this count to obtain the average L3 hit latency.	
03H	08H	UNC_GQ_ALLOC.RT_TO_RTID_ACQUIRED	Counts the number of GQ read tracker entries that are allocated in the read tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ read tracker L3 miss to RTID acquired occupancy count is divided by this count to obtain the average latency for a read L3 miss to acquire an RTID.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
03H	10H	UNC_GQ_ALLOC.WT_TO_RTID_ACQUIRED	Counts the number of GQ write tracker entries that are allocated in the write tracker, have missed in the L3 and have not acquired a Request Transaction ID. The GQ write tracker L3 miss to RTID occupancy count is divided by this count to obtain the average latency for a write L3 miss to acquire an RTID.	
03H	20H	UNC_GQ_ALLOC.WRITE_TRACKER	Counts the number of GQ write tracker entries that are allocated in the write tracker queue that miss the L3. The GQ write tracker occupancy count is divided by the this count to obtain the average L3 write miss latency.	
03H	40H	UNC_GQ_ALLOC.PEER_PROBE_TRACKER	Counts the number of GQ peer probe tracker (snoop) entries that are allocated in the peer probe tracker queue that miss the L3. The GQ peer probe occupancy count is divided by this count to obtain the average L3 peer probe miss latency.	
04H	01H	UNC_GQ_DATA.FROM_QPI	Cycles Global Queue Quickpath Interface input data port is busy importing data from the Quickpath Interface. Each cycle the input port can transfer 8 or 16 bytes of data.	
04H	02H	UNC_GQ_DATA.FROM_QMC	Cycles Global Queue Quickpath Memory Interface input data port is busy importing data from the Quickpath Memory Interface. Each cycle the input port can transfer 8 or 16 bytes of data.	
04H	04H	UNC_GQ_DATA.FROM_L3	Cycles GQ L3 input data port is busy importing data from the Last Level Cache. Each cycle the input port can transfer 32 bytes of data.	
04H	08H	UNC_GQ_DATA.FROM_CORES_02	Cycles GQ Core 0 and 2 input data port is busy importing data from processor cores 0 and 2. Each cycle the input port can transfer 32 bytes of data.	
04H	10H	UNC_GQ_DATA.FROM_CORES_13	Cycles GQ Core 1 and 3 input data port is busy importing data from processor cores 1 and 3. Each cycle the input port can transfer 32 bytes of data.	
05H	01H	UNC_GQ_DATA.TO_QPI_QMC	Cycles GQ QPI and QMC output data port is busy sending data to the Quickpath Interface or Quickpath Memory Interface. Each cycle the output port can transfer 32 bytes of data.	
05H	02H	UNC_GQ_DATA.TO_L3	Cycles GQ L3 output data port is busy sending data to the Last Level Cache. Each cycle the output port can transfer 32 bytes of data.	
05H	04H	UNC_GQ_DATA.TO_CORES	Cycles GQ Core output data port is busy sending data to the Cores. Each cycle the output port can transfer 32 bytes of data.	
06H	01H	UNC_SNP_RESP_TO_LOCAL_HOME.I_STATE	Number of snoop responses to the local home that L3 does not have the referenced cache line.	
06H	02H	UNC_SNP_RESP_TO_LOCAL_HOME.S_STATE	Number of snoop responses to the local home that L3 has the referenced line cached in the S state.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
06H	04H	UNC_SNP_RESP_TO_LOCAL_HOME.FWD_S_STATE	Number of responses to code or data read snoops to the local home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the local home in the S state.	
06H	08H	UNC_SNP_RESP_TO_LOCAL_HOME.FWD_I_STATE	Number of responses to read invalidate snoops to the local home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the local home in the M state.	
06H	10H	UNC_SNP_RESP_TO_LOCAL_HOME.CONFLICT	Number of conflict snoop responses sent to the local home.	
06H	20H	UNC_SNP_RESP_TO_LOCAL_HOME.WB	Number of responses to code or data read snoops to the local home that the L3 has the referenced line cached in the M state.	
07H	01H	UNC_SNP_RESP_TO_REMOTE_HOME.I_STATE	Number of snoop responses to a remote home that L3 does not have the referenced cache line.	
07H	02H	UNC_SNP_RESP_TO_REMOTE_HOME.S_STATE	Number of snoop responses to a remote home that L3 has the referenced line cached in the S state.	
07H	04H	UNC_SNP_RESP_TO_REMOTE_HOME.FWD_S_STATE	Number of responses to code or data read snoops to a remote home that the L3 has the referenced cache line in the E state. The L3 cache line state is changed to the S state and the line is forwarded to the remote home in the S state.	
07H	08H	UNC_SNP_RESP_TO_REMOTE_HOME.FWD_I_STATE	Number of responses to read invalidate snoops to a remote home that the L3 has the referenced cache line in the M state. The L3 cache line state is invalidated and the line is forwarded to the remote home in the M state.	
07H	10H	UNC_SNP_RESP_TO_REMOTE_HOME.CONFLICT	Number of conflict snoop responses sent to the local home.	
07H	20H	UNC_SNP_RESP_TO_REMOTE_HOME.WB	Number of responses to code or data read snoops to a remote home that the L3 has the referenced line cached in the M state.	
07H	24H	UNC_SNP_RESP_TO_REMOTE_HOME.HITM	Number of HITM snoop responses to a remote home	
08H	01H	UNC_L3_HITS.READ	Number of code read, data read and RFO requests that hit in the L3	
08H	02H	UNC_L3_HITS.WRITE	Number of writeback requests that hit in the L3. Writebacks from the cores will always result in L3 hits due to the inclusive property of the L3.	
08H	04H	UNC_L3_HITS.PROBE	Number of snoops from IOH or remote sockets that hit in the L3.	
08H	03H	UNC_L3_HITS.ANY	Number of reads and writes that hit the L3.	
09H	01H	UNC_L3_MISS.READ	Number of code read, data read and RFO requests that miss the L3.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
09H	02H	UNC_L3_MISS.WRITE	Number of writeback requests that miss the L3. Should always be zero as writebacks from the cores will always result in L3 hits due to the inclusive property of the L3.	
09H	04H	UNC_L3_MISS.PROBE	Number of snoops from IOH or remote sockets that miss the L3.	
09H	03H	UNC_L3_MISS.ANY	Number of reads and writes that miss the L3.	
0AH	01H	UNC_L3_LINES_IN.M_STATE	Counts the number of L3 lines allocated in M state. The only time a cache line is allocated in the M state is when the line was forwarded in M state is forwarded due to a Snoop Read Invalidate Own request.	
0AH	02H	UNC_L3_LINES_IN.E_STATE	Counts the number of L3 lines allocated in E state.	
0AH	04H	UNC_L3_LINES_IN.S_STATE	Counts the number of L3 lines allocated in S state.	
0AH	08H	UNC_L3_LINES_IN.F_STATE	Counts the number of L3 lines allocated in F state.	
0AH	0FH	UNC_L3_LINES_IN.ANY	Counts the number of L3 lines allocated in any state.	
0BH	01H	UNC_L3_LINES_OUT.M_STATE	Counts the number of L3 lines victimized that were in the M state. When the victim cache line is in M state, the line is written to its home cache agent which can be either local or remote.	
0BH	02H	UNC_L3_LINES_OUT.E_STATE	Counts the number of L3 lines victimized that were in the E state.	
0BH	04H	UNC_L3_LINES_OUT.S_STATE	Counts the number of L3 lines victimized that were in the S state.	
0BH	08H	UNC_L3_LINES_OUT.I_STATE	Counts the number of L3 lines victimized that were in the I state.	
0BH	10H	UNC_L3_LINES_OUT.F_STATE	Counts the number of L3 lines victimized that were in the F state.	
0BH	1FH	UNC_L3_LINES_OUT.ANY	Counts the number of L3 lines victimized in any state.	
0CH	01H	UNC_GQ_SNOOP.GOTO_S	Counts the number of remote snoops that have requested a cache line be set to the S state.	
0CH	02H	UNC_GQ_SNOOP.GOTO_I	Counts the number of remote snoops that have requested a cache line be set to the I state.	
0CH	04H	UNC_GQ_SNOOP.GOTO_S_HIT_E	Counts the number of remote snoops that have requested a cache line be set to the S state from E state.	Requires writing MSR 301H with mask = 2H
0CH	04H	UNC_GQ_SNOOP.GOTO_S_HIT_F	Counts the number of remote snoops that have requested a cache line be set to the S state from F (forward) state.	Requires writing MSR 301H with mask = 8H
0CH	04H	UNC_GQ_SNOOP.GOTO_S_HIT_M	Counts the number of remote snoops that have requested a cache line be set to the S state from M state.	Requires writing MSR 301H with mask = 1H
0CH	04H	UNC_GQ_SNOOP.GOTO_S_HIT_S	Counts the number of remote snoops that have requested a cache line be set to the S state from S state.	Requires writing MSR 301H with mask = 4H
0CH	08H	UNC_GQ_SNOOP.GOTO_I_HIT_E	Counts the number of remote snoops that have requested a cache line be set to the I state from E state.	Requires writing MSR 301H with mask = 2H

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
0CH	08H	UNC_GQ_SNOOP.GOTO_I_HIT_F	Counts the number of remote snoops that have requested a cache line be set to the I state from F (forward) state.	Requires writing MSR 301H with mask = 8H
0CH	08H	UNC_GQ_SNOOP.GOTO_I_HIT_M	Counts the number of remote snoops that have requested a cache line be set to the I state from M state.	Requires writing MSR 301H with mask = 1H
0CH	08H	UNC_GQ_SNOOP.GOTO_I_HIT_S	Counts the number of remote snoops that have requested a cache line be set to the I state from S state.	Requires writing MSR 301H with mask = 4H
20H	01H	UNC_QHL_REQUESTS.IOH_READS	Counts number of Quickpath Home Logic read requests from the IOH.	
20H	02H	UNC_QHL_REQUESTS.IOH_WRITES	Counts number of Quickpath Home Logic write requests from the IOH.	
20H	04H	UNC_QHL_REQUESTS.REMOTE_READS	Counts number of Quickpath Home Logic read requests from a remote socket.	
20H	08H	UNC_QHL_REQUESTS.REMOTE_WRITES	Counts number of Quickpath Home Logic write requests from a remote socket.	
20H	10H	UNC_QHL_REQUESTS.LOCAL_READS	Counts number of Quickpath Home Logic read requests from the local socket.	
20H	20H	UNC_QHL_REQUESTS.LOCAL_WRITES	Counts number of Quickpath Home Logic write requests from the local socket.	
21H	01H	UNC_QHL_CYCLES_FULL.IOH	Counts uclk cycles all entries in the Quickpath Home Logic IOH are full.	
21H	02H	UNC_QHL_CYCLES_FULL.REMOTE	Counts uclk cycles all entries in the Quickpath Home Logic remote tracker are full.	
21H	04H	UNC_QHL_CYCLES_FULL.LOCAL	Counts uclk cycles all entries in the Quickpath Home Logic local tracker are full.	
22H	01H	UNC_QHL_CYCLES_NOT_EMPTY.IOH	Counts uclk cycles all entries in the Quickpath Home Logic IOH is busy.	
22H	02H	UNC_QHL_CYCLES_NOT_EMPTY.REMOTE	Counts uclk cycles all entries in the Quickpath Home Logic remote tracker is busy.	
22H	04H	UNC_QHL_CYCLES_NOT_EMPTY.LOCAL	Counts uclk cycles all entries in the Quickpath Home Logic local tracker is busy.	
23H	01H	UNC_QHL_OCCUPANCY.IOH	QHL IOH tracker allocate to deallocate read occupancy.	
23H	02H	UNC_QHL_OCCUPANCY.REMOTE	QHL remote tracker allocate to deallocate read occupancy.	
23H	04H	UNC_QHL_OCCUPANCY.LOCAL	QHL local tracker allocate to deallocate read occupancy.	
24H	02H	UNC_QHL_ADDRESS_CONFLICTS.2WAY	Counts number of QHL Active Address Table (AAT) entries that saw a max of 2 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
24H	04H	UNC_QHL_ADDRESS_CONFLICTS.3WAY	Counts number of QHL Active Address Table (AAT) entries that saw a max of 3 conflicts. The AAT is a structure that tracks requests that are in conflict. The requests themselves are in the home tracker entries. The count is reported when an AAT entry deallocates.	
25H	01H	UNC_QHL_CONFLICT_CYCLES.IOH	Counts cycles the Quickpath Home Logic IOH Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.	
25H	02H	UNC_QHL_CONFLICT_CYCLES.REMOTE	Counts cycles the Quickpath Home Logic Remote Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.	
25H	04H	UNC_QHL_CONFLICT_CYCLES.LOCAL	Counts cycles the Quickpath Home Logic Local Tracker contains two or more requests with an address conflict. A max of 3 requests can be in conflict.	
26H	01H	UNC_QHL_TO_QMC_BYPASS	Counts number or requests to the Quickpath Memory Controller that bypass the Quickpath Home Logic. All local accesses can be bypassed. For remote requests, only read requests can be bypassed.	
28H	01H	UNC_QMC_ISOC_FULL.READ.CH0	Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous read requests.	
28H	02H	UNC_QMC_ISOC_FULL.READ.CH1	Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous read requests.	
28H	04H	UNC_QMC_ISOC_FULL.READ.CH2	Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous read requests.	
28H	08H	UNC_QMC_ISOC_FULL.WRITE.CH0	Counts cycles all the entries in the DRAM channel 0 high priority queue are occupied with isochronous write requests.	
28H	10H	UNC_QMC_ISOC_FULL.WRITE.CH1	Counts cycles all the entries in the DRAM channel 1 high priority queue are occupied with isochronous write requests.	
28H	20H	UNC_QMC_ISOC_FULL.WRITE.CH2	Counts cycles all the entries in the DRAM channel 2 high priority queue are occupied with isochronous write requests.	
29H	01H	UNC_QMC_BUSY.READ.CH0	Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 0.	
29H	02H	UNC_QMC_BUSY.READ.CH1	Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 1.	
29H	04H	UNC_QMC_BUSY.READ.CH2	Counts cycles where Quickpath Memory Controller has at least 1 outstanding read request to DRAM channel 2.	
29H	08H	UNC_QMC_BUSY.WRITE.CH0	Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 0.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
29H	10H	UNC_QMC_BUSY.WRITE.CH1	Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 1.	
29H	20H	UNC_QMC_BUSY.WRITE.CH2	Counts cycles where Quickpath Memory Controller has at least 1 outstanding write request to DRAM channel 2.	
2AH	01H	UNC_QMC_OCCUPANCY.CH0	IMC channel 0 normal read request occupancy.	
2AH	02H	UNC_QMC_OCCUPANCY.CH1	IMC channel 1 normal read request occupancy.	
2AH	04H	UNC_QMC_OCCUPANCY.CH2	IMC channel 2 normal read request occupancy.	
2AH	07H	UNC_QMC_OCCUPANCY.ANY	Normal read request occupancy for any channel.	
2BH	01H	UNC_QMC_ISSOC_OCCUPANCY.CH0	IMC channel 0 issoc read request occupancy.	
2BH	02H	UNC_QMC_ISSOC_OCCUPANCY.CH1	IMC channel 1 issoc read request occupancy.	
2BH	04H	UNC_QMC_ISSOC_OCCUPANCY.CH2	IMC channel 2 issoc read request occupancy.	
2BH	07H	UNC_QMC_ISSOC_READS.ANY	IMC issoc read request occupancy.	
2CH	01H	UNC_QMC_NORMAL_READS.CH0	Counts the number of Quickpath Memory Controller channel 0 medium and low priority read requests. The QMC channel 0 normal read occupancy divided by this count provides the average QMC channel 0 read latency.	
2CH	02H	UNC_QMC_NORMAL_READS.CH1	Counts the number of Quickpath Memory Controller channel 1 medium and low priority read requests. The QMC channel 1 normal read occupancy divided by this count provides the average QMC channel 1 read latency.	
2CH	04H	UNC_QMC_NORMAL_READS.CH2	Counts the number of Quickpath Memory Controller channel 2 medium and low priority read requests. The QMC channel 2 normal read occupancy divided by this count provides the average QMC channel 2 read latency.	
2CH	07H	UNC_QMC_NORMAL_READS.ANY	Counts the number of Quickpath Memory Controller medium and low priority read requests. The QMC normal read occupancy divided by this count provides the average QMC read latency.	
2DH	01H	UNC_QMC_HIGH_PRIORITY_READS.CH0	Counts the number of Quickpath Memory Controller channel 0 high priority isochronous read requests.	
2DH	02H	UNC_QMC_HIGH_PRIORITY_READS.CH1	Counts the number of Quickpath Memory Controller channel 1 high priority isochronous read requests.	
2DH	04H	UNC_QMC_HIGH_PRIORITY_READS.CH2	Counts the number of Quickpath Memory Controller channel 2 high priority isochronous read requests.	
2DH	07H	UNC_QMC_HIGH_PRIORITY_READS.ANY	Counts the number of Quickpath Memory Controller high priority isochronous read requests.	
2EH	01H	UNC_QMC_CRITICAL_PRIORITY_READS.CH0	Counts the number of Quickpath Memory Controller channel 0 critical priority isochronous read requests.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
2EH	02H	UNC_QMC_CRITICAL_PRIORITY_READS.CH1	Counts the number of Quickpath Memory Controller channel 1 critical priority isochronous read requests.	
2EH	04H	UNC_QMC_CRITICAL_PRIORITY_READS.CH2	Counts the number of Quickpath Memory Controller channel 2 critical priority isochronous read requests.	
2EH	07H	UNC_QMC_CRITICAL_PRIORITY_READS.ANY	Counts the number of Quickpath Memory Controller critical priority isochronous read requests.	
2FH	01H	UNC_QMC_WRITES.FULL.CHO	Counts number of full cache line writes to DRAM channel 0.	
2FH	02H	UNC_QMC_WRITES.FULL.CH1	Counts number of full cache line writes to DRAM channel 1.	
2FH	04H	UNC_QMC_WRITES.FULL.CH2	Counts number of full cache line writes to DRAM channel 2.	
2FH	07H	UNC_QMC_WRITES.FULL.ANY	Counts number of full cache line writes to DRAM.	
2FH	08H	UNC_QMC_WRITES.PARTIAL.CH0	Counts number of partial cache line writes to DRAM channel 0.	
2FH	10H	UNC_QMC_WRITES.PARTIAL.CH1	Counts number of partial cache line writes to DRAM channel 1.	
2FH	20H	UNC_QMC_WRITES.PARTIAL.CH2	Counts number of partial cache line writes to DRAM channel 2.	
2FH	38H	UNC_QMC_WRITES.PARTIAL.ANY	Counts number of partial cache line writes to DRAM.	
30H	01H	UNC_QMC_CANCEL.CH0	Counts number of DRAM channel 0 cancel requests.	
30H	02H	UNC_QMC_CANCEL.CH1	Counts number of DRAM channel 1 cancel requests.	
30H	04H	UNC_QMC_CANCEL.CH2	Counts number of DRAM channel 2 cancel requests.	
30H	07H	UNC_QMC_CANCEL.ANY	Counts number of DRAM cancel requests.	
31H	01H	UNC_QMC_PRIORITY_UPDATE.S.CH0	Counts number of DRAM channel 0 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.	
31H	02H	UNC_QMC_PRIORITY_UPDATE.S.CH1	Counts number of DRAM channel 1 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.	
31H	04H	UNC_QMC_PRIORITY_UPDATE.S.CH2	Counts number of DRAM channel 2 priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
31H	07H	UNC_QMC_PRIORITY_UPDATE.S.ANY	Counts number of DRAM priority updates. A priority update occurs when an ISOC high or critical request is received by the QHL and there is a matching request with normal priority that has already been issued to the QMC. In this instance, the QHL will send a priority update to QMC to expedite the request.	
32H	01H	UNC_IMC_RETRY.CH0	Counts number of IMC DRAM channel 0 retries. DRAM retry only occurs when configured in RAS mode.	
32H	02H	UNC_IMC_RETRY.CH1	Counts number of IMC DRAM channel 1 retries. DRAM retry only occurs when configured in RAS mode.	
32H	04H	UNC_IMC_RETRY.CH2	Counts number of IMC DRAM channel 2 retries. DRAM retry only occurs when configured in RAS mode.	
32H	07H	UNC_IMC_RETRY.ANY	Counts number of IMC DRAM retries from any channel. DRAM retry only occurs when configured in RAS mode.	
33H	01H	UNC_QHL_FRC_ACK_CNFLTS.IOH	Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the IOH.	
33H	02H	UNC_QHL_FRC_ACK_CNFLTS.REMOTE	Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the remote home.	
33H	04H	UNC_QHL_FRC_ACK_CNFLTS.LOCAL	Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic to the local home.	
33H	07H	UNC_QHL_FRC_ACK_CNFLTS.ANY	Counts number of Force Acknowledge Conflict messages sent by the Quickpath Home Logic.	
34H	01H	UNC_QHL_SLEEPS.IOH_ORDER	Counts number of occurrences a request was put to sleep due to IOH ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.	
34H	02H	UNC_QHL_SLEEPS.REMOTE_ORDER	Counts number of occurrences a request was put to sleep due to remote socket ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.	
34H	04H	UNC_QHL_SLEEPS.LOCAL_ORDER	Counts number of occurrences a request was put to sleep due to local socket ordering (write after read) conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.	
34H	08H	UNC_QHL_SLEEPS.IOH_CONFLICT	Counts number of occurrences a request was put to sleep due to IOH address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.	
34H	10H	UNC_QHL_SLEEPS.REMOTE_CONFLICT	Counts number of occurrences a request was put to sleep due to remote socket address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.	
34H	20H	UNC_QHL_SLEEPS.LOCAL_CONFLICT	Counts number of occurrences a request was put to sleep due to local socket address conflicts. While in the sleep state, the request is not eligible to be scheduled to the QMC.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
35H	01H	UNC_ADDR_OPCODE_MATCH.IOH	Counts number of requests from the IOH, address/opcode of request is qualified by mask value written to MSR 396H. The following mask values are supported: 0: NONE 40000000_00000000H:RSPFWDI 40001A00_00000000H:RSPFWDS 40001D00_00000000H:RSPIWB	Match opcode/address by writing MSR 396H with mask supported mask value
35H	02H	UNC_ADDR_OPCODE_MATCH.REMOTE	Counts number of requests from the remote socket, address/opcode of request is qualified by mask value written to MSR 396H. The following mask values are supported: 0: NONE 40000000_00000000H:RSPFWDI 40001A00_00000000H:RSPFWDS 40001D00_00000000H:RSPIWB	Match opcode/address by writing MSR 396H with mask supported mask value
35H	04H	UNC_ADDR_OPCODE_MATCH.LOCAL	Counts number of requests from the local socket, address/opcode of request is qualified by mask value written to MSR 396H. The following mask values are supported: 0: NONE 40000000_00000000H:RSPFWDI 40001A00_00000000H:RSPFWDS 40001D00_00000000H:RSPIWB	Match opcode/address by writing MSR 396H with mask supported mask value
40H	01H	UNC_QPI_TX_STALLED_SINGLE_FLIT.HOME.LINK_0	Counts cycles the Quickpath outbound link 0 HOME virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	02H	UNC_QPI_TX_STALLED_SINGLE_FLIT.SNOOP.LINK_0	Counts cycles the Quickpath outbound link 0 SNOOP virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	04H	UNC_QPI_TX_STALLED_SINGLE_FLIT.NDR.LINK_0	Counts cycles the Quickpath outbound link 0 non-data response virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	08H	UNC_QPI_TX_STALLED_SINGLE_FLIT.HOME.LINK_1	Counts cycles the Quickpath outbound link 1 HOME virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
40H	10H	UNC_QPI_TX_STALLED_SINGLE_FLIT.SNOOP.LINK_1	Counts cycles the Quickpath outbound link 1 SNOOP virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	20H	UNC_QPI_TX_STALLED_SINGLE_FLIT.NDR.LINK_1	Counts cycles the Quickpath outbound link 1 non-data response virtual channel is stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	07H	UNC_QPI_TX_STALLED_SINGLE_FLIT.LINK_0	Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
40H	38H	UNC_QPI_TX_STALLED_SINGLE_FLIT.LINK_1	Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of a VNA and VNO credit. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	01H	UNC_QPI_TX_STALLED_MULTIFLIT.DRS.LINK_0	Counts cycles the Quickpath outbound link 0 Data Response virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	02H	UNC_QPI_TX_STALLED_MULTIFLIT.NCB.LINK_0	Counts cycles the Quickpath outbound link 0 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	04H	UNC_QPI_TX_STALLED_MULTIFLIT.NCS.LINK_0	Counts cycles the Quickpath outbound link 0 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	08H	UNC_QPI_TX_STALLED_MULTIFLIT.DRS.LINK_1	Counts cycles the Quickpath outbound link 1 Data Response virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	10H	UNC_QPI_TX_STALLED_MULTIFLIT.NCB.LINK_1	Counts cycles the Quickpath outbound link 1 Non-Coherent Bypass virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
41H	20H	UNC_QPI_TX_STALLED_MULTIFLIT.NCS.LINK_1	Counts cycles the Quickpath outbound link 1 Non-Coherent Standard virtual channel is stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	07H	UNC_QPI_TX_STALLED_MULTIFLIT.LINK_0	Counts cycles the Quickpath outbound link 0 virtual channels are stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
41H	38H	UNC_QPI_TX_STALLED_MULTIFLIT.LINK_1	Counts cycles the Quickpath outbound link 1 virtual channels are stalled due to lack of VNA and VNO credits. Note that this event does not filter out when a flit would not have been selected for arbitration because another virtual channel is getting arbitrated.	
42H	01H	UNC_QPI_TX_HEADER.FULL.LINK_0	Number of cycles that the header buffer in the Quickpath Interface outbound link 0 is full.	
42H	02H	UNC_QPI_TX_HEADER.BUSY.LINK_0	Number of cycles that the header buffer in the Quickpath Interface outbound link 0 is busy.	
42H	04H	UNC_QPI_TX_HEADER.FULL.LINK_1	Number of cycles that the header buffer in the Quickpath Interface outbound link 1 is full.	
42H	08H	UNC_QPI_TX_HEADER.BUSY.LINK_1	Number of cycles that the header buffer in the Quickpath Interface outbound link 1 is busy.	
43H	01H	UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_0	Number of cycles that snoop packets incoming to the Quickpath Interface link 0 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries.	
43H	02H	UNC_QPI_RX_NO_PPT_CREDIT.STALLS.LINK_1	Number of cycles that snoop packets incoming to the Quickpath Interface link 1 are stalled and not sent to the GQ because the GQ Peer Probe Tracker (PPT) does not have any available entries.	
60H	01H	UNC_DRAM_OPEN.CH0	Counts number of DRAM Channel 0 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.	
60H	02H	UNC_DRAM_OPEN.CH1	Counts number of DRAM Channel 1 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.	
60H	04H	UNC_DRAM_OPEN.CH2	Counts number of DRAM Channel 2 open commands issued either for read or write. To read or write data, the referenced DRAM page must first be opened.	
61H	01H	UNC_DRAM_PAGE_CLOSE.CH0	DRAM channel 0 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.	
61H	02H	UNC_DRAM_PAGE_CLOSE.CH1	DRAM channel 1 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
61H	04H	UNC_DRAM_PAGE_CLOSE.CH2	DRAM channel 2 command issued to CLOSE a page due to page idle timer expiration. Closing a page is done by issuing a precharge.	
62H	01H	UNC_DRAM_PAGE_MISS.CH0	Counts the number of precharges (PRE) that were issued to DRAM channel 0 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge.	
62H	02H	UNC_DRAM_PAGE_MISS.CH1	Counts the number of precharges (PRE) that were issued to DRAM channel 1 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge.	
62H	04H	UNC_DRAM_PAGE_MISS.CH2	Counts the number of precharges (PRE) that were issued to DRAM channel 2 because there was a page miss. A page miss refers to a situation in which a page is currently open and another page from the same bank needs to be opened. The new page experiences a page miss. Closing of the old page is done by issuing a precharge.	
63H	01H	UNC_DRAM_READ_CAS.CH0	Counts the number of times a read CAS command was issued on DRAM channel 0.	
63H	02H	UNC_DRAM_READ_CAS.AUTO PRE_CH0	Counts the number of times a read CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode.	
63H	04H	UNC_DRAM_READ_CAS.CH1	Counts the number of times a read CAS command was issued on DRAM channel 1.	
63H	08H	UNC_DRAM_READ_CAS.AUTO PRE_CH1	Counts the number of times a read CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode.	
63H	10H	UNC_DRAM_READ_CAS.CH2	Counts the number of times a read CAS command was issued on DRAM channel 2.	
63H	20H	UNC_DRAM_READ_CAS.AUTO PRE_CH2	Counts the number of times a read CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode.	
64H	01H	UNC_DRAM_WRITE_CAS.CH0	Counts the number of times a write CAS command was issued on DRAM channel 0.	
64H	02H	UNC_DRAM_WRITE_CAS.AUTO PRE_CH0	Counts the number of times a write CAS command was issued on DRAM channel 0 where the command issued used the auto-precharge (auto page close) mode.	
64H	04H	UNC_DRAM_WRITE_CAS.CH1	Counts the number of times a write CAS command was issued on DRAM channel 1.	
64H	08H	UNC_DRAM_WRITE_CAS.AUTO PRE_CH1	Counts the number of times a write CAS command was issued on DRAM channel 1 where the command issued used the auto-precharge (auto page close) mode.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
64H	10H	UNC_DRAM_WRITE_CAS.CH2	Counts the number of times a write CAS command was issued on DRAM channel 2.	
64H	20H	UNC_DRAM_WRITE_CAS.AUTO_PRE_CH2	Counts the number of times a write CAS command was issued on DRAM channel 2 where the command issued used the auto-precharge (auto page close) mode.	
65H	01H	UNC_DRAM_REFRESH.CH0	Counts number of DRAM channel 0 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.	
65H	02H	UNC_DRAM_REFRESH.CH1	Counts number of DRAM channel 1 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.	
65H	04H	UNC_DRAM_REFRESH.CH2	Counts number of DRAM channel 2 refresh commands. DRAM loses data content over time. In order to keep correct data content, the data values have to be refreshed periodically.	
66H	01H	UNC_DRAM_PRE_ALL.CH0	Counts number of DRAM Channel 0 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode.	
66H	02H	UNC_DRAM_PRE_ALL.CH1	Counts number of DRAM Channel 1 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode.	
66H	04H	UNC_DRAM_PRE_ALL.CH2	Counts number of DRAM Channel 2 precharge-all (PREALL) commands that close all open pages in a rank. PREALL is issued when the DRAM needs to be refreshed or needs to go into a power down mode.	
67H	01H	UNC_DRAM_THERMAL_THROTTLED	Uncore cycles DRAM was throttled due to its temperature being above the thermal throttling threshold.	
80H	01H	UNC_THERMAL_THROTTLING_TEMP.CORE_0	Cycles that the PCU records that core 0 is above the thermal throttling threshold temperature.	
80H	02H	UNC_THERMAL_THROTTLING_TEMP.CORE_1	Cycles that the PCU records that core 1 is above the thermal throttling threshold temperature.	
80H	04H	UNC_THERMAL_THROTTLING_TEMP.CORE_2	Cycles that the PCU records that core 2 is above the thermal throttling threshold temperature.	
80H	08H	UNC_THERMAL_THROTTLING_TEMP.CORE_3	Cycles that the PCU records that core 3 is above the thermal throttling threshold temperature.	
81H	01H	UNC_THERMAL_THROTTLED_TEMP.CORE_0	Cycles that the PCU records that core 0 is in the power throttled state due to core's temperature being above the thermal throttling threshold.	
81H	02H	UNC_THERMAL_THROTTLED_TEMP.CORE_1	Cycles that the PCU records that core 1 is in the power throttled state due to core's temperature being above the thermal throttling threshold.	

**Table 19-14. Non-Architectural Performance Events In the Processor Uncore for Processors Based on Intel® Microarchitecture Code Name Westmere (Contd.)**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
81H	04H	UNC_THERMAL_THROTTLED_TEMP.CORE_2	Cycles that the PCU records that core 2 is in the power throttled state due to core's temperature being above the thermal throttling threshold.	
81H	08H	UNC_THERMAL_THROTTLED_TEMP.CORE_3	Cycles that the PCU records that core 3 is in the power throttled state due to core's temperature being above the thermal throttling threshold.	
82H	01H	UNC_PROCHOT_ASSERTION	Number of system assertions of PROCHOT indicating the entire processor has exceeded the thermal limit.	
83H	01H	UNC_THERMAL_THROTTLING_PROCHOT.CORE_0	Cycles that the PCU records that core 0 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit.	
83H	02H	UNC_THERMAL_THROTTLING_PROCHOT.CORE_1	Cycles that the PCU records that core 1 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit.	
83H	04H	UNC_THERMAL_THROTTLING_PROCHOT.CORE_2	Cycles that the PCU records that core 2 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit.	
83H	08H	UNC_THERMAL_THROTTLING_PROCHOT.CORE_3	Cycles that the PCU records that core 3 is a low power state due to the system asserting PROCHOT the entire processor has exceeded the thermal limit.	
84H	01H	UNC_TURBO_MODE.CORE_0	Uncore cycles that core 0 is operating in turbo mode.	
84H	02H	UNC_TURBO_MODE.CORE_1	Uncore cycles that core 1 is operating in turbo mode.	
84H	04H	UNC_TURBO_MODE.CORE_2	Uncore cycles that core 2 is operating in turbo mode.	
84H	08H	UNC_TURBO_MODE.CORE_3	Uncore cycles that core 3 is operating in turbo mode.	
85H	02H	UNC_CYCLES_UNHALTED_L3_FLL_ENABLE	Uncore cycles that at least one core is unhalted and all L3 ways are enabled.	
86H	01H	UNC_CYCLES_UNHALTED_L3_FLL_DISABLE	Uncore cycles that at least one core is unhalted and all L3 ways are disabled.	

## 19.7 PERFORMANCE MONITORING EVENTS FOR INTEL® XEON® PROCESSOR 5200, 5400 SERIES AND INTEL® CORE™ 2 EXTREME PROCESSORS QX 9000 SERIES

Processors based on the Enhanced Intel Core microarchitecture support the architectural and non-architectural performance-monitoring events listed in Table 19-1 and Table 19-17. In addition, they also support the following non-architectural performance-monitoring events listed in Table 19-15. Fixed counters support the architecture events defined in Table 19-16.

**Table 19-15. Non-Architectural Performance Events for Processors Based on Enhanced Intel Core Microarchitecture**

Event Num.	Umask Value	Event Mask Mnemonic	Description	Comment
COH	08H	INST_RETIRED.VM_HOST	Instruction retired while in VMX root operations.	
D2H	10H	RAT_STAALS.OTHER_SERIALI ZATION_STALLS	This events counts the number of stalls due to other RAT resource serialization not counted by Umask value 0FH.	

## 19.8 PERFORMANCE MONITORING EVENTS FOR INTEL® XEON® PROCESSOR 3000, 3200, 5100, 5300 SERIES AND INTEL® CORE™ 2 DUO PROCESSORS

Processors based on the Intel® Core™ microarchitecture support architectural and non-architectural performance-monitoring events.

Fixed-function performance counters are introduced first on processors based on Intel Core microarchitecture. Table 19-16 lists pre-defined performance events that can be counted using fixed-function performance counters.

**Table 19-16. Fixed-Function Performance Counter and Pre-defined Performance Events**

Fixed-Function Performance Counter	Address	Event Mask Mnemonic	Description
MSR_PERF_FIXED_CTR0/IA32_PERF_FIXED_CTR0	309H	Inst_Retired.Any	This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continue counting during hardware interrupts, traps, and inside interrupt handlers.
MSR_PERF_FIXED_CTR1/IA32_PERF_FIXED_CTR1	30AH	CPU_CLK_UNHALTED.CORE	This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.  The core frequency may change from time to time due to transitions associated with Enhanced Intel SpeedStep Technology or TM2. For this reason this event may have a changing ratio with regards to time. When the core frequency is constant, this event can approximate elapsed time while the core was not in halt state.
MSR_PERF_FIXED_CTR2/IA32_PERF_FIXED_CTR2	30BH	CPU_CLK_UNHALTED.REF	This event counts the number of reference cycles when the core is not in a halt state and not in a TM stop-clock state. The core enters the halt state when it is running the HLT instruction or the MWAIT instruction.

**Table 19-16. Fixed-Function Performance Counter and Pre-defined Performance Events (Contd.)**

Fixed-Function Performance Counter	Address	Event Mask Mnemonic	Description
			<p>This event is not affected by core frequency changes (e.g., P states) but counts at the same frequency as the time stamp counter. This event can approximate elapsed time while the core was not in halt state and not in a TM stop-clock state.</p> <p>This event has a constant ratio with the CPU_CLK_UNHALTED.BUS event.</p>

Table 19-17 lists general-purpose non-architectural performance-monitoring events supported in processors based on Intel® Core™ microarchitecture. For convenience, Table 19-17 also includes architectural events and describes minor model-specific behavior where applicable. Software must use a general-purpose performance counter to count events listed in Table 19-17.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture**

Event Num	Umask Value	Event Name	Definition	Description and Comment
03H	02H	LOAD_BLOCK.STA	Loads blocked by a preceding store with unknown address	<p>This event indicates that loads are blocked by preceding stores. A load is blocked when there is a preceding store to an address that is not yet calculated. The number of events is greater or equal to the number of load operations that were blocked.</p> <p>If the load and the store are always to different addresses, check why the memory disambiguation mechanism is not working. To avoid such blocks, increase the distance between the store and the following load so that the store address is known at the time the load is dispatched.</p>
03H	04H	LOAD_BLOCK.STD	Loads blocked by a preceding store with unknown data	<p>This event indicates that loads are blocked by preceding stores. A load is blocked when there is a preceding store to the same address and the stored data value is not yet known. The number of events is greater or equal to the number of load operations that were blocked.</p> <p>To avoid such blocks, increase the distance between the store and the dependant load, so that the store data is known at the time the load is dispatched.</p>
03H	08H	LOAD_BLOCK.OVERLAP_STORE	Loads that partially overlap an earlier store, or 4-Kbyte aliased with a previous store	<p>This event indicates that loads are blocked due to a variety of reasons. Some of the triggers for this event are when a load is blocked by a preceding store, in one of the following:</p> <ul style="list-style-type: none"> <li>▪ Some of the loaded byte locations are written by the preceding store and some are not.</li> <li>▪ The load is from bytes written by the preceding store, the store is aligned to its size and either:                             <ul style="list-style-type: none"> <li>▪ The load's data size is one or two bytes and it is not aligned to the store.</li> <li>▪ The load's data size is of four or eight bytes and the load is misaligned.</li> </ul> </li> </ul>

Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)

Event Num	Umask Value	Event Name	Definition	Description and Comment
				<ul style="list-style-type: none"> <li>The load is from bytes written by the preceding store, the store is misaligned and the load is not aligned on the beginning of the store.</li> <li>The load is split over an eight byte boundary (excluding 16-byte loads).</li> <li>The load and store have the same offset relative to the beginning of different 4-KByte pages. This case is also called 4-KByte aliasing.</li> <li>In all these cases the load is blocked until after the blocking store retires and the stored data is committed to the cache hierarchy.</li> </ul>
03H	10H	LOAD_BLOCK.UNTIL_RETIRE	Loads blocked until retirement	This event indicates that load operations were blocked until retirement. The number of events is greater or equal to the number of load operations that were blocked. This includes mainly uncacheable loads and split loads (loads that cross the cache line boundary) but may include other cases where loads are blocked until retirement.
03H	20H	LOAD_BLOCK.L1D	Loads blocked by the L1 data cache	This event indicates that loads are blocked due to one or more reasons. Some triggers for this event are: <ul style="list-style-type: none"> <li>The number of L1 data cache misses exceeds the maximum number of outstanding misses supported by the processor. This includes misses generated as result of demand fetches, software prefetches or hardware prefetches.</li> <li>Cache line split loads.</li> <li>Partial reads, such as reads to un-cacheable memory, I/O instructions and more.</li> <li>A locked load operation is in progress. The number of events is greater or equal to the number of load operations that were blocked.</li> </ul>
04H	01H	SB_DRAIN_CYCLES	Cycles while stores are blocked due to store buffer drain	This event counts every cycle during which the store buffer is draining. This includes: <ul style="list-style-type: none"> <li>Serializing operations such as CPUID</li> <li>Synchronizing operations such as XCHG</li> <li>Interrupt acknowledgment</li> <li>Other conditions, such as cache flushing</li> </ul>
04H	02H	STORE_BLOCK.ORDER	Cycles while store is waiting for a preceding store to be globally observed	This event counts the total duration, in number of cycles, which stores are waiting for a preceding stored cache line to be observed by other cores. This situation happens as a result of the strong store ordering behavior, as defined in "Memory Ordering," Chapter 8, <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A</i> .  The stall may occur and be noticeable if there are many cases when a store either misses the L1 data cache or hits a cache line in the Shared state. If the store requires a bus transaction to read the cache line then the stall ends when snoop response for the bus transaction arrives.
04H	08H	STORE_BLOCK.SNOOP	A store is blocked due to a conflict with an external or internal snoop.	This event counts the number of cycles the store port was used for snooping the L1 data cache and a store was stalled by the snoop. The store is typically resubmitted one cycle later.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
06H	00H	SEGMENT_REG_LOADS	Number of segment register loads	<p>This event counts the number of segment register load operations. Instructions that load new values into segment registers cause a penalty.</p> <p>This event indicates performance issues in 16-bit code. If this event occurs frequently, it may be useful to calculate the number of instructions retired per segment register load. If the resulting calculation is low (on average a small number of instructions are executed between segment register loads), then the code's segment register usage should be optimized.</p> <p>As a result of branch misprediction, this event is speculative and may include segment register loads that do not actually occur. However, most segment register loads are internally serialized and such speculative effects are minimized.</p>
07H	00H	SSE_PRE_EXEC.NTA	Streaming SIMD Extensions (SSE) Prefetch NTA instructions executed	<p>This event counts the number of times the SSE instruction prefetchNTA is executed.</p> <p>This instruction prefetches the data to the L1 data cache.</p>
07H	01H	SSE_PRE_EXEC.L1	Streaming SIMD Extensions (SSE) PrefetchT0 instructions executed	<p>This event counts the number of times the SSE instruction prefetchT0 is executed. This instruction prefetches the data to the L1 data cache and L2 cache.</p>
07H	02H	SSE_PRE_EXEC.L2	Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions executed	<p>This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 are executed. These instructions prefetch the data to the L2 cache.</p>
07H	03H	SSE_PRE_EXEC.STORES	Streaming SIMD Extensions (SSE) Weakly-ordered store instructions executed	<p>This event counts the number of times SSE non-temporal store instructions are executed.</p>
08H	01H	DTLB_MISSES.ANY	Memory accesses that missed the DTLB	<p>This event counts the number of Data Table Lookaside Buffer (DTLB) misses. The count includes misses detected as a result of speculative accesses.</p> <p>Typically a high count for this event indicates that the code accesses a large number of data pages.</p>
08H	02H	DTLB_MISSES.MISS_LD	DTLB misses due to load operations	<p>This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to load operations.</p> <p>This count includes misses detected as a result of speculative accesses.</p>
08H	04H	DTLB_MISSES.LO_MISS_LD	LO DTLB misses due to load operations	<p>This event counts the number of level 0 Data Table Lookaside Buffer (DTLBO) misses due to load operations.</p> <p>This count includes misses detected as a result of speculative accesses. Loads that miss that DTLBO and hit the DTLB1 can incur two-cycle penalty.</p>

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
08H	08H	DTLB_MISSES. MISS_ST	TLB misses due to store operations	This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to store operations.  This count includes misses detected as a result of speculative accesses. Address translation for store operations is performed in the DTLB1.
09H	01H	MEMORY_ DISAMBIGUATION.RESET	Memory disambiguation reset cycles	This event counts the number of cycles during which memory disambiguation misprediction occurs. As a result the execution pipeline is cleaned and execution of the mispredicted load instruction and all succeeding instructions restarts.  This event occurs when the data address accessed by a load instruction, collides infrequently with preceding stores, but usually there is no collision. It happens rarely, and may have a penalty of about 20 cycles.
09H	02H	MEMORY_DISAMBIGUATIO N.SUCCESS	Number of loads successfully disambiguated.	This event counts the number of load operations that were successfully disambiguated. Loads are preceded by a store with an unknown address, but they are not blocked.
0CH	01H	PAGE_WALKS. .COUNT	Number of page-walks executed	This event counts the number of page-walks executed due to either a DTLB or ITLB miss.  The page walk duration, PAGE_WALKS.CYCLES, divided by number of page walks is the average duration of a page walk. The average can hint whether most of the page-walks are satisfied by the caches or cause an L2 cache miss.
0CH	02H	PAGE_WALKS. CYCLES	Duration of page-walks in core cycles	This event counts the duration of page-walks in core cycles. The paging mode in use typically affects the duration of page walks.  Page walk duration divided by number of page walks is the average duration of page-walks. The average can hint at whether most of the page-walks are satisfied by the caches or cause an L2 cache miss.
10H	00H	FP_COMP_OPS _EXE	Floating point computational micro-ops executed	This event counts the number of floating point computational micro-ops executed. Use IA32_PMC0 only.
11H	00H	FP_ASSIST	Floating point assists	This event counts the number of floating point operations executed that required micro-code assist intervention. Assists are required in the following cases: <ul style="list-style-type: none"> <li>▪ Streaming SIMD Extensions (SSE) instructions:</li> <li>▪ Denormal input when the DAZ (Denormals Are Zeros) flag is off</li> <li>▪ Underflow result when the FTZ (Flush To Zero) flag is off</li> <li>▪ X87 instructions:</li> <li>▪ NaN or denormal are loaded to a register or used as input from memory</li> <li>▪ Division by 0</li> <li>▪ Underflow output</li> </ul> Use IA32_PMC1 only.
12H	00H	MUL	Multiply operations executed	This event counts the number of multiply operations executed. This includes integer as well as floating point multiply operations. Use IA32_PMC1 only.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
13H	OOH	DIV	Divide operations executed	This event counts the number of divide operations executed. This includes integer divides, floating point divides and square-root operations executed. Use IA32_PMC1 only.
14H	OOH	CYCLES_DIV_BUSY	Cycles the divider busy	This event counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE. Use IA32_PMC0 only.
18H	OOH	IDLE_DURING_DIV	Cycles the divider is busy and all other execution units are idle.	This event counts the number of cycles the divider is busy (with a divide or a square root operation) and no other execution unit or load operation is in progress. Load operations are assumed to hit the L1 data cache. This event considers only micro-ops dispatched after the divider started operating. Use IA32_PMC0 only.
19H	OOH	DELAYED_BYPASS.FP	Delayed bypass to FP operation	This event counts the number of times floating point operations use data immediately after the data was generated by a non-floating point execution unit. Such cases result in one penalty cycle due to data bypass between the units. Use IA32_PMC1 only.
19H	01H	DELAYED_BYPASS.SIMD	Delayed bypass to SIMD operation	This event counts the number of times SIMD operations use data immediately after the data was generated by a non-SIMD execution unit. Such cases result in one penalty cycle due to data bypass between the units. Use IA32_PMC1 only.
19H	02H	DELAYED_BYPASS.LOAD	Delayed bypass to load operation	This event counts the number of delayed bypass penalty cycles that a load operation incurred. When load operations use data immediately after the data was generated by an integer execution unit, they may (pending on certain dynamic internal conditions) incur one penalty cycle due to delayed data bypass between the units. Use IA32_PMC1 only.
21H	See Table 18-2	L2_ADS.(Core)	Cycles L2 address bus is in use	This event counts the number of cycles the L2 address bus is being used for accesses to the L2 cache or bus queue. It can count occurrences for this core or both cores.
23H	See Table 18-2	L2_DBUS_BUSY_RD.(Core)	Cycles the L2 transfers data to the core	This event counts the number of cycles during which the L2 data bus is busy transferring data from the L2 cache to the core. It counts for all L1 cache misses (data and instruction) that hit the L2 cache. This event can count occurrences for this core or both cores.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
24H	Combined mask from Table 18-2 and Table 18-4	L2_LINES_IN. (Core, Prefetch)	L2 cache misses	This event counts the number of cache lines allocated in the L2 cache. Cache lines are allocated in the L2 cache as a result of requests from the L1 data and instruction caches and the L2 hardware prefetchers to cache lines that are missing in the L2 cache.  This event can count occurrences for this core or both cores. It can also count demand requests and L2 hardware prefetch requests together or separately.
25H	See Table 18-2	L2_M_LINES_IN. (Core)	L2 cache line modifications	This event counts whenever a modified cache line is written back from the L1 data cache to the L2 cache.  This event can count occurrences for this core or both cores.
26H	See Table 18-2 and Table 18-4	L2_LINES_OUT. (Core, Prefetch)	L2 cache lines evicted	This event counts the number of L2 cache lines evicted.  This event can count occurrences for this core or both cores. It can also count evictions due to demand requests and L2 hardware prefetch requests together or separately.
27H	See Table 18-2 and Table 18-4	L2_M_LINES_OUT.(Core, Prefetch)	Modified lines evicted from the L2 cache	This event counts the number of L2 modified cache lines evicted. These lines are written back to memory unless they also exist in a modified-state in one of the L1 data caches.  This event can count occurrences for this core or both cores. It can also count evictions due to demand requests and L2 hardware prefetch requests together or separately.
28H	Combined mask from Table 18-2 and Table 18-5	L2_IFETCH.(Core, Cache Line State)	L2 cacheable instruction fetch requests	This event counts the number of instruction cache line requests from the IFU. It does not include fetch requests from uncacheable memory. It does not include ITLB miss accesses.  This event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states.
29H	Combined mask from Table 18-2, Table 18-4, and Table 18-5	L2_LD.(Core, Prefetch, Cache Line State)	L2 cache reads	This event counts L2 cache read requests coming from the L1 data cache and L2 prefetchers.  The event can count occurrences: <ul style="list-style-type: none"> <li>▪ for this core or both cores</li> <li>▪ due to demand requests and L2 hardware prefetch requests together or separately</li> <li>▪ of accesses to cache lines at different MESI states</li> </ul>
2AH	See Table 18-2 and Table 18-5	L2_ST.(Core, Cache Line State)	L2 store requests	This event counts all store operations that miss the L1 data cache and request the data from the L2 cache.  The event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
2BH	See Table 18-2 and Table 18-5	L2_LOCK.(Core, Cache Line State)	L2 locked accesses	This event counts all locked accesses to cache lines that miss the L1 data cache.  The event can count occurrences for this core or both cores. It can also count accesses to cache lines at different MESI states.
2EH	See Table 18-2, Table 18-4, and Table 18-5	L2_RQSTS.(Core, Prefetch, Cache Line State)	L2 cache requests	This event counts all completed L2 cache requests. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, instruction fetches, and all L2 hardware prefetch requests.  This event can count occurrences: <ul style="list-style-type: none"> <li>▪ for this core or both cores.</li> <li>▪ due to demand requests and L2 hardware prefetch requests together, or separately</li> <li>▪ of accesses to cache lines at different MESI states</li> </ul>
2EH	41H	L2_RQSTS.SELF.DEMAND.I_STATE	L2 cache demand requests from this core that missed the L2	This event counts all completed L2 cache demand requests from this core that miss the L2 cache. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.  This is an architectural performance event.
2EH	4FH	L2_RQSTS.SELF.DEMAND.MESI	L2 cache demand requests from this core	This event counts all completed L2 cache demand requests from this core. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches.  This is an architectural performance event.
30H	See Table 18-2, Table 18-4, and Table 18-5	L2_REJECT_BUSQ.(Core, Prefetch, Cache Line State)	Rejected L2 cache requests	This event indicates that a pending L2 cache request that requires a bus transaction is delayed from moving to the bus queue. Some of the reasons for this event are: <ul style="list-style-type: none"> <li>▪ The bus queue is full.</li> <li>▪ The bus queue already holds an entry for a cache line in the same set.</li> </ul> The number of events is greater or equal to the number of requests that were rejected. <ul style="list-style-type: none"> <li>▪ for this core or both cores.</li> <li>▪ due to demand requests and L2 hardware prefetch requests together, or separately.</li> <li>▪ of accesses to cache lines at different MESI states.</li> </ul>
32H	See Table 18-2	L2_NO_REQ.(Core)	Cycles no L2 cache requests are pending	This event counts the number of cycles that no L2 cache requests were pending from a core. When using the BOTH_CORE modifier, the event counts only if none of the cores have a pending request. The event counts also when one core is halted and the other is not halted.  The event can count occurrences for this core or both cores.
3AH	OOH	EIST_TRANS	Number of Enhanced Intel SpeedStep Technology (EIST) transitions	This event counts the number of transitions that include a frequency change, either with or without voltage change. This includes Enhanced Intel SpeedStep Technology (EIST) and TM2 transitions.  The event is incremented only while the counting core is in C0 state. Since transitions to higher-numbered CxE states and TM2 transitions include a frequency change or voltage transition, the event is incremented accordingly.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
3BH	COH	THERMAL_TRIP	Number of thermal trips	This event counts the number of thermal trips. A thermal trip occurs whenever the processor temperature exceeds the thermal trip threshold temperature.  Following a thermal trip, the processor automatically reduces frequency and voltage. The processor checks the temperature every millisecond and returns to normal when the temperature falls below the thermal trip threshold temperature.
3CH	OOH	CPU_CLK_UNHALTED.CORE_P	Core cycles when core is not halted	This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.  The core frequency may change due to transitions associated with Enhanced Intel SpeedStep Technology or TM2. For this reason, this event may have a changing ratio in regard to time.  When the core frequency is constant, this event can give approximate elapsed time while the core not in halt state. This is an architectural performance event.
3CH	01H	CPU_CLK_UNHALTED.BUS	Bus cycles when core is not halted	This event counts the number of bus cycles while the core is not in the halt state. This event can give a measurement of the elapsed time while the core was not in the halt state. The core enters the halt state when it is running the HLT instruction.  The event also has a constant ratio with CPU_CLK_UNHALTED.REF event, which is the maximum bus to processor frequency ratio.  Non-halted bus cycles are a component in many key event ratios.
3CH	02H	CPU_CLK_UNHALTED.NO_OTHER	Bus cycles when core is active and the other is halted	This event counts the number of bus cycles during which the core remains non-halted and the other core on the processor is halted.  This event can be used to determine the amount of parallelism exploited by an application or a system. Divide this event count by the bus frequency to determine the amount of time that only one core was in use.
40H	See Table 18-5	L1D_CACHE_LD.(Cache Line State)	L1 cacheable data reads	This event counts the number of data reads from cacheable memory. Locked reads are not counted.
41H	See Table 18-5	L1D_CACHE_ST.(Cache Line State)	L1 cacheable data writes	This event counts the number of data writes to cacheable memory. Locked writes are not counted.
42H	See Table 18-5	L1D_CACHE_LOCK.(Cache Line State)	L1 data cacheable locked reads	This event counts the number of locked data reads from cacheable memory.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
42H	10H	L1D_CACHE_LOCK_DURATION	Duration of L1 data cacheable locked operation	This event counts the number of cycles during which any cache line is locked by any locking instruction. Locking happens at retirement and therefore the event does not occur for instructions that are speculatively executed. Locking duration is shorter than locked instruction execution duration.
43H	01H	L1D_ALL_REF	All references to the L1 data cache	This event counts all references to the L1 data cache, including all loads and stores with any memory types. The event counts memory accesses only when they are actually performed. For example, a load blocked by unknown store address and later performed is only counted once. The event includes non-cacheable accesses, such as I/O accesses.
43H	02H	L1D_ALL_CACHE_REF	L1 Data cacheable reads and writes	This event counts the number of data reads and writes from cacheable memory, including locked operations. This event is a sum of: <ul style="list-style-type: none"> <li>▪ L1D_CACHE_LD.MESI</li> <li>▪ L1D_CACHE_ST.MESI</li> <li>▪ L1D_CACHE_LOCK.MESI</li> </ul>
45H	0FH	L1D_REPL	Cache lines allocated in the L1 data cache	This event counts the number of lines brought into the L1 data cache.
46H	00H	L1D_M_REPL	Modified cache lines allocated in the L1 data cache	This event counts the number of modified lines brought into the L1 data cache.
47H	00H	L1D_M_EVICT	Modified cache lines evicted from the L1 data cache	This event counts the number of modified lines evicted from the L1 data cache, whether due to replacement or by snoop HITM intervention.
48H	00H	L1D_PEND_MISS	Total number of outstanding L1 data cache misses at any cycle	This event counts the number of outstanding L1 data cache misses at any cycle. An L1 data cache miss is outstanding from the cycle on which the miss is determined until the first chunk of data is available. This event counts: <ul style="list-style-type: none"> <li>▪ all cacheable demand requests</li> <li>▪ L1 data cache hardware prefetch requests</li> <li>▪ requests to write through memory</li> <li>▪ requests to write combine memory</li> </ul> Uncacheable requests are not counted. The count of this event divided by the number of L1 data cache misses, L1D_REPL, is the average duration in core cycles of an L1 data cache miss.
49H	01H	L1D_SPLIT.LOADS	Cache line split loads from the L1 data cache	This event counts the number of load operations that span two cache lines. Such load operations are also called split loads. Split load operations are executed at retirement.
49H	02H	L1D_SPLIT.STORES	Cache line split stores to the L1 data cache	This event counts the number of store operations that span two cache lines.
4BH	00H	SSE_PRE_MISS.NTA	Streaming SIMD Extensions (SSE) Prefetch NTA instructions missing all cache levels	This event counts the number of times the SSE instructions prefetchNTA were executed and missed all cache levels. Due to speculation an executed instruction might not retire. This instruction prefetches the data to the L1 data cache.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
4BH	01H	SSE_PRE_MISS.L1	Streaming SIMD Extensions (SSE) PrefetchT0 instructions missing all cache levels	This event counts the number of times the SSE instructions prefetchT0 were executed and missed all cache levels. Due to speculation executed instruction might not retire. The prefetchT0 instruction prefetches data to the L2 cache and L1 data cache.
4BH	02H	SSE_PRE_MISS.L2	Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions missing all cache levels	This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 were executed and missed all cache levels. Due to speculation, an executed instruction might not retire. The prefetchT1 and PrefetchNT2 instructions prefetch data to the L2 cache.
4CH	00H	LOAD_HIT_PRE	Load operations conflicting with a software prefetch to the same address	This event counts load operations sent to the L1 data cache while a previous Streaming SIMD Extensions (SSE) prefetch instruction to the same cache line has started prefetching but has not yet finished.
4EH	10H	L1D_PREFETCH.REQUESTS	L1 data cache prefetch requests	This event counts the number of times the L1 data cache requested to prefetch a data cache line. Requests can be rejected when the L2 cache is busy and resubmitted later or lost. All requests are counted, including those that are rejected.
60H	See Table 18-2 and Table 18-3	BUS_REQUEST_OUTSTANDING. (Core and Bus Agents)	Outstanding cacheable data read bus requests duration	This event counts the number of pending full cache line read transactions on the bus occurring in each cycle. A read transaction is pending from the cycle it is sent on the bus until the full cache line is received by the processor. The event counts only full-line cacheable read requests from either the L1 data cache or the L2 prefetchers. It does not count Read for Ownership transactions, instruction byte fetch transactions, or any other bus transaction.
61H	See Table 18-3.	BUS_BNR_DRV. (Bus Agents)	Number of Bus Not Ready signals asserted	This event counts the number of Bus Not Ready (BNR) signals that the processor asserts on the bus to suspend additional bus requests by other bus agents. A bus agent asserts the BNR signal when the number of data and snoop transactions is close to the maximum that the bus can handle. To obtain the number of bus cycles during which the BNR signal is asserted, multiply the event count by two. While this signal is asserted, new transactions cannot be submitted on the bus. As a result, transaction latency may have higher impact on program performance.
62H	See Table 18-3	BUS_DRDY_CLOCKS. (Bus Agents)	Bus cycles when data is sent on the bus	This event counts the number of bus cycles during which the DRDY (Data Ready) signal is asserted on the bus. The DRDY signal is asserted when data is sent on the bus. With the 'THIS_AGENT' mask this event counts the number of bus cycles during which this agent (the processor) writes data on the bus back to memory or to other bus agents. This includes all explicit and implicit data writebacks, as well as partial writes. With the 'ALL_AGENTS' mask, this event counts the number of bus cycles during which any bus agent sends data on the bus. This includes all data reads and writes on the bus.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
63H	See Table 18-2 and Table 18-3	BUS_LOCK_CLOCKS.(Core and Bus Agents)	Bus cycles when a LOCK signal asserted	This event counts the number of bus cycles, during which the LOCK signal is asserted on the bus. A LOCK signal is asserted when there is a locked memory access, due to: <ul style="list-style-type: none"> <li>▪ uncacheable memory</li> <li>▪ locked operation that spans two cache lines</li> <li>▪ page-walk from an uncacheable page table</li> </ul> Bus locks have a very high performance penalty and it is highly recommended to avoid such accesses.
64H	See Table 18-2	BUS_DATA_RCV.(Core)	Bus cycles while processor receives data	This event counts the number of bus cycles during which the processor is busy receiving data.
65H	See Table 18-2 and Table 18-3	BUS_TRANS_BRD.(Core and Bus Agents)	Burst read bus transactions	This event counts the number of burst read transactions including: <ul style="list-style-type: none"> <li>▪ L1 data cache read misses (and L1 data cache hardware prefetches)</li> <li>▪ L2 hardware prefetches by the DPL and L2 streamer</li> <li>▪ IFU read misses of cacheable lines.</li> </ul> It does not include RFO transactions.
66H	See Table 18-2 and Table 18-3.	BUS_TRANS_RFO.(Core and Bus Agents)	RFO bus transactions	This event counts the number of Read For Ownership (RFO) bus transactions, due to store operations that miss the L1 data cache and the L2 cache. It also counts RFO bus transactions due to locked operations.
67H	See Table 18-2 and Table 18-3.	BUS_TRANS_WB.(Core and Bus Agents)	Explicit writeback bus transactions	This event counts all explicit writeback bus transactions due to dirty line evictions. It does not count implicit writebacks due to invalidation by a snoop request.
68H	See Table 18-2 and Table 18-3	BUS_TRANS_IFETCH.(Core and Bus Agents)	Instruction-fetch bus transactions	This event counts all instruction fetch full cache line bus transactions.
69H	See Table 18-2 and Table 18-3	BUS_TRANS_INVALID.(Core and Bus Agents)	Invalidate bus transactions	This event counts all invalidate transactions. Invalidate transactions are generated when: <ul style="list-style-type: none"> <li>▪ A store operation hits a shared line in the L2 cache.</li> <li>▪ A full cache line write misses the L2 cache or hits a shared line in the L2 cache.</li> </ul>
6AH	See Table 18-2 and Table 18-3	BUS_TRANS_PWR.(Core and Bus Agents)	Partial write bus transaction	This event counts partial write bus transactions.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
6BH	See Table 18-2 and Table 18-3	BUS_TRANS_P.(Core and Bus Agents)	Partial bus transactions	This event counts all (read and write) partial bus transactions.
6CH	See Table 18-2 and Table 18-3	BUS_TRANS_IO.(Core and Bus Agents)	IO bus transactions	This event counts the number of completed I/O bus transactions as a result of IN and OUT instructions. The count does not include memory mapped IO.
6DH	See Table 18-2 and Table 18-3	BUS_TRANS_DEF.(Core and Bus Agents)	Deferred bus transactions	This event counts the number of deferred transactions.
6EH	See Table 18-2 and Table 18-3	BUS_TRANS_BURST.(Core and Bus Agents)	Burst (full cache-line) bus transactions	This event counts burst (full cache line) transactions including: <ul style="list-style-type: none"> <li>▪ Burst reads</li> <li>▪ RFOs</li> <li>▪ Explicit writebacks</li> <li>▪ Write combine lines</li> </ul>
6FH	See Table 18-2 and Table 18-3	BUS_TRANS_MEM.(Core and Bus Agents)	Memory bus transactions	This event counts all memory bus transactions including: <ul style="list-style-type: none"> <li>▪ Burst transactions</li> <li>▪ Partial reads and writes - invalidate transactions</li> </ul> The BUS_TRANS_MEM count is the sum of BUS_TRANS_BURST, BUS_TRANS_P and BUS_TRANS_IVAL.
70H	See Table 18-2 and Table 18-3	BUS_TRANS_ANY.(Core and Bus Agents)	All bus transactions	This event counts all bus transactions. This includes: <ul style="list-style-type: none"> <li>▪ Memory transactions</li> <li>▪ IO transactions (non memory-mapped)</li> <li>▪ Deferred transaction completion</li> <li>▪ Other less frequent transactions, such as interrupts</li> </ul>
77H	See Table 18-2 and Table 18-6	EXT_SNOOP.(Bus Agents, Snoop Response)	External snoops	This event counts the snoop responses to bus transactions. Responses can be counted separately by type and by bus agent.  With the 'THIS_AGENT' mask, the event counts snoop responses from this processor to bus transactions sent by this processor. With the 'ALL_AGENTS' mask the event counts all snoop responses seen on the bus.
78H	See Table 18-2 and Table 18-7	CMP_SNOOP.(Core, Snoop Type)	L1 data cache snooped by other core	This event counts the number of times the L1 data cache is snooped for a cache line that is needed by the other core in the same processor. The cache line is either missing in the L1 instruction or data caches of the other core, or is available for reading only and the other core wishes to write the cache line.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
				<p>The snoop operation may change the cache line state. If the other core issued a read request that hit this core in E state, typically the state changes to S state in this core. If the other core issued a read for ownership request (due a write miss or hit to S state) that hits this core’s cache line in E or S state, this typically results in invalidation of the cache line in this core. If the snoop hits a line in M state, the state is changed at a later opportunity.</p> <p>These snoops are performed through the L1 data cache store port. Therefore, frequent snoops may conflict with extensive stores to the L1 data cache, which may increase store latency and impact performance.</p>
7AH	See Table 18-3	BUS_HIT_DRV. (Bus Agents)	HIT signal asserted	This event counts the number of bus cycles during which the processor drives the HIT# pin to signal HIT snoop response.
7BH	See Table 18-3	BUS_HITM_DRV. (Bus Agents)	HITM signal asserted	This event counts the number of bus cycles during which the processor drives the HITM# pin to signal HITM snoop response.
7DH	See Table 18-2	BUSQ_EMPTY. (Core)	Bus queue empty	<p>This event counts the number of cycles during which the core did not have any pending transactions in the bus queue. It also counts when the core is halted and the other core is not halted.</p> <p>This event can count occurrences for this core or both cores.</p>
7EH	See Table 18-2 and Table 18-3	SNOOP_STALL_DRV. (Core and Bus Agents)	Bus stalled for snoops	<p>This event counts the number of times that the bus snoop stall signal is asserted. To obtain the number of bus cycles during which snoops on the bus are prohibited, multiply the event count by two.</p> <p>During the snoop stall cycles, no new bus transactions requiring a snoop response can be initiated on the bus. A bus agent asserts a snoop stall signal if it cannot response to a snoop request within three bus cycles.</p>
7FH	See Table 18-2	BUS_IO_WAIT. (Core)	IO requests waiting in the bus queue	<p>This event counts the number of core cycles during which IO requests wait in the bus queue. With the SELF modifier this event counts IO requests per core.</p> <p>With the BOTH_CORE modifier, this event increments by one for any cycle for which there is a request from either core.</p>
80H	00H	L1I_READS	Instruction fetches	This event counts all instruction fetches, including uncacheable fetches that bypass the Instruction Fetch Unit (IFU).
81H	00H	L1I_MISSES	Instruction Fetch Unit misses	<p>This event counts all instruction fetches that miss the Instruction Fetch Unit (IFU) or produce memory requests. This includes uncacheable fetches.</p> <p>An instruction fetch miss is counted only once and not once for every cycle it is outstanding.</p>
82H	02H	ITLB.SMALL_MISS	ITLB small page misses	This event counts the number of instruction fetches from small pages that miss the ITLB.
82H	10H	ITLB.LARGE_MISS	ITLB large page misses	This event counts the number of instruction fetches from large pages that miss the ITLB.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
82H	40H	ITLB.FLUSH	ITLB flushes	This event counts the number of ITLB flushes. This usually happens upon CR3 or CR0 writes, which are executed by the operating system during process switches.
82H	12H	ITLB.MISSES	ITLB misses	This event counts the number of instruction fetches from either small or large pages that miss the ITLB.
83H	02H	INST_QUEUE.FULL	Cycles during which the instruction queue is full	This event counts the number of cycles during which the instruction queue is full. In this situation, the core front-end stops fetching more instructions. This is an indication of very long stalls in the back-end pipeline stages.
86H	00H	CYCLES_L1L_MEM_STALLED	Cycles during which instruction fetches stalled	This event counts the number of cycles for which an instruction fetch stalls, including stalls due to any of the following reasons: <ul style="list-style-type: none"> <li>▪ instruction Fetch Unit cache misses</li> <li>▪ instruction TLB misses</li> <li>▪ instruction TLB faults</li> </ul>
87H	00H	ILD_STALL	Instruction Length Decoder stall cycles due to a length changing prefix	This event counts the number of cycles during which the instruction length decoder uses the slow length decoder. Usually, instruction length decoding is done in one cycle. When the slow decoder is used, instruction decoding requires 6 cycles.  The slow decoder is used in the following cases: <ul style="list-style-type: none"> <li>▪ operand override prefix (66H) preceding an instruction with immediate data</li> <li>▪ address override prefix (67H) preceding an instruction with a modr/m in real, big real, 16-bit protected or 32-bit protected modes</li> </ul> To avoid instruction length decoding stalls, generate code using imm8 or imm32 values instead of imm16 values. If you must use an imm16 value, store the value in a register using "mov reg, imm32" and use the register format of the instruction.
88H	00H	BR_INST_EXEC	Branch instructions executed	This event counts all executed branches (not necessarily retired). This includes only instructions and not micro-op branches.  Frequent branching is not necessarily a major performance issue. However frequent branch mispredictions may be a problem.
89H	00H	BR_MISSP_EXEC	Mispredicted branch instructions executed	This event counts the number of mispredicted branch instructions that were executed.
8AH	00H	BR_BAC_MISSP_EXEC	Branch instructions mispredicted at decoding	This event counts the number of branch instructions that were mispredicted at decoding.
8BH	00H	BR_CND_EXEC	Conditional branch instructions executed.	This event counts the number of conditional branch instructions executed, but not necessarily retired.
8CH	00H	BR_CND_MISSP_EXEC	Mispredicted conditional branch instructions executed	This event counts the number of mispredicted conditional branch instructions that were executed.
8DH	00H	BR_IND_EXEC	Indirect branch instructions executed	This event counts the number of indirect branch instructions that were executed.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
8EH	00H	BR_IND_MISSP_EXEC	Mispredicted indirect branch instructions executed	This event counts the number of mispredicted indirect branch instructions that were executed.
8FH	00H	BR_RET_EXEC	RET instructions executed	This event counts the number of RET instructions that were executed.
90H	00H	BR_RET_MISSP_EXEC	Mispredicted RET instructions executed	This event counts the number of mispredicted RET instructions that were executed.
91H	00H	BR_RET_BAC_MISSP_EXEC	RET instructions executed mispredicted at decoding	This event counts the number of RET instructions that were executed and were mispredicted at decoding.
92H	00H	BR_CALL_EXEC	CALL instructions executed	This event counts the number of CALL instructions executed.
93H	00H	BR_CALL_MISSP_EXEC	Mispredicted CALL instructions executed	This event counts the number of mispredicted CALL instructions that were executed.
94H	00H	BR_IND_CALL_EXEC	Indirect CALL instructions executed	This event counts the number of indirect CALL instructions that were executed.
97H	00H	BR_TKN_BUBBLE_1	Branch predicted taken with bubble 1	The events BR_TKN_BUBBLE_1 and BR_TKN_BUBBLE_2 together count the number of times a taken branch prediction incurred a one-cycle penalty. The penalty incurs when: <ul style="list-style-type: none"> <li>Too many taken branches are placed together. To avoid this, unroll loops and add a non-taken branch in the middle of the taken sequence.</li> <li>The branch target is unaligned. To avoid this, align the branch target.</li> </ul>
98H	00H	BR_TKN_BUBBLE_2	Branch predicted taken with bubble 2	The events BR_TKN_BUBBLE_1 and BR_TKN_BUBBLE_2 together count the number of times a taken branch prediction incurred a one-cycle penalty. The penalty incurs when: <ul style="list-style-type: none"> <li>Too many taken branches are placed together. To avoid this, unroll loops and add a non-taken branch in the middle of the taken sequence.</li> <li>The branch target is unaligned. To avoid this, align the branch target.</li> </ul>
A0H	00H	RS_UOPS_DISPATCHED	Micro-ops dispatched for execution	This event counts the number of micro-ops dispatched for execution. Up to six micro-ops can be dispatched in each cycle.
A1H	01H	RS_UOPS_DISPATCHED.PORT0	Cycles micro-ops dispatched for execution on port 0	This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Issue Ports are described in <i>Intel® 64 and IA-32 Architectures Optimization Reference Manual</i> . Use IA32_PMC0 only.
A1H	02H	RS_UOPS_DISPATCHED.PORT1	Cycles micro-ops dispatched for execution on port 1	This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.
A1H	04H	RS_UOPS_DISPATCHED.PORT2	Cycles micro-ops dispatched for execution on port 2	This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
A1H	08H	RS_UOPS_DISPATCHED.PORT3	Cycles micro-ops dispatched for execution on port 3	This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.
A1H	10H	RS_UOPS_DISPATCHED.PORT4	Cycles micro-ops dispatched for execution on port 4	This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.
A1H	20H	RS_UOPS_DISPATCHED.PORT5	Cycles micro-ops dispatched for execution on port 5	This event counts the number of cycles for which micro-ops dispatched for execution. Each cycle, at most one micro-op can be dispatched on the port. Use IA32_PMC0 only.
AAH	01H	MACRO_INSTS_DECODED	Instructions decoded	This event counts the number of instructions decoded (but not necessarily executed or retired).
AAH	08H	MACRO_INSTS_CISC_DECODED	CISC Instructions decoded	This event counts the number of complex instructions decoded. Complex instructions usually have more than four micro-ops. Only one complex instruction can be decoded at a time.
ABH	01H	ESP.SYNCH	ESP register content synchronization	This event counts the number of times that the ESP register is explicitly used in the address expression of a load or store operation, after it is implicitly used, for example by a push or a pop instruction.  ESP synch micro-op uses resources from the rename pipe-stage and up to retirement. The expected ratio of this event divided by the number of ESP implicit changes is 0.2. If the ratio is higher, consider rearranging your code to avoid ESP synchronization events.
ABH	02H	ESP.ADDITIONS	ESP register automatic additions	This event counts the number of ESP additions performed automatically by the decoder. A high count of this event is good, since each automatic addition performed by the decoder saves a micro-op from the execution units.  To maximize the number of ESP additions performed automatically by the decoder, choose instructions that implicitly use the ESP, such as PUSH, POP, CALL, and RET instructions whenever possible.
B0H	00H	SIMD_UOPS_EXEC	SIMD micro-ops executed (excluding stores)	This event counts all the SIMD micro-ops executed. It does not count MOVQ and MOVD stores from register to memory.
B1H	00H	SIMD_SAT_UOP_EXEC	SIMD saturated arithmetic micro-ops executed	This event counts the number of SIMD saturated arithmetic micro-ops executed.
B3H	01H	SIMD_UOP_TYPE_EXEC.MUL	SIMD packed multiply micro-ops executed	This event counts the number of SIMD packed multiply micro-ops executed.
B3H	02H	SIMD_UOP_TYPE_EXEC.SHIFT	SIMD packed shift micro-ops executed	This event counts the number of SIMD packed shift micro-ops executed.
B3H	04H	SIMD_UOP_TYPE_EXEC.PACK	SIMD pack micro-ops executed	This event counts the number of SIMD pack micro-ops executed.
B3H	08H	SIMD_UOP_TYPE_EXEC.UNPACK	SIMD unpack micro-ops executed	This event counts the number of SIMD unpack micro-ops executed.
B3H	10H	SIMD_UOP_TYPE_EXEC.LOGICAL	SIMD packed logical micro-ops executed	This event counts the number of SIMD packed logical micro-ops executed.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
B3H	20H	SIMD_UOP_TYPE_EXEC.ARITHMETIC	SIMD packed arithmetic micro-ops executed	This event counts the number of SIMD packed arithmetic micro-ops executed.
COH	00H	INST_RETIRED.ANY_P	Instructions retired	This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continue counting during hardware interrupts, traps, and inside interrupt handlers. INST_RETIRED.ANY_P is an architectural performance event.
COH	01H	INST_RETIRED.LOADS	Instructions retired, which contain a load	This event counts the number of instructions retired that contain a load operation.
COH	02H	INST_RETIRED.STORES	Instructions retired, which contain a store	This event counts the number of instructions retired that contain a store operation.
COH	04H	INST_RETIRED.OTHER	Instructions retired, with no load or store operation	This event counts the number of instructions retired that do not contain a load or a store operation.
C1H	01H	X87_OPS_RETIRED.FXCH	FXCH instructions retired	This event counts the number of FXCH instructions retired. Modern compilers generate more efficient code and are less likely to use this instruction. If you obtain a high count for this event consider recompiling the code.
C1H	FEH	X87_OPS_RETIRED.ANY	Retired floating-point computational operations (precise event)	<p>This event counts the number of floating-point computational operations retired. It counts:</p> <ul style="list-style-type: none"> <li>▪ floating point computational operations executed by the assist handler</li> <li>▪ sub-operations of complex floating-point instructions like transcendental instructions</li> </ul> <p>This event does not count:</p> <ul style="list-style-type: none"> <li>▪ floating-point computational operations that cause traps or assists.</li> <li>▪ floating-point loads and stores.</li> </ul> <p>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.</p>
C2H	01H	UOPS_RETIRED.LD_IND_BR	Fused load+op or load+indirect branch retired	<p>This event counts the number of retired micro-ops that fused a load with another operation. This includes:</p> <ul style="list-style-type: none"> <li>▪ Fusion of a load and an arithmetic operation, such as with the following instruction: ADD EAX, [EBX] where the content of the memory location specified by EBX register is loaded, added to EAX register, and the result is stored in EAX.</li> <li>▪ Fusion of a load and a branch in an indirect branch operation, such as with the following instructions:                             <ul style="list-style-type: none"> <li>▪ JMP [RDI+200]</li> <li>▪ RET</li> </ul> </li> <li>▪ Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code is using the processor resources effectively.</li> </ul>

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
C2H	02H	UOPS_RETIREDD. STD_STA	Fused store address + data retired	This event counts the number of store address calculations that are fused with store data emission into one micro-op. Traditionally, each store operation required two micro-ops. This event counts fusion of retired micro-ops only. Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code is using the processor resources effectively.
C2H	04H	UOPS_RETIREDD. MACRO_FUSION	Retired instruction pairs fused into one micro-op	This event counts the number of times CMP or TEST instructions were fused with a conditional branch instruction into one micro-op. It counts fusion by retired micro-ops only. Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code uses the processor resources more effectively.
C2H	07H	UOPS_RETIREDD. FUSED	Fused micro-ops retired	This event counts the total number of retired fused micro-ops. The counts include the following fusion types: <ul style="list-style-type: none"> <li>▪ Fusion of load operation with an arithmetic operation or with an indirect branch (counted by event UOPS_RETIREDD.LD_IND_BR)</li> <li>▪ Fusion of store address and data (counted by event UOPS_RETIREDD.STD_STA)</li> <li>▪ Fusion of CMP or TEST instruction with a conditional branch instruction (counted by event UOPS_RETIREDD.MACRO_FUSION)</li> </ul> Fusion decreases the number of micro-ops in the processor pipeline. A high value for this event count indicates that the code is using the processor resources effectively.
C2H	08H	UOPS_RETIREDD. NON_FUSED	Non-fused micro-ops retired	This event counts the number of micro-ops retired that were not fused.
C2H	0FH	UOPS_RETIREDD. ANY	Micro-ops retired	This event counts the number of micro-ops retired. The processor decodes complex macro instructions into a sequence of simpler micro-ops. Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. In some cases micro-op sequences are fused or whole instructions are fused into one micro-op. See other UOPS_RETIREDD events for differentiating retired fused and non-fused micro-ops.
C3H	01H	MACHINE_ NUKES.SMC	Self-Modifying Code detected	This event counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel 64 and IA-32 processors.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
C3H	04H	MACHINE_NUKES.MEM_ORDER	Execution pipeline restart due to memory ordering conflict or memory disambiguation misprediction	This event counts the number of times the pipeline is restarted due to either multi-threaded memory ordering conflicts or memory disambiguation misprediction.  A multi-threaded memory ordering conflict occurs when a store, which is executed in another core, hits a load that is executed out of order in this core but not yet retired. As a result, the load needs to be restarted to satisfy the memory ordering model.  See Chapter 8, "Multiple-Processor Management" in the <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A</i> .  To count memory disambiguation mispredictions, use the event MEMORY_DISAMBIGUATION.RESET.
C4H	00H	BR_INST_RETIRED.ANY	Retired branch instructions	This event counts the number of branch instructions retired. This is an architectural performance event.
C4H	01H	BR_INST_RETIRED.PRED_NOT_TAKEN	Retired branch instructions that were predicted not-taken	This event counts the number of branch instructions retired that were correctly predicted to be not-taken.
C4H	02H	BR_INST_RETIRED.MISPRED_NOT_TAKEN	Retired branch instructions that were mispredicted not-taken	This event counts the number of branch instructions retired that were mispredicted and not-taken.
C4H	04H	BR_INST_RETIRED.PRED_TAKEN	Retired branch instructions that were predicted taken	This event counts the number of branch instructions retired that were correctly predicted to be taken.
C4H	08H	BR_INST_RETIRED.MISPRED_TAKEN	Retired branch instructions that were mispredicted taken	This event counts the number of branch instructions retired that were mispredicted and taken.
C4H	0CH	BR_INST_RETIRED.TAKEN	Retired taken branch instructions	This event counts the number of branches retired that were taken.
C5H	00H	BR_INST_RETIRED.MISPRED	Retired mispredicted branch instructions. (precise event)	This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa.  This is an architectural performance event.
C6H	01H	CYCLES_INT_MASKED	Cycles during which interrupts are disabled	This event counts the number of cycles during which interrupts are disabled.
C6H	02H	CYCLES_INT_PENDING_AND_MASKED	Cycles during which interrupts are pending and disabled	This event counts the number of cycles during which there are pending interrupts but interrupts are disabled.
C7H	01H	SIMD_INST_RETIRED.PACKED_SINGLE	Retired SSE packed-single instructions	This event counts the number of SSE packed-single instructions retired.
C7H	02H	SIMD_INST_RETIRED.SCALAR_SINGLE	Retired SSE scalar-single instructions	This event counts the number of SSE scalar-single instructions retired.
C7H	04H	SIMD_INST_RETIRED.PACKED_DOUBLE	Retired SSE2 packed-double instructions	This event counts the number of SSE2 packed-double instructions retired.
C7H	08H	SIMD_INST_RETIRED.SCALAR_DOUBLE	Retired SSE2 scalar-double instructions	This event counts the number of SSE2 scalar-double instructions retired.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
C7H	10H	SIMD_INST_RETIRE.D.VECTOR	Retired SSE2 vector integer instructions	This event counts the number of SSE2 vector integer instructions retired.
C7H	1FH	SIMD_INST_RETIRE.ANY	Retired Streaming SIMD instructions (precise event)	This event counts the overall number of retired SIMD instructions that use XMM registers. To count each type of SIMD instruction separately, use the following events: <ul style="list-style-type: none"> <li>▪ SIMD_INST_RETIRE.PACKED_SINGLE</li> <li>▪ SIMD_INST_RETIRE.SCALAR_SINGLE</li> <li>▪ SIMD_INST_RETIRE.PACKED_DOUBLE</li> <li>▪ SIMD_INST_RETIRE.SCALAR_DOUBLE</li> <li>▪ and SIMD_INST_RETIRE.VECTOR</li> </ul> When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.
C8H	00H	HW_INT_RCV	Hardware interrupts received	This event counts the number of hardware interrupts received by the processor.
C9H	00H	ITLB_MISS_RETIRE	Retired instructions that missed the ITLB	This event counts the number of retired instructions that missed the ITLB when they were fetched.
CAH	01H	SIMD_COMP_INST_RETIRE.PACKED_SINGLE	Retired computational SSE packed-single instructions	This event counts the number of computational SSE packed-single instructions retired. Computational instructions perform arithmetic computations (for example: add, multiply and divide). Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.
CAH	02H	SIMD_COMP_INST_RETIRE.SCALAR_SINGLE	Retired computational SSE scalar-single instructions	This event counts the number of computational SSE scalar-single instructions retired. Computational instructions perform arithmetic computations (for example: add, multiply and divide). Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.
CAH	04H	SIMD_COMP_INST_RETIRE.PACKED_DOUBLE	Retired computational SSE2 packed-double instructions	This event counts the number of computational SSE2 packed-double instructions retired. Computational instructions perform arithmetic computations (for example: add, multiply and divide). Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.
CAH	08H	SIMD_COMP_INST_RETIRE.D.SCALAR_DOUBLE	Retired computational SSE2 scalar-double instructions	This event counts the number of computational SSE2 scalar-double instructions retired. Computational instructions perform arithmetic computations (for example: add, multiply and divide). Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
CBH	01H	MEM_LOAD_RETIREDD.L1D_MISS	Retired loads that miss the L1 data cache (precise event)	<p>This event counts the number of retired load operations that missed the L1 data cache. This includes loads from cache lines that are currently being fetched, due to a previous L1 data cache miss to the same cache line.</p> <p>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.</p> <p>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.</p> <p>Use IA32_PMC0 only.</p>
CBH	02H	MEM_LOAD_RETIREDD.L1D_LINE_MISS	L1 data cache line missed by retired loads (precise event)	<p>This event counts the number of load operations that miss the L1 data cache and send a request to the L2 cache to fetch the missing cache line. That is the missing cache line fetching has not yet started.</p> <p>The event count is equal to the number of cache lines fetched from the L2 cache by retired loads.</p> <p>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.</p> <p>The event might not be counted if the load is blocked (see LOAD_BLOCK events).</p> <p>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.</p> <p>Use IA32_PMC0 only.</p>
CBH	04H	MEM_LOAD_RETIREDD.L2_MISS	Retired loads that miss the L2 cache (precise event)	<p>This event counts the number of retired load operations that missed the L2 cache.</p> <p>This event counts loads from cacheable memory only. It does not count loads by software prefetches.</p> <p>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.</p> <p>Use IA32_PMC0 only.</p>

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
CBH	08H	MEM_LOAD_RETIRED.L2_LINE_MISS	L2 cache line missed by retired loads (precise event)	<p>This event counts the number of load operations that miss the L2 cache and result in a bus request to fetch the missing cache line. That is the missing cache line fetching has not yet started.</p> <p>This event count is equal to the number of cache lines fetched from memory by retired loads.</p> <p>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.</p> <p>The event might not be counted if the load is blocked (see LOAD_BLOCK events).</p> <p>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.</p> <p>Use IA32_PMC0 only.</p>
CBH	10H	MEM_LOAD_RETIRED.DTLB_MISS	Retired loads that miss the DTLB (precise event)	<p>This event counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault.</p> <p>This event counts loads from cacheable memory only. The event does not count loads by software prefetches.</p> <p>When this event is captured with the precise event mechanism, the collected samples contain the address of the instruction that was executed immediately after the instruction that caused the event.</p> <p>Use IA32_PMC0 only.</p>
CCH	01H	FP_MMX_TRANS_TO_MMX	Transitions from Floating Point to MMX Instructions	This event counts the first MMX instructions following a floating-point instruction. Use this event to estimate the penalties for the transitions between floating-point and MMX states.
CCH	02H	FP_MMX_TRANS_TO_FP	Transitions from MMX Instructions to Floating Point Instructions	This event counts the first floating-point instructions following any MMX instruction. Use this event to estimate the penalties for the transitions between floating-point and MMX states.
CDH	00H	SIMD_ASSIST	SIMD assists invoked	This event counts the number of SIMD assists invoked. SIMD assists are invoked when an EMMS instruction is executed, changing the MMX state in the floating point stack.
CEH	00H	SIMD_INSTR_RETIRED	SIMD Instructions retired	This event counts the number of retired SIMD instructions that use MMX registers.
CFH	00H	SIMD_SAT_INSTR_RETIRED	Saturated arithmetic instructions retired	This event counts the number of saturated arithmetic SIMD instructions that retired.
D2H	01H	RAT_STALLS.ROB_READ_PORT	ROB read port stalls cycles	<p>This event counts the number of cycles when ROB read port stalls occurred, which did not allow new micro-ops to enter the out-of-order pipeline.</p> <p>Note that, at this stage in the pipeline, additional stalls may occur at the same cycle and prevent the stalled micro-ops from entering the pipe. In such a case, micro-ops retry entering the execution pipe in the next cycle and the ROB-read-port stall is counted again.</p>

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
D2H	02H	RAT_STALLS.PARTIAL_CYCLES	Partial register stall cycles	This event counts the number of cycles instruction execution latency became longer than the defined latency because the instruction uses a register that was partially written by previous instructions.
D2H	04H	RAT_STALLS.FLAGS	Flag stall cycles	This event counts the number of cycles during which execution stalled due to several reasons, one of which is a partial flag register stall. A partial register stall may occur when two conditions are met: <ul style="list-style-type: none"> <li>an instruction modifies some, but not all, of the flags in the flag register</li> <li>the next instruction, which depends on flags, depends on flags that were not modified by this instruction</li> </ul>
D2H	08H	RAT_STALLS.FPSW	FPU status word stall	This event indicates that the FPU status word (FPSW) is written. To obtain the number of times the FPSW is written divide the event count by 2. The FPSW is written by instructions with long latency; a small count may indicate a high penalty.
D2H	0FH	RAT_STALLS.ANY	All RAT stall cycles	This event counts the number of stall cycles due to conditions described by: <ul style="list-style-type: none"> <li>RAT_STALLS.ROB_READ_PORT</li> <li>RAT_STALLS.PARTIAL</li> <li>RAT_STALLS.FLAGS</li> <li>RAT_STALLS.FPSW.</li> </ul>
D4H	01H	SEG_RENAME_STALLS.ES	Segment rename stalls - ES	This event counts the number of stalls due to the lack of renaming resources for the ES segment register. If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.
D4H	02H	SEG_RENAME_STALLS.DS	Segment rename stalls - DS	This event counts the number of stalls due to the lack of renaming resources for the DS segment register. If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.
D4H	04H	SEG_RENAME_STALLS.FS	Segment rename stalls - FS	This event counts the number of stalls due to the lack of renaming resources for the FS segment register. If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.
D4H	08H	SEG_RENAME_STALLS.GS	Segment rename stalls - GS	This event counts the number of stalls due to the lack of renaming resources for the GS segment register. If a segment is renamed, but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.
D4H	0FH	SEG_RENAME_STALLS.ANY	Any (ES/DS/FS/GS) segment rename stall	This event counts the number of stalls due to the lack of renaming resources for the ES, DS, FS, and GS segment registers. If a segment is renamed but not retired and a second update to the same segment occurs, a stall occurs in the front-end of the pipeline until the renamed segment retires.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
D5H	01H	SEG_REG_RENAMES.ES	Segment renames - ES	This event counts the number of times the ES segment register is renamed.
D5H	02H	SEG_REG_RENAMES.DS	Segment renames - DS	This event counts the number of times the DS segment register is renamed.
D5H	04H	SEG_REG_RENAMES.FS	Segment renames - FS	This event counts the number of times the FS segment register is renamed.
D5H	08H	SEG_REG_RENAMES.GS	Segment renames - GS	This event counts the number of times the GS segment register is renamed.
D5H	0FH	SEG_REG_RENAMES.ANY	Any (ES/DS/FS/GS) segment rename	This event counts the number of times any of the four segment registers (ES/DS/FS/GS) is renamed.
DCH	01H	RESOURCE_STALLS.ROB_FULL	Cycles during which the ROB full	This event counts the number of cycles when the number of instructions in the pipeline waiting for retirement reaches the limit the processor can handle.  A high count for this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, and other instructions that depend on these cannot execute until the former instructions complete execution). In this situation new instructions can not enter the pipe and start execution.
DCH	02H	RESOURCE_STALLS.RS_FULL	Cycles during which the RS full	This event counts the number of cycles when the number of instructions in the pipeline waiting for execution reaches the limit the processor can handle.  A high count of this event indicates that there are long latency operations in the pipe (possibly load and store operations that miss the L2 cache, and other instructions that depend on these cannot execute until the former instructions complete execution). In this situation new instructions can not enter the pipe and start execution.
DCH	04	RESOURCE_STALLS.LD_ST	Cycles during which the pipeline has exceeded load or store limit or waiting to commit all stores	This event counts the number of cycles while resource-related stalls occur due to: <ul style="list-style-type: none"> <li>▪ The number of load instructions in the pipeline reached the limit the processor can handle. The stall ends when a loading instruction retires.</li> <li>▪ The number of store instructions in the pipeline reached the limit the processor can handle. The stall ends when a storing instruction commits its data to the cache or memory.</li> <li>▪ There is an instruction in the pipe that can be executed only when all previous stores complete and their data is committed in the caches or memory. For example, the SFENCE and MFENCE instructions require this behavior.</li> </ul>
DCH	08H	RESOURCE_STALLS.FPCW	Cycles stalled due to FPU control word write	This event counts the number of cycles while execution was stalled due to writing the floating-point unit (FPU) control word.
DCH	10H	RESOURCE_STALLS.BR_MISS_CLEAR	Cycles stalled due to branch misprediction	This event counts the number of cycles after a branch misprediction is detected at execution until the branch and all older micro-ops retire. During this time new micro-ops cannot enter the out-of-order pipeline.

**Table 19-17. Non-Architectural Performance Events in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Event Num	Umask Value	Event Name	Definition	Description and Comment
DCH	1FH	RESOURCE_STALLS.ANY	Resource related stalls	This event counts the number of cycles while resource-related stalls occurs for any conditions described by the following events: <ul style="list-style-type: none"> <li>▪ RESOURCE_STALLS.ROB_FULL</li> <li>▪ RESOURCE_STALLS.RS_FULL</li> <li>▪ RESOURCE_STALLS.ID_ST</li> <li>▪ RESOURCE_STALLS.FPCW</li> <li>▪ RESOURCE_STALLS.BR_MISS_CLEAR</li> </ul>
E0H	00H	BR_INST_DECODED	Branch instructions decoded	This event counts the number of branch instructions decoded.
E4H	00H	BOGUS_BR	Bogus branches	This event counts the number of byte sequences that were mistakenly detected as taken branch instructions. This results in a BACLEAR event. This occurs mainly after task switches.
E6H	00H	BACLEAR_S	BACLEAR_S asserted	This event counts the number of times the front end is re-steered, mainly when the BPU cannot provide a correct prediction and this is corrected by other branch handling mechanisms at the front end. This can occur if the code has many branches such that they cannot be consumed by the BPU.  Each BACLEAR asserted costs approximately 7 cycles of instruction fetch. The effect on total execution time depends on the surrounding code.
F0	00H	PREF_RQSTS_UP	Upward prefetches issued from DPL	This event counts the number of upward prefetches issued from the Data Prefetch Logic (DPL) to the L2 cache. A prefetch request issued to the L2 cache cannot be cancelled and the requested cache line is fetched to the L2 cache.
F8	00H	PREF_RQSTS_DN	Downward prefetches issued from DPL.	This event counts the number of downward prefetches issued from the Data Prefetch Logic (DPL) to the L2 cache. A prefetch request issued to the L2 cache cannot be cancelled and the requested cache line is fetched to the L2 cache.

## 19.9 PERFORMANCE MONITORING EVENTS FOR PROCESSORS BASED ON THE SILVERMONT MICROARCHITECTURE

Processors based on the Silvermont microarchitecture support the architectural performance-monitoring events listed in Table 19-1 and fixed-function performance events using fixed counter. In addition, they also support the following non-architectural performance-monitoring events listed in Table 19-18.

**Table 19-18. Performance Events for Silvermont Microarchitecture**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
03H	01H	REHABQ.LD_BLOCK_S T_FORWARD	Loads blocked due to store forward restriction	This event counts the number of retired loads that were prohibited from receiving forwarded data from the store because of address mismatch.
03H	02H	REHABQ.LD_BLOCK_S TD_NOTREADY	Loads blocked due to store data not ready	This event counts the cases where a forward was technically possible, but did not occur because the store data was not available at the right time
03H	04H	REHABQ.ST_SPLITS	Store uops that split cache line boundary	This event counts the number of retire stores that experienced cache line boundary splits
03H	08H	REHABQ.LD_SPLITS	Load uops that split cache line boundary	This event counts the number of retire loads that experienced cache line boundary splits
03H	10H	REHABQ.LOCK	Uops with lock semantics	This event counts the number of retired memory operations with lock semantics. These are either implicit locked instructions such as the XCHG instruction or instructions with an explicit LOCK prefix (0xF0).
03H	20H	REHABQ.STA_FULL	Store address buffer full	This event counts the number of retired stores that are delayed because there is not a store address buffer available.
03H	40H	REHABQ.ANY_LD	Any reissued load uops	This event counts the number of load uops reissued from Rehabq
03H	80H	REHABQ.ANY_ST	Any reissued store uops	This event counts the number of store uops reissued from Rehabq
<p>REHABQ is an internal queue in the Silvermont microarchitecture that holds memory reference micro-ops which cannot complete for one reason or another. The micro-ops remain in the REHABQ until they can be re-issued and successfully completed.</p> <p>Examples of bottlenecks that cause micro-ops to go into REHABQ include, but are not limited to: cache line splits, blocked store forward and data not ready. There are many other conditions that might cause a load or store to be sent to the REHABQ-- for instance, if an older store has an unknown address, all subsequent stores must be sent to the REHABQ until that older stores address becomes known</p>				
04H	01H	MEM_UOPS_RETIREDD.L 1_MISS_LOADS	Loads retired that missed L1 data cache	This event counts the number of load ops retired that miss in L1 Data cache. Note that prefetch misses will not be counted.
04H	02H	MEM_UOPS_RETIREDD.L 2_HIT_LOADS	Loads retired that hit L2	This event counts the number of load micro-ops retired that hit L2.
04H	04H	MEM_UOPS_RETIREDD.L 2_MISS_LOADS	Loads retired that missed L2	This event counts the number of load micro-ops retired that missed L2.
04H	08H	MEM_UOPS_RETIREDD. DTLB_MISS_LOADS	Loads missed DTLB	This event counts the number of load ops retired that had DTLB miss.
04H	10H	MEM_UOPS_RETIREDD. UTLB_MISS	Loads missed UTLB	This event counts the number of load ops retired that had UTLB miss.
04H	20H	MEM_UOPS_RETIREDD. HITM	Cross core or cross module hitm	This event counts the number of load ops retired that got data from the other core or from the other module.
04H	40H	MEM_UOPS_RETIREDD. ALL_LOADS	All Loads	This event counts the number of load ops retired

**Table 19-18. Performance Events for Silvermont Microarchitecture**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
04H	80H	MEM_UOP_RETIRED.ALL_STORES	All Stores	This event counts the number of store ops retired
05H	01H	PAGE_WALKS.D_SIDE_CYCLES	Duration of D-side page-walks in core cycles	This event counts every cycle when a D-side (walks due to a load) page walk is in progress. Page walk duration divided by number of page walks is the average duration of page-walks. Edge trigger bit must be cleared. Set Edge to count the number of page walks.
05H	02H	PAGE_WALKS.I_SIDE_CYCLES	Duration of I-side page-walks in core cycles	This event counts every cycle when a I-side (walks due to an instruction fetch) page walk is in progress. Page walk duration divided by number of page walks is the average duration of page-walks. Edge trigger bit must be cleared. Set Edge to count the number of page walks.
05H	03H	PAGE_WALKS.WALKS	Total number of page-walks that are completed (I-side and D-side)	This event counts when a data (D) page walk or an instruction (I) page walk is completed or started. Since a page walk implies a TLB miss, the number of TLB misses can be counted by counting the number of pagewalks. Edge trigger bit must be set. Clear Edge to count the number of cycles.
2EH	41H	LONGEST_LAT_CACHE.MISS	L2 cache request misses	This event counts the total number of L2 cache references and the number of L2 cache misses respectively. L3 is not supported in Silvermont microarchitecture.
2EH	4FH	LONGEST_LAT_CACHE.REFERENCE	L2 cache requests from this core	This event counts requests originating from the core that references a cache line in the L2 cache. L3 is not supported in Silvermont microarchitecture.
30H	00H	L2_REJECT_XQ.ALL	Counts the number of request from the L2 that were not accepted into the XQ	This event counts the number of demand and prefetch transactions that the L2 XQ rejects due to a full or near full condition which likely indicates back pressure from the IDI link. The XQ may reject transactions from the L2Q (non-cacheable requests), BBS (L2 misses) and WOB (L2 write-back victims)
<p>When a memory reference misses the 1st level cache, the request goes to the L2 Queue (L2Q). If the request also misses the 2nd level cache, the request is sent to the XQ, where it waits for an opportunity to be issued to memory across the IDI link. Note that since the L2 is shared between a pair of processor cores, a single L2Q is shared between those two cores. Similarly, there is a single XQ for a pair of processors, situated between the L2Q and the IDI link.</p> <p>The XQ will fill up when the response rate from the IDI link is smaller than the rate at which new requests arrive at the XQ. The event L2_reject_XQ indicates that a request is unable to move from the L2 Queue to the XQ because the XQ is full, and thus indicates that the memory system is oversubscribed</p>				
31H	00H	CORE_REJECT_L2Q.ALL	Counts the number of request that were not accepted into the L2Q because the L2Q is FULL.	This event counts the number of demand and L1 prefetcher requests rejected by the L2Q due to a full or nearly full condition which likely indicates back pressure from L2Q. It also counts requests that would have gone directly to the XQ, but are rejected due to a full or nearly full condition, indicating back pressure from the IDI link. The L2Q may also reject transactions from a core to insure fairness between cores, or to delay a core's dirty eviction when the address conflicts incoming external snoops. (Note that L2 prefetcher requests that are dropped are not counted by this event.)

Table 19-18. Performance Events for Silvermont Microarchitecture

Event Num.	Umask Value	Event Name	Definition	Description and Comment
<p>The core_reject event indicates that a request from the core cannot be accepted at the L2Q. However, there are several additional reasons why a request might be rejected from the L2Q. Beyond rejecting a request because the L2Q is full, a request from one core can be rejected to maintain fairness to the other core. That is, one core is not permitted to monopolize the shared connection to the L2Q/cache/XQ/IDI links, and might have its requests rejected even when there is room available in the L2Q. In addition, if the request from the core is a dirty L1 cache eviction, the hardware must insure that this eviction does not conflict with any pending request in the L2Q. (pending requests can include an external snoop). In the event of a conflict, the dirty eviction request might be rejected even when there is room in the L2Q.</p> <p>Thus, while the L2_reject_XQ event indicates that the request rate to memory from both cores exceeds the response rate of the memory, the Core_reject event is more subtle. It can indicate that the request rate to the L2Q exceeds the response rate from the XQ, or it can indicate that the request rate to the L2Q exceeds the response rate from the L2, or it can indicate that one core is attempting to request more than its fair share of response from the L2Q. Or, it can be an indicator of conflict between dirty evictions and other pending requests.</p> <p>In short, the L2_reject_XQ event indicates memory oversubscription. The Core_reject event can indicate either (1) memory oversubscription, (2) L2 oversubscription, (3) rejecting one cores requests to insure fairness to the other core, or (4) a conflict between dirty evictions and other pending requests.</p>				
3CH	00H	CPU_CLK_UNHALTED.CORE_P	Core cycles when core is not halted	This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. In mobile systems the core frequency may change from time to time. For this reason this event may have a changing ratio with regards to time.
N/A	01H	CPU_CLK_UNHALTED.CORE	Instructions retired	This uses the fixed counter 1 to count the condition as CPU_CLK_UNHALTED.CORE_P does.
3CH	01H	CPU_CLK_UNHALTED.REF_P	Reference cycles when core is not halted	This event counts the number of reference cycles that the core is not in a halt state. The core enters the halt state when it is running the HLT instruction.  In mobile systems the core frequency may change from time. This event is not affected by core frequency changes but counts as if the core is running at the maximum frequency all the time.
N/A	02H	CPU_CLK_UNHALTED.REF_TSC	Instructions retired	This uses the fixed counter 2 to count the same condition as CPU_CLK_UNHALTED.REF_P does.
80H	01H	ICACHE.HIT	Instruction fetches from lcache	This event counts all instruction fetches from the instruction cache.
80H	02H	ICACHE.MISSES	lcache miss	This event counts all instruction fetches that miss the Instruction cache or produce memory requests. This includes uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding.
80H	03H	ICACHE.ACCESSSES	Instruction fetches	This event counts all instruction fetches, including uncacheable fetches.
B6H	04H	NIP_STALL.ICACHE_MISSES	Counts the number of cycles the NIP stalls because of an icache miss.	Counts the number of cycles the NIP stalls because of an icache miss. This is a cumulative count of cycles the NIP stalled for all icache misses
B7H	01H	OFFCORE_RESPONSE_0	see Section 18.6.2	Requires MSR_OFFCORE_RESP0 to specify request type and response.
B7H	02H	OFFCORE_RESPONSE_1	see Section 18.6.2	Requires MSR_OFFCORE_RESP1 to specify request type and response.

**Table 19-18. Performance Events for Silvermont Microarchitecture**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
C0H	00H	INST_RETIRED.ANY_P	Instructions retired (PEBS supported with IA32_PMC0).	This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers.
N/A	00H	INST_RETIRED.ANY	Instructions retired	This uses the fixed counter 0 to count the same condition as INST_RETIRED.ANY_P does.
C2H	01H	UOPS_RETIRED.MS	MSROM micro-ops retired	This event counts the number of micro-ops retired that were supplied from MSROM.
C2H	10H	UOPS_RETIRED.ALL	Micro-ops retired	This event counts the number of micro-ops retired.
<p>The processor decodes complex macro instructions into a sequence of simpler micro-ops. Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. In some cases micro-op sequences are fused or whole instructions are fused into one micro-op. See other UOPS_RETIRED events for differentiating retired fused and non-fused micro-ops.</p>				
C3H	01H	MACHINE_CLEARS.SMC	Self-Modifying Code detected	This event counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel® architecture processors.
C3H	02H	MACHINE_CLEARS.MEMORY_ORDERING	Stalls due to Memory ordering	This event counts the number of times that pipeline was cleared due to memory ordering issues.
C3H	04H	MACHINE_CLEARS.FP_ASSIST	Stalls due to FP assists	This event counts the number of times that pipeline stalled due to FP operations needing assists.
C3H	08H	MACHINE_CLEARS.ALL	Stalls due to any causes	This event counts the number of times that pipeline stalled due to due to any causes (including SMC, MO, FP assist, etc).
<p>There are many conditions that might cause a machine clear (including the receipt of an interrupt, or a trap or a fault). All those conditions (including but not limited to MO, SMC and FP) are captured in the ANY event. In addition, some conditions can be specifically counted (i.e. SMC, MO, FP). However, the sum of SMC, MO and FP machine clears will not necessarily equal the number of ANY.</p> <p>FP Assist: Most of the time, the floating point execute unit can properly produce the correct output bits. On rare occasions, it needs a little help. When help is needed, a machine clear is asserted against the instruction. After this machine clear (as described above), the front end of the machine begins to deliver instructions that will figure out exactly what FP operation was asked for, and they will do the extra work to produce the correct FP result (for instance, if the result was a floating point denormal, sometimes the hardware asks the help to produce the correctly rounded IEEE compliant result).</p> <p>SMC: (Self modifying code) The SMC happens when the machine fears that an instruction “in flight” is being changed. For instance, if you wrote a piece of code that wrote to the instruction stream ahead of where you were executing. In the Silvermont microarchitecture, the detection works in a 1K aligned region.</p> <p>If you write to memory within 1K of where you are executing, the hardware may get concerned that an instruction is being modified and a machine clear might be signaled. Since the machine clear allows the store pipeline to drain, when front end restart occurs the correct instructions (after the write) will be executed.</p> <p>MO: (Memory order) The MO machine clear happens when a snoop request occurs and the machine is uncertain if memory ordering will be preserved. For instance, suppose you have two loads, one to address X followed by another to address Y in the program order. Both loads have been issued; however, load to Y completes first and all the dependent ops on this load continue with the data loaded by this load. Load to X is still waiting for the data. Suppose that at the same time another processor writes to the same address Y and causes a snoop to address Y.</p> <p>This presents a problem: the load to Y got the old value, but we have not yet finished loading X. So the other processor saw the loads in a different order by not consuming the latest value from the store to address Y. So we need to un-do everything from the load to address Y so that we will see the post-write data. Note we do not have to un-do load Y if there were no other pending reads-- the fact that the load to X is not yet finished causes this ordering problem.</p>				
C4H	00H	BR_INST_RETIRED.ALL_BRANCHES	Retired branch instructions	This event counts the number of branch instructions retired.

Table 19-18. Performance Events for Silvermont Microarchitecture

Event Num.	Umask Value	Event Name	Definition	Description and Comment
C4H	7EH	BR_INST_RETIRED.JCC	Retired branch instructions that were conditional jumps	This event counts the number of branch instructions retired that were conditional jumps.
C4H	BFH	BR_INST_RETIRED.FAR_BRANCH	Retired far branch instructions	This event counts the number of far branch instructions retired.
C4H	EBH	BR_INST_RETIRED.NO_N_RETURN_IND	Retired instructions of near indirect Jmp or call	This event counts the number of branch instructions retired that were near indirect call or near indirect jmp.
C4H	F7H	BR_INST_RETIRED.RETURN	Retired near return instructions	This event counts the number of near RET branch instructions retired
C4H	F9H	BR_INST_RETIRED.CALL	Retired near call instructions	This event counts the number of near CALL branch instructions retired
C4H	FBH	BR_INST_RETIRED.IND_CALL	Retired near indirect call instructions	This event counts the number of near indirect CALL branch instructions retired
C4H	FDH	BR_INST_RETIRED.REL_CALL	Retired near relative call instructions	This event counts the number of near relative CALL branch instructions retired
C4H	FEH	BR_INST_RETIRED.TAKEN_JCC	Retired conditional jumps that were predicted taken	This event counts the number of branch instructions retired that were conditional jumps and predicted taken.
C5H	00H	BR_MISP_RETIRED.ALL_BRANCHES	Retired mispredicted branch instructions	This event counts the number of mispredicted branch instructions retired.
C5H	7EH	BR_MISP_RETIRED.JCC	Retired mispredicted conditional jumps	This event counts the number of mispredicted branch instructions retired that were conditional jumps.
C5H	BFH	BR_MISP_RETIRED.FAR	Retired mispredicted far branch instructions	This event counts the number of mispredicted far branch instructions retired.
C5H	EBH	BR_MISP_RETIRED.NO_N_RETURN_IND	Retired mispredicted instructions of near indirect Jmp or call	This event counts the number of mispredicted branch instructions retired that were near indirect call or near indirect jmp.
C5H	F7H	BR_MISP_RETIRED.RETURN	Retired mispredicted near return instructions	This event counts the number of mispredicted near RET branch instructions retired
C5H	F9H	BR_MISP_RETIRED.CALL	Retired mispredicted near call instructions	This event counts the number of mispredicted near CALL branch instructions retired
C5H	FBH	BR_MISP_RETIRED.IND_CALL	Retired mispredicted near indirect call instructions	This event counts the number of mispredicted near indirect CALL branch instructions retired
C5H	FDH	BR_MISP_RETIRED.REL_CALL	Retired mispredicted near relative call instructions	This event counts the number of mispredicted near relative CALL branch instructions retired
C5H	FEH	BR_MISP_RETIRED.TAKEN_JCC	Retired mispredicted conditional jumps that were predicted taken	This event counts the number of mispredicted branch instructions retired that were conditional jumps and predicted taken.
CAH	01H	NO_ALLOC_CYCLES.ROB_FULL	Counts the number of cycles when no uops are allocated and the ROB is full (less than 2 entries available)	Counts the number of cycles when no uops are allocated and the ROB is full (less than 2 entries available)

**Table 19-18. Performance Events for Silvermont Microarchitecture**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
CAH	20H	NO_ALLOC_CYCLES.RAT_STALL	Counts the number of cycles when no uops are allocated and a RATstall is asserted.	Counts the number of cycles when no uops are allocated and a RATstall is asserted.
CAH	3FH	NO_ALLOC_CYCLES.AL	Front end not delivering	This event counts the number of cycles when the front-end does not provide any instructions to be allocated for any reason
CAH	50H	NO_ALLOC_CYCLES.NO_T_DELIVERED	Front end not delivering backend not stalled	This event counts the number of cycles when the front-end does not provide any instructions to be allocated but the back end is not stalled
<p>The front-end is responsible for fetching the instruction, decoding into micro-ops (uops) and putting them into a micro-op queue to be consumed by back end. The back-end then takes these micro-ops, allocates the required resources. When all resources are ready, micro-ops are executed. If the back-end is not ready to accept micro-ops from the front-end, then we do not want to count these as front-end bottlenecks. However, whenever we have bottlenecks in the back-end, we will have allocation unit stalls and eventually forcing the front-end to wait until the back-end is ready to receive more UOPS. This event counts the cycles only when back-end is requesting more micro-uops and front-end is not able to provide them.</p>				
CBH	01H	RS_FULL_STALL.MEC	MEC RS full	This event counts the number of cycles the allocation pipe line stalled due to the RS for the MEC cluster is full
CBH	1FH	RS_FULL_STALL.ALL	Any RS full	This event counts the number of cycles that the allocation pipe line stalled due to any one of the RS is full
<p>The Silvermont microarchitecture has an allocation pipeline (AKA the RAT) that moves UOPS from the front end to the backend. At the end of the allocate pipe a UOP needs to be written into one of 6 reservation stations (the RS). Each RS holds UOPS that are to be sent to a specific execution (or memory) cluster. Each RS has a finite capacity, and it may accumulate UOPS when it is unable to send a UOP to its execution cluster. Typical reasons why an RS may fill include, but are not limited to, execution of long latency UOPS like divide, or inability to schedule UOPS due to dependencies, or too many outstanding memory references. When the RS becomes full, it is unable to accept more UOPS, and it will stall the allocation pipeline. The RS_FULL_STALL.ANY event will be asserted on any cycle when the allocation is stalled for any one of the RSs being full and not for other reasons. (i.e. the allocate pipeline might be stalled for some other reason, but if RS is not full, the RS_FULL_STALL.ANY will not count) The subevents allow discovery of exactly which RS (or RSs) that are full that prevent further allocation.</p>				
CDH	01H	CYCLES_DIV_BUSY.ANY	Divider Busy	This event counts the number of cycles the divider is busy.
<p>This event counts the cycles when the divide unit is unable to accept a new divide UOP because it is busy processing a previously dispatched UOP. The cycles will be counted irrespective of whether or not another divide UOP is waiting to enter the divide unit (from the RS). This event will count cycles while a divide is in progress even if the RS is empty.</p>				
E6H	01H	BACLEARS.ALL	BACLEARS asserted for any branch	This event counts the number of baclears for any type of branch.
E6H	08H	BACLEARS.RETURN	BACLEARS asserted for return branch	This event counts the number of baclears for return branches.
E6H	10H	BACLEARS.COND	BACLEARS asserted for conditional branch	This event counts the number of baclears for conditional branches.
E7H	01H	MS_DECODED.MS_ENTRY	MS Decode starts	This event counts the number of times the MSROM starts a flow of UOPS.

## 19.10 PERFORMANCE MONITORING EVENTS FOR INTEL® ATOM™ PROCESSORS

Processors based on the Intel® Atom™ microarchitecture support the architectural performance-monitoring events listed in Table 19-1 and fixed-function performance events using fixed counter listed in Table 19-16. In addition, they also support the following non-architectural performance-monitoring events listed in Table 19-19.

**Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
02H	81H	STORE_FORWARDS.GOOD	Good store forwards	This event counts the number of times store data was forwarded directly to a load.
06H	00H	SEGMENT_REG_LOADS.ANY	Number of segment register loads	This event counts the number of segment register load operations. Instructions that load new values into segment registers cause a penalty. This event indicates performance issues in 16-bit code. If this event occurs frequently, it may be useful to calculate the number of instructions retired per segment register load. If the resulting calculation is low (on average a small number of instructions are executed between segment register loads), then the code's segment register usage should be optimized.  As a result of branch misprediction, this event is speculative and may include segment register loads that do not actually occur. However, most segment register loads are internally serialized and such speculative effects are minimized.
07H	01H	PREFETCH.PREFETCHT0	Streaming SIMD Extensions (SSE) PrefetchT0 instructions executed.	This event counts the number of times the SSE instruction prefetchT0 is executed. This instruction prefetches the data to the L1 data cache and L2 cache.
07H	06H	PREFETCH.SW_L2	Streaming SIMD Extensions (SSE) PrefetchT1 and PrefetchT2 instructions executed	This event counts the number of times the SSE instructions prefetchT1 and prefetchT2 are executed. These instructions prefetch the data to the L2 cache.
07H	08H	PREFETCH.PREFETCHNTA	Streaming SIMD Extensions (SSE) Prefetch NTA instructions executed	This event counts the number of times the SSE instruction prefetchNTA is executed. This instruction prefetches the data to the L1 data cache.
08H	07H	DATA_TLB_MISSES.DTLB_MISS	Memory accesses that missed the DTLB	This event counts the number of Data Table Lookaside Buffer (DTLB) misses. The count includes misses detected as a result of speculative accesses. Typically a high count for this event indicates that the code accesses a large number of data pages.
08H	05H	DATA_TLB_MISSES.DTLB_MISS_LD	DTLB misses due to load operations	This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to load operations. This count includes misses detected as a result of speculative accesses.
08H	09H	DATA_TLB_MISSES.LO_DTLB_MISS_LD	LO_DTLB misses due to load operations	This event counts the number of LO_DTLB misses due to load operations. This count includes misses detected as a result of speculative accesses.
08H	06H	DATA_TLB_MISSES.DTLB_MISS_ST	DTLB misses due to store operations	This event counts the number of Data Table Lookaside Buffer (DTLB) misses due to store operations. This count includes misses detected as a result of speculative accesses.

**Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
0CH	03H	PAGE_WALKS.WALKS	Number of page-walks executed	This event counts the number of page-walks executed due to either a DTLB or ITLB miss. The page walk duration, PAGE_WALKS.CYCLES, divided by number of page walks is the average duration of a page walk. This can hint to whether most of the page-walks are satisfied by the caches or cause an L2 cache miss. Edge trigger bit must be set.
0CH	03H	PAGE_WALKS.CYCLES	Duration of page-walks in core cycles	This event counts the duration of page-walks in core cycles. The paging mode in use typically affects the duration of page walks. Page walk duration divided by number of page walks is the average duration of page-walks. This can hint at whether most of the page-walks are satisfied by the caches or cause an L2 cache miss. Edge trigger bit must be cleared.
10H	01H	X87_COMP_OPS_EXE.ANY.S	Floating point computational micro-ops executed	This event counts the number of x87 floating point computational micro-ops executed.
10H	81H	X87_COMP_OPS_EXE.ANY.AR	Floating point computational micro-ops retired	This event counts the number of x87 floating point computational micro-ops retired.
11H	01H	FP_ASSIST	Floating point assists	This event counts the number of floating point operations executed that required micro-code assist intervention. These assists are required in the following cases: X87 instructions: 1. NaN or denormal are loaded to a register or used as input from memory 2. Division by 0 3. Underflow output
11H	81H	FP_ASSIST.AR	Floating point assists	This event counts the number of floating point operations executed that required micro-code assist intervention. These assists are required in the following cases: X87 instructions: 1. NaN or denormal are loaded to a register or used as input from memory 2. Division by 0 3. Underflow output
12H	01H	MUL.S	Multiply operations executed	This event counts the number of multiply operations executed. This includes integer as well as floating point multiply operations.
12H	81H	MUL.AR	Multiply operations retired	This event counts the number of multiply operations retired. This includes integer as well as floating point multiply operations.
13H	01H	DIV.S	Divide operations executed	This event counts the number of divide operations executed. This includes integer divides, floating point divides and square-root operations executed.
13H	81H	DIV.AR	Divide operations retired	This event counts the number of divide operations retired. This includes integer divides, floating point divides and square-root operations executed.

**Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
14H	01H	CYCLES_DIV_BUSY	Cycles the divider is busy	This event counts the number of cycles the divider is busy executing divide or square root operations. The divide can be integer, X87 or Streaming SIMD Extensions (SSE). The square root operation can be either X87 or SSE.
21H	See Table 18-2	L2_ADS	Cycles L2 address bus is in use	This event counts the number of cycles the L2 address bus is being used for accesses to the L2 cache or bus queue. This event can count occurrences for this core or both cores.
22H	See Table 18-2	L2_DBUS_BUSY	Cycles the L2 cache data bus is busy	This event counts core cycles during which the L2 cache data bus is busy transferring data from the L2 cache to the core. It counts for all L1 cache misses (data and instruction) that hit the L2 cache. The count will increment by two for a full cache-line request.
24H	See Table 18-2 and Table 18-4	L2_LINES_IN	L2 cache misses	This event counts the number of cache lines allocated in the L2 cache. Cache lines are allocated in the L2 cache as a result of requests from the L1 data and instruction caches and the L2 hardware prefetchers to cache lines that are missing in the L2 cache. This event can count occurrences for this core or both cores. This event can also count demand requests and L2 hardware prefetch requests together or separately.
25H	See Table 18-2	L2_M_LINES_IN	L2 cache line modifications	This event counts whenever a modified cache line is written back from the L1 data cache to the L2 cache. This event can count occurrences for this core or both cores.
26H	See Table 18-2 and Table 18-4	L2_LINES_OUT	L2 cache lines evicted	This event counts the number of L2 cache lines evicted. This event can count occurrences for this core or both cores. This event can also count evictions due to demand requests and L2 hardware prefetch requests together or separately.
27H	See Table 18-2 and Table 18-4	L2_M_LINES_OUT	Modified lines evicted from the L2 cache	This event counts the number of L2 modified cache lines evicted. These lines are written back to memory unless they also exist in a shared-state in one of the L1 data caches. This event can count occurrences for this core or both cores. This event can also count evictions due to demand requests and L2 hardware prefetch requests together or separately.
28H	See Table 18-2 and Table 18-5	L2_IFETCH	L2 cacheable instruction fetch requests	This event counts the number of instruction cache line requests from the ICache. It does not include fetch requests from uncacheable memory. It does not include ITLB miss accesses. This event can count occurrences for this core or both cores. This event can also count accesses to cache lines at different MESI states.

**Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
29H	See Table 18-2, Table 18-4 and Table 18-5	L2_LD	L2 cache reads	This event counts L2 cache read requests coming from the L1 data cache and L2 prefetchers. This event can count occurrences for this core or both cores. This event can count occurrences - for this core or both cores. - due to demand requests and L2 hardware prefetch requests together or separately. - of accesses to cache lines at different MESI states.
2AH	See Table 18-2 and Table 18-5	L2_ST	L2 store requests	This event counts all store operations that miss the L1 data cache and request the data from the L2 cache. This event can count occurrences for this core or both cores. This event can also count accesses to cache lines at different MESI states.
2BH	See Table 18-2 and Table 18-5	L2_LOCK	L2 locked accesses	This event counts all locked accesses to cache lines that miss the L1 data cache. This event can count occurrences for this core or both cores. This event can also count accesses to cache lines at different MESI states.
2EH	See Table 18-2, Table 18-4 and Table 18-5	L2_RQSTS	L2 cache requests	This event counts all completed L2 cache requests. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, instruction fetches, and all L2 hardware prefetch requests. This event can count occurrences - for this core or both cores. - due to demand requests and L2 hardware prefetch requests together, or separately. - of accesses to cache lines at different MESI states.
2EH	41H	L2_RQSTS.SELF.DEMAND.I_STATE	L2 cache demand requests from this core that missed the L2	This event counts all completed L2 cache demand requests from this core that miss the L2 cache. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches. <b>This is an architectural performance event.</b>
2EH	4FH	L2_RQSTS.SELF.DEMAND.MESI	L2 cache demand requests from this core	This event counts all completed L2 cache demand requests from this core. This includes L1 data cache reads, writes, and locked accesses, L1 data prefetch requests, and instruction fetches. <b>This is an architectural performance event.</b>

Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

Event Num.	Umask Value	Event Name	Definition	Description and Comment
30H	See Table 18-2, Table 18-4 and Table 18-5	L2_REJECT_BUSQ	Rejected L2 cache requests	<p>This event indicates that a pending L2 cache request that requires a bus transaction is delayed from moving to the bus queue. Some of the reasons for this event are:</p> <ul style="list-style-type: none"> <li>- The bus queue is full.</li> <li>- The bus queue already holds an entry for a cache line in the same set.</li> </ul> <p>The number of events is greater or equal to the number of requests that were rejected.</p> <ul style="list-style-type: none"> <li>- for this core or both cores.</li> <li>- due to demand requests and L2 hardware prefetch requests together, or separately.</li> <li>- of accesses to cache lines at different MESI states.</li> </ul>
32H	See Table 18-2	L2_NO_REQ	Cycles no L2 cache requests are pending	This event counts the number of cycles that no L2 cache requests are pending.
3AH	00H	EIST_TRANS	Number of Enhanced Intel SpeedStep(R) Technology (EIST) transitions	<p>This event counts the number of Enhanced Intel SpeedStep(R) Technology (EIST) transitions that include a frequency change, either with or without VID change. This event is incremented only while the counting core is in C0 state. In situations where an EIST transition was caused by hardware as a result of CxE state transitions, those EIST transitions will also be registered in this event.</p> <p>Enhanced Intel Speedstep Technology transitions are commonly initiated by OS, but can be initiated by HW internally. For example: CxE states are C-states (C1,C2,C3...) which not only place the CPU into a sleep state by turning off the clock and other components, but also lower the voltage (which reduces the leakage power consumption). The same is true for thermal throttling transition which uses Enhanced Intel Speedstep Technology internally.</p>
3BH	COH	THERMAL_TRIP	Number of thermal trips	This event counts the number of thermal trips. A thermal trip occurs whenever the processor temperature exceeds the thermal trip threshold temperature. Following a thermal trip, the processor automatically reduces frequency and voltage. The processor checks the temperature every millisecond, and returns to normal when the temperature falls below the thermal trip threshold temperature.

**Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
3CH	00H	CPU_CLK_UNHALTED.CORE_P	Core cycles when core is not halted	<p>This event counts the number of core cycles while the core is not in a halt state. The core enters the halt state when it is running the HLT instruction. This event is a component in many key event ratios.</p> <p>In mobile systems the core frequency may change from time to time. For this reason this event may have a changing ratio with regards to time. In systems with a constant core frequency, this event can give you a measurement of the elapsed time while the core was not in halt state by dividing the event count by the core frequency.</p> <p>-This is an architectural performance event.                      - The event CPU_CLK_UNHALTED.CORE_P is counted by a programmable counter.                      - The event CPU_CLK_UNHALTED.CORE is counted by a designated fixed counter, leaving the two programmable counters available for other events.</p>
3CH	01H	CPU_CLK_UNHALTED.BUS	Bus cycles when core is not halted	<p>This event counts the number of bus cycles while the core is not in the halt state. This event can give you a measurement of the elapsed time while the core was not in the halt state, by dividing the event count by the bus frequency. The core enters the halt state when it is running the HLT instruction.</p> <p>The event also has a constant ratio with CPU_CLK_UNHALTED.REF event, which is the maximum bus to processor frequency ratio.</p> <p>Non-halted bus cycles are a component in many key event ratios.</p>
3CH	02H	CPU_CLK_UNHALTED.NO_OTHER	Bus cycles when core is active and the other is halted	<p>This event counts the number of bus cycles during which the core remains non-halted, and the other core on the processor is halted.</p> <p>This event can be used to determine the amount of parallelism exploited by an application or a system. Divide this event count by the bus frequency to determine the amount of time that only one core was in use.</p>
40H	21H	L1D_CACHE.LD	L1 Cacheable Data Reads	This event counts the number of data reads from cacheable memory.
40H	22H	L1D_CACHE.ST	L1 Cacheable Data Writes	This event counts the number of data writes to cacheable memory.
60H	See Table 18-2 and Table 18-3	BUS_REQUEST_OUTSTANDING	Outstanding cacheable data read bus requests duration	This event counts the number of pending full cache line read transactions on the bus occurring in each cycle. A read transaction is pending from the cycle it is sent on the bus until the full cache line is received by the processor. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.

Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

Event Num.	Umask Value	Event Name	Definition	Description and Comment
61H	See Table 18-3	BUS_BNR_DRV	Number of Bus Not Ready signals asserted	<p>This event counts the number of Bus Not Ready (BNR) signals that the processor asserts on the bus to suspend additional bus requests by other bus agents. A bus agent asserts the BNR signal when the number of data and snoop transactions is close to the maximum that the bus can handle.</p> <p>While this signal is asserted, new transactions cannot be submitted on the bus. As a result, transaction latency may have higher impact on program performance. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.</p>
62H	See Table 18-3	BUS_DRDY_CLOCKS	Bus cycles when data is sent on the bus	<p>This event counts the number of bus cycles during which the DRDY (Data Ready) signal is asserted on the bus. The DRDY signal is asserted when data is sent on the bus.</p> <p>This event counts the number of bus cycles during which this agent (the processor) writes data on the bus back to memory or to other bus agents. This includes all explicit and implicit data writebacks, as well as partial writes.</p> <p><b>NOTE:</b> This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.</p>
63H	See Table 18-2 and Table 18-3	BUS_LOCK_CLOCKS	Bus cycles when a LOCK signal is asserted.	<p>This event counts the number of bus cycles, during which the LOCK signal is asserted on the bus. A LOCK signal is asserted when there is a locked memory access, due to:</p> <ul style="list-style-type: none"> <li>- Uncacheable memory</li> <li>- Locked operation that spans two cache lines</li> <li>- Page-walk from an uncacheable page table.</li> </ul> <p>Bus locks have a very high performance penalty and it is highly recommended to avoid such accesses. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.</p>
64H	See Table 18-2	BUS_DATA_RCV	Bus cycles while processor receives data	<p>This event counts the number of cycles during which the processor is busy receiving data. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.</p>
65H	See Table 18-2 and Table 18-3	BUS_TRANS_BRD	Burst read bus transactions	<p>This event counts the number of burst read transactions including:</p> <ul style="list-style-type: none"> <li>- L1 data cache read misses (and L1 data cache hardware prefetches)</li> <li>- L2 hardware prefetches by the DPL and L2 streamer</li> <li>- IFU read misses of cacheable lines.</li> </ul> <p>It does not include RFO transactions.</p>
66H	See Table 18-2 and Table 18-3	BUS_TRANS_RFO	RFO bus transactions	<p>This event counts the number of Read For Ownership (RFO) bus transactions, due to store operations that miss the L1 data cache and the L2 cache. This event also counts RFO bus transactions due to locked operations.</p>

**Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
67H	See Table 18-2 and Table 18-3	BUS_TRANS_WB	Explicit writeback bus transactions	This event counts all explicit writeback bus transactions due to dirty line evictions. It does not count implicit writebacks due to invalidation by a snoop request.
68H	See Table 18-2 and Table 18-3	BUS_TRANS_IFETCH	Instruction-fetch bus transactions.	This event counts all instruction fetch full cache line bus transactions.
69H	See Table 18-2 and Table 18-3	BUS_TRANS_INVALID	Invalidate bus transactions	This event counts all invalidate transactions. Invalidate transactions are generated when: - A store operation hits a shared line in the L2 cache. - A full cache line write misses the L2 cache or hits a shared line in the L2 cache.
6AH	See Table 18-2 and Table 18-3	BUS_TRANS_PWR	Partial write bus transaction.	This event counts partial write bus transactions.
6BH	See Table 18-2 and Table 18-3	BUS_TRANS_P	Partial bus transactions	This event counts all (read and write) partial bus transactions.
6CH	See Table 18-2 and Table 18-3	BUS_TRANS_IO	IO bus transactions	This event counts the number of completed I/O bus transactions as a result of IN and OUT instructions. The count does not include memory mapped IO.
6DH	See Table 18-2 and Table 18-3	BUS_TRANS_DEF	Deferred bus transactions	This event counts the number of deferred transactions.
6EH	See Table 18-2 and Table 18-3	BUS_TRANS_BURST	Burst (full cache-line) bus transactions.	This event counts burst (full cache line) transactions including: - Burst reads - RFOs - Explicit writebacks - Write combine lines

Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

Event Num.	Umask Value	Event Name	Definition	Description and Comment
6FH	See Table 18-2 and Table 18-3	BUS_TRANS_MEM	Memory bus transactions	This event counts all memory bus transactions including: <ul style="list-style-type: none"> <li>- burst transactions</li> <li>- partial reads and writes</li> <li>- invalidate transactions</li> </ul> The BUS_TRANS_MEM count is the sum of BUS_TRANS_BURST, BUS_TRANS_P and BUS_TRANS_INVALID.
70H	See Table 18-2 and Table 18-3	BUS_TRANS_ANY	All bus transactions	This event counts all bus transactions. This includes: <ul style="list-style-type: none"> <li>- Memory transactions</li> <li>- IO transactions (non memory-mapped)</li> <li>- Deferred transaction completion</li> <li>- Other less frequent transactions, such as interrupts</li> </ul>
77H	See Table 18-2 and Table 18-5	EXT_SNOOP	External snoops	This event counts the snoop responses to bus transactions. Responses can be counted separately by type and by bus agent. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.
7AH	See Table 18-3	BUS_HIT_DRV	HIT signal asserted	This event counts the number of bus cycles during which the processor drives the HIT# pin to signal HIT snoop response. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.
7BH	See Table 18-3	BUS_HITM_DRV	HITM signal asserted	This event counts the number of bus cycles during which the processor drives the HITM# pin to signal HITM snoop response. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.
7DH	See Table 18-2	BUSQ_EMPTY	Bus queue is empty	This event counts the number of cycles during which the core did not have any pending transactions in the bus queue. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.
7EH	See Table 18-2 and Table 18-3	SNOOP_STALL_DRV	Bus stalled for snoops	This event counts the number of times that the bus snoop stall signal is asserted. During the snoop stall cycles no new bus transactions requiring a snoop response can be initiated on the bus. NOTE: This event is thread-independent and will not provide a count per logical processor when AnyThr is disabled.
7FH	See Table 18-2	BUS_IO_WAIT	IO requests waiting in the bus queue	This event counts the number of core cycles during which IO requests wait in the bus queue. This event counts IO requests from the core.
80H	03H	ICACHE.ACCESSSES	Instruction fetches	This event counts all instruction fetches, including uncacheable fetches.
80H	02H	ICACHE.MISSES	Icache miss	This event counts all instruction fetches that miss the Instruction cache or produce memory requests. This includes uncacheable fetches. An instruction fetch miss is counted only once and not once for every cycle it is outstanding.
82H	04H	ITLB.FLUSH	ITLB flushes	This event counts the number of ITLB flushes.
82H	02H	ITLB.MISSES	ITLB misses	This event counts the number of instruction fetches that miss the ITLB.

Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

Event Num.	Umask Value	Event Name	Definition	Description and Comment
AAH	02H	MACRO_INSTS.CISC_DECODED	CISC macro instructions decoded	This event counts the number of complex instructions decoded, but not necessarily executed or retired. Only one complex instruction can be decoded at a time.
AAH	03H	MACRO_INSTS.ALL_DECODED	All Instructions decoded	This event counts the number of instructions decoded.
B0H	00H	SIMD_UOPS_EXEC.S	SIMD micro-ops executed (excluding stores)	This event counts all the SIMD micro-ops executed. This event does not count MOVQ and MOVD stores from register to memory.
B0H	80H	SIMD_UOPS_EXEC.AR	SIMD micro-ops retired (excluding stores)	This event counts the number of SIMD saturated arithmetic micro-ops executed.
B1H	00H	SIMD_SAT_UOP_EXEC.S	SIMD saturated arithmetic micro-ops executed	This event counts the number of SIMD saturated arithmetic micro-ops executed.
B1H	80H	SIMD_SAT_UOP_EXEC.AR	SIMD saturated arithmetic micro-ops retired	This event counts the number of SIMD saturated arithmetic micro-ops retired.
B3H	01H	SIMD_UOP_TYPE_EXEC.MUL.S	SIMD packed multiply micro-ops executed	This event counts the number of SIMD packed multiply micro-ops executed.
B3H	81H	SIMD_UOP_TYPE_EXEC.MUL.AR	SIMD packed multiply micro-ops retired	This event counts the number of SIMD packed multiply micro-ops retired.
B3H	02H	SIMD_UOP_TYPE_EXEC.SHIFT.S	SIMD packed shift micro-ops executed	This event counts the number of SIMD packed shift micro-ops executed.
B3H	82H	SIMD_UOP_TYPE_EXEC.SHIFT.AR	SIMD packed shift micro-ops retired	This event counts the number of SIMD packed shift micro-ops retired.
B3H	04H	SIMD_UOP_TYPE_EXEC.PACK.S	SIMD pack micro-ops executed	This event counts the number of SIMD pack micro-ops executed.
B3H	84H	SIMD_UOP_TYPE_EXEC.PACK.AR	SIMD pack micro-ops retired	This event counts the number of SIMD pack micro-ops retired.
B3H	08H	SIMD_UOP_TYPE_EXEC.UNPACK.S	SIMD unpack micro-ops executed	This event counts the number of SIMD unpack micro-ops executed.
B3H	88H	SIMD_UOP_TYPE_EXEC.UNPACK.AR	SIMD unpack micro-ops retired	This event counts the number of SIMD unpack micro-ops retired.
B3H	10H	SIMD_UOP_TYPE_EXEC.LOGICAL.S	SIMD packed logical micro-ops executed	This event counts the number of SIMD packed logical micro-ops executed.
B3H	90H	SIMD_UOP_TYPE_EXEC.LOGICAL.AR	SIMD packed logical micro-ops retired	This event counts the number of SIMD packed logical micro-ops retired.
B3H	20H	SIMD_UOP_TYPE_EXEC.ARITHMETIC.S	SIMD packed arithmetic micro-ops executed	This event counts the number of SIMD packed arithmetic micro-ops executed.
B3H	A0H	SIMD_UOP_TYPE_EXEC.ARITHMETIC.AR	SIMD packed arithmetic micro-ops retired	This event counts the number of SIMD packed arithmetic micro-ops retired.
COH	00H	INST_RETIRED.ANY_P	Instructions retired (precise event).	This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers.

Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

Event Num.	Umask Value	Event Name	Definition	Description and Comment
N/A	00H	INST_RETIRED.ANY	Instructions retired	This event counts the number of instructions that retire execution. For instructions that consist of multiple micro-ops, this event counts the retirement of the last micro-op of the instruction. The counter continues counting during hardware interrupts, traps, and inside interrupt handlers.
C2H	10H	UOPS_RETIRED.ANY	Micro-ops retired	This event counts the number of micro-ops retired. The processor decodes complex macro instructions into a sequence of simpler micro-ops. Most instructions are composed of one or two micro-ops. Some instructions are decoded into longer sequences such as repeat instructions, floating point transcendental instructions, and assists. In some cases micro-op sequences are fused or whole instructions are fused into one micro-op. See other UOPS_RETIRED events for differentiating retired fused and non-fused micro-ops.
C3H	01H	MACHINE_CLEAR.SMC	Self-Modifying Code detected	This event counts the number of times that a program writes to a code section. Self-modifying code causes a severe penalty in all Intel® architecture processors.
C4H	00H	BR_INST_RETIRED.ANY	Retired branch instructions	This event counts the number of branch instructions retired. <b>This is an architectural performance event.</b>
C4H	01H	BR_INST_RETIRED.PRED_NOT_TAKEN	Retired branch instructions that were predicted not-taken	This event counts the number of branch instructions retired that were correctly predicted to be not-taken.
C4H	02H	BR_INST_RETIRED.MISPRED_NOT_TAKEN	Retired branch instructions that were mispredicted not-taken	This event counts the number of branch instructions retired that were mispredicted and not-taken.
C4H	04H	BR_INST_RETIRED.PRED_TAKEN	Retired branch instructions that were predicted taken	This event counts the number of branch instructions retired that were correctly predicted to be taken.
C4H	08H	BR_INST_RETIRED.MISPRED_TAKEN	Retired branch instructions that were mispredicted taken	This event counts the number of branch instructions retired that were mispredicted and taken.
C4H	0AH	BR_INST_RETIRED.MISPRED	Retired mispredicted branch instructions (precise event)	This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa. Mispredicted branches degrade the performance because the processor starts executing instructions along a wrong path it predicts. When the misprediction is discovered, all the instructions executed in the wrong path must be discarded, and the processor must start again on the correct path.  Using the Profile-Guided Optimization (PGO) features of the Intel® C++ compiler may help reduce branch mispredictions. See the compiler documentation for more information on this feature.

**Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
				<p>To determine the branch misprediction ratio, divide the BR_INST_RETIREDMISPRED event count by the number of BR_INST_RETIREDAANY event count. To determine the number of mispredicted branches per instruction, divide the number of mispredicted branches by the INST_RETIREDAANY event count. To measure the impact of the branch mispredictions use the event RESOURCE_STALLS.BR_MISS_CLEAR.</p> <p><b>Tips:</b></p> <ul style="list-style-type: none"> <li>- See the optimization guide for tips on reducing branch mispredictions.</li> <li>- PGO's purpose is to have straight line code for the most frequent execution paths, reducing branches taken and increasing the "basic block" size, possibly also reducing the code footprint or working-set.</li> </ul>
C4H	0CH	BR_INST_RETIREDTAKEN	Retired taken branch instructions	This event counts the number of branches retired that were taken.
C4H	0FH	BR_INST_RETIREDAANY1	Retired branch instructions	This event counts the number of branch instructions retired that were mispredicted. This event is a duplicate of BR_INST_RETIREDMISPRED.
C5H	00H	BR_INST_RETIREDMISPRED	Retired mispredicted branch instructions (precise event).	<p>This event counts the number of retired branch instructions that were mispredicted by the processor. A branch misprediction occurs when the processor predicts that the branch would be taken, but it is not, or vice-versa. Mispredicted branches degrade the performance because the processor starts executing instructions along a wrong path it predicts. When the misprediction is discovered, all the instructions executed in the wrong path must be discarded, and the processor must start again on the correct path.</p> <p>Using the Profile-Guided Optimization (PGO) features of the Intel® C++ compiler may help reduce branch mispredictions. See the compiler documentation for more information on this feature.</p> <p>To determine the branch misprediction ratio, divide the BR_INST_RETIREDMISPRED event count by the number of BR_INST_RETIREDAANY event count. To determine the number of mispredicted branches per instruction, divide the number of mispredicted branches by the INST_RETIREDAANY event count. To measure the impact of the branch mispredictions use the event RESOURCE_STALLS.BR_MISS_CLEAR.</p> <p><b>Tips:</b></p> <ul style="list-style-type: none"> <li>- See the optimization guide for tips on reducing branch mispredictions.</li> <li>- PGO's purpose is to have straight line code for the most frequent execution paths, reducing branches taken and increasing the "basic block" size, possibly also reducing the code footprint or working-set.</li> </ul>
C6H	01H	CYCLES_INT_MASKED.CYCLES_INT_MASKED	Cycles during which interrupts are disabled	This event counts the number of cycles during which interrupts are disabled.
C6H	02H	CYCLES_INT_MASKED.CYCLES_INT_PENDING_AND_MASKED	Cycles during which interrupts are pending and disabled	This event counts the number of cycles during which there are pending interrupts but interrupts are disabled.

Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)

Event Num.	Umask Value	Event Name	Definition	Description and Comment
C7H	01H	SIMD_INST_RETIREDPACKED_SINGLE	Retired Streaming SIMD Extensions (SSE) packed-single instructions	This event counts the number of SSE packed-single instructions retired.
C7H	02H	SIMD_INST_RETIREDSALAR_SINGLE	Retired Streaming SIMD Extensions (SSE) scalar-single instructions	This event counts the number of SSE scalar-single instructions retired.
C7H	04H	SIMD_INST_RETIREDPACKED_DOUBLE	Retired Streaming SIMD Extensions 2 (SSE2) packed-double instructions	This event counts the number of SSE2 packed-double instructions retired.
C7H	08H	SIMD_INST_RETIREDSALAR_DOUBLE	Retired Streaming SIMD Extensions 2 (SSE2) scalar-double instructions.	This event counts the number of SSE2 scalar-double instructions retired.
C7H	10H	SIMD_INST_RETIREDVVECTOR	Retired Streaming SIMD Extensions 2 (SSE2) vector instructions.	This event counts the number of SSE2 vector instructions retired.
C7H	1FH	SIMD_INST_RETIREDAANY	Retired Streaming SIMD instructions	This event counts the overall number of SIMD instructions retired. To count each type of SIMD instruction separately, use the following events: SIMD_INST_RETIREDPACKED_SINGLE, SIMD_INST_RETIREDSALAR_SINGLE, SIMD_INST_RETIREDPACKED_DOUBLE, SIMD_INST_RETIREDSALAR_DOUBLE, and SIMD_INST_RETIREDVVECTOR.
C8H	00H	HW_INT_RCV	Hardware interrupts received	This event counts the number of hardware interrupts received by the processor. This event will count twice for dual-pipe micro-ops.
CAH	01H	SIMD_COMP_INST_RETIRED.PACKED_SINGLE	Retired computational Streaming SIMD Extensions (SSE) packed-single instructions.	This event counts the number of computational SSE packed-single instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.
CAH	02H	SIMD_COMP_INST_RETIRED.SALAR_SINGLE	Retired computational Streaming SIMD Extensions (SSE) scalar-single instructions.	This event counts the number of computational SSE scalar-single instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.
CAH	04H	SIMD_COMP_INST_RETIRED.PACKED_DOUBLE	Retired computational Streaming SIMD Extensions 2 (SSE2) packed-double instructions.	This event counts the number of computational SSE2 packed-double instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.

**Table 19-19. Non-Architectural Performance Events for Intel® Atom™ Processors (Contd.)**

Event Num.	Umask Value	Event Name	Definition	Description and Comment
CAH	08H	SIMD_COMP_INST_RETIRED.SCALAR_DOUBLE	Retired computational Streaming SIMD Extensions 2 (SSE2) scalar-double instructions	This event counts the number of computational SSE2 scalar-double instructions retired. Computational instructions perform arithmetic computations, like add, multiply and divide. Instructions that perform load and store operations or logical operations, like XOR, OR, and AND are not counted by this event.
CBH	01H	MEM_LOAD_RETIRED.L2_HIT	Retired loads that hit the L2 cache (precise event)	This event counts the number of retired load operations that missed the L1 data cache and hit the L2 cache.
CBH	02H	MEM_LOAD_RETIRED.L2_MISS	Retired loads that miss the L2 cache (precise event)	This event counts the number of retired load operations that missed the L2 cache.
CBH	04H	MEM_LOAD_RETIRED.DTLB_MISS	Retired loads that miss the DTLB (precise event)	This event counts the number of retired loads that missed the DTLB. The DTLB miss is not counted if the load operation causes a fault.
CDH	00H	SIMD_ASSIST	SIMD assists invoked	This event counts the number of SIMD assists invoked. SIMD assists are invoked when an EMMS instruction is executed after MMX™ technology code has changed the MMX state in the floating point stack. For example, these assists are required in the following cases: Streaming SIMD Extensions (SSE) instructions: 1. Denormal input when the DAZ (Denormals Are Zeros) flag is off 2. Underflow result when the FTZ (Flush To Zero) flag is off
CEH	00H	SIMD_INSTR_RETIRED	SIMD Instructions retired	This event counts the number of SIMD instructions that retired.
CFH	00H	SIMD_SAT_INSTR_RETIRED	Saturated arithmetic instructions retired	This event counts the number of saturated arithmetic SIMD instructions that retired.
E0H	01H	BR_INST_DECODED	Branch instructions decoded	This event counts the number of branch instructions decoded.
E4H	01H	BOGUS_BR	Bogus branches	This event counts the number of byte sequences that were mistakenly detected as taken branch instructions. This results in a BACLEAR event and the BTB is flushed. This occurs mainly after task switches.
E6H	01H	BACLEAR.ANY	BACLEARs asserted	This event counts the number of times the front end is redirected for a branch prediction, mainly when an early branch prediction is corrected by other branch handling mechanisms in the front-end. This can occur if the code has many branches such that they cannot be consumed by the branch predictor. Each Baclear asserted costs approximately 7 cycles. The effect on total execution time depends on the surrounding code.

## 19.11 PERFORMANCE MONITORING EVENTS FOR INTEL® CORE™ SOLO AND INTEL® CORE™ DUO PROCESSORS

Table 19-20 lists non-architectural performance events for Intel® Core™ Duo processors. If a non-architectural event requires qualification in core specificity, it is indicated in the comment column. Table 19-20 also applies to Intel® Core™ Solo processors; bits in the unit mask corresponding to core-specificity are reserved and should be 00B.

**Table 19-20. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors**

Event Num.	Event Mask Mnemonic	Umask Value	Description	Comment
03H	LD_Blocks	00H	Load operations delayed due to store buffer blocks. The preceding store may be blocked due to unknown address, unknown data, or conflict due to partial overlap between the load and store.	
04H	SD_Drains	00H	Cycles while draining store buffers.	
05H	Misalign_Mem_Ref	00H	Misaligned data memory references (MOB splits of loads and stores).	
06H	Seg_Reg_Loads	00H	Segment register loads.	
07H	SSE_PrefNta_Ret	00H	SSE software prefetch instruction PREFETCHNTA retired.	
07H	SSE_PrefT1_Ret	01H	SSE software prefetch instruction PREFETCHT1 retired.	
07H	SSE_PrefT2_Ret	02H	SSE software prefetch instruction PREFETCHT2 retired.	
07H	SSE_NTStores_Ret	03H	SSE streaming store instruction retired.	
10H	FP_Comps_Op_Exe	00H	FP computational Instruction executed. FADD, FSUB, FCOM, FMULs, MUL, IMUL, FDIVs, DIV, IDIV, FPREMs, FSQRT are included; but exclude FADD or FMUL used in the middle of a transcendental instruction.	
11H	FP_Assist	00H	FP exceptions experienced microcode assists.	IA32_PMC1 only.
12H	Mul	00H	Multiply operations (a speculative count, including FP and integer multiplies).	IA32_PMC1 only.
13H	Div	00H	Divide operations (a speculative count, including FP and integer divisions).	IA32_PMC1 only.
14H	Cycles_Div_Busy	00H	Cycles the divider is busy.	IA32_PMC0 only.
21H	L2_ADS	00H	L2 Address strobos.	Requires core-specificity
22H	Dbus_Busy	00H	Core cycle during which data bus was busy (increments by 4).	Requires core-specificity
23H	Dbus_Busy_Rd	00H	Cycles data bus is busy transferring data to a core (increments by 4).	Requires core-specificity
24H	L2_Lines_In	00H	L2 cache lines allocated.	Requires core-specificity and HW prefetch qualification
25H	L2_M_Lines_In	00H	L2 Modified-state cache lines allocated.	Requires core-specificity
26H	L2_Lines_Out	00H	L2 cache lines evicted.	Requires core-specificity and HW prefetch qualification
27H	L2_M_Lines_Out	00H	L2 Modified-state cache lines evicted.	Requires core-specificity and HW prefetch qualification

**Table 19-20. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

Event Num.	Event Mask Mnemonic	Umask Value	Description	Comment
28H	L2_IFetch	Requires MESI qualification	L2 instruction fetches from instruction fetch unit (includes speculative fetches).	Requires core-specificity
29H	L2_LD	Requires MESI qualification	L2 cache reads.	Requires core-specificity
2AH	L2_ST	Requires MESI qualification	L2 cache writes (includes speculation).	Requires core-specificity
2EH	L2_Rqsts	Requires MESI qualification	L2 cache reference requests.	Requires core-specificity, HW prefetch qualification
30H	L2_Reject_Cycles	Requires MESI qualification	Cycles L2 is busy and rejecting new requests.	
32H	L2_No_Request_Cycles	Requires MESI qualification	Cycles there is no request to access L2.	
3AH	EST_Trans_All	00H	Any Intel Enhanced SpeedStep(R) Technology transitions.	
3AH	EST_Trans_All	10H	Intel Enhanced SpeedStep Technology frequency transitions.	
3BH	Thermal_Trip	C0H	Duration in a thermal trip based on the current core clock.	Use edge trigger to count occurrence
3CH	NonHlt_Ref_Cycles	01H	Non-halted bus cycles.	
3CH	Serial_Execution_Cycles	02H	Non-halted bus cycles of this core executing code while the other core is halted.	
40H	DCache_Cache_LD	Requires MESI qualification	L1 cacheable data read operations.	
41H	DCache_Cache_ST	Requires MESI qualification	L1 cacheable data write operations.	
42H	DCache_Cache_Lock	Requires MESI qualification	L1 cacheable lock read operations to invalid state.	
43H	Data_Mem_Ref	01H	L1 data read and writes of cacheable and non-cacheable types.	
44H	Data_Mem_Cache_Ref	02H	L1 data cacheable read and write operations.	
45H	DCache_Repl	0FH	L1 data cache line replacements.	
46H	DCache_M_Repl	00H	L1 data M-state cache line allocated.	
47H	DCache_M_Evict	00H	L1 data M-state cache line evicted.	
48H	DCache_Pend_Miss	00H	Weighted cycles of L1 miss outstanding.	Use Cmask =1 to count duration.
49H	Dtlb_Miss	00H	Data references that missed TLB.	
4BH	SSE_PrefNta_Miss	00H	PREFETCHNTA missed all caches.	
4BH	SSE_PrefT1_Miss	01H	PREFETCHT1 missed all caches.	
4BH	SSE_PrefT2_Miss	02H	PREFETCHT2 missed all caches.	
4BH	SSE_NTStores_Miss	03H	SSE streaming store instruction missed all caches.	
4FH	L1_Pref_Req	00H	L1 prefetch requests due to DCU cache misses.	May overcount if request re-submitted

**Table 19-20. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

Event Num.	Event Mask Mnemonic	Umask Value	Description	Comment
60H	Bus_Req_Outstanding	00; Requires core-specificity, and agent specificity	Weighted cycles of cacheable bus data read requests. This event counts full-line read request from DCU or HW prefetcher, but not RFO, write, instruction fetches, or others.	Use Cmask =1 to count duration. Use Umask bit 12 to include HWP or exclude HWP separately.
61H	Bus_BNR_Clocks	00H	External bus cycles while BNR asserted.	
62H	Bus_DRDY_Clocks	00H	External bus cycles while DRDY asserted.	Requires agent specificity
63H	Bus_Locks_Clocks	00H	External bus cycles while bus lock signal asserted.	Requires core specificity
64H	Bus_Data_Rcv	40H	Number of data chunks received by this processor.	
65H	Bus_Trans_Brd	See comment.	Burst read bus transactions (data or code).	Requires core specificity
66H	Bus_Trans_RFO	See comment.	Completed read for ownership (RFO) transactions.	Requires agent specificity
68H	Bus_Trans_Ifetch	See comment.	Completed instruction fetch transactions.	Requires core specificity
69H	Bus_Trans_Inval	See comment.	Completed invalidate transactions.	Each transaction counts its address strobe
6AH	Bus_Trans_Pwr	See comment.	Completed partial write transactions.	Retried transaction may be counted more than once
6BH	Bus_Trans_P	See comment.	Completed partial transactions (include partial read + partial write + line write).	
6CH	Bus_Trans_IO	See comment.	Completed I/O transactions (read and write).	
6DH	Bus_Trans_Def	20H	Completed defer transactions.	Requires core specificity Retried transaction may be counted more than once
67H	Bus_Trans_WB	COH	Completed writeback transactions from DCU (does not include L2 writebacks).	Requires agent specificity
6EH	Bus_Trans_Burst	COH	Completed burst transactions (full line transactions include reads, write, RFO, and writebacks).	Each transaction counts its address strobe
6FH	Bus_Trans_Mem	COH	Completed memory transactions. This includes Bus_Trans_Burst + Bus_Trans_P+Bus_Trans_Inval.	Retried transaction may be counted more than once
70H	Bus_Trans_Any	COH	Any completed bus transactions.	
77H	Bus_Snoops	00H	Counts any snoop on the bus.	Requires MESI qualification Requires agent specificity
78H	DCU_Snoop_To_Share	01H	DCU snoops to share-state L1 cache line due to L1 misses.	Requires core specificity
7DH	Bus_Not_In_Use	00H	Number of cycles there is no transaction from the core.	Requires core specificity
7EH	Bus_Snoop_Stall	00H	Number of bus cycles while bus snoop is stalled.	
80H	ICache_Reads	00H	Number of instruction fetches from ICache, streaming buffers (both cacheable and uncacheable fetches).	
81H	ICache_Misses	00H	Number of instruction fetch misses from ICache, streaming buffers.	
85H	ITLB_Misses	00H	Number of iTLB misses.	

**Table 19-20. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

Event Num.	Event Mask Mnemonic	Umask Value	Description	Comment
86H	IFU_Mem_Stall	00H	Cycles IFU is stalled while waiting for data from memory.	
87H	ILD_Stall	00H	Number of instruction length decoder stalls (Counts number of LCP stalls).	
88H	Br_Inst_Exec	00H	Branch instruction executed (includes speculation).	
89H	Br_Missp_Exec	00H	Branch instructions executed and mispredicted at execution (includes branches that do not have prediction or mispredicted).	
8AH	Br_BAC_Missp_Exec	00H	Branch instructions executed that were mispredicted at front end.	
8BH	Br_Cnd_Exec	00H	Conditional branch instructions executed.	
8CH	Br_Cnd_Missp_Exec	00H	Conditional branch instructions executed that were mispredicted.	
8DH	Br_Ind_Exec	00H	Indirect branch instructions executed.	
8EH	Br_Ind_Missp_Exec	00H	Indirect branch instructions executed that were mispredicted.	
8FH	Br_Ret_Exec	00H	Return branch instructions executed.	
90H	Br_Ret_Missp_Exec	00H	Return branch instructions executed that were mispredicted.	
91H	Br_Ret_BAC_Missp_Exec	00H	Return branch instructions executed that were mispredicted at the front end.	
92H	Br_Call_Exec	00H	Return call instructions executed.	
93H	Br_Call_Missp_Exec	00H	Return call instructions executed that were mispredicted.	
94H	Br_Ind_Call_Exec	00H	Indirect call branch instructions executed.	
A2H	Resource_Stall	00H	Cycles while there is a resource related stall (renaming, buffer entries) as seen by allocator.	
B0H	MMX_Instr_Exec	00H	Number of MMX instructions executed (does not include MOVQ and MOVD stores).	
B1H	SIMD_Int_Sat_Exec	00H	Number of SIMD Integer saturating instructions executed.	
B3H	SIMD_Int_Pmul_Exec	01H	Number of SIMD Integer packed multiply instructions executed.	
B3H	SIMD_Int_Psft_Exec	02H	Number of SIMD Integer packed shift instructions executed.	
B3H	SIMD_Int_Pck_Exec	04H	Number of SIMD Integer pack operations instruction executed.	
B3H	SIMD_Int_Upck_Exec	08H	Number of SIMD Integer unpack instructions executed.	
B3H	SIMD_Int_Plog_Exec	10H	Number of SIMD Integer packed logical instructions executed.	
B3H	SIMD_Int_Pari_Exec	20H	Number of SIMD Integer packed arithmetic instructions executed.	
C0H	Instr_Ret	00H	Number of instruction retired (Macro fused instruction count as 2).	

**Table 19-20. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

Event Num.	Event Mask Mnemonic	Umask Value	Description	Comment
C1H	FP_Comp_Instr_Ret	00H	Number of FP compute instructions retired (X87 instruction or instruction that contain X87 operations).	Use IA32_PMC0 only.
C2H	Uops_Ret	00H	Number of micro-ops retired (include fused uops).	
C3H	SMC_Detected	00H	Number of times self-modifying code condition detected.	
C4H	Br_Instr_Ret	00H	Number of branch instructions retired.	
C5H	Br_MisPred_Ret	00H	Number of mispredicted branch instructions retired.	
C6H	Cycles_Int_Masked	00H	Cycles while interrupt is disabled.	
C7H	Cycles_Int_Pedning_Masked	00H	Cycles while interrupt is disabled and interrupts are pending.	
C8H	HW_Int_Rx	00H	Number of hardware interrupts received.	
C9H	Br_Taken_Ret	00H	Number of taken branch instruction retired.	
CAH	Br_MisPred_Taken_Ret	00H	Number of taken and mispredicted branch instructions retired.	
CCH	MMX_FP_Trans	00H	Number of transitions from MMX to X87.	
CCH	FP_MMX_Trans	01H	Number of transitions from X87 to MMX.	
CDH	MMX_Assist	00H	Number of EMMS executed.	
CEH	MMX_Instr_Ret	00H	Number of MMX instruction retired.	
D0H	Instr_Decoded	00H	Number of instruction decoded.	
D7H	ESP_Uops	00H	Number of ESP folding instruction decoded.	
D8H	SIMD_FP_SP_Ret	00H	Number of SSE/SSE2 single precision instructions retired (packed and scalar).	
D8H	SIMD_FP_SP_S_Ret	01H	Number of SSE/SSE2 scalar single precision instructions retired.	
D8H	SIMD_FP_DP_P_Ret	02H	Number of SSE/SSE2 packed double precision instructions retired.	
D8H	SIMD_FP_DP_S_Ret	03H	Number of SSE/SSE2 scalar double precision instructions retired.	
D8H	SIMD_Int_128_Ret	04H	Number of SSE2 128 bit integer instructions retired.	
D9H	SIMD_FP_SP_P_Comp_Ret	00H	Number of SSE/SSE2 packed single precision compute instructions retired (does not include AND, OR, XOR).	
D9H	SIMD_FP_SP_S_Comp_Ret	01H	Number of SSE/SSE2 scalar single precision compute instructions retired (does not include AND, OR, XOR).	
D9H	SIMD_FP_DP_P_Comp_Ret	02H	Number of SSE/SSE2 packed double precision compute instructions retired (does not include AND, OR, XOR).	
D9H	SIMD_FP_DP_S_Comp_Ret	03H	Number of SSE/SSE2 scalar double precision compute instructions retired (does not include AND, OR, XOR).	
DAH	Fused_Uops_Ret	00H	All fused uops retired.	

**Table 19-20. Non-Architectural Performance Events in Intel® Core™ Solo and Intel® Core™ Duo Processors (Contd.)**

Event Num.	Event Mask Mnemonic	Umask Value	Description	Comment
DAH	Fused_Ld_Uops_Ret	01H	Fused load uops retired.	
DAH	Fused_St_Uops_Ret	02H	Fused store uops retired.	
DBH	Unfusion	00H	Number of unfusion events in the ROB (due to exception).	
E0H	Br_Instr_Decoded	00H	Branch instructions decoded.	
E2H	BTB_Misses	00H	Number of branches the BTB did not produce a prediction.	
E4H	Br_Bogus	00H	Number of bogus branches.	
E6H	BAClears	00H	Number of BAClears asserted.	
F0H	Pref_Rqsts_Up	00H	Number of hardware prefetch requests issued in forward streams.	
F8H	Pref_Rqsts_Dn	00H	Number of hardware prefetch requests issued in backward streams.	

## 19.12 PENTIUM® 4 AND INTEL® XEON® PROCESSOR PERFORMANCE-MONITORING EVENTS

Tables 19-21, 19-22 and list performance-monitoring events that can be counted or sampled on processors based on Intel NetBurst® microarchitecture. Table 19-21 lists the non-retirement events, and Table 19-22 lists the at-retirement events. Tables 19-24, 19-25, and 19-26 describes three sets of parameters that are available for three of the at-retirement counting events defined in Table 19-22. Table 19-27 shows which of the non-retirement and at retirement events are logical processor specific (TS) (see Section 18.13.4, “Performance Monitoring Events”) and which are non-logical processor specific (TI).

Some of the Pentium 4 and Intel Xeon processor performance-monitoring events may be available only to specific models. The performance-monitoring events listed in Tables 19-21 and 19-22 apply to processors with CPUID signature that matches family encoding 15, model encoding 0, 1, 2 3, 4, or 6. Table applies to processors with a CPUID signature that matches family encoding 15, model encoding 3, 4 or 6.

The functionality of performance-monitoring events in Pentium 4 and Intel Xeon processors is also available when IA-32e mode is enabled.

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting**

Event Name	Event Parameters	Parameter Value	Description
TC_deliver_mode			This event counts the duration (in clock cycles) of the operating modes of the trace cache and decode engine in the processor package. The mode is specified by one or more of the event mask bits.
	ESCR restrictions	MSR_TC_ESCR0 MSR_TC_ESCR1	
	Counter numbers per ESCR	ESCR0: 4, 5 ESCR1: 6, 7	
	ESCR Event Select	01H	ESCR[31:25]

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	ESCR Event Mask	Bit	ESCR[24:9]
		0: DD	Both logical processors are in deliver mode.
		1: DB	Logical processor 0 is in deliver mode and logical processor 1 is in build mode.
		2: DI	Logical processor 0 is in deliver mode and logical processor 1 is either halted, under a machine clear condition or transitioning to a long microcode flow.
		3: BD	Logical processor 0 is in build mode and logical processor 1 is in deliver mode.
		4: BB	Both logical processors are in build mode.
		5: BI	Logical processor 0 is in build mode and logical processor 1 is either halted, under a machine clear condition or transitioning to a long microcode flow.
		6: ID	Logical processor 0 is either halted, under a machine clear condition or transitioning to a long microcode flow. Logical processor 1 is in deliver mode.
		7: IB	Logical processor 0 is either halted, under a machine clear condition or transitioning to a long microcode flow. Logical processor 1 is in build mode.
	CCCR Select	01H	CCCR[15:13]
	Event Specific Notes		If only one logical processor is available from a physical processor package, the event mask should be interpreted as logical processor 1 is halted. Event mask bit 2 was previously known as "DELIVER", bit 5 was previously known as "BUILD".
BPU_fetch_request			This event counts instruction fetch requests of specified request type by the Branch Prediction unit. Specify one or more mask bits to qualify the request type(s).
	ESCR restrictions	MSR_BPU_ESCR0 MSR_BPU_ESCR1	
	Counter numbers per ESCR	ESCR0: 0, 1 ESCR1: 2, 3	
	ESCR Event Select	03H	ESCR[31:25]
	ESCR Event Mask	Bit 0: TCMISS	ESCR[24:9] Trace cache lookup miss
		CCCR Select	00H
ITLB_reference			This event counts translations using the Instruction Translation Look-aside Buffer (ITLB).

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	ESCR restrictions	MSR_ITLB_ESCR0 MSR_ITLB_ESCR1	
	Counter numbers per ESCR	ESCR0: 0, 1 ESCR1: 2, 3	
	ESCR Event Select	18H	ESCR[31:25]
	ESCR Event Mask	Bit 0: HIT 1: MISS 2: HIT_UC	ESCR[24:9]  ITLB hit ITLB miss Uncacheable ITLB hit
	CCCR Select	03H	CCCR[15:13]
	Event Specific Notes		All page references regardless of the page size are looked up as actual 4-KByte pages. Use the page_walk_type event with the ITMISS mask for a more conservative count.
	memory_cancel		
ESCR restrictions		MSR_DAC_ESCR0 MSR_DAC_ESCR1	
Counter numbers per ESCR		ESCR0: 8, 9 ESCR1: 10, 11	
ESCR Event Select		02H	ESCR[31:25]
ESCR Event Mask		Bit 2: ST_RB_FULL 3: 64K_CONF	ESCR[24:9]  Replayed because no store request buffer is available Conflicts due to 64-KByte aliasing
CCCR Select		05H	CCCR[15:13]
Event Specific Notes			All_CACHE_MISS includes uncacheable memory in count.
memory_complete			This event counts the completion of a load split, store split, uncacheable (UC) split, or UC load. Specify one or more mask bits to select the operations to be counted.
	ESCR restrictions	MSR_SAAT_ESCR0 MSR_SAAT_ESCR1	
	Counter numbers per ESCR	ESCR0: 8, 9 ESCR1: 10, 11

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
		Bit 0: RD_2ndL_HITS 1: RD_2ndL_HITE 2: RD_2ndL_HITM 3: RD_3rdL_HITS 4: RD_3rdL_HITE 5: RD_3rdL_HITM	ESCR[24:9]  Read 2nd level cache hit Shared (includes load and RFO) Read 2nd level cache hit Exclusive (includes load and RFO) Read 2nd level cache hit Modified (includes load and RFO) Read 3rd level cache hit Shared (includes load and RFO)  Read 3rd level cache hit Exclusive (includes load and RFO) Read 3rd level cache hit Modified (includes load and RFO)
	ESCR Event Mask	8: RD_2ndL_MISS 9: RD_3rdL_MISS 10: WR_2ndL_MISS	Read 2nd level cache miss (includes load and RFO) Read 3rd level cache miss (includes load and RFO) A Writeback lookup from DAC misses the 2nd level cache (unlikely to happen)
	CCCR Select	07H	CCCR[15:13]
	Event Specific Notes		1: The implementation of this event in current Pentium 4 and Xeon processors treats either a load operation or a request for ownership (RFO) request as a "read" type operation. 2: Currently this event causes both over and undercounting by as much as a factor of two due to an erratum. 3: It is possible for a transaction that is started as a prefetch to change the transaction's internal status, making it no longer a prefetch, or change the access result status (hit, miss) as seen by this event.
IOQ_allocation			This event counts the various types of transactions on the bus. A count is generated each time a transaction is allocated into the IOQ that matches the specified mask bits. An allocated entry can be a sector (64 bytes) or a chunks of 8 bytes.  Requests are counted once per retry. The event mask bits constitute 4 bit fields. A transaction type is specified by interpreting the values of each bit field.  Specify one or more event mask bits in a bit field to select the value of the bit field.  Each field (bits 0-4 are one field) are independent of and can be ORed with the others. The request type field is further combined with bit 5 and 6 to form a binary expression. Bits 7 and 8 form a bit field to specify the memory type of the target address.  Bits 13 and 14 form a bit field to specify the source agent of the request. Bit 15 affects read operation only. The event is triggered by evaluating the logical expression: (((Request type) OR Bit 5 OR Bit 6) OR (Memory type)) AND (Source agent).

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	ESCR restrictions	MSR_FSB_ESCR0, MSR_FSB_ESCR1	
	Counter numbers per ESCR	ESCR0: 0, 1; ESCR1: 2, 3	
	ESCR Event Select	03H	ESCR[31:25]

Count write-protected (WP) memory access entries  Count WB memory access entries. Count all store requests driven by processor, as opposed to other processor or DMA. Count all requests driven by other processors or DMA. Include HW and SW prefetch requests in the count.
	CCCR Select	06H	CCCR[15:13]
	Event Specific Notes		<p>1: If PREFETCH bit is cleared, sectors fetched using prefetch are excluded in the counts. If PREFETCH bit is set, all sectors or chunks read are counted.</p> <p>2: Specify the edge trigger in CCCR to avoid double counting.</p> <p>3: The mapping of interpreted bit field values to transaction types may differ with different processor model implementations of the Pentium 4 processor family. Applications that program performance monitoring events should use CPUID to determine processor models when using this event. The logic equations that trigger the event are model-specific (see 4a and 4b below).</p> <p>4a: For Pentium 4 and Xeon Processors starting with CPUID Model field encoding equal to 2 or greater, this event is triggered by evaluating the logical expression ((Request type) and (Bit 5 or Bit 6) and (Memory type) and (Source agent)).</p> <p>4b: For Pentium 4 and Xeon Processors with CPUID Model field encoding less than 2, this event is triggered by evaluating the logical expression [((Request type) or Bit 5 or Bit 6) or (Memory type)] and (Source agent). Note that event mask bits for memory type are ignored if either ALL_READ or ALL_WRITE is specified.</p>

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description	
			<p>5: This event is known to ignore CPL in early implementations of Pentium 4 and Xeon Processors. Both user requests and OS requests are included in the count. This behavior is fixed starting with Pentium 4 and Xeon Processors with CPUID signature 0xF27 (Family 15, Model 2, Stepping 7).</p> <p>6: For write-through (WT) and write-protected (WP) memory types, this event counts reads as the number of 64-byte sectors. Writes are counted by individual chunks.</p> <p>7: For uncacheable (UC) memory types, this events counts the number of 8-byte chunks allocated.</p> <p>8: For Pentium 4 and Xeon Processors with CPUID Signature less than 0xf27, only MSR_FSB_ESCR0 is available.</p>	
IOQ_active_entries			<p>This event counts the number of entries (clipped at 15) in the IOQ that are active. An allocated entry can be a sector (64 bytes) or a chunks of 8 bytes.</p> <p>The event must be programmed in conjunction with IOQ_allocation. Specify one or more event mask bits to select the transactions that is counted.</p>	
	ESCR restrictions	MSR_FSB_ESCR1		
	Counter numbers per ESCR	ESCR1: 2, 3		
	ESCR Event Select	01AH	ESCR[30:25]

				Count write-through (WT) memory access entries. Count write-protected (WP) memory access entries.
				Count WB memory access entries. Count all store requests driven by processor, as opposed to other processor or DMA.
		14: OTHER 15: PREFETCH		Count all requests driven by other processors or DMA. Include HW and SW prefetch requests in the count.
CCCR Select	06H	CCCR[15:13]		
Event Specific Notes			1: Specified desired mask bits in ESCR0 and ESCR1. 2: See the ioq_allocation event for descriptions of the mask bits. 3: Edge triggering should not be used when counting cycles.	

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
			<p>4: The mapping of interpreted bit field values to transaction types may differ across different processor model implementations of the Pentium 4 processor family. Applications that programs performance monitoring events should use the CPUID instruction to detect processor models when using this event. The logical expression that triggers this event as describe below:</p> <p>5a:For Pentium 4 and Xeon Processors starting with CPUID MODEL field encoding equal to 2 or greater, this event is triggered by evaluating the logical expression ((Request type) and (Bit 5 or Bit 6) and (Memory type) and (Source agent)).</p> <p>5b:For Pentium 4 and Xeon Processors starting with CPUID MODEL field encoding less than 2, this event is triggered by evaluating the logical expression [((Request type) or Bit 5 or Bit 6) or (Memory type)] and (Source agent). Event mask bits for memory type are ignored if either ALL_READ or ALL_WRITE is specified.</p> <p>5c: This event is known to ignore CPL in the current implementations of Pentium 4 and Xeon Processors Both user requests and OS requests are included in the count.</p> <p>6: An allocated entry can be a full line (64 bytes) or in individual chunks of 8 bytes.</p>
FSB_data_activity			This event increments once for each DRDY or DBSY event that occurs on the front side bus. The event allows selection of a specific DRDY or DBSY event.
	ESCR restrictions	MSR_FSB_ESCR0 MSR_FSB_ESCR1	
	Counter numbers per ESCR	ESCR0: 0, 1 ESCR1: 2, 3	
	ESCR Event Select	17H	ESCR[31:25]
	ESCR Event Mask	Bit 0: DRDY_DRV	
1: DRDY_OWN			Count when this processor reads data from the bus - includes loads and some PIC transactions. Asserted two processor clock cycles for partial reads and 4 processor clocks (usually in consecutive bus clocks) for full line reads.  Count DRDY events that we drive. Count DRDY events sampled that we own.
2: DRDY_OTHER			Count when data is on the bus but not being sampled by the processor. It may or may not be being driven by this processor.  Asserted two processor clock cycles for partial transactions and 4 processor clocks (usually in consecutive bus clocks) for full line transactions.

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
		3: DBSY_DRV	Count when this processor reserves the bus for use in the next bus cycle in order to drive data. Asserted for two processor clock cycles for full line writes and not at all for partial line writes. May be asserted multiple times (in consecutive bus clocks) if we stall the bus waiting for a cache lock to complete.
		4: DBSY_OWN	Count when some agent reserves the bus for use in the next bus cycle to drive data that this processor will sample. Asserted for two processor clock cycles for full line writes and not at all for partial line writes. May be asserted multiple times (all one bus clock apart) if we stall the bus for some reason.
		5:DBSY_OTHER	Count when some agent reserves the bus for use in the next bus cycle to drive data that this processor will NOT sample. It may or may not be being driven by this processor. Asserted two processor clock cycles for partial transactions and 4 processor clocks (usually in consecutive bus clocks) for full line transactions.
	CCCR Select	06H	CCCR[15:13]
	Event Specific Notes		Specify edge trigger in the CCCR MSR to avoid double counting. DRDY_OWN and DRDY_OTHER are mutually exclusive; similarly for DBSY_OWN and DBSY_OTHER.
BSQ_allocation			This event counts allocations in the Bus Sequence Unit (BSQ) according to the specified mask bit encoding. The event mask bits consist of four sub-groups: <ul style="list-style-type: none"> <li>▪ request type,</li> <li>▪ request length</li> <li>▪ memory type</li> <li>▪ and sub-group consisting mostly of independent bits (bits 5, 6, 7, 8, 9, and 10)</li> </ul> Specify an encoding for each sub-group.
	ESCR restrictions	MSR_BSU_ESCR0	
	Counter numbers per ESCR	ESCR0: 0, 1	
	ESCR Event Select	05H	ESCR[31:25]
	ESCR Event Mask	Bit 0: REQ_TYPE0 1: REQ_TYPE1  2: REQ_LEN0 3: REQ_LEN1	ESCR[24:9]  Request type encoding (bit 0 and 1) are: 0 - Read (excludes read invalidate) 1 - Read invalidate 2 - Write (other than writebacks) 3 - Writeback (evicted from cache). (public)  Request length encoding (bit 2, 3) are: 0 - 0 chunks 1 - 1 chunks 3 - 8 chunks

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
		5: REQ_IO_TYPE	Request type is input or output.
		6: REQ_LOCK_TYPE	Request type is bus lock.
		7: REQ_CACHE_TYPE	Request type is cacheable.
		8: REQ_SPLIT_TYPE	Request type is a bus 8-byte chunk split across 8-byte boundary.
		9: REQ_DEM_TYPE	Request type is a demand if set. Request type is HW.SW prefetch if 0.
		10: REQ_ORD_TYPE	Request is an ordered type.
		11: MEM_TYPE0 12: MEM_TYPE1 13: MEM_TYPE2	Memory type encodings (bit 11-13) are: 0 - UC 1 - WC 4 - WT 5 - WP 6 - WB
	CCCR Select	07H	CCCR[15:13]
	Event Specific Notes		<p>1: Specify edge trigger in CCCR to avoid double counting.</p> <p>2: A writebacks to 3rd level cache from 2nd level cache counts as a separate entry, this is in additional to the entry allocated for a request to the bus.</p> <p>3: A read request to WB memory type results in a request to the 64-byte sector, containing the target address, followed by a prefetch request to an adjacent sector.</p> <p>4: For Pentium 4 and Xeon processors with CPUID model encoding value equals to 0 and 1, an allocated BSQ entry includes both the demand sector and prefetched 2nd sector.</p> <p>5: An allocated BSQ entry for a data chunk is any request less than 64 bytes.</p> <p>6a: This event may undercount for requests of split type transactions if the data address straddled across modulo-64 byte boundary.</p> <p>6b: This event may undercount for requests of read request of 16-byte operands from WC or UC address.</p> <p>6c: This event may undercount WC partial requests originated from store operands that are dwords.</p>
bsq_active_entries			<p>This event represents the number of BSQ entries (clipped at 15) currently active (valid) which meet the subevent mask criteria during allocation in the BSQ. Active request entries are allocated on the BSQ until de-allocated.</p> <p>De-allocation of an entry does not necessarily imply the request is filled. This event must be programmed in conjunction with BSQ_allocation. Specify one or more event mask bits to select the transactions that is counted.</p>
	ESCR restrictions	ESCR1	

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	Counter numbers per ESCR	ESCR1: 2, 3	
	ESCR Event Select	06H	ESCR[30:25]
	ESCR Event Mask		ESCR[24:9]
	CCCR Select	07H	CCCR[15:13]
	Event Specific Notes		<p>1: Specified desired mask bits in ESCR0 and ESCR1.</p> <p>2: See the BSQ_allocation event for descriptions of the mask bits.</p> <p>3: Edge triggering should not be used when counting cycles.</p> <p>4: This event can be used to estimate the latency of a transaction from allocation to de-allocation in the BSQ. The latency observed by BSQ_allocation includes the latency of FSB, plus additional overhead.</p> <p>5: Additional overhead may include the time it takes to issue two requests (the sector by demand and the adjacent sector via prefetch). Since adjacent sector prefetches have lower priority than demand fetches, on a heavily used system there is a high probability that the adjacent sector prefetch will have to wait until the next bus arbitration.</p> <p>6: For Pentium 4 and Xeon processors with CPUID model encoding value less than 3, this event is updated every clock.</p> <p>7: For Pentium 4 and Xeon processors with CPUID model encoding value equals to 3 or 4, this event is updated every other clock.</p>
SSE_input_assist			This event counts the number of times an assist is requested to handle problems with input operands for SSE/SSE2/SSE3 operations; most notably denormal source operands when the DAZ bit is not set. Set bit 15 of the event mask to use this event.
	ESCR restrictions	MSR_FIRM_ESCR0 MSR_FIRM_ESCR1	
	Counter numbers per ESCR	ESCR0: 8, 9 ESCR1: 10, 11	
	ESCR Event Select	34H	ESCR[31:25]
	ESCR Event Mask	15: ALL	ESCR[24:9] Count assists for SSE/SSE2/SSE3 $\mu$ ops.
	CCCR Select	01H	CCCR[15:13]
	Event Specific Notes		1: Not all requests for assists are actually taken. This event is known to overcount in that it counts requests for assists from instructions on the non-retired path that do not incur a performance penalty. An assist is actually taken only for non-bogus $\mu$ ops. Any appreciable counts for this event are an indication that the DAZ or FTZ bit should be set and/or the source code should be changed to eliminate the condition.

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
			<p>2: Two common situations for an SSE/SSE2/SSE3 operation needing an assist are: (1) when a denormal constant is used as an input and the Denormals-Are-Zero (DAZ) mode is not set, (2) when the input operand uses the underflowed result of a previous SSE/SSE2/SSE3 operation and neither the DAZ nor Flush-To-Zero (FTZ) modes are set.</p> <p>3: Enabling the DAZ mode prevents SSE/SSE2/SSE3 operations from needing assists in the first situation. Enabling the FTZ mode prevents SSE/SSE2/SSE3 operations from needing assists in the second situation.</p>
packed_SP_uop			This event increments for each packed single-precision $\mu$ op, specified through the event mask for detection.
	ESCR restrictions	MSR_FIRM_ESCR0 MSR_FIRM_ESCR1	
	Counter numbers per ESCR	ESCR0: 8, 9 ESCR1: 10, 11	
	ESCR Event Select	08H	ESCR[31:25]
	ESCR Event Mask	Bit 15: ALL	ESCR[24:9] Count all $\mu$ ops operating on packed single-precision operands.
	CCCR Select	01H	CCCR[15:13]
	Event Specific Notes		<p>1: If an instruction contains more than one packed SP <math>\mu</math>ops, each packed SP <math>\mu</math>op that is specified by the event mask will be counted.</p> <p>2: This metric counts instances of packed memory <math>\mu</math>ops in a repeat move string.</p>
packed_DP_uop			This event increments for each packed double-precision $\mu$ op, specified through the event mask for detection.
	ESCR restrictions	MSR_FIRM_ESCR0 MSR_FIRM_ESCR1	
	Counter numbers per ESCR	ESCR0: 8, 9 ESCR1: 10, 11	
	ESCR Event Select	0CH	ESCR[31:25]

	CCCR Select	06H	CCCR[15:13]
tc_ms_xfer			This event counts the number of times that uop delivery changed from TC to MS ROM.
	ESCR restrictions	MSR_MS_ESCR0 MSR_MS_ESCR1	

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	Counter numbers per ESCR	ESCR0: 4, 5 ESCR1: 6, 7	
	ESCR Event Select	05H	ESCR[31:25]
	ESCR Event Mask	Bit 0: CISC	ESCR[24:9] A TC to MS transfer occurred.
	CCCR Select	0H	CCCR[15:13]
uop_queue_writes			This event counts the number of valid uops written to the uop queue. Specify one or more mask bits to select the source type of writes.
	ESCR restrictions	MSR_MS_ESCR0 MSR_MS_ESCR1	
	Counter numbers per ESCR	ESCR0: 4, 5 ESCR1: 6, 7	
	ESCR Event Select	09H	ESCR[31:25]
	ESCR Event Mask	Bit 0: FROM_TC_BUILD 1: FROM_TC_DELIVER 2: FROM_ROM	ESCR[24:9]  The uops being written are from TC build mode.  The uops being written are from TC deliver mode. The uops being written are from microcode ROM.
	CCCR Select	0H	CCCR[15:13]
retired_mispred_branch_type			This event counts retiring mispredicted branches by type.
	ESCR restrictions	MSR_TBPU_ESCR0 MSR_TBPU_ESCR1	
	Counter numbers per ESCR	ESCR0: 4, 5 ESCR1: 6, 7	
	ESCR Event Select	05H	ESCR[30:25]
	ESCR Event Mask	Bit 1: CONDITIONAL 2: CALL	ESCR[24:9]  Conditional jumps. Indirect call branches.
		3: RETURN 4: INDIRECT	Return branches. Returns, indirect calls, or indirect jumps.
	CCCR Select	02H	CCCR[15:13]
	Event Specific Notes		This event may overcount conditional branches if: <ul style="list-style-type: none"> <li>▪ Mispredictions cause the trace cache and delivery engine to build new traces.</li> <li>▪ When the processor's pipeline is being cleared.</li> </ul>
retired_branch_type			This event counts retiring branches by type. Specify one or more mask bits to qualify the branch by its type.

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	ESCR restrictions	MSR_TBPU_ESCR0 MSR_TBPU_ESCR1	
	Counter numbers per ESCR	ESCR0: 4, 5 ESCR1: 6, 7	
	ESCR Event Select	04H	ESCR[30:25]
	ESCR Event Mask	Bit 1: CONDITIONAL 2: CALL 3: RETURN 4: INDIRECT	ESCR[24:9]  Conditional jumps. Direct or indirect calls. Return branches. Returns, indirect calls, or indirect jumps.
	CCCR Select	02H	CCCR[15:13]
	Event Specific Notes		This event may overcount conditional branches if : <ul style="list-style-type: none"> <li>▪ Mispredictions cause the trace cache and delivery engine to build new traces.</li> <li>▪ When the processor’s pipeline is being cleared.</li> </ul>
	resource_stall		
	ESCR restrictions	MSR_ALF_ESCR0 MSR_ALF_ESCR1	
	Counter numbers per ESCR	ESCR0: 12, 13, 16 ESCR1: 14, 15, 17	
	ESCR Event Select	01H	ESCR[30:25]
	Event Masks	Bit 5: SBFULL	ESCR[24:9]  A Stall due to lack of store buffers.
	CCCR Select	01H	CCCR[15:13]
	Event Specific Notes		This event may not be supported in all models of the processor family.
	WC_Buffer		
	ESCR restrictions	MSR_DAC_ESCR0 MSR_DAC_ESCR1	
	Counter numbers per ESCR	ESCR0: 8, 9 ESCR1: 10, 11	
	ESCR Event Select	05H	ESCR[30:25]
	Event Masks	Bit 0: WCB_EVICTS	ESCR[24:9]  WC Buffer evictions of all causes.
		1: WCB_FULL_EVICT	WC Buffer eviction: no WC buffer is available.

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	CCCR Select	05H	CCCR[15:13]
	Event Specific Notes		This event is useful for detecting the subset of 64K aliasing cases that are more costly (i.e. 64K aliasing cases involving stores) as long as there are no significant contributions due to write combining buffer full or hit-modified conditions.
b2b_cycles			This event can be configured to count the number back-to-back bus cycles using sub-event mask bits 1 through 6.
	ESCR restrictions	MSR_FSB_ESCR0 MSR_FSB_ESCR1	
	Counter numbers per ESCR	ESCR0: 0, 1 ESCR1: 2, 3	
	ESCR Event Select	016H	ESCR[30:25]
	Event Masks	Bit	ESCR[24:9]
	CCCR Select	03H	CCCR[15:13]
	Event Specific Notes		This event may not be supported in all models of the processor family.
bnr			This event can be configured to count bus not ready conditions using sub-event mask bits 0 through 2.
	ESCR restrictions	MSR_FSB_ESCR0 MSR_FSB_ESCR1	
	Counter numbers per ESCR	ESCR0: 0, 1 ESCR1: 2, 3	
	ESCR Event Select	08H	ESCR[30:25]
	Event Masks	Bit	ESCR[24:9]
	CCCR Select	03H	CCCR[15:13]
	Event Specific Notes		This event may not be supported in all models of the processor family.
snoop			This event can be configured to count snoop hit modified bus traffic using sub-event mask bits 2, 6 and 7.
	ESCR restrictions	MSR_FSB_ESCR0 MSR_FSB_ESCR1	
	Counter numbers per ESCR	ESCR0: 0, 1 ESCR1: 2, 3	
	ESCR Event Select	06H	ESCR[30:25]
	Event Masks	Bit	ESCR[24:9]
	CCCR Select	03H	CCCR[15:13]
	Event Specific Notes		This event may not be supported in all models of the processor family.
Response			This event can be configured to count different types of responses using sub-event mask bits 1,2, 8, and 9.
	ESCR restrictions	MSR_FSB_ESCR0 MSR_FSB_ESCR1	

**Table 19-21. Performance Monitoring Events Supported by Intel NetBurst® Microarchitecture for Non-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	Counter numbers per ESCR	ESCR0: 0, 1 ESCR1: 2, 3	
	ESCR Event Select	04H	ESCR[30:25]
	Event Masks	Bit	ESCR[24:9]
	CCCR Select	03H	CCCR[15:13]
	Event Specific Notes		This event may not be supported in all models of the processor family.

**Table 19-22. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting**

Event Name	Event Parameters	Parameter Value	Description
front_end_event			This event counts the retirement of tagged $\mu$ ops, which are specified through the front-end tagging mechanism. The event mask specifies bogus or non-bogus $\mu$ ops.
	ESCR restrictions	MSR_CRU_ESCR2 MSR_CRU_ESCR3	
	Counter numbers per ESCR	ESCR2: 12, 13, 16 ESCR3: 14, 15, 17	
	ESCR Event Select	08H	ESCR[31:25]
	ESCR Event Mask	Bit 0: NBOGUS 1: BOGUS	ESCR[24:9]  The marked $\mu$ ops are not bogus. The marked $\mu$ ops are bogus.
	CCCR Select	05H	CCCR[15:13]
	Can Support PEBS	Yes	
	Require Additional MSRs for tagging	Selected ESCRs and/or MSR_TC_PRECISE_EVENT	See list of metrics supported by Front_end tagging in Table A-3
execution_event			This event counts the retirement of tagged $\mu$ ops, which are specified through the execution tagging mechanism.  The event mask allows from one to four types of $\mu$ ops to be specified as either bogus or non-bogus $\mu$ ops to be tagged.
	ESCR restrictions	MSR_CRU_ESCR2 MSR_CRU_ESCR3	
	Counter numbers per ESCR	ESCR2: 12, 13, 16 ESCR3: 14, 15, 17	
	ESCR Event Select	0CH	ESCR[31:25]

**Table 19-22. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	ESCR Event Mask	Bit 0: NBOGUS0 1: NBOGUS1 2: NBOGUS2 3: NBOGUS3 4: BOGUS0 5: BOGUS1 6: BOGUS2 7: BOGUS3	ESCR[24:9]  The marked $\mu$ ops are not bogus. The marked $\mu$ ops are not bogus. The marked $\mu$ ops are not bogus. The marked $\mu$ ops are not bogus. The marked $\mu$ ops are bogus. The marked $\mu$ ops are bogus. The marked $\mu$ ops are bogus. The marked $\mu$ ops are bogus.
	CCCR Select	05H	CCCR[15:13]
	Event Specific Notes		Each of the 4 slots to specify the bogus/non-bogus $\mu$ ops must be coordinated with the 4 TagValue bits in the ESCR (for example, NBOGUS0 must accompany a '1' in the lowest bit of the TagValue field in ESCR, NBOGUS1 must accompany a '1' in the next but lowest bit of the TagValue field).
	Can Support PEBS	Yes	
	Require Additional MSRs for tagging	An ESCR for an upstream event	See list of metrics supported by execution tagging in Table A-4.
replay_event			This event counts the retirement of tagged $\mu$ ops, which are specified through the replay tagging mechanism. The event mask specifies bogus or non-bogus $\mu$ ops.
	ESCR restrictions	MSR_CRU_ESCR2 MSR_CRU_ESCR3	
	Counter numbers per ESCR	ESCR2: 12, 13, 16 ESCR3: 14, 15, 17	
	ESCR Event Select	09H	ESCR[31:25]
	ESCR Event Mask	Bit 0: NBOGUS 1: BOGUS	ESCR[24:9]  The marked $\mu$ ops are not bogus. The marked $\mu$ ops are bogus.
	CCCR Select	05H	CCCR[15:13]
	Event Specific Notes		Supports counting tagged $\mu$ ops with additional MSRs.
	Can Support PEBS	Yes	
	Require Additional MSRs for tagging	IA32_PEBS_ENABLE MSR_PEBS_MATRIX_VERT Selected ESCR	See list of metrics supported by replay tagging in Table A-5.
instr_retired			This event counts instructions that are retired during a clock cycle. Mask bits specify bogus or non-bogus (and whether they are tagged using the front-end tagging mechanism).

**Table 19-22. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	ESCR restrictions	MSR_CRU_ESCR0 MSR_CRU_ESCR1	
	Counter numbers per ESCR	ESCR0: 12, 13, 16 ESCR1: 14, 15, 17	
	ESCR Event Select	02H	ESCR[31:25]
	ESCR Event Mask	Bit 0: NBOGUSNTAG  1: NBOGUSTAG 2: BOGUSNTAG 3: BOGUSTAG	ESCR[24:9]  Non-bogus instructions that are not tagged. Non-bogus instructions that are tagged.  Bogus instructions that are not tagged. Bogus instructions that are tagged.
	CCCR Select	04H	CCCR[15:13]
	Event Specific Notes		1: The event count may vary depending on the microarchitectural states of the processor when the event detection is enabled. 2: The event may count more than once for some instructions with complex uop flows and were interrupted before retirement.
	Can Support PEBS	No	
uops_retired			This event counts $\mu$ ops that are retired during a clock cycle. Mask bits specify bogus or non-bogus.
	ESCR restrictions	MSR_CRU_ESCR0 MSR_CRU_ESCR1	
	Counter numbers per ESCR	ESCR0: 12, 13, 16 ESCR1: 14, 15, 17	
	ESCR Event Select	01H	ESCR[31:25]
	ESCR Event Mask	Bit 0: NBOGUS 1: BOGUS	ESCR[24:9]  The marked $\mu$ ops are not bogus. The marked $\mu$ ops are bogus.
	CCCR Select	04H	CCCR[15:13]
	Event Specific Notes		P6: EMON_UOPS_RETIRED
	Can Support PEBS	No	
uop_type			This event is used in conjunction with the front-end at-retirement mechanism to tag load and store $\mu$ ops.
	ESCR restrictions	MSR_RAT_ESCR0 MSR_RAT_ESCR1	
	Counter numbers per ESCR	ESCR0: 12, 13, 16 ESCR1: 14, 15, 17	
	ESCR Event Select	02H	ESCR[31:25]

**Table 19-22. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	ESCR Event Mask	Bit 1: TAGLOADS 2: TAGSTORES	ESCR[24:9]  The $\mu$ op is a load operation. The $\mu$ op is a store operation.
	CCCR Select	02H	CCCR[15:13]
	Event Specific Notes		Setting the TAGLOADS and TAGSTORES mask bits does not cause a counter to increment. They are only used to tag uops.
	Can Support PEBS	No	
branch_retired			This event counts the retirement of a branch. Specify one or more mask bits to select any combination of taken, not-taken, predicted and mispredicted.
	ESCR restrictions	MSR_CRU_ESCR2 MSR_CRU_ESCR3	See Table 18-45 for the addresses of the ESCR MSRs
	Counter numbers per ESCR	ESCR2: 12, 13, 16 ESCR3: 14, 15, 17	The counter numbers associated with each ESCR are provided. The performance counters and corresponding CCCRs can be obtained from Table 18-45.
	ESCR Event Select	06H	ESCR[31:25]
	ESCR Event Mask	Bit 0: MMNP 1: MMNM 2: MMTP 3: MMTM	ESCR[24:9]  Branch not-taken predicted Branch not-taken mispredicted Branch taken predicted Branch taken mispredicted
	CCCR Select	05H	CCCR[15:13]
	Event Specific Notes		P6: EMON_BR_INST_RETIRED
	Can Support PEBS	No	
mispred_branch_retired			This event represents the retirement of mispredicted branch instructions.
	ESCR restrictions	MSR_CRU_ESCR0 MSR_CRU_ESCR1	
	Counter numbers per ESCR	ESCR0: 12, 13, 16 ESCR1: 14, 15, 17	
	ESCR Event Select	03H	ESCR[31:25]
	ESCR Event Mask	Bit 0: NBOGUS	ESCR[24:9] The retired instruction is not bogus.
	CCCR Select	04H	CCCR[15:13]
	Can Support PEBS	No	
x87_assist			This event counts the retirement of x87 instructions that required special handling. Specifies one or more event mask bits to select the type of assistance.

**Table 19-22. Performance Monitoring Events For Intel NetBurst® Microarchitecture for At-Retirement Counting (Contd.)**

Event Name	Event Parameters	Parameter Value	Description
	ESCR restrictions	MSR_CRU_ESCR2 MSR_CRU_ESCR3	
	Counter numbers per ESCR	ESCR2: 12, 13, 16 ESCR3: 14, 15, 17	
	ESCR Event Select	03H	ESCR[31:25]
	ESCR Event Mask	Bit 0: FPSU 1: FPSO 2: POAO 3: POAU 4: PREA	ESCR[24:9]  Handle FP stack underflow Handle FP stack overflow Handle x87 output overflow Handle x87 output underflow Handle x87 input assist
	CCCR Select	05H	CCCR[15:13]
	Can Support PEBS	No	
machine_clear			This event increments according to the mask bit specified while the entire pipeline of the machine is cleared. Specify one of the mask bit to select the cause.
	ESCR restrictions	MSR_CRU_ESCR2 MSR_CRU_ESCR3	
	Counter numbers per ESCR	ESCR2: 12, 13, 16 ESCR3: 14, 15, 17	
	ESCR Event Select	02H	ESCR[31:25]
	ESCR Event Mask	Bit 0: CLEAR  2: MOCLEAR  6: SMCLEAR	ESCR[24:9]  Counts for a portion of the many cycles while the machine is cleared for any cause. Use Edge triggering for this bit only to get a count of occurrence versus a duration.  Increments each time the machine is cleared due to memory ordering issues.  Increments each time the machine is cleared due to self-modifying code issues.
	CCCR Select	05H	CCCR[15:13]
	Can Support PEBS	No	

**Table 19-23. Intel NetBurst® Microarchitecture Model-Specific Performance Monitoring Events  
(For Model Encoding 3, 4 or 6)**

Event Name	Event Parameters	Parameter Value	Description
instr_completed			This event counts instructions that have completed and retired during a clock cycle. Mask bits specify whether the instruction is bogus or non-bogus and whether they are:
	ESCR restrictions	MSR_CRU_ESCR0 MSR_CRU_ESCR1	
	Counter numbers per ESCR	ESCR0: 12, 13, 16 ESCR1: 14, 15, 17	
	ESCR Event Select	07H	ESCR[31:25]
	ESCR Event Mask	Bit 0: NBOGUS 1: BOGUS	ESCR[24:9]  Non-bogus instructions Bogus instructions
	CCCR Select	04H	CCCR[15:13]
	Event Specific Notes		This metric differs from instr_retired, since it counts instructions completed, rather than the number of times that instructions started.
	Can Support PEBS	No	

**Table 19-24. List of Metrics Available for Front\_end Tagging (For Front\_end Event Only)**

Front-end metric <sup>1</sup>	MSR_TC_PRECISE_EVENT MSR Bit field	Additional MSR	Event mask value for Front_end_event
memory_loads	None	Set TAGLOADS bit in ESCR corresponding to event Uop_Type.	NBOGUS
memory_stores	None	Set TAGSTORES bit in the ESCR corresponding to event Uop_Type.	NBOGUS

**NOTES:**

1. There may be some undercounting of front end events when there is an overflow or underflow of the floating point stack.

**Table 19-25. List of Metrics Available for Execution Tagging (For Execution Event Only)**

Execution metric	Upstream ESCR	TagValue in Upstream ESCR	Event mask value for execution_event
packed_SP_retired	Set ALL bit in event mask, TagUop bit in ESCR of packed_SP_uop.	1	NBOGUS0
packed_DP_retired	Set ALL bit in event mask, TagUop bit in ESCR of packed_DP_uop.	1	NBOGUS0
scalar_SP_retired	Set ALL bit in event mask, TagUop bit in ESCR of scalar_SP_uop.	1	NBOGUS0
scalar_DP_retired	Set ALL bit in event mask, TagUop bit in ESCR of scalar_DP_uop.	1	NBOGUS0
128_bit_MMX_retired	Set ALL bit in event mask, TagUop bit in ESCR of 128_bit_MMX_uop.	1	NBOGUS0
64_bit_MMX_retired	Set ALL bit in event mask, TagUop bit in ESCR of 64_bit_MMX_uop.	1	NBOGUS0

**Table 19-25. List of Metrics Available for Execution Tagging (For Execution Event Only) (Contd.)**

Execution metric	Upstream ESCR	TagValue in Upstream ESCR	Event mask value for execution_event
X87_FP_retired	Set ALL bit in event mask, TagUop bit in ESCR of x87_FP_uop.	1	NBOGUS0
X87_SIMD_memory_moves_retired	Set ALLP0, ALLP2 bits in event mask, TagUop bit in ESCR of X87_SIMD_moves_uop.	1	NBOGUS0

**Table 19-26. List of Metrics Available for Replay Tagging (For Replay Event Only)**

Replay metric <sup>1</sup>	IA32_PEBS_ENABLE Field to Set	MSR_PEBS_MATRIX_VERT Bit Field to Set	Additional MSR/ Event	Event Mask Value for Replay_event
1stL_cache_load_miss_retired	Bit 0, Bit 24, Bit 25	Bit 0	None	NBOGUS
2ndL_cache_load_miss_retired <sup>2</sup>	Bit 1, Bit 24, Bit 25	Bit 0	None	NBOGUS
DTLB_load_miss_retired	Bit 2, Bit 24, Bit 25	Bit 0	None	NBOGUS
DTLB_store_miss_retired	Bit 2, Bit 24, Bit 25	Bit 1	None	NBOGUS
DTLB_all_miss_retired	Bit 2, Bit 24, Bit 25	Bit 0, Bit 1	None	NBOGUS
Tagged_mispred_branch	Bit 15, Bit 16, Bit 24, Bit 25	Bit 4	None	NBOGUS
MOB_load_replay_retired <sup>3</sup>	Bit 9, Bit 24, Bit 25	Bit 0	Select MOB_load_replay event and set PARTIAL_DATA and UNALGN_ADDR bit.	NBOGUS
split_load_retired	Bit 10, Bit 24, Bit 25	Bit 0	Select load_port_replay event with the MSR_SAAT_ESCR1 MSR and set the SPLIT_LD mask bit.	NBOGUS
split_store_retired	Bit 10, Bit 24, Bit 25	Bit 1	Select store_port_replay event with the MSR_SAAT_ESCR0 MSR and set the SPLIT_ST mask bit.	NBOGUS

**NOTES:**

1. Certain kinds of  $\mu$ ops cannot be tagged. These include I/O operations, UC and locked accesses, returns, and far transfers.
2. 2nd-level misses retired does not count all 2nd-level misses. It only includes those references that are found to be misses by the fast detection logic and not those that are later found to be misses.
3. While there are several causes for a MOB replay, the event counted with this event mask setting is the case where the data from a load that would otherwise be forwarded is not an aligned subset of the data from a preceding store.

## 19.13 PERFORMANCE MONITORING EVENTS FOR INTEL® PENTIUM® M PROCESSORS

The Pentium M processor's performance-monitoring events are based on monitoring events for the P6 family of processors. All of these performance events are model specific for the Pentium M processor and are not available in this form in other processors. Table 19-28 lists the Performance-Monitoring events that were added in the Pentium M processor.

**Table 19-28. Performance Monitoring Events on Intel® Pentium® M Processors**

Name	Hex Values	Descriptions
Power Management		
EMON_EST_TRANS	58H	Number of Enhanced Intel SpeedStep technology transitions: Mask = 00H - All transitions Mask = 02H - Only Frequency transitions
EMON_THERMAL_TRIP	59H	Duration/Occurrences in thermal trip; to count number of thermal trips: bit 22 in PerfEvtSel0/1 needs to be set to enable edge detect.
BPU		
BR_INST_EXEC	88H	Branch instructions that were executed (not necessarily retired).
BR_MISSP_EXEC	89H	Branch instructions executed that were mispredicted at execution.
BR_BAC_MISSP_EXEC	8AH	Branch instructions executed that were mispredicted at front end (BAC).
BR_CND_EXEC	8BH	Conditional branch instructions that were executed.
BR_CND_MISSP_EXEC	8CH	Conditional branch instructions executed that were mispredicted.
BR_IND_EXEC	8DH	Indirect branch instructions executed.
BR_IND_MISSP_EXEC	8EH	Indirect branch instructions executed that were mispredicted.
BR_RET_EXEC	8FH	Return branch instructions executed.
BR_RET_MISSP_EXEC	90H	Return branch instructions executed that were mispredicted at execution.
BR_RET_BAC_MISSP_EXEC	91H	Return branch instructions executed that were mispredicted at front end (BAC).
BR_CALL_EXEC	92H	CALL instruction executed.
BR_CALL_MISSP_EXEC	93H	CALL instruction executed and miss predicted.
BR_IND_CALL_EXEC	94H	Indirect CALL instructions executed.
Decoder		
EMON_SIMD_INSTR_RETIRED	CEH	Number of retired MMX instructions.
EMON_SYNCH_UOPS	D3H	Sync micro-ops
EMON_ESP_UOPS	D7H	Total number of micro-ops
EMON_FUSED_UOPS_RET	DAH	Number of retired fused micro-ops: Mask = 0 - Fused micro-ops Mask = 1 - Only load+Op micro-ops Mask = 2 - Only std+sta micro-ops
EMON_UNFUSION	DBH	Number of unfusion events in the ROB, happened on a FP exception to a fused $\mu$ op.
Prefetcher		
EMON_PREF_RQSTS_UP	FOH	Number of upward prefetches issued
EMON_PREF_RQSTS_DN	F8H	Number of downward prefetches issued

A number of P6 family processor performance monitoring events are modified for the Pentium M processor. Table 19-29 lists the performance monitoring events that were changed in the Pentium M processor, and differ from performance monitoring events for the P6 family of processors.

**Table 19-29. Performance Monitoring Events Modified on Intel® Pentium® M Processors**

Name	Hex Values	Descriptions
CPU_CLK_UNHALTED	79H	Number of cycles during which the processor is not halted, and not in a thermal trip.
EMON_SSE_SSE2_INST_RETIRE	D8H	Streaming SIMD Extensions Instructions Retired: Mask = 0 - SSE packed single and scalar single Mask = 1 - SSE scalar-single Mask = 2 - SSE2 packed-double Mask = 3 - SSE2 scalar-double
EMON_SSE_SSE2_COMP_INST_RETIRE	D9H	Computational SSE Instructions Retired: Mask = 0 - SSE packed single Mask = 1 - SSE Scalar-single Mask = 2 - SSE2 packed-double Mask = 3 - SSE2 scalar-double
L2_LD	29H	L2 data loads
L2_LINES_IN	24H	L2 lines allocated
L2_LINES_OUT	26H	L2 lines evicted
L2_M_LINES_OUT	27H	Lw M-state lines evicted
		Mask[0] = 1 - count I state lines Mask[1] = 1 - count S state lines Mask[2] = 1 - count E state lines Mask[3] = 1 - count M state lines Mask[5:4]: 00H - Excluding hardware-prefetched lines 01H - Hardware-prefetched lines only 02H/03H - All (HW-prefetched lines and non HW -- Prefetched lines)

## 19.14 P6 FAMILY PROCESSOR PERFORMANCE-MONITORING EVENTS

Table 19-30 lists the events that can be counted with the performance-monitoring counters and read with the RDPIC instruction for the P6 family processors. The unit column gives the microarchitecture or bus unit that produces the event; the event number column gives the hexadecimal number identifying the event; the mnemonic event name column gives the name of the event; the unit mask column gives the unit mask required (if any); the description column describes the event; and the comments column gives additional information about the event.

All of these performance events are model specific for the P6 family processors and are not available in this form in the Pentium 4 processors or the Pentium processors. Some events (such as those added in later generations of the P6 family processors) are only available in specific processors in the P6 family. All performance event encodings not listed in Table 19-30 are reserved and their use will result in undefined counter results.

See the end of the table for notes related to certain entries in the table.

**Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters**

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
Data Cache Unit (DCU)	43H	DATA_MEM_REFS	00H	All loads from any memory type. All stores to any memory type. Each part of a split is counted separately. The internal logic counts not only memory loads and stores, but also internal retries.  80-bit floating-point accesses are double counted, since they are decomposed into a 16-bit exponent load and a 64-bit mantissa load. Memory accesses are only counted when they are actually performed (such as a load that gets squashed because a previous cache miss is outstanding to the same address, and which finally gets performed, is only counted once).  Does not include I/O accesses, or other nonmemory accesses.	
	45H	DCU_LINES_IN	00H	Total lines allocated in DCU.	
	46H	DCU_M_LINES_IN	00H	Number of M state lines allocated in DCU.	
	47H	DCU_M_LINES_OUT	00H	Number of M state lines evicted from DCU. This includes evictions via snoop HITM, intervention or replacement.	
	48H	DCU_MISS_OUTSTANDING	00H	Weighted number of cycles while a DCU miss is outstanding, incremented by the number of outstanding cache misses at any particular time.  Cacheable read requests only are considered.  Uncacheable requests are excluded.  Read-for-ownerships are counted, as well as line fills, invalidates, and stores.	An access that also misses the L2 is short-changed by 2 cycles (i.e., if counts N cycles, should be N+2 cycles).  Subsequent loads to the same cache line will not result in any additional counts.  Count value not precise, but still useful.
Instruction Fetch Unit (IFU)	80H	IFU_IFETCH	00H	Number of instruction fetches, both cacheable and noncacheable, including UC fetches.	
	81H	IFU_IFETCH_MISS	00H	Number of instruction fetch misses All instruction fetches that do not hit the IFU (i.e., that produce memory requests). This includes UC accesses.	
	85H	ITLB_MISS	00H	Number of ITLB misses.	
	86H	IFU_MEM_STALL	00H	Number of cycles instruction fetch is stalled, for any reason.  Includes IFU cache misses, ITLB misses, ITLB faults, and other minor stalls.	
	87H	ILD_STALL	00H	Number of cycles that the instruction length decoder is stalled.	
L2 Cache <sup>1</sup>	28H	L2_IFETCH	MESI 0FH	Number of L2 instruction fetches.  This event indicates that a normal instruction fetch was received by the L2.	

Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
				The count includes only L2 cacheable instruction fetches; it does not include UC instruction fetches. It does not include ITLB miss accesses.	
	29H	L2_LD	MESI 0FH	Number of L2 data loads. This event indicates that a normal, unlocked, load memory access was received by the L2. It includes only L2 cacheable memory accesses; it does not include I/O accesses, other nonmemory accesses, or memory accesses such as UC/WT memory accesses. It does include L2 cacheable TLB miss memory accesses.	
	2AH	L2_ST	MESI 0FH	Number of L2 data stores. This event indicates that a normal, unlocked, store memory access was received by the L2.  it indicates that the DCU sent a read-for-ownership request to the L2. It also includes Invalid to Modified requests sent by the DCU to the L2.  It includes only L2 cacheable memory accesses; it does not include I/O accesses, other nonmemory accesses, or memory accesses such as UC/WT memory accesses. It includes TLB miss memory accesses.	
	24H	L2_LINES_IN	00H	Number of lines allocated in the L2.	
	26H	L2_LINES_OUT	00H	Number of lines removed from the L2 for any reason.	
	25H	L2_M_LINES_INM	00H	Number of modified lines allocated in the L2.	
	27H	L2_M_LINES_OUTM	00H	Number of modified lines removed from the L2 for any reason.	
	2EH	L2_RQSTS	MESI 0FH	Total number of L2 requests.	
	21H	L2_ADS	00H	Number of L2 address strobes.	
	22H	L2_DBUS_BUSY	00H	Number of cycles during which the L2 cache data bus was busy.	
	23H	L2_DBUS_BUSY_RD	00H	Number of cycles during which the data bus was busy transferring read data from L2 to the processor.	
External Bus Logic (EBL) <sup>2</sup>	62H	BUS_DRDY_CLOCKS	00H (Self) 20H (Any)	Number of clocks during which DRDY# is asserted. Utilization of the external system data bus during data transfers.	Unit Mask = 00H counts bus clocks when the processor is driving DRDY#. Unit Mask = 20H counts in processor clocks when any agent is driving DRDY#.

**Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
	63H	BUS_LOCK_CLOCKS	00H (Self) 20H (Any)	Number of clocks during which LOCK# is asserted on the external system bus. <sup>3</sup>	Always counts in processor clocks.
	60H	BUS_REQ_OUTSTANDING	00H (Self)	Number of bus requests outstanding. This counter is incremented by the number of cacheable read bus requests outstanding in any given cycle.	Counts only DCU full-line cacheable reads, not RFOs, writes, instruction fetches, or anything else. Counts "waiting for bus to complete" (last data chunk received).
	65H	BUS_TRAN_BRD	00H (Self) 20H (Any)	Number of burst read transactions.	
	66H	BUS_TRAN_RFO	00H (Self) 20H (Any)	Number of completed read for ownership transactions.	
	67H	BUS_TRANS_WB	00H (Self) 20H (Any)	Number of completed write back transactions.	
	68H	BUS_TRAN_IFETCH	00H (Self) 20H (Any)	Number of completed instruction fetch transactions.	
	69H	BUS_TRAN_INVALID	00H (Self) 20H (Any)	Number of completed invalidate transactions.	
	6AH	BUS_TRAN_PWR	00H (Self) 20H (Any)	Number of completed partial write transactions.	
	6BH	BUS_TRANS_P	00H (Self) 20H (Any)	Number of completed partial transactions.	
	6CH	BUS_TRANS_IO	00H (Self) 20H (Any)	Number of completed I/O transactions.	
	6DH	BUS_TRAN_DEF	00H (Self) 20H (Any)	Number of completed deferred transactions.	

Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
	6EH	BUS_TRAN_BURST	00H (Self) 20H (Any)	Number of completed burst transactions.	
	70H	BUS_TRAN_ANY	00H (Self) 20H (Any)	Number of all completed bus transactions. Address bus utilization can be calculated knowing the minimum address bus occupancy. Includes special cycles, etc.	
	6FH	BUS_TRAN_MEM	00H (Self) 20H (Any)	Number of completed memory transactions.	
	64H	BUS_DATA_RCV	00H (Self)	Number of bus clock cycles during which this processor is receiving data.	
	61H	BUS_BNR_DRV	00H (Self)	Number of bus clock cycles during which this processor is driving the BNR# pin.	
	7AH	BUS_HIT_DRV	00H (Self)	Number of bus clock cycles during which this processor is driving the HIT# pin.	Includes cycles due to snoop stalls. The event counts correctly, but BPM <sub>i</sub> (breakpoint monitor) pins function as follows based on the setting of the PC bits (bit 19 in the PerfEvtSel0 and PerfEvtSel1 registers): <ul style="list-style-type: none"> <li>▪ If the core-clock-to-bus-clock ratio is 2:1 or 3:1, and a PC bit is set, the BPM<sub>i</sub> pins will be asserted for a single clock when the counters overflow.</li> <li>▪ If the PC bit is clear, the processor toggles the BPM<sub>i</sub> pins when the counter overflows.</li> <li>▪ If the clock ratio is not 2:1 or 3:1, the BPM<sub>i</sub> pins will not function for these performance-monitoring counter events.</li> </ul>
	7BH	BUS_HITM_DRV	00H (Self)	Number of bus clock cycles during which this processor is driving the HITM# pin.	Includes cycles due to snoop stalls. The event counts correctly, but BPM <sub>i</sub> (breakpoint monitor) pins function as follows based on the setting of the PC bits (bit 19 in the PerfEvtSel0 and PerfEvtSel1 registers): <ul style="list-style-type: none"> <li>▪ If the core-clock-to-bus-clock ratio is 2:1 or 3:1, and a PC bit is set, the BPM<sub>i</sub> pins will be asserted for a single clock when the counters overflow.</li> </ul>

**Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
					<ul style="list-style-type: none"> <li>If the PC bit is clear, the processor toggles the BPM<sub>i</sub> pins when the counter overflows.</li> <li>If the clock ratio is not 2:1 or 3:1, the BPM<sub>i</sub> pins will not function for these performance-monitoring counter events.</li> </ul>
	7EH	BUS_SNOOP_STALL	00H (Self)	Number of clock cycles during which the bus is snoop stalled.	
Floating-Point Unit	C1H	FLOPS	00H	<p>Number of computational floating-point operations retired.</p> <p>Excludes floating-point computational operations that cause traps or assists.</p> <p>Includes floating-point computational operations executed by the assist handler.</p> <p>Includes internal sub-operations for complex floating-point instructions like transcendentals.</p> <p>Excludes floating-point loads and stores.</p>	Counter 0 only.
	10H	FP_COMP_OPS_EXE	00H	<p>Number of computational floating-point operations executed.</p> <p>The number of FADD, FSUB, FCOM, FMULs, integer MULs and IMULs, FDIVs, FPREM, FSQRTS, integer DIVs, and IDIVs.</p> <p>This number does not include the number of cycles, but the number of operations.</p> <p>This event does not distinguish an FADD used in the middle of a transcendental flow from a separate FADD instruction.</p>	Counter 0 only.
	11H	FP_ASSIST	00H	Number of floating-point exception cases handled by microcode.	Counter 1 only. This event includes counts due to speculative execution.
	12H	MUL	00H	<p>Number of multiplies.</p> <p>This count includes integer as well as FP multiplies and is speculative.</p>	Counter 1 only.
	13H	DIV	00H	<p>Number of divides.</p> <p>This count includes integer as well as FP divides and is speculative.</p>	Counter 1 only.
	14H	CYCLES_DIV_BUSY	00H	<p>Number of cycles during which the divider is busy, and cannot accept new divides.</p> <p>This includes integer and FP divides, FPREM, FPSQRT, etc. and is speculative.</p>	Counter 0 only.

Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
Memory Ordering	03H	LD_BLOCKS	00H	Number of load operations delayed due to store buffer blocks.  Includes counts caused by preceding stores whose addresses are unknown, preceding stores whose addresses are known but whose data is unknown, and preceding stores that conflicts with the load but which incompletely overlap the load.	
	04H	SB_DRAINS	00H	Number of store buffer drain cycles.  Incremented every cycle the store buffer is draining.  Draining is caused by serializing operations like CPUID, synchronizing operations like XCHG, interrupt acknowledgment, as well as other conditions (such as cache flushing).	
	05H	MISALIGN_MEM_REF	00H	Number of misaligned data memory references.  Incremented by 1 every cycle, during which either the processor's load or store pipeline dispatches a misaligned $\mu$ op.  Counting is performed if it is the first or second half, or if it is blocked, squashed, or missed.  In this context, misaligned means crossing a 64-bit boundary.	MISALIGN_MEM_REF is only an approximation to the true number of misaligned memory references.  The value returned is roughly proportional to the number of misaligned memory accesses (the size of the problem).
	07H	EMON_KNI_PREF_DISPATCHED	00H 01H 02H 03H	Number of Streaming SIMD extensions prefetch/weakly-ordered instructions dispatched (speculative prefetches are included in counting):  0: prefetch NTA 1: prefetch T1 2: prefetch T2 3: weakly ordered stores	Counters 0 and 1. Pentium III processor only.
	4BH	EMON_KNI_PREF_MISS	00H 01H 02H 03H	Number of prefetch/weakly-ordered instructions that miss all caches:  0: prefetch NTA 1: prefetch T1 2: prefetch T2 3: weakly ordered stores	Counters 0 and 1. Pentium III processor only.
Instruction Decoding and Retirement	COH	INST_RETIRED	00H	Number of instructions retired.	A hardware interrupt received during/after the last iteration of the REP STOS flow causes the counter to undercount by 1 instruction.
					An SMI received while executing a HLT instruction will cause the performance counter to not count the RSM instruction and undercount by 1.

**Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
	C2H	UOPS_RETIRE	00H	Number of $\mu$ ops retired.	
	D0H	INST_DECODED	00H	Number of instructions decoded.	
	D8H	EMON_KNI_INST_RETIRE	00H 01H	Number of Streaming SIMD extensions retired: 0: packed & scalar 1: scalar	Counters 0 and 1. Pentium III processor only.
	D9H	EMON_KNI_COMP_INST_RET	00H 01H	Number of Streaming SIMD extensions computation instructions retired: 0: packed and scalar 1: scalar	Counters 0 and 1. Pentium III processor only.
Interrupts	C8H	HW_INT_RX	00H	Number of hardware interrupts received.	
	C6H	CYCLES_INT_MASKED	00H	Number of processor cycles for which interrupts are disabled.	
	C7H	CYCLES_INT_PENDING_AND_MASKED	00H	Number of processor cycles for which interrupts are disabled and interrupts are pending.	
Branches	C4H	BR_INST_RETIRE	00H	Number of branch instructions retired.	
	C5H	BR_MISS_PRED_RETIRE	00H	Number of mispredicted branches retired.	
	C9H	BR_TAKEN_RETIRE	00H	Number of taken branches retired.	
	CAH	BR_MISS_PRED_TAKEN_RET	00H	Number of taken mispredictions branches retired.	
	E0H	BR_INST_DECODED	00H	Number of branch instructions decoded.	
	E2H	BTB_MISSES	00H	Number of branches for which the BTB did not produce a prediction.	
	E4H	BR_BOGUS	00H	Number of bogus branches.	
	E6H	BACLEAR	00H	Number of times BACLEAR is asserted. This is the number of times that a static branch prediction was made, in which the branch decoder decided to make a branch prediction because the BTB did not.	
Stalls	A2H	RESOURCE_STALLS	00H	Incremented by 1 during every cycle for which there is a resource related stall. Includes register renaming buffer entries, memory buffer entries.	

Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
				Does not include stalls due to bus queue full, too many cache misses, etc. In addition to resource related stalls, this event counts some other events. Includes stalls arising during branch misprediction recovery, such as if retirement of the mispredicted branch is delayed and stalls arising while store buffer is draining from synchronizing operations.	
	D2H	PARTIAL_RAT_STALLS	00H	Number of cycles or events for partial stalls. This includes flag partial stalls.	
Segment Register Loads	06H	SEGMENT_REG_LOADS	00H	Number of segment register loads.	
Clocks	79H	CPU_CLK_UNHALTED	00H	Number of cycles during which the processor is not halted.	
MMX Unit	B0H	MMX_INSTR_EXEC	00H	Number of MMX Instructions Executed.	Available in Intel Celeron, Pentium II and Pentium II Xeon processors only. Does not account for MOVQ and MOVD stores from register to memory.
	B1H	MMX_SAT_INSTR_EXEC	00H	Number of MMX Saturating Instructions Executed.	Available in Pentium II and Pentium III processors only.
	B2H	MMX_UOPS_EXEC	0FH	Number of MMX $\mu$ ops Executed.	Available in Pentium II and Pentium III processors only.
	B3H	MMX_INSTR_TYPE_EXEC	01H	MMX packed multiply instructions executed.	Available in Pentium II and Pentium III processors only.
			02H	MMX packed shift instructions executed.	
			04H	MMX pack operation instructions executed.	
			08H	MMX unpack operation instructions executed.	
			10H	MMX packed logical instructions executed.	
	20H	MMX packed arithmetic instructions executed.			
CCH	FP_MMX_TRANS	00H	Transitions from MMX instruction to floating-point instructions.	Available in Pentium II and Pentium III processors only.	
01H	Transitions from floating-point instructions to MMX instructions.				
CDH	MMX_ASSIST	00H	Number of MMX Assists (that is, the number of EMMS instructions executed).	Available in Pentium II and Pentium III processors only.	
CEH	MMX_INSTR_RET	00H	Number of MMX Instructions Retired.	Available in Pentium II processors only.	
Segment Register Renaming	D4H	SEG_RENAME_STALLS		Number of Segment Register Renaming Stalls:	Available in Pentium II and Pentium III processors only.

**Table 19-30. Events That Can Be Counted with the P6 Family Performance-Monitoring Counters (Contd.)**

Unit	Event Num.	Mnemonic Event Name	Unit Mask	Description	Comments
			02H 04H 08H 0FH	Segment register ES Segment register DS Segment register FS Segment register FS Segment registers ES + DS + FS + GS	
	D5H	SEG_REG_RENAMES	01H 02H 04H 08H 0FH	Number of Segment Register Renames: Segment register ES Segment register DS Segment register FS Segment register FS Segment registers ES + DS + FS + GS	Available in Pentium II and Pentium III processors only.
	D6H	RET_SEG_RENAMES	00H	Number of segment register rename events retired.	Available in Pentium II and Pentium III processors only.

**NOTES:**

- Several L2 cache events, where noted, can be further qualified using the Unit Mask (UMSK) field in the PerfEvtSel0 and PerfEvtSel1 registers. The lower 4 bits of the Unit Mask field are used in conjunction with L2 events to indicate the cache state or cache states involved.  
The P6 family processors identify cache states using the "MESI" protocol and consequently each bit in the Unit Mask field represents one of the four states: UMSK[3] = M (8H) state, UMSK[2] = E (4H) state, UMSK[1] = S (2H) state, and UMSK[0] = I (1H) state. UMSK[3:0] = MESI" (FH) should be used to collect data for all states; UMSK = 0H, for the applicable events, will result in nothing being counted.
- All of the external bus logic (EBL) events, except where noted, can be further qualified using the Unit Mask (UMSK) field in the PerfEvtSel0 and PerfEvtSel1 registers.  
Bit 5 of the UMSK field is used in conjunction with the EBL events to indicate whether the processor should count transactions that are self-generated (UMSK[5] = 0) or transactions that result from any processor on the bus (UMSK[5] = 1).
- L2 cache locks, so it is possible to have a zero count.

## 19.15 PENTIUM PROCESSOR PERFORMANCE-MONITORING EVENTS

Table 19-31 lists the events that can be counted with the performance-monitoring counters for the Pentium processor. The Event Number column gives the hexadecimal code that identifies the event and that is entered in the ESO or ES1 (event select) fields of the CESR MSR. The Mnemonic Event Name column gives the name of the event, and the Description and Comments columns give detailed descriptions of the events. Most events can be counted with either counter 0 or counter 1; however, some events can only be counted with only counter 0 or only counter 1 (as noted).

**NOTE**

The events in the table that are shaded are implemented only in the Pentium processor with MMX technology.

**Table 19-31. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters**

Event Num.	Mnemonic Event Name	Description	Comments
00H	DATA_READ	Number of memory data reads (internal data cache hit and miss combined).	Split cycle reads are counted individually. Data Memory Reads that are part of TLB miss processing are not included. These events may occur at a maximum of two per clock. I/O is not included.
01H	DATA_WRITE	Number of memory data writes (internal data cache hit and miss combined); I/O not included.	Split cycle writes are counted individually. These events may occur at a maximum of two per clock. I/O is not included.
0H2	DATA_TLB_MISS	Number of misses to the data cache translation look-aside buffer.	
03H	DATA_READ_MISS	Number of memory read accesses that miss the internal data cache whether or not the access is cacheable or noncacheable.	Additional reads to the same cache line after the first BRDY# of the burst line fill is returned but before the final (fourth) BRDY# has been returned, will not cause the counter to be incremented additional times. Data accesses that are part of TLB miss processing are not included. Accesses directed to I/O space are not included.
04H	DATA WRITE MISS	Number of memory write accesses that miss the internal data cache whether or not the access is cacheable or noncacheable.	Data accesses that are part of TLB miss processing are not included. Accesses directed to I/O space are not included.
05H	WRITE_HIT_TO_M_OR_E-STATE_LINES	Number of write hits to exclusive or modified lines in the data cache.	These are the writes that may be held up if EWBE# is inactive. These events may occur a maximum of two per clock.
06H	DATA_CACHE_LINES_WRITTEN_BACK	Number of dirty lines (all) that are written back, regardless of the cause.	Replacements and internal and external snoops can all cause writeback and are counted.
07H	EXTERNAL_SNOOPS	Number of accepted external snoops whether they hit in the code cache or data cache or neither.	Assertions of EADS# outside of the sampling interval are not counted, and no internal snoops are counted.
08H	EXTERNAL_DATA_CACHE_SNOOP_HITS	Number of external snoops to the data cache.	Snoop hits to a valid line in either the data cache, the data line fill buffer, or one of the write back buffers are all counted as hits.
09H	MEMORY ACCESSES IN BOTH PIPES	Number of data memory reads or writes that are paired in both pipes of the pipeline.	These accesses are not necessarily run in parallel due to cache misses, bank conflicts, etc.
0AH	BANK CONFLICTS	Number of actual bank conflicts.	
0BH	MISALIGNED DATA MEMORY OR I/O REFERENCES	Number of memory or I/O reads or writes that are misaligned.	A 2- or 4-byte access is misaligned when it crosses a 4-byte boundary; an 8-byte access is misaligned when it crosses an 8-byte boundary. Ten byte accesses are treated as two separate accesses of 8 and 2 bytes each.
0CH	CODE READ	Number of instruction reads; whether the read is cacheable or noncacheable.	Individual 8-byte noncacheable instruction reads are counted.
0DH	CODE TLB MISS	Number of instruction reads that miss the code TLB whether the read is cacheable or noncacheable.	Individual 8-byte noncacheable instruction reads are counted.
0EH	CODE CACHE MISS	Number of instruction reads that miss the internal code cache; whether the read is cacheable or noncacheable.	Individual 8-byte noncacheable instruction reads are counted.

**Table 19-31. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

Event Num.	Mnemonic Event Name	Description	Comments
0FH	ANY SEGMENT REGISTER LOADED	Number of writes into any segment register in real or protected mode including the LDTR, GDTR, IDTR, and TR.	Segment loads are caused by explicit segment register load instructions, far control transfers, and task switches. Far control transfers and task switches causing a privilege level change will signal this event twice. Interrupts and exceptions may initiate a far control transfer.
10H	Reserved		
11H	Reserved		
12H	Branches	Number of taken and not taken branches, including: conditional branches, jumps, calls, returns, software interrupts, and interrupt returns.	Also counted as taken branches are serializing instructions, VERR and VERW instructions, some segment descriptor loads, hardware interrupts (including FLUSH#), and programmatic exceptions that invoke a trap or fault handler. The pipe is not necessarily flushed. The number of branches actually executed is measured, not the number of predicted branches.
13H	BTB_HITS	Number of BTB hits that occur.	Hits are counted only for those instructions that are actually executed.
14H	TAKEN_BRANCH_OR_BTБ_HIT	Number of taken branches or BTB hits that occur.	This event type is a logical OR of taken branches and BTB hits. It represents an event that may cause a hit in the BTB. Specifically, it is either a candidate for a space in the BTB or it is already in the BTB.
15H	PIPELINE FLUSHES	Number of pipeline flushes that occur Pipeline flushes are caused by BTB misses on taken branches, mispredictions, exceptions, interrupts, and some segment descriptor loads.	The counter will not be incremented for serializing instructions (serializing instructions cause the prefetch queue to be flushed but will not trigger the Pipeline Flushed event counter) and software interrupts (software interrupts do not flush the pipeline).
16H	INSTRUCTIONS_EXECUTED	Number of instructions executed (up to two per clock).	Invocations of a fault handler are considered instructions. All hardware and software interrupts and exceptions will also cause the count to be incremented. Repeat prefixed string instructions will only increment this counter once despite the fact that the repeat loop executes the same instruction multiple times until the loop criteria is satisfied. This applies to all the Repeat string instruction prefixes (i.e., REP, REPE, REPZ, REPNE, and REPNZ). This counter will also only increment once per each HLT instruction executed regardless of how many cycles the processor remains in the HALT state.
17H	INSTRUCTIONS_EXECUTED_V PIPE	Number of instructions executed in the V_pipe. The event indicates the number of instructions that were paired.	This event is the same as the 16H event except it only counts the number of instructions actually executed in the V-pipe.
18H	BUS_CYCLE_DURATION	Number of clocks while a bus cycle is in progress. This event measures bus use.	The count includes HLDA, AHOLD, and BOFF# clocks.
19H	WRITE_BUFFER_FULL_STALL_DURATION	Number of clocks while the pipeline is stalled due to full write buffers.	Full write buffers stall data memory read misses, data memory write misses, and data memory write hits to S-state lines. Stalls on I/O accesses are not included.

**Table 19-31. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

Event Num.	Mnemonic Event Name	Description	Comments
1AH	WAITING_FOR_DATA_MEMORY_READ_STALL_DURATION	Number of clocks while the pipeline is stalled while waiting for data memory reads.	Data TLB Miss processing is also included in the count. The pipeline stalls while a data memory read is in progress including attempts to read that are not bypassed while a line is being filled.
1BH	STALL ON WRITE TO AN E- OR M-STATE LINE	Number of stalls on writes to E- or M-state lines.	
1CH	LOCKED BUS CYCLE	Number of locked bus cycles that occur as the result of the LOCK prefix or LOCK instruction, page-table updates, and descriptor table updates.	Only the read portion of the locked read-modify-write is counted. Split locked cycles (SCYC active) count as two separate accesses. Cycles restarted due to BOFF# are not re-counted.
1DH	I/O READ OR WRITE CYCLE	Number of bus cycles directed to I/O space.	Misaligned I/O accesses will generate two bus cycles. Bus cycles restarted due to BOFF# are not re-counted.
1EH	NONCACHEABLE_MEMORY_READS	Number of noncacheable instruction or data memory read bus cycles. The count includes read cycles caused by TLB misses, but does not include read cycles to I/O space.	Cycles restarted due to BOFF# are not re-counted.
1FH	PIPELINE_AGI_STALLS	Number of address generation interlock (AGI) stalls. An AGI occurring in both the U- and V-pipelines in the same clock signals this event twice.	An AGI occurs when the instruction in the execute stage of either of U- or V-pipelines is writing to either the index or base address register of an instruction in the D2 (address generation) stage of either the U- or V- pipelines.
20H	Reserved		
21H	Reserved		
22H	FLOPS	Number of floating-point operations that occur.	Number of floating-point adds, subtracts, multiplies, divides, remainders, and square roots are counted. The transcendental instructions consist of multiple adds and multiplies and will signal this event multiple times. Instructions generating the divide-by-zero, negative square root, special operand, or stack exceptions will not be counted.  Instructions generating all other floating-point exceptions will be counted. The integer multiply instructions and other instructions which use the x87 FPU will be counted.
23H	BREAKPOINT MATCH ON DRO REGISTER	Number of matches on register DRO breakpoint.	The counters is incremented regardless if the breakpoints are enabled or not. However, if breakpoints are not enabled, code breakpoint matches will not be checked for instructions executed in the V-pipe and will not cause this counter to be incremented. (They are checked on instruction executed in the U-pipe only when breakpoints are not enabled.)  These events correspond to the signals driven on the BP[3:0] pins. Refer to Chapter 17, "Debugging, Branch Profiling, and Time-Stamp Counter" for more information.
24H	BREAKPOINT MATCH ON DR1 REGISTER	Number of matches on register DR1 breakpoint.	See comment for 23H event.

**Table 19-31. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

Event Num.	Mnemonic Event Name	Description	Comments
25H	BREAKPOINT MATCH ON DR2 REGISTER	Number of matches on register DR2 breakpoint.	See comment for 23H event.
26H	BREAKPOINT MATCH ON DR3 REGISTER	Number of matches on register DR3 breakpoint.	See comment for 23H event.
27H	HARDWARE INTERRUPTS	Number of taken INTR and NMI interrupts.	
28H	DATA_READ_OR_WRITE	Number of memory data reads and/or writes (internal data cache hit and miss combined).	Split cycle reads and writes are counted individually. Data Memory Reads that are part of TLB miss processing are not included. These events may occur at a maximum of two per clock. I/O is not included.
29H	DATA_READ_MISS OR_WRITE MISS	Number of memory read and/or write accesses that miss the internal data cache, whether or not the access is cacheable or noncacheable.	Additional reads to the same cache line after the first BRDY# of the burst line fill is returned but before the final (fourth) BRDY# has been returned, will not cause the counter to be incremented additional times. Data accesses that are part of TLB miss processing are not included. Accesses directed to I/O space are not included.
2AH	BUS_OWNERSHIP_LATENCY (Counter 0)	The time from LRM bus ownership request to bus ownership granted (that is, the time from the earlier of a PBREQ (0), PHITM# or HITM# assertion to a PBGNT assertion)	The ratio of the 2AH events counted on counter 0 and counter 1 is the average stall time due to bus ownership conflict.
2AH	BUS OWNERSHIP TRANSFERS (Counter 1)	The number of buss ownership transfers (that is, the number of PBREQ (0) assertions	The ratio of the 2AH events counted on counter 0 and counter 1 is the average stall time due to bus ownership conflict.
2BH	MMX_INSTRUCTIONS_EXECUTED_U-PIPE (Counter 0)	Number of MMX instructions executed in the U-pipe	
2BH	MMX_INSTRUCTIONS_EXECUTED_V-PIPE (Counter 1)	Number of MMX instructions executed in the V-pipe	
2CH	CACHE_M-STATE_LINE_SHARING (Counter 0)	Number of times a processor identified a hit to a modified line due to a memory access in the other processor (PHITM (0))	If the average memory latencies of the system are known, this event enables the user to count the Write Backs on PHITM(0) penalty and the Latency on Hit Modified(I) penalty.
2CH	CACHE_LINE_SHARING (Counter 1)	Number of shared data lines in the L1 cache (PHIT (0))	
2DH	EMMS_INSTRUCTIONS_EXECUTED (Counter 0)	Number of EMMS instructions executed	

**Table 19-31. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

Event Num.	Mnemonic Event Name	Description	Comments
2DH	TRANSITIONS_BETWEEN_MMX_AND_FP_INSTRUCTIONS (Counter 1)	Number of transitions between MMX and floating-point instructions or vice versa  An even count indicates the processor is in MMX state. an odd count indicates it is in FP state.	This event counts the first floating-point instruction following an MMX instruction or first MMX instruction following a floating-point instruction.  The count may be used to estimate the penalty in transitions between floating-point state and MMX state.
2EH	BUS_UTILIZATION_DUE_TO_PROCESSOR_ACTIVITY (Counter 0)	Number of clocks the bus is busy due to the processor's own activity (the bus activity that is caused by the processor)	
2EH	WRITES_TO_NONCACHEABLE_MEMORY (Counter 1)	Number of write accesses to noncacheable memory	The count includes write cycles caused by TLB misses and I/O write cycles.  Cycles restarted due to BOFF# are not re-counted.
2FH	SATURATING_MMX_INSTRUCTIONS_EXECUTED (Counter 0)	Number of saturating MMX instructions executed, independently of whether they actually saturated.	
2FH	SATURATIONS_PERFORMED (Counter 1)	Number of MMX instructions that used saturating arithmetic when at least one of its results actually saturated	If an MMX instruction operating on 4 doublewords saturated in three out of the four results, the counter will be incremented by one only.
30H	NUMBER_OF_CYCLES_NOT_IN_HALT_STATE (Counter 0)	Number of cycles the processor is not idle due to HLT instruction	This event will enable the user to calculate "net CPI". Note that during the time that the processor is executing the HLT instruction, the Time-Stamp Counter is not disabled. Since this event is controlled by the Counter Controls CCO, CC1 it can be used to calculate the CPI at CPL=3, which the TSC cannot provide.
30H	DATA_CACHE_TLB_MISS_STALL_DURATION (Counter 1)	Number of clocks the pipeline is stalled due to a data cache translation look-aside buffer (TLB) miss	
31H	MMX_INSTRUCTION_DATA_READS (Counter 0)	Number of MMX instruction data reads	
31H	MMX_INSTRUCTION_DATA_READ_MISSES (Counter 1)	Number of MMX instruction data read misses	
32H	FLOATING_POINT_STALLS_DURATION (Counter 0)	Number of clocks while pipe is stalled due to a floating-point freeze	
32H	TAKEN_BRANCHES (Counter 1)	Number of taken branches	

**Table 19-31. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

Event Num.	Mnemonic Event Name	Description	Comments
33H	D1_STARVATION_AND_FIFO_IS_EMPTY (Counter 0)	Number of times D1 stage cannot issue ANY instructions since the FIFO buffer is empty	The D1 stage can issue 0, 1, or 2 instructions per clock if those are available in an instructions FIFO buffer.
33H	D1_STARVATION_AND_ONLY_ONE_INSTRUCTION_IN_FIFO (Counter 1)	Number of times the D1 stage issues a single instruction (since the FIFO buffer had just one instruction ready)	The D1 stage can issue 0, 1, or 2 instructions per clock if those are available in an instructions FIFO buffer. When combined with the previously defined events, Instruction Executed (16H) and Instruction Executed in the V-pipe (17H), this event enables the user to calculate the numbers of time pairing rules prevented issuing of two instructions.
34H	MMX_INSTRUCTION_DATA_WRITES (Counter 0)	Number of data writes caused by MMX instructions	
34H	MMX_INSTRUCTION_DATA_WRITE_MISSES (Counter 1)	Number of data write misses caused by MMX instructions	
35H	PIPELINE_FLUSHES_DUE_TO_WRONG_BRANCH_PREDICTIONS (Counter 0)	Number of pipeline flushes due to wrong branch predictions resolved in either the E-stage or the WB-stage	The count includes any pipeline flush due to a branch that the pipeline did not follow correctly. It includes cases where a branch was not in the BTB, cases where a branch was in the BTB but was mispredicted, and cases where a branch was correctly predicted but to the wrong address. Branches are resolved in either the Execute stage (E-stage) or the Writeback stage (WB-stage). In the later case, the misprediction penalty is larger by one clock. The difference between the 35H event count in counter 0 and counter 1 is the number of E-stage resolved branches.
35H	PIPELINE_FLUSHES_DUE_TO_WRONG_BRANCH_PREDICTIONS_RESOLVED_IN_WB-STAGE (Counter 1)	Number of pipeline flushes due to wrong branch predictions resolved in the WB-stage	See note for event 35H (Counter 0).
36H	MISALIGNED_DATA_MEMORY_REFERENCE_ON_MMX_INSTRUCTIONS (Counter 0)	Number of misaligned data memory references when executing MMX instructions	
36H	PIPELINE_ISTALL_FOR_MMX_INSTRUCTION_DATA_MEMORY_READS (Counter 1)	Number clocks during pipeline stalls caused by waits form MMX instruction data memory reads	T3:

**Table 19-31. Events That Can Be Counted with Pentium Processor Performance-Monitoring Counters (Contd.)**

Event Num.	Mnemonic Event Name	Description	Comments
37H	MISPREDICTED_OR_UNPREDICTED_RETURNS (Counter 1)	Number of returns predicted incorrectly or not predicted at all	The count is the difference between the total number of executed returns and the number of returns that were correctly predicted. Only RET instructions are counted (for example, IRET instructions are not counted).
37H	PREDICTED_RETURNS (Counter 1)	Number of predicted returns (whether they are predicted correctly and incorrectly)	Only RET instructions are counted (for example, IRET instructions are not counted).
38H	MMX_MULTIPLY_UNIT_INTERLOCK (Counter 0)	Number of clocks the pipe is stalled since the destination of previous MMX multiply instruction is not ready yet	The counter will not be incremented if there is another cause for a stall. For each occurrence of a multiply interlock, this event will be counted twice (if the stalled instruction comes on the next clock after the multiply) or by once (if the stalled instruction comes two clocks after the multiply).
38H	MOVD/MOVQ_STORE_STALL_DUE_TO_PREVIOUS_MMX_OPERATION (Counter 1)	Number of clocks a MOVD/MOVQ instruction store is stalled in D2 stage due to a previous MMX operation with a destination to be used in the store instruction.	
39H	RETURNS (Counter 0)	Number of returns executed.	Only RET instructions are counted; IRET instructions are not counted. Any exception taken on a RET instruction and any interrupt recognized by the processor on the instruction boundary prior to the execution of the RET instruction will also cause this counter to be incremented.
39H	Reserved		
3AH	BTB_FALSE_ENTRIES (Counter 0)	Number of false entries in the Branch Target Buffer	False entries are causes for misprediction other than a wrong prediction.
3AH	BTB_MISS_PREDICTION_ON_NOT-TAKEN_BRANCH (Counter 1)	Number of times the BTB predicted a not-taken branch as taken	
3BH	FULL_WRITE_BUFFER_STALL_DURATION_WHILE_EXECUTING_MMX_INSTRUCTIONS (Counter 0)	Number of clocks while the pipeline is stalled due to full write buffers while executing MMX instructions	
3BH	STALL_ON_MMX_INSTRUCTION_WRITE_TO_E_OR_M-STATE_LINE (Counter 1)	Number of clocks during stalls on MMX instructions writing to E- or M-state lines	

IA-32 processors (beginning with the Intel386 processor) provide two ways to execute new or legacy programs that are assembled and/or compiled to run on an Intel 8086 processor:

- Real-address mode.
- Virtual-8086 mode.

Figure 2-3 shows the relationship of these operating modes to protected mode and system management mode (SMM).

When the processor is powered up or reset, it is placed in the real-address mode. This operating mode almost exactly duplicates the execution environment of the Intel 8086 processor, with some extensions. Virtually any program assembled and/or compiled to run on an Intel 8086 processor will run on an IA-32 processor in this mode.

When running in protected mode, the processor can be switched to virtual-8086 mode to run 8086 programs. This mode also duplicates the execution environment of the Intel 8086 processor, with extensions. In virtual-8086 mode, an 8086 program runs as a separate protected-mode task. Legacy 8086 programs are thus able to run under an operating system (such as Microsoft Windows\*) that takes advantage of protected mode and to use protected-mode facilities, such as the protected-mode interrupt- and exception-handling facilities. Protected-mode multitasking permits multiple virtual-8086 mode tasks (with each task running a separate 8086 program) to be run on the processor along with other non-virtual-8086 mode tasks.

This section describes both the basic real-address mode execution environment and the virtual-8086-mode execution environment, available on the IA-32 processors beginning with the Intel386 processor.

## 20.1 REAL-ADDRESS MODE

The IA-32 architecture's real-address mode runs programs written for the Intel 8086, Intel 8088, Intel 80186, and Intel 80188 processors, or for the real-address mode of the Intel 286, Intel386, Intel486, Pentium, P6 family, Pentium 4, and Intel Xeon processors.

The execution environment of the processor in real-address mode is designed to duplicate the execution environment of the Intel 8086 processor. To an 8086 program, a processor operating in real-address mode behaves like a high-speed 8086 processor. The principal features of this architecture are defined in Chapter 3, "Basic Execution Environment", of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*.

The following is a summary of the core features of the real-address mode execution environment as would be seen by a program written for the 8086:

- The processor supports a nominal 1-MByte physical address space (see Section 20.1.1, "Address Translation in Real-Address Mode", for specific details). This address space is divided into segments, each of which can be up to 64 KBytes in length. The base of a segment is specified with a 16-bit segment selector, which is zero extended to form a 20-bit offset from address 0 in the address space. An operand within a segment is addressed with a 16-bit offset from the base of the segment. A physical address is thus formed by adding the offset to the 20-bit segment base (see Section 20.1.1, "Address Translation in Real-Address Mode").
- All operands in "native 8086 code" are 8-bit or 16-bit values. (Operand size override prefixes can be used to access 32-bit operands.)
- Eight 16-bit general-purpose registers are provided: AX, BX, CX, DX, SP, BP, SI, and DI. The extended 32 bit registers (EAX, EBX, ECX, EDX, ESP, EBP, ESI, and EDI) are accessible to programs that explicitly perform a size override operation.
- Four segment registers are provided: CS, DS, SS, and ES. (The FS and GS registers are accessible to programs that explicitly access them.) The CS register contains the segment selector for the code segment; the DS and ES registers contain segment selectors for data segments; and the SS register contains the segment selector for the stack segment.
- The 8086 16-bit instruction pointer (IP) is mapped to the lower 16-bits of the EIP register. Note this register is a 32-bit register and unintentional address wrapping may occur.

- The 16-bit FLAGS register contains status and control flags. (This register is mapped to the 16 least significant bits of the 32-bit EFLAGS register.)
- All of the Intel 8086 instructions are supported (see Section 20.1.3, “Instructions Supported in Real-Address Mode”).
- A single, 16-bit-wide stack is provided for handling procedure calls and invocations of interrupt and exception handlers. This stack is contained in the stack segment identified with the SS register. The SP (stack pointer) register contains an offset into the stack segment. The stack grows down (toward lower segment offsets) from the stack pointer. The BP (base pointer) register also contains an offset into the stack segment that can be used as a pointer to a parameter list. When a CALL instruction is executed, the processor pushes the current instruction pointer (the 16 least-significant bits of the EIP register and, on far calls, the current value of the CS register) onto the stack. On a return, initiated with a RET instruction, the processor pops the saved instruction pointer from the stack into the EIP register (and CS register on far returns). When an implicit call to an interrupt or exception handler is executed, the processor pushes the EIP, CS, and EFLAGS (low-order 16-bits only) registers onto the stack. On a return from an interrupt or exception handler, initiated with an IRET instruction, the processor pops the saved instruction pointer and EFLAGS image from the stack into the EIP, CS, and EFLAGS registers.
- A single interrupt table, called the “interrupt vector table” or “interrupt table,” is provided for handling interrupts and exceptions (see Figure 20-2). The interrupt table (which has 4-byte entries) takes the place of the interrupt descriptor table (IDT, with 8-byte entries) used when handling protected-mode interrupts and exceptions. Interrupt and exception vector numbers provide an index to entries in the interrupt table. Each entry provides a pointer (called a “vector”) to an interrupt- or exception-handling procedure. See Section 20.1.4, “Interrupt and Exception Handling”, for more details. It is possible for software to relocate the IDT by means of the LIDT instruction on IA-32 processors beginning with the Intel386 processor.
- The x87 FPU is active and available to execute x87 FPU instructions in real-address mode. Programs written to run on the Intel 8087 and Intel 287 math coprocessors can be run in real-address mode without modification.

The following extensions to the Intel 8086 execution environment are available in the IA-32 architecture’s real-address mode. If backwards compatibility to Intel 286 and Intel 8086 processors is required, these features should not be used in new programs written to run in real-address mode.

- Two additional segment registers (FS and GS) are available.
- Many of the integer and system instructions that have been added to later IA-32 processors can be executed in real-address mode (see Section 20.1.3, “Instructions Supported in Real-Address Mode”).
- The 32-bit operand prefix can be used in real-address mode programs to execute the 32-bit forms of instructions. This prefix also allows real-address mode programs to use the processor’s 32-bit general-purpose registers.
- The 32-bit address prefix can be used in real-address mode programs, allowing 32-bit offsets.

The following sections describe address formation, registers, available instructions, and interrupt and exception handling in real-address mode. For information on I/O in real-address mode, see Chapter 16, “Input/Output”, of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1*.

### 20.1.1 Address Translation in Real-Address Mode

In real-address mode, the processor does not interpret segment selectors as indexes into a descriptor table; instead, it uses them directly to form linear addresses as the 8086 processor does. It shifts the segment selector left by 4 bits to form a 20-bit base address (see Figure 20-1). The offset into a segment is added to the base address to create a linear address that maps directly to the physical address space.

When using 8086-style address translation, it is possible to specify addresses larger than 1 MByte. For example, with a segment selector value of FFFFH and an offset of FFFFH, the linear (and physical) address would be 10FFEFH (1 megabyte plus 64 KBytes). The 8086 processor, which can form addresses only up to 20 bits long, truncates the high-order bit, thereby “wrapping” this address to FFEFH. When operating in real-address mode, however, the processor does not truncate such an address and uses it as a physical address. (Note, however, that for IA-32 processors beginning with the Intel486 processor, the A20M# signal can be used in real-address mode to mask address line A20, thereby mimicking the 20-bit wrap-around behavior of the 8086 processor.) Care should be taken to ensure that A20M# based address wrapping is handled correctly in multiprocessor based system.

**Figure 20-1. Real-Address Mode Address Translation**

The IA-32 processors beginning with the Intel386 processor can generate 32-bit offsets using an address override prefix; however, in real-address mode, the value of a 32-bit offset may not exceed FFFFH without causing an exception.

For full compatibility with Intel 286 real-address mode, pseudo-protection faults (interrupt 12 or 13) occur if a 32-bit offset is generated outside the range 0 through FFFFH.

## 20.1.2 Registers Supported in Real-Address Mode

The register set available in real-address mode includes all the registers defined for the 8086 processor plus the new registers introduced in later IA-32 processors, such as the FS and GS segment registers, the debug registers, the control registers, and the floating-point unit registers. The 32-bit operand prefix allows a real-address mode program to use the 32-bit general-purpose registers (EAX, EBX, ECX, EDX, ESP, EBP, ESI, and EDI).

## 20.1.3 Instructions Supported in Real-Address Mode

The following instructions make up the core instruction set for the 8086 processor. If backwards compatibility to the Intel 286 and Intel 8086 processors is required, only these instructions should be used in a new program written to run in real-address mode.

- Move (MOV) instructions that move operands between general-purpose registers, segment registers, and between memory and general-purpose registers.
- The exchange (XCHG) instruction.
- Load segment register instructions LDS and LES.
- Arithmetic instructions ADD, ADC, SUB, SBB, MUL, IMUL, DIV, IDIV, INC, DEC, CMP, and NEG.
- Logical instructions AND, OR, XOR, and NOT.
- Decimal instructions DAA, DAS, AAA, AAS, AAM, and AAD.
- Stack instructions PUSH and POP (to general-purpose registers and segment registers).
- Type conversion instructions CWD, CDQ, CBW, and CWDE.
- Shift and rotate instructions SAL, SHL, SHR, SAR, ROL, ROR, RCL, and RCR.
- TEST instruction.
- Control instructions JMP, *Jcc*, CALL, RET, LOOP, LOOPE, and LOOPNE.
- Interrupt instructions INT *n*, INTO, and IRET.
- EFLAGS control instructions STC, CLC, CMC, CLD, STD, LAHF, SAHF, PUSHF, and POPF.
- I/O instructions IN, INS, OUT, and OUTS.
- Load effective address (LEA) instruction, and translate (XLATB) instruction.

- LOCK prefix.
- Repeat prefixes REP, REPE, REPZ, REPNE, and REPNZ.
- Processor halt (HLT) instruction.
- No operation (NOP) instruction.

The following instructions, added to later IA-32 processors (some in the Intel 286 processor and the remainder in the Intel386 processor), can be executed in real-address mode, if backwards compatibility to the Intel 8086 processor is not required.

- Move (MOV) instructions that operate on the control and debug registers.
- Load segment register instructions LSS, LFS, and LGS.
- Generalized multiply instructions and multiply immediate data.
- Shift and rotate by immediate counts.
- Stack instructions PUSHA, PUSHAD, POPA and POPAD, and PUSH immediate data.
- Move with sign extension instructions MOVSX and MOVZX.
- Long-displacement Jcc instructions.
- Exchange instructions CMPXCHG, CMPXCHG8B, and XADD.
- String instructions MOVS, CMPS, SCAS, LODS, and STOS.
- Bit test and bit scan instructions BT, BTS, BTR, BTC, BSF, and BSR; the byte-set-on condition instruction SETcc; and the byte swap (BSWAP) instruction.
- Double shift instructions SHLD and SHRD.
- EFLAGS control instructions PUSHF and POPF.
- ENTER and LEAVE control instructions.
- BOUND instruction.
- CPU identification (CPUID) instruction.
- System instructions CLTS, INVD, WINVD, INVLPG, LGDT, SGDT, LIDT, SIDT, LMSW, SMSW, RDMSR, WRMSR, RDTSC, and RDTSC.

Execution of any of the other IA-32 architecture instructions (not given in the previous two lists) in real-address mode result in an invalid-opcode exception (#UD) being generated.

### 20.1.4 Interrupt and Exception Handling

When operating in real-address mode, software must provide interrupt and exception-handling facilities that are separate from those provided in protected mode. Even during the early stages of processor initialization when the processor is still in real-address mode, elementary real-address mode interrupt and exception-handling facilities must be provided to insure reliable operation of the processor, or the initialization code must insure that no interrupts or exceptions will occur.

The IA-32 processors handle interrupts and exceptions in real-address mode similar to the way they handle them in protected mode. When a processor receives an interrupt or generates an exception, it uses the vector number of the interrupt or exception as an index into the interrupt table. (In protected mode, the interrupt table is called the **interrupt descriptor table (IDT)**, but in real-address mode, the table is usually called the **interrupt vector table**, or simply the **interrupt table**.) The entry in the interrupt vector table provides a pointer to an interrupt- or exception-handler procedure. (The pointer consists of a segment selector for a code segment and a 16-bit offset into the segment.) The processor performs the following actions to make an implicit call to the selected handler:

1. Pushes the current values of the CS and EIP registers onto the stack. (Only the 16 least-significant bits of the EIP register are pushed.)
2. Pushes the low-order 16 bits of the EFLAGS register onto the stack.
3. Clears the IF flag in the EFLAGS register to disable interrupts.
4. Clears the TF, RC, and AC flags, in the EFLAGS register.

5. Transfers program control to the location specified in the interrupt vector table.

An IRET instruction at the end of the handler procedure reverses these steps to return program control to the interrupted program. Exceptions do not return error codes in real-address mode.

The interrupt vector table is an array of 4-byte entries (see Figure 20-2). Each entry consists of a far pointer to a handler procedure, made up of a segment selector and an offset. The processor scales the interrupt or exception vector by 4 to obtain an offset into the interrupt table. Following reset, the base of the interrupt vector table is located at physical address 0 and its limit is set to 3FFH. In the Intel 8086 processor, the base address and limit of the interrupt vector table cannot be changed. In the later IA-32 processors, the base address and limit of the interrupt vector table are contained in the IDTR register and can be changed using the LIDT instruction.

(For backward compatibility to Intel 8086 processors, the default base address and limit of the interrupt vector table should not be changed.)

**Figure 20-2. Interrupt Vector Table in Real-Address Mode**

Table 20-1 shows the interrupt and exception vectors that can be generated in real-address mode and virtual-8086 mode, and in the Intel 8086 processor. See Chapter 6, "Interrupt and Exception Handling", for a description of the exception conditions.

## 20.2 VIRTUAL-8086 MODE

Virtual-8086 mode is actually a special type of a task that runs in protected mode. When the operating-system or executive switches to a virtual-8086-mode task, the processor emulates an Intel 8086 processor. The execution environment of the processor while in the 8086-emulation state is the same as is described in Section 20.1, "Real-Address Mode" for real-address mode, including the extensions. The major difference between the two modes is that in virtual-8086 mode the 8086 emulator uses some protected-mode services (such as the protected-mode interrupt and exception-handling and paging facilities).

As in real-address mode, any new or legacy program that has been assembled and/or compiled to run on an Intel 8086 processor will run in a virtual-8086-mode task. And several 8086 programs can be run as virtual-8086-mode tasks concurrently with normal protected-mode tasks, using the processor's multitasking facilities.

**Table 20-1. Real-Address Mode Exceptions and Interrupts**

Vector No.	Description	Real-Address Mode	Virtual-8086 Mode	Intel 8086 Processor
0	Divide Error (#DE)	Yes	Yes	Yes
1	Debug Exception (#DB)	Yes	Yes	No
2	NMI Interrupt	Yes	Yes	Yes
3	Breakpoint (#BP)	Yes	Yes	Yes
4	Overflow (#OF)	Yes	Yes	Yes
5	BOUND Range Exceeded (#BR)	Yes	Yes	Reserved
6	Invalid Opcode (#UD)	Yes	Yes	Reserved
7	Device Not Available (#NM)	Yes	Yes	Reserved
8	Double Fault (#DF)	Yes	Yes	Reserved
9	(Intel reserved. Do not use.)	Reserved	Reserved	Reserved
10	Invalid TSS (#TS)	Reserved	Yes	Reserved
11	Segment Not Present (#NP)	Reserved	Yes	Reserved
12	Stack Fault (#SS)	Yes	Yes	Reserved
13	General Protection (#GP)*	Yes	Yes	Reserved
14	Page Fault (#PF)	Reserved	Yes	Reserved
15	(Intel reserved. Do not use.)	Reserved	Reserved	Reserved
16	Floating-Point Error (#MF)	Yes	Yes	Reserved
17	Alignment Check (#AC)	Reserved	Yes	Reserved
18	Machine Check (#MC)	Yes	Yes	Reserved
19-31	(Intel reserved. Do not use.)	Reserved	Reserved	Reserved
32-255	User Defined Interrupts	Yes	Yes	Yes

**NOTE:**

\* In the real-address mode, vector 13 is the segment overrun exception. In protected and virtual-8086 modes, this exception covers all general-protection error conditions, including traps to the virtual-8086 monitor from virtual-8086 mode.

## 20.2.1 Enabling Virtual-8086 Mode

The processor runs in virtual-8086 mode when the VM (virtual machine) flag in the EFLAGS register is set. This flag can only be set when the processor switches to a new protected-mode task or resumes virtual-8086 mode via an IRET instruction.

System software cannot change the state of the VM flag directly in the EFLAGS register (for example, by using the POPFD instruction). Instead it changes the flag in the image of the EFLAGS register stored in the TSS or on the stack following a call to an interrupt- or exception-handler procedure. For example, software sets the VM flag in the EFLAGS image in the TSS when first creating a virtual-8086 task.

The processor tests the VM flag under three general conditions:

- When loading segment registers, to determine whether to use 8086-style address translation.
- When decoding instructions, to determine which instructions are not supported in virtual-8086 mode and which instructions are sensitive to IOPL.

- When checking privileged instructions, on page accesses, or when performing other permission checks. (Virtual-8086 mode always executes at CPL 3.)

## 20.2.2 Structure of a Virtual-8086 Task

A virtual-8086-mode task consists of the following items:

- A 32-bit TSS for the task.
- The 8086 program.
- A virtual-8086 monitor.
- 8086 operating-system services.

The TSS of the new task must be a 32-bit TSS, not a 16-bit TSS, because the 16-bit TSS does not load the most-significant word of the EFLAGS register, which contains the VM flag. All TSS's, stacks, data, and code used to handle exceptions when in virtual-8086 mode must also be 32-bit segments.

The processor enters virtual-8086 mode to run the 8086 program and returns to protected mode to run the virtual-8086 monitor.

The virtual-8086 monitor is a 32-bit protected-mode code module that runs at a CPL of 0. The monitor consists of initialization, interrupt- and exception-handling, and I/O emulation procedures that emulate a personal computer or other 8086-based platform. Typically, the monitor is either part of or closely associated with the protected-mode general-protection (#GP) exception handler, which also runs at a CPL of 0. As with any protected-mode code module, code-segment descriptors for the virtual-8086 monitor must exist in the GDT or in the task's LDT. The virtual-8086 monitor also may need data-segment descriptors so it can examine the IDT or other parts of the 8086 program in the first 1 MByte of the address space. The linear addresses above 10FFEFH are available for the monitor, the operating system, and other system software.

The 8086 operating-system services consists of a kernel and/or operating-system procedures that the 8086 program makes calls to. These services can be implemented in either of the following two ways:

- They can be included in the 8086 program. This approach is desirable for either of the following reasons:
  - The 8086 program code modifies the 8086 operating-system services.
  - There is not sufficient development time to merge the 8086 operating-system services into main operating system or executive.
- They can be implemented or emulated in the virtual-8086 monitor. This approach is desirable for any of the following reasons:
  - The 8086 operating-system procedures can be more easily coordinated among several virtual-8086 tasks.
  - Memory can be saved by not duplicating 8086 operating-system procedure code for several virtual-8086 tasks.
  - The 8086 operating-system procedures can be easily emulated by calls to the main operating system or executive.

The approach chosen for implementing the 8086 operating-system services may result in different virtual-8086-mode tasks using different 8086 operating-system services.

## 20.2.3 Paging of Virtual-8086 Tasks

Even though a program running in virtual-8086 mode can use only 20-bit linear addresses, the processor converts these addresses into 32-bit linear addresses before mapping them to the physical address space. If paging is being used, the 8086 address space for a program running in virtual-8086 mode can be paged and located in a set of pages in physical address space. If paging is used, it is transparent to the program running in virtual-8086 mode just as it is for any task running on the processor.

Paging is not necessary for a single virtual-8086-mode task, but paging is useful or necessary in the following situations:

- When running multiple virtual-8086-mode tasks. Here, paging allows the lower 1 MByte of the linear address space for each virtual-8086-mode task to be mapped to a different physical address location.
- When emulating the 8086 address-wraparound that occurs at 1 MByte. When using 8086-style address translation, it is possible to specify addresses larger than 1 MByte. These addresses automatically wraparound in the Intel 8086 processor (see Section 20.1.1, “Address Translation in Real-Address Mode”). If any 8086 programs depend on address wraparound, the same effect can be achieved in a virtual-8086-mode task by mapping the linear addresses between 100000H and 110000H and linear addresses between 0 and 10000H to the same physical addresses.
- When sharing the 8086 operating-system services or ROM code that is common to several 8086 programs running as different 8086-mode tasks.
- When redirecting or trapping references to memory-mapped I/O devices.

### 20.2.4 Protection within a Virtual-8086 Task

Protection is not enforced between the segments of an 8086 program. Either of the following techniques can be used to protect the system software running in a virtual-8086-mode task from the 8086 program:

- Reserve the first 1 MByte plus 64 KBytes of each task’s linear address space for the 8086 program. An 8086 processor task cannot generate addresses outside this range.
- Use the U/S flag of page-table entries to protect the virtual-8086 monitor and other system software in the virtual-8086 mode task space. When the processor is in virtual-8086 mode, the CPL is 3. Therefore, an 8086 processor program has only user privileges. If the pages of the virtual-8086 monitor have supervisor privilege, they cannot be accessed by the 8086 program.

### 20.2.5 Entering Virtual-8086 Mode

Figure 20-3 summarizes the methods of entering and leaving virtual-8086 mode. The processor switches to virtual-8086 mode in either of the following situations:

- Task switch when the VM flag is set to 1 in the EFLAGS register image stored in the TSS for the task. Here the task switch can be initiated in either of two ways:
  - A CALL or JMP instruction.
  - An IRET instruction, where the NT flag in the EFLAGS image is set to 1.
- Return from a protected-mode interrupt or exception handler when the VM flag is set to 1 in the EFLAGS register image on the stack.

When a task switch is used to enter virtual-8086 mode, the TSS for the virtual-8086-mode task must be a 32-bit TSS. (If the new TSS is a 16-bit TSS, the upper word of the EFLAGS register is not in the TSS, causing the processor to clear the VM flag when it loads the EFLAGS register.) The processor updates the VM flag prior to loading the segment registers from their images in the new TSS. The new setting of the VM flag determines whether the processor interprets the contents of the segment registers as 8086-style segment selectors or protected-mode segment selectors. When the VM flag is set, the segment registers are loaded from the TSS, using 8086-style address translation to form base addresses.

See Section 20.3, “Interrupt and Exception Handling in Virtual-8086 Mode”, for information on entering virtual-8086 mode on a return from an interrupt or exception handler.

Figure 20-3. Entering and Leaving Virtual-8086 Mode

## 20.2.6 Leaving Virtual-8086 Mode

The processor can leave the virtual-8086 mode only through an interrupt or exception. The following are situations where an interrupt or exception will lead to the processor leaving virtual-8086 mode (see Figure 20-3):

- The processor services a hardware interrupt generated to signal the suspension of execution of the virtual-8086 application. This hardware interrupt may be generated by a timer or other external mechanism. Upon receiving the hardware interrupt, the processor enters protected mode and switches to a protected-mode (or another virtual-8086 mode) task either through a task gate in the protected-mode IDT or through a trap or interrupt gate that points to a handler that initiates a task switch. A task switch from a virtual-8086 task to another task loads the EFLAGS register from the TSS of the new task. The value of the VM flag in the new EFLAGS determines if the new task executes in virtual-8086 mode or not.
- The processor services an exception caused by code executing the virtual-8086 task or services a hardware interrupt that “belongs to” the virtual-8086 task. Here, the processor enters protected mode and services the

exception or hardware interrupt through the protected-mode IDT (normally through an interrupt or trap gate) and the protected-mode exception- and interrupt-handlers. The processor may handle the exception or interrupt within the context of the virtual 8086 task and return to virtual-8086 mode on a return from the handler procedure. The processor may also execute a task switch and handle the exception or interrupt in the context of another task.

- The processor services a software interrupt generated by code executing in the virtual-8086 task (such as a software interrupt to call a MS-DOS\* operating system routine). The processor provides several methods of handling these software interrupts, which are discussed in detail in Section 20.3.3, “Class 3—Software Interrupt Handling in Virtual-8086 Mode”. Most of them involve the processor entering protected mode, often by means of a general-protection (#GP) exception. In protected mode, the processor can send the interrupt to the virtual-8086 monitor for handling and/or redirect the interrupt back to the application program running in virtual-8086 mode task for handling.

IA-32 processors that incorporate the virtual mode extension (enabled with the VME flag in control register CR4) are capable of redirecting software-generated interrupts back to the program’s interrupt handlers without leaving virtual-8086 mode. See Section 20.3.3.4, “Method 5: Software Interrupt Handling”, for more information on this mechanism.

- A hardware reset initiated by asserting the RESET or INIT pin is a special kind of interrupt. When a RESET or INIT is signaled while the processor is in virtual-8086 mode, the processor leaves virtual-8086 mode and enters real-address mode.
- Execution of the HLT instruction in virtual-8086 mode will cause a general-protection (GP#) fault, which the protected-mode handler generally sends to the virtual-8086 monitor. The virtual-8086 monitor then determines the correct execution sequence after verifying that it was entered as a result of a HLT execution.

See Section 20.3, “Interrupt and Exception Handling in Virtual-8086 Mode”, for information on leaving virtual-8086 mode to handle an interrupt or exception generated in virtual-8086 mode.

## 20.2.7 Sensitive Instructions

When an IA-32 processor is running in virtual-8086 mode, the CLI, STI, PUSHF, POPF, INT *n*, and IRET instructions are sensitive to IOPL. The IN, INS, OUT, and OUTS instructions, which are sensitive to IOPL in protected mode, are not sensitive in virtual-8086 mode.

The CPL is always 3 while running in virtual-8086 mode; if the IOPL is less than 3, an attempt to use the IOPL-sensitive instructions listed above triggers a general-protection exception (#GP). These instructions are sensitive to IOPL to give the virtual-8086 monitor a chance to emulate the facilities they affect.

## 20.2.8 Virtual-8086 Mode I/O

Many 8086 programs written for non-multitasking systems directly access I/O ports. This practice may cause problems in a multitasking environment. If more than one program accesses the same port, they may interfere with each other. Most multitasking systems require application programs to access I/O ports through the operating system. This results in simplified, centralized control.

The processor provides I/O protection for creating I/O that is compatible with the environment and transparent to 8086 programs. Designers may take any of several possible approaches to protecting I/O ports:

- Protect the I/O address space and generate exceptions for all attempts to perform I/O directly.
- Let the 8086 program perform I/O directly.
- Generate exceptions on attempts to access specific I/O ports.
- Generate exceptions on attempts to access specific memory-mapped I/O ports.

The method of controlling access to I/O ports depends upon whether they are I/O-port mapped or memory mapped.

### 20.2.8.1 I/O-Port-Mapped I/O

The I/O permission bit map in the TSS can be used to generate exceptions on attempts to access specific I/O port addresses. The I/O permission bit map of each virtual-8086-mode task determines which I/O addresses generate exceptions for that task. Because each task may have a different I/O permission bit map, the addresses that generate exceptions for one task may be different from the addresses for another task. This differs from protected mode in which, if the CPL is less than or equal to the IOPL, I/O access is allowed without checking the I/O permission bit map. See Chapter 16, “Input/Output”, in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1*, for more information about the I/O permission bit map.

### 20.2.8.2 Memory-Mapped I/O

In systems which use memory-mapped I/O, the paging facilities of the processor can be used to generate exceptions for attempts to access I/O ports. The virtual-8086 monitor may use paging to control memory-mapped I/O in these ways:

- Map part of the linear address space of each task that needs to perform I/O to the physical address space where I/O ports are placed. By putting the I/O ports at different addresses (in different pages), the paging mechanism can enforce isolation between tasks.
- Map part of the linear address space to pages that are not-present. This generates an exception whenever a task attempts to perform I/O to those pages. System software then can interpret the I/O operation being attempted.

Software emulation of the I/O space may require too much operating system intervention under some conditions. In these cases, it may be possible to generate an exception for only the first attempt to access I/O. The system software then may determine whether a program can be given exclusive control of I/O temporarily, the protection of the I/O space may be lifted, and the program allowed to run at full speed.

### 20.2.8.3 Special I/O Buffers

Buffers of intelligent controllers (for example, a bit-mapped frame buffer) also can be emulated using page mapping. The linear space for the buffer can be mapped to a different physical space for each virtual-8086-mode task. The virtual-8086 monitor then can control which virtual buffer to copy onto the real buffer in the physical address space.

## 20.3 INTERRUPT AND EXCEPTION HANDLING IN VIRTUAL-8086 MODE

When the processor receives an interrupt or detects an exception condition while in virtual-8086 mode, it invokes an interrupt or exception handler, just as it does in protected or real-address mode. The interrupt or exception handler that is invoked and the mechanism used to invoke it depends on the class of interrupt or exception that has been detected or generated and the state of various system flags and fields.

In virtual-8086 mode, the interrupts and exceptions are divided into three classes for the purposes of handling:

- **Class 1** — All processor-generated exceptions and all hardware interrupts, including the NMI interrupt and the hardware interrupts sent to the processor’s external interrupt delivery pins. All class 1 exceptions and interrupts are handled by the protected-mode exception and interrupt handlers.
- **Class 2** — Special case for maskable hardware interrupts (Section 6.3.2, “Maskable Hardware Interrupts”) when the virtual mode extensions are enabled.
- **Class 3** — All software-generated interrupts, that is interrupts generated with the INT *n* instruction<sup>1</sup>.

The method the processor uses to handle class 2 and 3 interrupts depends on the setting of the following flags and fields:

- **IOPL field (bits 12 and 13 in the EFLAGS register)** — Controls how class 3 software interrupts are handled when the processor is in virtual-8086 mode (see Section 2.3, “System Flags and Fields in the EFLAGS

1. The INT 3 instruction is a special case (see the description of the INT *n* instruction in Chapter 3, “Instruction Set Reference, A-M”, of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2A*).

Register”). This field also controls the enabling of the VIF and VIP flags in the EFLAGS register when the VME flag is set. The VIF and VIP flags are provided to assist in the handling of class 2 maskable hardware interrupts.

- **VME flag (bit 0 in control register CR4)** — Enables the virtual mode extension for the processor when set (see Section 2.5, “Control Registers”).
- **Software interrupt redirection bit map (32 bytes in the TSS, see Figure 20-5)** — Contains 256 flags that indicates how class 3 software interrupts should be handled when they occur in virtual-8086 mode. A software interrupt can be directed either to the interrupt and exception handlers in the currently running 8086 program or to the protected-mode interrupt and exception handlers.
- **The virtual interrupt flag (VIF) and virtual interrupt pending flag (VIP) in the EFLAGS register** — Provides **virtual interrupt support** for the handling of class 2 maskable hardware interrupts (see Section 20.3.2, “Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism”).

### NOTE

The VME flag, software interrupt redirection bit map, and VIF and VIP flags are only available in IA-32 processors that support the virtual mode extensions. These extensions were introduced in the IA-32 architecture with the Pentium processor.

The following sections describe the actions that processor takes and the possible actions of interrupt and exception handlers for the two classes of interrupts described in the previous paragraphs. These sections describe three possible types of interrupt and exception handlers:

- **Protected-mode interrupt and exceptions handlers** — These are the standard handlers that the processor calls through the protected-mode IDT.
- **Virtual-8086 monitor interrupt and exception handlers** — These handlers are resident in the virtual-8086 monitor, and they are commonly accessed through a general-protection exception (#GP, interrupt 13) that is directed to the protected-mode general-protection exception handler.
- **8086 program interrupt and exception handlers** — These handlers are part of the 8086 program that is running in virtual-8086 mode.

The following sections describe how these handlers are used, depending on the selected class and method of interrupt and exception handling.

## 20.3.1 Class 1—Hardware Interrupt and Exception Handling in Virtual-8086 Mode

In virtual-8086 mode, the Pentium, P6 family, Pentium 4, and Intel Xeon processors handle hardware interrupts and exceptions in the same manner as they are handled by the Intel486 and Intel386 processors. They invoke the protected-mode interrupt or exception handler that the interrupt or exception vector points to in the IDT. Here, the IDT entry must contain either a 32-bit trap or interrupt gate or a task gate. The following sections describe various ways that a virtual-8086 mode interrupt or exception can be handled after the protected-mode handler has been invoked.

See Section 20.3.2, “Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism”, for a description of the virtual interrupt mechanism that is available for handling maskable hardware interrupts while in virtual-8086 mode. When this mechanism is either not available or not enabled, maskable hardware interrupts are handled in the same manner as exceptions, as described in the following sections.

### 20.3.1.1 Handling an Interrupt or Exception Through a Protected-Mode Trap or Interrupt Gate

When an interrupt or exception vector points to a 32-bit trap or interrupt gate in the IDT, the gate must in turn point to a nonconforming, privilege-level 0, code segment. When accessing this code segment, processor performs the following steps.

1. Switches to 32-bit protected mode and privilege level 0.
2. Saves the state of the processor on the privilege-level 0 stack. The states of the EIP, CS, EFLAGS, ESP, SS, ES, DS, FS, and GS registers are saved (see Figure 20-4).

3. Clears the segment registers. Saving the DS, ES, FS, and GS registers on the stack and then clearing the registers lets the interrupt or exception handler safely save and restore these registers regardless of the type segment selectors they contain (protected-mode or 8086-style). The interrupt and exception handlers, which may be called in the context of either a protected-mode task or a virtual-8086-mode task, can use the same code sequences for saving and restoring the registers for any task. Clearing these registers before execution of the IRET instruction does not cause a trap in the interrupt handler. Interrupt procedures that expect values in the segment registers or that return values in the segment registers must use the register images saved on the stack for privilege level 0.
4. Clears VM, NT, RF and TF flags (in the EFLAGS register). If the gate is an interrupt gate, clears the IF flag.
5. Begins executing the selected interrupt or exception handler.

If the trap or interrupt gate references a procedure in a conforming segment or in a segment at a privilege level other than 0, the processor generates a general-protection exception (#GP). Here, the error code is the segment selector of the code segment to which a call was attempted.

**Figure 20-4. Privilege Level 0 Stack After Interrupt or Exception in Virtual-8086 Mode**

Interrupt and exception handlers can examine the VM flag on the stack to determine if the interrupted procedure was running in virtual-8086 mode. If so, the interrupt or exception can be handled in one of three ways:

- The protected-mode interrupt or exception handler that was called can handle the interrupt or exception.
- The protected-mode interrupt or exception handler can call the virtual-8086 monitor to handle the interrupt or exception.
- The virtual-8086 monitor (if called) can in turn pass control back to the 8086 program's interrupt and exception handler.

If the interrupt or exception is handled with a protected-mode handler, the handler can return to the interrupted program in virtual-8086 mode by executing an IRET instruction. This instruction loads the EFLAGS and segment registers from the images saved in the privilege level 0 stack (see Figure 20-4). A set VM flag in the EFLAGS image causes the processor to switch back to virtual-8086 mode. The CPL at the time the IRET instruction is executed must be 0, otherwise the processor does not change the state of the VM flag.

The virtual-8086 monitor runs at privilege level 0, like the protected-mode interrupt and exception handlers. It is commonly closely tied to the protected-mode general-protection exception (#GP, vector 13) handler. If the protected-mode interrupt or exception handler calls the virtual-8086 monitor to handle the interrupt or exception, the return from the virtual-8086 monitor to the interrupted virtual-8086 mode program requires two return instructions: a RET instruction to return to the protected-mode handler and an IRET instruction to return to the interrupted program.

The virtual-8086 monitor has the option of directing the interrupt and exception back to an interrupt or exception handler that is part of the interrupted 8086 program, as described in Section 20.3.1.2, "Handling an Interrupt or Exception With an 8086 Program Interrupt or Exception Handler".

### 20.3.1.2 Handling an Interrupt or Exception With an 8086 Program Interrupt or Exception Handler

Because it was designed to run on an 8086 processor, an 8086 program running in a virtual-8086-mode task contains an 8086-style interrupt vector table, which starts at linear address 0. If the virtual-8086 monitor correctly directs an interrupt or exception vector back to the virtual-8086-mode task it came from, the handlers in the 8086 program can handle the interrupt or exception. The virtual-8086 monitor must carry out the following steps to send an interrupt or exception back to the 8086 program:

1. Use the 8086 interrupt vector to locate the appropriate handler procedure in the 8086 program interrupt table.
2. Store the EFLAGS (low-order 16 bits only), CS and EIP values of the 8086 program on the privilege-level 3 stack. This is the stack that the virtual-8086-mode task is using. (The 8086 handler may use or modify this information.)
3. Change the return link on the privilege-level 0 stack to point to the privilege-level 3 handler procedure.
4. Execute an IRET instruction to pass control to the 8086 program handler.
5. When the IRET instruction from the privilege-level 3 handler triggers a general-protection exception (#GP) and thus effectively again calls the virtual-8086 monitor, restore the return link on the privilege-level 0 stack to point to the original, interrupted, privilege-level 3 procedure.
6. Copy the low order 16 bits of the EFLAGS image from the privilege-level 3 stack to the privilege-level 0 stack (because some 8086 handlers modify these flags to return information to the code that caused the interrupt).
7. Execute an IRET instruction to pass control back to the interrupted 8086 program.

Note that if an operating system intends to support all 8086 MS-DOS-based programs, it is necessary to use the actual 8086 interrupt and exception handlers supplied with the program. The reason for this is that some programs modify their own interrupt vector table to substitute (or hook in series) their own specialized interrupt and exception handlers.

### 20.3.1.3 Handling an Interrupt or Exception Through a Task Gate

When an interrupt or exception vector points to a task gate in the IDT, the processor performs a task switch to the selected interrupt- or exception-handling task. The following actions are carried out as part of this task switch:

1. The EFLAGS register with the VM flag set is saved in the current TSS.
2. The link field in the TSS of the called task is loaded with the segment selector of the TSS for the interrupted virtual-8086-mode task.
3. The EFLAGS register is loaded from the image in the new TSS, which clears the VM flag and causes the processor to switch to protected mode.
4. The NT flag in the EFLAGS register is set.
5. The processor begins executing the selected interrupt- or exception-handler task.

When an IRET instruction is executed in the handler task and the NT flag in the EFLAGS register is set, the processor switches from a protected-mode interrupt- or exception-handler task back to a virtual-8086-mode task. Here, the EFLAGS and segment registers are loaded from images saved in the TSS for the virtual-8086-mode task. If the VM flag is set in the EFLAGS image, the processor switches back to virtual-8086 mode on the task switch. The CPL at the time the IRET instruction is executed must be 0, otherwise the processor does not change the state of the VM flag.

## 20.3.2 Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism

Maskable hardware interrupts are those interrupts that are delivered through the INTR# pin or through an interrupt request to the local APIC (see Section 6.3.2, “Maskable Hardware Interrupts”). These interrupts can be inhibited (masked) from interrupting an executing program or task by clearing the IF flag in the EFLAGS register.

When the VME flag in control register CR4 is set and the IOPL field in the EFLAGS register is less than 3, two additional flags are activated in the EFLAGS register:

- VIF (virtual interrupt) flag, bit 19 of the EFLAGS register.
- VIP (virtual interrupt pending) flag, bit 20 of the EFLAGS register.

These flags provide the virtual-8086 monitor with more efficient control over handling maskable hardware interrupts that occur during virtual-8086 mode tasks. They also reduce interrupt-handling overhead, by eliminating the need for all IF related operations (such as PUSHF, POPF, CLI, and STI instructions) to trap to the virtual-8086 monitor. The purpose and use of these flags are as follows.

### NOTE

The VIF and VIP flags are only available in IA-32 processors that support the virtual mode extensions. These extensions were introduced in the IA-32 architecture with the Pentium processor. When this mechanism is either not available or not enabled, maskable hardware interrupts are handled as class 1 interrupts. Here, if VIF and VIP flags are needed, the virtual-8086 monitor can implement them in software.

Existing 8086 programs commonly set and clear the IF flag in the EFLAGS register to enable and disable maskable hardware interrupts, respectively; for example, to disable interrupts while handling another interrupt or an exception. This practice works well in single task environments, but can cause problems in multitasking and multiple-processor environments, where it is often desirable to prevent an application program from having direct control over the handling of hardware interrupts. When using earlier IA-32 processors, this problem was often solved by creating a virtual IF flag in software. The IA-32 processors (beginning with the Pentium processor) provide hardware support for this virtual IF flag through the VIF and VIP flags.

The VIF flag is a virtualized version of the IF flag, which an application program running from within a virtual-8086 task can use to control the handling of maskable hardware interrupts. When the VIF flag is enabled, the CLI and STI instructions operate on the VIF flag instead of the IF flag. When an 8086 program executes the CLI instruction, the processor clears the VIF flag to request that the virtual-8086 monitor inhibit maskable hardware interrupts from interrupting program execution; when it executes the STI instruction, the processor sets the VIF flag requesting that the virtual-8086 monitor enable maskable hardware interrupts for the 8086 program. But actually the IF flag, managed by the operating system, always controls whether maskable hardware interrupts are enabled. Also, if under these circumstances an 8086 program tries to read or change the IF flag using the PUSHF or POPF instructions, the processor will change the VIF flag instead, leaving IF unchanged.

The VIP flag provides software a means of recording the existence of a deferred (or pending) maskable hardware interrupt. This flag is read by the processor but never explicitly written by the processor; it can only be written by software.

If the IF flag is set and the VIF and VIP flags are enabled, and the processor receives a maskable hardware interrupt (interrupt vector 0 through 255), the processor performs and the interrupt handler software should perform the following operations:

1. The processor invokes the protected-mode interrupt handler for the interrupt received, as described in the following steps. These steps are almost identical to those described for method 1 interrupt and exception handling in Section 20.3.1.1, “Handling an Interrupt or Exception Through a Protected-Mode Trap or Interrupt Gate”:
  - a. Switches to 32-bit protected mode and privilege level 0.
  - b. Saves the state of the processor on the privilege-level 0 stack. The states of the EIP, CS, EFLAGS, ESP, SS, ES, DS, FS, and GS registers are saved (see Figure 20-4).
  - c. Clears the segment registers.

- d. Clears the VM flag in the EFLAGS register.
  - e. Begins executing the selected protected-mode interrupt handler.
2. The recommended action of the protected-mode interrupt handler is to read the VM flag from the EFLAGS image on the stack. If this flag is set, the handler makes a call to the virtual-8086 monitor.
  3. The virtual-8086 monitor should read the VIF flag in the EFLAGS register.
    - If the VIF flag is clear, the virtual-8086 monitor sets the VIP flag in the EFLAGS image on the stack to indicate that there is a deferred interrupt pending and returns to the protected-mode handler.
    - If the VIF flag is set, the virtual-8086 monitor can handle the interrupt if it “belongs” to the 8086 program running in the interrupted virtual-8086 task; otherwise, it can call the protected-mode interrupt handler to handle the interrupt.
  4. The protected-mode handler executes a return to the program executing in virtual-8086 mode.
  5. Upon returning to virtual-8086 mode, the processor continues execution of the 8086 program.

When the 8086 program is ready to receive maskable hardware interrupts, it executes the STI instruction to set the VIF flag (enabling maskable hardware interrupts). Prior to setting the VIF flag, the processor automatically checks the VIP flag and does one of the following, depending on the state of the flag:

- If the VIP flag is clear (indicating no pending interrupts), the processor sets the VIF flag.
- If the VIP flag is set (indicating a pending interrupt), the processor generates a general-protection exception (#GP).

The recommended action of the protected-mode general-protection exception handler is to then call the virtual-8086 monitor and let it handle the pending interrupt. After handling the pending interrupt, the typical action of the virtual-8086 monitor is to clear the VIP flag and set the VIF flag in the EFLAGS image on the stack, and then execute a return to the virtual-8086 mode. The next time the processor receives a maskable hardware interrupt, it will then handle it as described in steps 1 through 5 earlier in this section.

If the processor finds that both the VIF and VIP flags are set at the beginning of an instruction, it generates a general-protection exception. This action allows the virtual-8086 monitor to handle the pending interrupt for the virtual-8086 mode task for which the VIF flag is enabled. Note that this situation can only occur immediately following execution of a POPF or IRET instruction or upon entering a virtual-8086 mode task through a task switch.

Note that the states of the VIF and VIP flags are not modified in real-address mode or during transitions between real-address and protected modes.

### NOTE

The virtual interrupt mechanism described in this section is also available for use in protected mode, see Section 20.4, “Protected-Mode Virtual Interrupts”.

## 20.3.3 Class 3—Software Interrupt Handling in Virtual-8086 Mode

When the processor receives a software interrupt (an interrupt generated with the INT *n* instruction) while in virtual-8086 mode, it can use any of six different methods to handle the interrupt. The method selected depends on the settings of the VME flag in control register CR4, the IOPL field in the EFLAGS register, and the software interrupt redirection bit map in the TSS. Table 20-2 lists the six methods of handling software interrupts in virtual-8086 mode and the respective settings of the VME flag, IOPL field, and the bits in the interrupt redirection bit map for each method. The table also summarizes the various actions the processor takes for each method.

The VME flag enables the virtual mode extensions for the Pentium and later IA-32 processors. When this flag is clear, the processor responds to interrupts and exceptions in virtual-8086 mode in the same manner as an Intel386 or Intel486 processor does. When this flag is set, the virtual mode extension provides the following enhancements to virtual-8086 mode:

- Speeds up the handling of software-generated interrupts in virtual-8086 mode by allowing the processor to bypass the virtual-8086 monitor and redirect software interrupts back to the interrupt handlers that are part of the currently running 8086 program.
- Supports virtual interrupts for software written to run on the 8086 processor.

The IOPL value interacts with the VME flag and the bits in the interrupt redirection bit map to determine how specific software interrupts should be handled.

The software interrupt redirection bit map (see Figure 20-5) is a 32-byte field in the TSS. This map is located directly below the I/O permission bit map in the TSS. Each bit in the interrupt redirection bit map is mapped to an interrupt vector. Bit 0 in the interrupt redirection bit map (which maps to vector zero in the interrupt table) is located at the I/O base map address in the TSS minus 32 bytes. When a bit in this bit map is set, it indicates that the associated software interrupt (interrupt generated with an INT *n* instruction) should be handled through the protected-mode IDT and interrupt and exception handlers. When a bit in this bit map is clear, the processor redirects the associated software interrupt back to the interrupt table in the 8086 program (located at linear address 0 in the program's address space).

### NOTE

The software interrupt redirection bit map does not affect hardware generated interrupts and exceptions. Hardware generated interrupts and exceptions are always handled by the protected-mode interrupt and exception handlers.

**Table 20-2. Software Interrupt Handling Methods While in Virtual-8086 Mode**

Method	VME	IOPL	Bit in Redir. Bitmap*	Processor Action
1	0	3	X	Interrupt directed to a protected-mode interrupt handler: <ul style="list-style-type: none"> <li>Switches to privilege-level 0 stack</li> <li>Pushes GS, FS, DS and ES onto privilege-level 0 stack</li> <li>Pushes SS, ESP, EFLAGS, CS and EIP of interrupted task onto privilege-level 0 stack</li> <li>Clears VM, RF, NT, and TF flags</li> <li>If serviced through interrupt gate, clears IF flag</li> <li>Clears GS, FS, DS and ES to 0</li> <li>Sets CS and EIP from interrupt gate</li> </ul>
2	0	< 3	X	Interrupt directed to protected-mode general-protection exception (#GP) handler.
3	1	< 3	1	Interrupt directed to a protected-mode general-protection exception (#GP) handler; VIF and VIP flag support for handling class 2 maskable hardware interrupts.
4	1	3	1	Interrupt directed to protected-mode interrupt handler: (see method 1 processor action).
5	1	3	0	Interrupt redirected to 8086 program interrupt handler: <ul style="list-style-type: none"> <li>Pushes EFLAGS</li> <li>Pushes CS and EIP (lower 16 bits only)</li> <li>Clears IF flag</li> <li>Clears TF flag</li> <li>Loads CS and EIP (lower 16 bits only) from selected entry in the interrupt vector table of the current virtual-8086 task</li> </ul>
6	1	< 3	0	Interrupt redirected to 8086 program interrupt handler; VIF and VIP flag support for handling class 2 maskable hardware interrupts: <ul style="list-style-type: none"> <li>Pushes EFLAGS with IOPL set to 3 and VIF copied to IF</li> <li>Pushes CS and EIP (lower 16 bits only)</li> <li>Clears the VIF flag</li> <li>Clears TF flag</li> <li>Loads CS and EIP (lower 16 bits only) from selected entry in the interrupt vector table of the current virtual-8086 task</li> </ul>

### NOTE:

\* When set to 0, software interrupt is redirected back to the 8086 program interrupt handler; when set to 1, interrupt is directed to protected-mode handler.

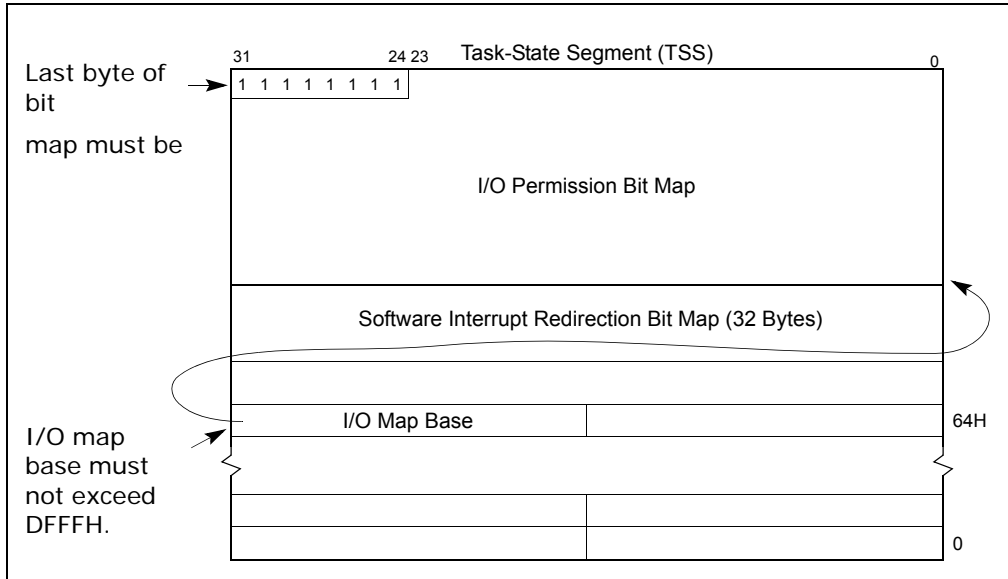

Figure 20-5. Software Interrupt Redirection Bit Map in TSS

Redirecting software interrupts back to the 8086 program potentially speeds up interrupt handling because a switch back and forth between virtual-8086 mode and protected mode is not required. This latter interrupt-handling technique is particularly useful for 8086 operating systems (such as MS-DOS) that use the `INT n` instruction to call operating system procedures.

The `CPUID` instruction can be used to verify that the virtual mode extension is implemented on the processor. Bit 1 of the feature flags register (EDX) indicates the availability of the virtual mode extension (see “`CPUID—CPU Identification`” in Chapter 3, “Instruction Set Reference, A-M”, of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2A*).

The following sections describe the six methods (or mechanisms) for handling software interrupts in virtual-8086 mode. See Section 20.3.2, “Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism”, for a description of the use of the `VIF` and `VIP` flags in the `EFLAGS` register for handling maskable hardware interrupts.

### 20.3.3.1 Method 1: Software Interrupt Handling

When the `VME` flag in control register `CR4` is clear and the `IOPL` field is 3, a Pentium or later IA-32 processor handles software interrupts in the same manner as they are handled by an Intel386 or Intel486 processor. It executes an implicit call to the interrupt handler in the protected-mode `IDT` pointed to by the interrupt vector. See Section 20.3.1, “Class 1—Hardware Interrupt and Exception Handling in Virtual-8086 Mode”, for a complete description of this mechanism and its possible uses.

### 20.3.3.2 Methods 2 and 3: Software Interrupt Handling

When a software interrupt occurs in virtual-8086 mode and the method 2 or 3 conditions are present, the processor generates a general-protection exception (`#GP`). Method 2 is enabled when the `VME` flag is set to 0 and the `IOPL` value is less than 3. Here the `IOPL` value is used to bypass the protected-mode interrupt handlers and cause any software interrupt that occurs in virtual-8086 mode to be treated as a protected-mode general-protection exception (`#GP`). The general-protection exception handler calls the virtual-8086 monitor, which can then emulate an 8086-program interrupt handler or pass control back to the 8086 program’s handler, as described in Section 20.3.1.2, “Handling an Interrupt or Exception With an 8086 Program Interrupt or Exception Handler”.

Method 3 is enabled when the `VME` flag is set to 1, the `IOPL` value is less than 3, and the corresponding bit for the software interrupt in the software interrupt redirection bit map is set to 1. Here, the processor performs the same

operation as it does for method 2 software interrupt handling. If the corresponding bit for the software interrupt in the software interrupt redirection bit map is set to 0, the interrupt is handled using method 6 (see Section 20.3.3.5, “Method 6: Software Interrupt Handling”).

### 20.3.3.3 Method 4: Software Interrupt Handling

Method 4 handling is enabled when the VME flag is set to 1, the IOPL value is 3, and the bit for the interrupt vector in the redirection bit map is set to 1. Method 4 software interrupt handling allows method 1 style handling when the virtual mode extension is enabled; that is, the interrupt is directed to a protected-mode handler (see Section 20.3.3.1, “Method 1: Software Interrupt Handling”).

### 20.3.3.4 Method 5: Software Interrupt Handling

Method 5 software interrupt handling provides a streamlined method of redirecting software interrupts (invoked with the INT *n* instruction) that occur in virtual 8086 mode back to the 8086 program’s interrupt vector table and its interrupt handlers. Method 5 handling is enabled when the VME flag is set to 1, the IOPL value is 3, and the bit for the interrupt vector in the redirection bit map is set to 0. The processor performs the following actions to make an implicit call to the selected 8086 program interrupt handler:

1. Pushes the low-order 16 bits of the EFLAGS register onto the stack.
2. Pushes the current values of the CS and EIP registers onto the current stack. (Only the 16 least-significant bits of the EIP register are pushed and no stack switch occurs.)
3. Clears the IF flag in the EFLAGS register to disable interrupts.
4. Clears the TF flag, in the EFLAGS register.
5. Locates the 8086 program interrupt vector table at linear address 0 for the 8086-mode task.
6. Loads the CS and EIP registers with values from the interrupt vector table entry pointed to by the interrupt vector number. Only the 16 low-order bits of the EIP are loaded and the 16 high-order bits are set to 0. The interrupt vector table is assumed to be at linear address 0 of the current virtual-8086 task.
7. Begins executing the selected interrupt handler.

An IRET instruction at the end of the handler procedure reverses these steps to return program control to the interrupted 8086 program.

Note that with method 5 handling, a mode switch from virtual-8086 mode to protected mode does not occur. The processor remains in virtual-8086 mode throughout the interrupt-handling operation.

The method 5 handling actions are virtually identical to the actions the processor takes when handling software interrupts in real-address mode. The benefit of using method 5 handling to access the 8086 program handlers is that it avoids the overhead of methods 2 and 3 handling, which requires first going to the virtual-8086 monitor, then to the 8086 program handler, then back again to the virtual-8086 monitor, before returning to the interrupted 8086 program (see Section 20.3.1.2, “Handling an Interrupt or Exception With an 8086 Program Interrupt or Exception Handler”).

#### NOTE

Methods 1 and 4 handling can handle a software interrupt in a virtual-8086 task with a regular protected-mode handler, but this approach requires all virtual-8086 tasks to use the same software interrupt handlers, which generally does not give sufficient latitude to the programs running in the virtual-8086 tasks, particularly MS-DOS programs.

### 20.3.3.5 Method 6: Software Interrupt Handling

Method 6 handling is enabled when the VME flag is set to 1, the IOPL value is less than 3, and the bit for the interrupt or exception vector in the redirection bit map is set to 0. With method 6 interrupt handling, software interrupts are handled in the same manner as was described for method 5 handling (see Section 20.3.3.4, “Method 5: Software Interrupt Handling”).

Method 6 differs from method 5 in that with the IOPL value set to less than 3, the VIF and VIP flags in the EFLAGS register are enabled, providing virtual interrupt support for handling class 2 maskable hardware interrupts (see Section 20.3.2, “Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism”). These flags provide the virtual-8086 monitor with an efficient means of handling maskable hardware interrupts that occur during a virtual-8086 mode task. Also, because the IOPL value is less than 3 and the VIF flag is enabled, the information pushed on the stack by the processor when invoking the interrupt handler is slightly different between methods 5 and 6 (see Table 20-2).

## 20.4 PROTECTED-MODE VIRTUAL INTERRUPTS

The IA-32 processors (beginning with the Pentium processor) also support the VIF and VIP flags in the EFLAGS register in protected mode by setting the PVI (protected-mode virtual interrupt) flag in the CR4 register. Setting the PVI flag allows applications running at privilege level 3 to execute the CLI and STI instructions without causing a general-protection exception (#GP) or affecting hardware interrupts.

When the PVI flag is set to 1, the CPL is 3, and the IOPL is less than 3, the STI and CLI instructions set and clear the VIF flag in the EFLAGS register, leaving IF unaffected. In this mode of operation, an application running in protected mode and at a CPL of 3 can inhibit interrupts in the same manner as is described in Section 20.3.2, “Class 2—Maskable Hardware Interrupt Handling in Virtual-8086 Mode Using the Virtual Interrupt Mechanism”, for a virtual-8086 mode task. When the application executes the CLI instruction, the processor clears the VIF flag. If the processor receives a maskable hardware interrupt, the processor invokes the protected-mode interrupt handler. This handler checks the state of the VIF flag in the EFLAGS register. If the VIF flag is clear (indicating that the active task does not want to have interrupts handled now), the handler sets the VIP flag in the EFLAGS image on the stack and returns to the privilege-level 3 application, which continues program execution. When the application executes a STI instruction to set the VIF flag, the processor automatically invokes the general-protection exception handler, which can then handle the pending interrupt. After handling the pending interrupt, the handler typically sets the VIF flag and clears the VIP flag in the EFLAGS image on the stack and executes a return to the application program. The next time the processor receives a maskable hardware interrupt, the processor will handle it in the normal manner for interrupts received while the processor is operating at a CPL of 3.

As with the virtual mode extension (enabled with the VME flag in the CR4 register), the protected-mode virtual interrupt extension only affects maskable hardware interrupts (interrupt vectors 32 through 255). NMI interrupts and exceptions are handled in the normal manner.

When protected-mode virtual interrupts are disabled (that is, when the PVI flag in control register CR4 is set to 0, the CPL is less than 3, or the IOPL value is 3), then the CLI and STI instructions execute in a manner compatible with the Intel486 processor. That is, if the CPL is greater (less privileged) than the I/O privilege level (IOPL), a general-protection exception occurs. If the IOPL value is 3, CLI and STI clear or set the IF flag, respectively.

PUSHF, POPF, IRET and INT are executed like in the Intel486 processor, regardless of whether protected-mode virtual interrupts are enabled.

It is only possible to enter virtual-8086 mode through a task switch or the execution of an IRET instruction, and it is only possible to leave virtual-8086 mode by faulting to a protected-mode interrupt handler (typically the general-protection exception handler, which in turn calls the virtual 8086-mode monitor). In both cases, the EFLAGS register is saved and restored. This is not true, however, in protected mode when the PVI flag is set and the processor is not in virtual-8086 mode. Here, it is possible to call a procedure at a different privilege level, in which case the EFLAGS register is not saved or modified. However, the states of VIF and VIP flags are never examined by the processor when the CPL is not 3.

Program modules written to run on IA-32 processors can be either 16-bit modules or 32-bit modules. Table 21-1 shows the characteristic of 16-bit and 32-bit modules.

**Table 21-1. Characteristics of 16-Bit and 32-Bit Program Modules**

Characteristic	16-Bit Program Modules	32-Bit Program Modules
Segment Size	0 to 64 KBytes	0 to 4 GBytes
Operand Sizes	8 bits and 16 bits	8 bits and 32 bits
Pointer Offset Size (Address Size)	16 bits	32 bits
Stack Pointer Size	16 Bits	32 Bits
Control Transfers Allowed to Code Segments of This Size	16 Bits	32 Bits

The IA-32 processors function most efficiently when executing 32-bit program modules. They can, however, also execute 16-bit program modules, in any of the following ways:

- In real-address mode.
- In virtual-8086 mode.
- System management mode (SMM).
- As a protected-mode task, when the code, data, and stack segments for the task are all configured as a 16-bit segments.
- By integrating 16-bit and 32-bit segments into a single protected-mode task.
- By integrating 16-bit operations into 32-bit code segments.

Real-address mode, virtual-8086 mode, and SMM are native 16-bit modes. A legacy program assembled and/or compiled to run on an Intel 8086 or Intel 286 processor should run in real-address mode or virtual-8086 mode without modification. Sixteen-bit program modules can also be written to run in real-address mode for handling system initialization or to run in SMM for handling system management functions. See Chapter 20, “8086 Emulation,” for detailed information on real-address mode and virtual-8086 mode; see Chapter 34, “System Management Mode,” for information on SMM.

This chapter describes how to integrate 16-bit program modules with 32-bit program modules when operating in protected mode and how to mix 16-bit and 32-bit code within 32-bit code segments.

## 21.1 DEFINING 16-BIT AND 32-BIT PROGRAM MODULES

The following IA-32 architecture mechanisms are used to distinguish between and support 16-bit and 32-bit segments and operations:

- The D (default operand and address size) flag in code-segment descriptors.
- The B (default stack size) flag in stack-segment descriptors.
- 16-bit and 32-bit call gates, interrupt gates, and trap gates.
- Operand-size and address-size instruction prefixes.
- 16-bit and 32-bit general-purpose registers.

The D flag in a code-segment descriptor determines the default operand-size and address-size for the instructions of a code segment. (In real-address mode and virtual-8086 mode, which do not use segment descriptors, the default is 16 bits.) A code segment with its D flag set is a 32-bit segment; a code segment with its D flag clear is a 16-bit segment.

The B flag in the stack-segment descriptor specifies the size of stack pointer (the 32-bit ESP register or the 16-bit SP register) used by the processor for implicit stack references. The B flag for all data descriptors also controls upper address range for expand down segments.

When transferring program control to another code segment through a call gate, interrupt gate, or trap gate, the operand size used during the transfer is determined by the type of gate used (16-bit or 32-bit), (not by the D-flag or prefix of the transfer instruction). The gate type determines how return information is saved on the stack (or stacks).

For most efficient and trouble-free operation of the processor, 32-bit programs or tasks should have the D flag in the code-segment descriptor and the B flag in the stack-segment descriptor set, and 16-bit programs or tasks should have these flags clear. Program control transfers from 16-bit segments to 32-bit segments (and vice versa) are handled most efficiently through call, interrupt, or trap gates.

Instruction prefixes can be used to override the default operand size and address size of a code segment. These prefixes can be used in real-address mode as well as in protected mode and virtual-8086 mode. An operand-size or address-size prefix only changes the size for the duration of the instruction.

## 21.2 MIXING 16-BIT AND 32-BIT OPERATIONS WITHIN A CODE SEGMENT

The following two instruction prefixes allow mixing of 32-bit and 16-bit operations within one segment:

- The operand-size prefix (66H)
- The address-size prefix (67H)

These prefixes reverse the default size selected by the D flag in the code-segment descriptor. For example, the processor can interpret the (MOV *mem, reg*) instruction in any of four ways:

- In a 32-bit code segment:
  - Moves 32 bits from a 32-bit register to memory using a 32-bit effective address.
  - If preceded by an operand-size prefix, moves 16 bits from a 16-bit register to memory using a 32-bit effective address.
  - If preceded by an address-size prefix, moves 32 bits from a 32-bit register to memory using a 16-bit effective address.
  - If preceded by both an address-size prefix and an operand-size prefix, moves 16 bits from a 16-bit register to memory using a 16-bit effective address.
- In a 16-bit code segment:
  - Moves 16 bits from a 16-bit register to memory using a 16-bit effective address.
  - If preceded by an operand-size prefix, moves 32 bits from a 32-bit register to memory using a 16-bit effective address.
  - If preceded by an address-size prefix, moves 16 bits from a 16-bit register to memory using a 32-bit effective address.
  - If preceded by both an address-size prefix and an operand-size prefix, moves 32 bits from a 32-bit register to memory using a 32-bit effective address.

The previous examples show that any instruction can generate any combination of operand size and address size regardless of whether the instruction is in a 16- or 32-bit segment. The choice of the 16- or 32-bit default for a code segment is normally based on the following criteria:

- **Performance** — Always use 32-bit code segments when possible. They run much faster than 16-bit code segments on P6 family processors, and somewhat faster on earlier IA-32 processors.
- **The operating system the code segment will be running on** — If the operating system is a 16-bit operating system, it may not support 32-bit program modules.
- **Mode of operation** — If the code segment is being designed to run in real-address mode, virtual-8086 mode, or SMM, it must be a 16-bit code segment.

- **Backward compatibility to earlier IA-32 processors** — If a code segment must be able to run on an Intel 8086 or Intel 286 processor, it must be a 16-bit code segment.

## 21.3 SHARING DATA AMONG MIXED-SIZE CODE SEGMENTS

Data segments can be accessed from both 16-bit and 32-bit code segments. When a data segment that is larger than 64 KBytes is to be shared among 16- and 32-bit code segments, the data that is to be accessed from the 16-bit code segments must be located within the first 64 KBytes of the data segment. The reason for this is that 16-bit pointers by definition can only point to the first 64 KBytes of a segment.

A stack that spans less than 64 KBytes can be shared by both 16- and 32-bit code segments. This class of stacks includes:

- Stacks in expand-up segments with the G (granularity) and B (big) flags in the stack-segment descriptor clear.
- Stacks in expand-down segments with the G and B flags clear.
- Stacks in expand-up segments with the G flag set and the B flag clear and where the stack is contained completely within the lower 64 KBytes. (Offsets greater than FFFFH can be used for data, other than the stack, which is not shared.)

See Section 3.4.5, “Segment Descriptors,” for a description of the G and B flags and the expand-down stack type.

The B flag cannot, in general, be used to change the size of stack used by a 16-bit code segment. This flag controls the size of the stack pointer only for implicit stack references such as those caused by interrupts, exceptions, and the PUSH, POP, CALL, and RET instructions. It does not control explicit stack references, such as accesses to parameters or local variables. A 16-bit code segment can use a 32-bit stack only if the code is modified so that all explicit references to the stack are preceded by the 32-bit address-size prefix, causing those references to use 32-bit addressing and explicit writes to the stack pointer are preceded by a 32-bit operand-size prefix.

In 32-bit, expand-down segments, all offsets may be greater than 64 KBytes; therefore, 16-bit code cannot use this kind of stack segment unless the code segment is modified to use 32-bit addressing.

## 21.4 TRANSFERRING CONTROL AMONG MIXED-SIZE CODE SEGMENTS

There are three ways for a procedure in a 16-bit code segment to safely make a call to a 32-bit code segment:

- Make the call through a 32-bit call gate.
- Make a 16-bit call to a 32-bit interface procedure. The interface procedure then makes a 32-bit call to the intended destination.
- Modify the 16-bit procedure, inserting an operand-size prefix before the call, to change it to a 32-bit call.

Likewise, there are three ways for procedure in a 32-bit code segment to safely make a call to a 16-bit code segment:

- Make the call through a 16-bit call gate. Here, the EIP value at the CALL instruction cannot exceed FFFFH.
- Make a 32-bit call to a 16-bit interface procedure. The interface procedure then makes a 16-bit call to the intended destination.
- Modify the 32-bit procedure, inserting an operand-size prefix before the call, changing it to a 16-bit call. Be certain that the return offset does not exceed FFFFH.

These methods of transferring program control overcome the following architectural limitations imposed on calls between 16-bit and 32-bit code segments:

- Pointers from 16-bit code segments (which by default can only be 16 bits) cannot be used to address data or code located beyond FFFFH in a 32-bit segment.
- The operand-size attributes for a CALL and its companion RETURN instruction must be the same to maintain stack coherency. This is also true for implicit calls to interrupt and exception handlers and their companion IRET instructions.
- A 32-bit parameters (particularly a pointer parameter) greater than FFFFH cannot be squeezed into a 16-bit parameter location on a stack.

- The size of the stack pointer (SP or ESP) changes when switching between 16-bit and 32-bit code segments. These limitations are discussed in greater detail in the following sections.

### 21.4.1 Code-Segment Pointer Size

For control-transfer instructions that use a pointer to identify the next instruction (that is, those that do not use gates), the operand-size attribute determines the size of the offset portion of the pointer. The implications of this rule are as follows:

- A JMP, CALL, or RET instruction from a 32-bit segment to a 16-bit segment is always possible using a 32-bit operand size, providing the 32-bit pointer does not exceed FFFFH.
- A JMP, CALL, or RET instruction from a 16-bit segment to a 32-bit segment cannot address a destination greater than FFFFH, unless the instruction is given an operand-size prefix.

See Section 21.4.5, "Writing Interface Procedures," for an interface procedure that can transfer program control from 16-bit segments to destinations in 32-bit segments beyond FFFFH.

### 21.4.2 Stack Management for Control Transfer

Because the stack is managed differently for 16-bit procedure calls than for 32-bit calls, the operand-size attribute of the RET instruction must match that of the CALL instruction (see Figure 21-1). On a 16-bit call, the processor pushes the contents of the 16-bit IP register and (for calls between privilege levels) the 16-bit SP register. The matching RET instruction must also use a 16-bit operand size to pop these 16-bit values from the stack into the 16-bit registers.

A 32-bit CALL instruction pushes the contents of the 32-bit EIP register and (for inter-privilege-level calls) the 32-bit ESP register. Here, the matching RET instruction must use a 32-bit operand size to pop these 32-bit values from the stack into the 32-bit registers. If the two parts of a CALL/RET instruction pair do not have matching operand sizes, the stack will not be managed correctly and the values of the instruction pointer and stack pointer will not be restored to correct values.

**Figure 21-1. Stack after Far 16- and 32-Bit Calls**

While executing 32-bit code, if a call is made to a 16-bit code segment which is at the same or a more privileged level (that is, the DPL of the called code segment is less than or equal to the CPL of the calling code segment) through a 16-bit call gate, then the upper 16-bits of the ESP register may be unreliable upon returning to the 32-bit code segment (that is, after executing a RET in the 16-bit code segment).

When the CALL instruction and its matching RET instruction are in code segments that have D flags with the same values (that is, both are 32-bit code segments or both are 16-bit code segments), the default settings may be used. When the CALL instruction and its matching RET instruction are in segments which have different D-flag settings, an operand-size prefix must be used.

#### 21.4.2.1 Controlling the Operand-Size Attribute For a Call

Three things can determine the operand-size of a call:

- The D flag in the segment descriptor for the calling code segment.
- An operand-size instruction prefix.
- The type of call gate (16-bit or 32-bit), if a call is made through a call gate.

When a call is made with a pointer (rather than a call gate), the D flag for the calling code segment determines the operand-size for the CALL instruction. This operand-size attribute can be overridden by prepending an operand-size prefix to the CALL instruction. So, for example, if the D flag for a code segment is set for 16 bits and the operand-size prefix is used with a CALL instruction, the processor will cause the information stored on the stack to

be stored in 32-bit format. If the call is to a 32-bit code segment, the instructions in that code segment will be able to read the stack coherently. Also, a RET instruction from the 32-bit code segment without an operand-size prefix will maintain stack coherency with the 16-bit code segment being returned to.

When a CALL instruction references a call-gate descriptor, the type of call is determined by the type of call gate (16-bit or 32-bit). The offset to the destination in the code segment being called is taken from the gate descriptor; therefore, if a 32-bit call gate is used, a procedure in a 16-bit code segment can call a procedure located more than 64 KBytes from the base of a 32-bit code segment, because a 32-bit call gate uses a 32-bit offset.

Note that regardless of the operand size of the call and how it is determined, the size of the stack pointer used (SP or ESP) is always controlled by the B flag in the stack-segment descriptor currently in use (that is, when B is clear, SP is used, and when B is set, ESP is used).

An unmodified 16-bit code segment that has run successfully on an 8086 processor or in real-mode on a later IA-32 architecture processor will have its D flag clear and will not use operand-size override prefixes. As a result, all CALL instructions in this code segment will use the 16-bit operand-size attribute. Procedures in these code segments can be modified to safely call procedures to 32-bit code segments in either of two ways:

- Relink the CALL instruction to point to 32-bit call gates (see Section 21.4.2.2, “Passing Parameters With a Gate”).
- Add a 32-bit operand-size prefix to each CALL instruction.

### 21.4.2.2 Passing Parameters With a Gate

When referencing 32-bit gates with 16-bit procedures, it is important to consider the number of parameters passed in each procedure call. The count field of the gate descriptor specifies the size of the parameter string to copy from the current stack to the stack of a more privileged (numerically lower privilege level) procedure. The count field of a 16-bit gate specifies the number of 16-bit words to be copied, whereas the count field of a 32-bit gate specifies the number of 32-bit doublewords to be copied. The count field for a 32-bit gate must thus be half the size of the number of words being placed on the stack by a 16-bit procedure. Also, the 16-bit procedure must use an even number of words as parameters.

### 21.4.3 Interrupt Control Transfers

A program-control transfer caused by an exception or interrupt is always carried out through an interrupt or trap gate (located in the IDT). Here, the type of the gate (16-bit or 32-bit) determines the operand-size attribute used in the implicit call to the exception or interrupt handler procedure in another code segment.

A 32-bit interrupt or trap gate provides a safe interface to a 32-bit exception or interrupt handler when the exception or interrupt occurs in either a 32-bit or a 16-bit code segment. It is sometimes impractical, however, to place exception or interrupt handlers in 16-bit code segments, because only 16-bit return addresses are saved on the stack. If an exception or interrupt occurs in a 32-bit code segment when the EIP was greater than FFFFH, the 16-bit handler procedure cannot provide the correct return address.

### 21.4.4 Parameter Translation

When segment offsets or pointers (which contain segment offsets) are passed as parameters between 16-bit and 32-bit procedures, some translation is required. If a 32-bit procedure passes a pointer to data located beyond 64 KBytes to a 16-bit procedure, the 16-bit procedure cannot use it. Except for this limitation, interface code can perform any format conversion between 32-bit and 16-bit pointers that may be needed.

Parameters passed by value between 32-bit and 16-bit code also may require translation between 32-bit and 16-bit formats. The form of the translation is application-dependent.

### 21.4.5 Writing Interface Procedures

Placing interface code between 32-bit and 16-bit procedures can be the solution to the following interface problems:

- Allowing procedures in 16-bit code segments to call procedures with offsets greater than FFFFH in 32-bit code segments.
- Matching operand-size attributes between companion CALL and RET instructions.
- Translating parameters (data), including managing parameter strings with a variable count or an odd number of 16-bit words.
- The possible invalidation of the upper bits of the ESP register.

The interface procedure is simplified where these rules are followed.

1. The interface procedure must reside in a 32-bit code segment (the D flag for the code-segment descriptor is set).
2. All procedures that may be called by 16-bit procedures must have offsets not greater than FFFFH.
3. All return addresses saved by 16-bit procedures must have offsets not greater than FFFFH.

The interface procedure becomes more complex if any of these rules are violated. For example, if a 16-bit procedure calls a 32-bit procedure with an entry point beyond FFFFH, the interface procedure will need to provide the offset to the entry point. The mapping between 16- and 32-bit addresses is only performed automatically when a call gate is used, because the gate descriptor for a call gate contains a 32-bit address. When a call gate is not used, the interface code must provide the 32-bit address.

The structure of the interface procedure depends on the types of calls it is going to support, as follows:

- **Calls from 16-bit procedures to 32-bit procedures** — Calls to the interface procedure from a 16-bit code segment are made with 16-bit CALL instructions (by default, because the D flag for the calling code-segment descriptor is clear), and 16-bit operand-size prefixes are used with RET instructions to return from the interface procedure to the calling procedure. Calls from the interface procedure to 32-bit procedures are performed with 32-bit CALL instructions (by default, because the D flag for the interface procedure's code segment is set), and returns from the called procedures to the interface procedure are performed with 32-bit RET instructions (also by default).
- **Calls from 32-bit procedures to 16-bit procedures** — Calls to the interface procedure from a 32-bit code segment are made with 32-bit CALL instructions (by default), and returns to the calling procedure from the interface procedure are made with 32-bit RET instructions (also by default). Calls from the interface procedure to 16-bit procedures require the CALL instructions to have the operand-size prefixes, and returns from the called procedures to the interface procedure are performed with 16-bit RET instructions (by default).

Intel 64 and IA-32 processors are binary compatible. Compatibility means that, within limited constraints, programs that execute on previous generations of processors will produce identical results when executed on later processors. The compatibility constraints and any implementation differences between the Intel 64 and IA-32 processors are described in this chapter.

Each new processor has enhanced the software visible architecture from that found in earlier Intel 64 and IA-32 processors. Those enhancements have been defined with consideration for compatibility with previous and future processors. This chapter also summarizes the compatibility considerations for those extensions.

## 22.1 PROCESSOR FAMILIES AND CATEGORIES

IA-32 processors are referred to in several different ways in this chapter, depending on the type of compatibility information being related, as described in the following:

- **IA-32 Processors** — All the Intel processors based on the Intel IA-32 Architecture, which include the 8086/88, Intel 286, Intel386, Intel486, Pentium, Pentium Pro, Pentium II, Pentium III, Pentium 4, and Intel Xeon processors.
- **32-bit Processors** — All the IA-32 processors that use a 32-bit architecture, which include the Intel386, Intel486, Pentium, Pentium Pro, Pentium II, Pentium III, Pentium 4, and Intel Xeon processors.
- **16-bit Processors** — All the IA-32 processors that use a 16-bit architecture, which include the 8086/88 and Intel 286 processors.
- **P6 Family Processors** — All the IA-32 processors that are based on the P6 microarchitecture, which include the Pentium Pro, Pentium II, and Pentium III processors.
- **Pentium® 4 Processors** — A family of IA-32 and Intel 64 processors that are based on the Intel NetBurst® microarchitecture.
- **Intel® Pentium® M Processors** — A family of IA-32 processors that are based on the Intel Pentium M processor microarchitecture.
- **Intel® Core™ Duo and Solo Processors** — Families of IA-32 processors that are based on an improved Intel Pentium M processor microarchitecture.
- **Intel® Xeon® Processors** — A family of IA-32 and Intel 64 processors that are based on the Intel NetBurst microarchitecture. This family includes the Intel Xeon processor and the Intel Xeon processor MP based on the Intel NetBurst microarchitecture. Intel Xeon processors 3000, 3100, 3200, 3300, 3200, 5100, 5200, 5300, 5400, 7200, 7300 series are based on Intel Core microarchitectures and support Intel 64 architecture.
- **Pentium® D Processors** — A family of dual-core Intel 64 processors that provides two processor cores in a physical package. Each core is based on the Intel NetBurst microarchitecture.
- **Pentium® Processor Extreme Editions** — A family of dual-core Intel 64 processors that provides two processor cores in a physical package. Each core is based on the Intel NetBurst microarchitecture and supports Intel Hyper-Threading Technology.
- **Intel® Core™ 2 Processor family**— A family of Intel 64 processors that are based on the Intel Core microarchitecture. Intel Pentium Dual-Core processors are also based on the Intel Core microarchitecture.
- **Intel® Atom™ Processors** — A family of IA-32 and Intel 64 processors that are based on the Intel Atom microarchitecture.

## 22.2 RESERVED BITS

Throughout this manual, certain bits are marked as reserved in many register and memory layout descriptions. When bits are marked as undefined or reserved, it is essential for compatibility with future processors that software

treat these bits as having a future, though unknown effect. Software should follow these guidelines in dealing with reserved bits:

- Do not depend on the states of any reserved bits when testing the values of registers or memory locations that contain such bits. Mask out the reserved bits before testing.
- Do not depend on the states of any reserved bits when storing them to memory or to a register.
- Do not depend on the ability to retain information written into any reserved bits.
- When loading a register, always load the reserved bits with the values indicated in the documentation, if any, or reload them with values previously read from the same register.

Software written for existing IA-32 processor that handles reserved bits correctly will port to future IA-32 processors without generating protection exceptions.

## 22.3 ENABLING NEW FUNCTIONS AND MODES

Most of the new control functions defined for the P6 family and Pentium processors are enabled by new mode flags in the control registers (primarily register CR4). This register is undefined for IA-32 processors earlier than the Pentium processor. Attempting to access this register with an Intel486 or earlier IA-32 processor results in an invalid-opcode exception (#UD). Consequently, programs that execute correctly on the Intel486 or earlier IA-32 processor cannot erroneously enable these functions. Attempting to set a reserved bit in register CR4 to a value other than its original value results in a general-protection exception (#GP). So, programs that execute on the P6 family and Pentium processors cannot erroneously enable functions that may be implemented in future IA-32 processors.

The P6 family and Pentium processors do not check for attempts to set reserved bits in model-specific registers; however these bits may be checked on more recent processors. It is the obligation of the software writer to enforce this discipline. These reserved bits may be used in future Intel processors.

## 22.4 DETECTING THE PRESENCE OF NEW FEATURES THROUGH SOFTWARE

Software can check for the presence of new architectural features and extensions in either of two ways:

1. Test for the presence of the feature or extension. Software can test for the presence of new flags in the EFLAGS register and control registers. If these flags are reserved (meaning not present in the processor executing the test), an exception is generated. Likewise, software can attempt to execute a new instruction, which results in an invalid-opcode exception (#UD) being generated if it is not supported.
2. Execute the CPUID instruction. The CPUID instruction (added to the IA-32 in the Pentium processor) indicates the presence of new features directly.

See Chapter 17, "Processor Identification and Feature Determination," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, for detailed information on detecting new processor features and extensions.

## 22.5 INTEL MMX TECHNOLOGY

The Pentium processor with MMX technology introduced the MMX technology and a set of MMX instructions to the IA-32. The MMX instructions are described in Chapter 9, "Programming with Intel® MMX™ Technology," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*. The MMX technology and MMX instructions are also included in the Pentium II, Pentium III, Pentium 4, and Intel Xeon processors.

## 22.6 STREAMING SIMD EXTENSIONS (SSE)

The Streaming SIMD Extensions (SSE) were introduced in the Pentium III processor. The SSE extensions consist of a new set of instructions and a new set of registers. The new registers include the eight 128-bit XMM registers and the 32-bit MXCSR control and status register. These instructions and registers are designed to allow SIMD computations to be made on single-precision floating-point numbers. Several of these new instructions also operate in the MMX registers. SSE instructions and registers are described in Section 10, "Programming with Streaming SIMD Extensions (SSE)," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*.

## 22.7 STREAMING SIMD EXTENSIONS 2 (SSE2)

The Streaming SIMD Extensions 2 (SSE2) were introduced in the Pentium 4 and Intel Xeon processors. They consist of a new set of instructions that operate on the XMM and MXCSR registers and perform SIMD operations on double-precision floating-point values and on integer values. Several of these new instructions also operate in the MMX registers. SSE2 instructions and registers are described in Chapter 11, "Programming with Streaming SIMD Extensions 2 (SSE2)," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*.

## 22.8 STREAMING SIMD EXTENSIONS 3 (SSE3)

The Streaming SIMD Extensions 3 (SSE3) were introduced in Pentium 4 processors supporting Intel Hyper-Threading Technology and Intel Xeon processors. SSE3 extensions include 13 instructions. Ten of these 13 instructions support the single instruction multiple data (SIMD) execution model used with SSE/SSE2 extensions. One SSE3 instruction accelerates x87 style programming for conversion to integer. The remaining two instructions (MONITOR and MWAIT) accelerate synchronization of threads. SSE3 instructions are described in Chapter 12, "Programming with SSE3, SSSE3 and SSE4," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*.

## 22.9 ADDITIONAL STREAMING SIMD EXTENSIONS

The Supplemental Streaming SIMD Extensions 3 (SSSE3) were introduced in the Intel Core 2 processor and Intel Xeon processor 5100 series. Streaming SIMD Extensions 4 provided 54 new instructions introduced in 45nm Intel Xeon processors and Intel Core 2 processors. SSSE3, SSE4.1 and SSE4.2 instructions are described in Chapter 12, "Programming with SSE3, SSSE3 and SSE4," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, and in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volumes 2A, 2B & 2C*.

## 22.10 INTEL HYPER-THREADING TECHNOLOGY

Intel Hyper-Threading Technology provides two logical processors that can execute two separate code streams (called *threads*) concurrently by using shared resources in a single processor core or in a physical package.

This feature was introduced in the Intel Xeon processor MP and later steppings of the Intel Xeon processor, and Pentium 4 processors supporting Intel Hyper-Threading Technology. The feature is also found in the Pentium processor Extreme Edition. See also: Section 8.7, "Intel® Hyper-Threading Technology Architecture."

Intel Atom processors also support Intel Hyper-Threading Technology.

## 22.11 MULTI-CORE TECHNOLOGY

The Pentium D processor and Pentium processor Extreme Edition provide two processor cores in each physical processor package. See also: Section 8.5, “Intel® Hyper-Threading Technology and Intel® Multi-Core Technology,” and Section 8.8, “Multi-Core Architecture.” Intel Core 2 Duo, Intel Pentium Dual-Core processors, Intel Xeon processors 3000, 3100, 5100, 5200 series provide two processor cores in each physical processor package. Intel Core 2 Extreme, Intel Core 2 Quad processors, Intel Xeon processors 3200, 3300, 5300, 5400, 7300 series provide two processor cores in each physical processor package.

## 22.12 SPECIFIC FEATURES OF DUAL-CORE PROCESSOR

Dual-core processors may have some processor-specific features. Use CPUID feature flags to detect the availability features. Note the following:

- **CPUID Brand String** — On Pentium processor Extreme Edition, the process will report the correct brand string only after the correct microcode updates are loaded.
- **Enhanced Intel SpeedStep Technology** — This feature is supported in Pentium D processor but not in Pentium processor Extreme Edition.

## 22.13 NEW INSTRUCTIONS IN THE PENTIUM AND LATER IA-32 PROCESSORS

Table 22-1 identifies the instructions introduced into the IA-32 in the Pentium processor and later IA-32 processors.

### 22.13.1 Instructions Added Prior to the Pentium Processor

The following instructions were added in the Intel486 processor:

- BSWAP (byte swap) instruction.
- XADD (exchange and add) instruction.
- CMPXCHG (compare and exchange) instruction.
- INVD (invalidate cache) instruction.
- WBINVD (write-back and invalidate cache) instruction.
- INVLPG (invalidate TLB entry) instruction.

**Table 22-1. New Instruction in the Pentium Processor and Later IA-32 Processors**

Instruction	CPUID Identification Bits	Introduced In
CMOV <sub>cc</sub> (conditional move)	EDX, Bit 15	Pentium Pro processor
FCMOV <sub>cc</sub> (floating-point conditional move)	EDX, Bits 0 and 15	
FCOMI (floating-point compare and set EFLAGS)	EDX, Bits 0 and 15	
RDPMC (read performance monitoring counters)	EAX, Bits 8-11, set to 6H; see Note 1	
UD2 (undefined)	EAX, Bits 8-11, set to 6H	
CMPXCHG8B (compare and exchange 8 bytes)	EDX, Bit 8	Pentium processor
CPUID (CPU identification)	None; see Note 2	
RDTSC (read time-stamp counter)	EDX, Bit 4	
RDMSR (read model-specific register)	EDX, Bit 5	
WRMSR (write model-specific register)	EDX, Bit 5	
MMX Instructions	EDX, Bit 23	

**Table 22-1. New Instruction in the Pentium Processor and Later IA-32 Processors (Contd.)**

Instruction	CPUID Identification Bits	Introduced In
-------------	---------------------------	---------------

**NOTES:**

1. The RDPNC instruction was introduced in the P6 family of processors and added to later model Pentium processors. This instruction is model specific in nature and not architectural.
2. The CPUID instruction is available in all Pentium and P6 family processors and in later models of the Intel486 processors. The ability to set and clear the ID flag (bit 21) in the EFLAGS register indicates the availability of the CPUID instruction.

The following instructions were added in the Intel386 processor:

- LSS, LFS, and LGS (load SS, FS, and GS registers).
- Long-displacement conditional jumps.
- Single-bit instructions.
- Bit scan instructions.
- Double-shift instructions.
- Byte set on condition instruction.
- Move with sign/zero extension.
- Generalized multiply instruction.
- MOV to and from control registers.
- MOV to and from test registers (now obsolete).
- MOV to and from debug registers.
- RSM (resume from SMM). This instruction was introduced in the Intel386 SL and Intel486 SL processors.

The following instructions were added in the Intel 387 math coprocessor:

- FPREM1.
- FUCOM, FUCOMP, and FUCOMPP.

## 22.14 OBSOLETE INSTRUCTIONS

The MOV to and from test registers instructions were removed from the Pentium processor and future IA-32 processors. Execution of these instructions generates an invalid-opcode exception (#UD).

## 22.15 UNDEFINED OPCODES

All new instructions defined for IA-32 processors use binary encodings that were reserved on earlier-generation processors. Attempting to execute a reserved opcode always results in an invalid-opcode (#UD) exception being generated. Consequently, programs that execute correctly on earlier-generation processors cannot erroneously execute these instructions and thereby produce unexpected results when executed on later IA-32 processors.

## 22.16 NEW FLAGS IN THE EFLAGS REGISTER

The section titled "EFLAGS Register" in Chapter 3, "Basic Execution Environment," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, shows the configuration of flags in the EFLAGS register for the P6 family processors. No new flags have been added to this register in the P6 family processors. The flags added to this register in the Pentium and Intel486 processors are described in the following sections.

The following flags were added to the EFLAGS register in the Pentium processor:

- VIF (virtual interrupt flag), bit 19.
- VIP (virtual interrupt pending), bit 20.

- ID (identification flag), bit 21.

The AC flag (bit 18) was added to the EFLAGS register in the Intel486 processor.

### 22.16.1 Using EFLAGS Flags to Distinguish Between 32-Bit IA-32 Processors

The following bits in the EFLAGS register that can be used to differentiate between the 32-bit IA-32 processors:

- Bit 18 (the AC flag) can be used to distinguish an Intel386 processor from the P6 family, Pentium, and Intel486 processors. Since it is not implemented on the Intel386 processor, it will always be clear.
- Bit 21 (the ID flag) indicates whether an application can execute the CPUID instruction. The ability to set and clear this bit indicates that the processor is a P6 family or Pentium processor. The CPUID instruction can then be used to determine which processor.
- Bits 19 (the VIF flag) and 20 (the VIP flag) will always be zero on processors that do not support virtual mode extensions, which includes all 32-bit processors prior to the Pentium processor.

See Chapter 17, "Processor Identification and Feature Determination," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*, for more information on identifying processors.

## 22.17 STACK OPERATIONS

This section identifies the differences in stack implementation between the various IA-32 processors.

### 22.17.1 PUSH SP

The P6 family, Pentium, Intel486, Intel386, and Intel 286 processors push a different value on the stack for a PUSH SP instruction than the 8086 processor. The 32-bit processors push the value of the SP register before it is decremented as part of the push operation; the 8086 processor pushes the value of the SP register after it is decremented. If the value pushed is important, replace PUSH SP instructions with the following three instructions:

```
PUSH BP
MOV BP, SP
XCHG BP, [BP]
```

This code functions as the 8086 processor PUSH SP instruction on the P6 family, Pentium, Intel486, Intel386, and Intel 286 processors.

### 22.17.2 EFLAGS Pushed on the Stack

The setting of the stored values of bits 12 through 15 (which includes the IOPL field and the NT flag) in the EFLAGS register by the PUSHF instruction, by interrupts, and by exceptions is different with the 32-bit IA-32 processors than with the 8086 and Intel 286 processors. The differences are as follows:

- 8086 processor—bits 12 through 15 are always set.
- Intel 286 processor—bits 12 through 15 are always cleared in real-address mode.
- 32-bit processors in real-address mode—bit 15 (reserved) is always cleared, and bits 12 through 14 have the last value loaded into them.

## 22.18 X87 FPU

This section addresses the issues that must be faced when porting floating-point software designed to run on earlier IA-32 processors and math coprocessors to a Pentium 4, Intel Xeon, P6 family, or Pentium processor with integrated x87 FPU. To software, a Pentium 4, Intel Xeon, or P6 family processor looks very much like a Pentium processor. Floating-point software which runs on a Pentium or Intel486 DX processor, or on an Intel486 SX

processor/Intel 487 SX math coprocessor system or an Intel386 processor/Intel 387 math coprocessor system, will run with at most minor modifications on a Pentium 4, Intel Xeon, or P6 family processor. To port code directly from an Intel 286 processor/Intel 287 math coprocessor system or an Intel 8086 processor/8087 math coprocessor system to a Pentium 4, Intel Xeon, P6 family, or Pentium processor, certain additional issues must be addressed.

In the following sections, the term “32-bit x87 FPUs” refers to the P6 family, Pentium, and Intel486 DX processors, and to the Intel 487 SX and Intel 387 math coprocessors; the term “16-bit IA-32 math coprocessors” refers to the Intel 287 and 8087 math coprocessors.

## 22.18.1 Control Register CR0 Flags

The ET, NE, and MP flags in control register CR0 control the interface between the integer unit of an IA-32 processor and either its internal x87 FPU or an external math coprocessor. The effect of these flags in the various IA-32 processors are described in the following paragraphs.

The ET (extension type) flag (bit 4 of the CR0 register) is used in the Intel386 processor to indicate whether the math coprocessor in the system is an Intel 287 math coprocessor (flag is clear) or an Intel 387 DX math coprocessor (flag is set). This bit is hardwired to 1 in the P6 family, Pentium, and Intel486 processors.

The NE (Numeric Exception) flag (bit 5 of the CR0 register) is used in the P6 family, Pentium, and Intel486 processors to determine whether unmasked floating-point exceptions are reported internally through interrupt vector 16 (flag is set) or externally through an external interrupt (flag is clear). On a hardware reset, the NE flag is initialized to 0, so software using the automatic internal error-reporting mechanism must set this flag to 1. This flag is nonexistent on the Intel386 processor.

As on the Intel 286 and Intel386 processors, the MP (monitor coprocessor) flag (bit 1 of register CR0) determines whether the WAIT/FWAIT instructions or waiting-type floating-point instructions trap when the context of the x87 FPU is different from that of the currently-executing task. If the MP and TS flag are set, then a WAIT/FWAIT instruction and waiting instructions will cause a device-not-available exception (interrupt vector 7). The MP flag is used on the Intel 286 and Intel386 processors to support the use of a WAIT/FWAIT instruction to wait on a device other than a math coprocessor. The device reports its status through the BUSY# pin. Since the P6 family, Pentium, and Intel486 processors do not have such a pin, the MP flag has no relevant use and should be set to 1 for normal operation.

## 22.18.2 x87 FPU Status Word

This section identifies differences to the x87 FPU status word for the different IA-32 processors and math coprocessors, the reason for the differences, and their impact on software.

### 22.18.2.1 Condition Code Flags (C0 through C3)

The following information pertains to differences in the use of the condition code flags (C0 through C3) located in bits 8, 9, 10, and 14 of the x87 FPU status word.

After execution of an FINIT instruction or a hardware reset on a 32-bit x87 FPU, the condition code flags are set to 0. The same operations on a 16-bit IA-32 math coprocessor leave these flags intact (they contain their prior value). This difference in operation has no impact on software and provides a consistent state after reset.

Transcendental instruction results in the core range of the P6 family and Pentium processors may differ from the Intel486 DX processor and Intel 487 SX math coprocessor by 2 to 3 units in the last place (ulps)—(see “Transcendental Instruction Accuracy” in Chapter 8, “Programming with the x87 FPU,” of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1*). As a result, the value saved in the C1 flag may also differ.

After an incomplete FPREM/FPREM1 instruction, the C0, C1, and C3 flags are set to 0 on the 32-bit x87 FPUs. After the same operation on a 16-bit IA-32 math coprocessor, these flags are left intact.

On the 32-bit x87 FPUs, the C2 flag serves as an incomplete flag for the FTAN instruction. On the 16-bit IA-32 math coprocessors, the C2 flag is undefined for the FPTAN instruction. This difference has no impact on software, because Intel 287 or 8087 programs do not check C2 after an FPTAN instruction. The use of this flag on later processors allows fast checking of operand range.

### 22.18.2.2 Stack Fault Flag

When unmasked stack overflow or underflow occurs on a 32-bit x87 FPU, the IE flag (bit 0) and the SF flag (bit 6) of the x87 FPU status word are set to indicate a stack fault and condition code flag C1 is set or cleared to indicate overflow or underflow, respectively. When unmasked stack overflow or underflow occurs on a 16-bit IA-32 math coprocessor, only the IE flag is set. Bit 6 is reserved on these processors. The addition of the SF flag on a 32-bit x87 FPU has no impact on software. Existing exception handlers need not change, but may be upgraded to take advantage of the additional information.

### 22.18.3 x87 FPU Control Word

Only affine closure is supported for infinity control on a 32-bit x87 FPU. The infinity control flag (bit 12 of the x87 FPU control word) remains programmable on these processors, but has no effect. This change was made to conform to the IEEE Standard 754 for Binary Floating-Point Arithmetic. On a 16-bit IA-32 math coprocessor, both affine and projective closures are supported, as determined by the setting of bit 12. After a hardware reset, the default value of bit 12 is projective. Software that requires projective infinity arithmetic may give different results.

### 22.18.4 x87 FPU Tag Word

When loading the tag word of a 32-bit x87 FPU, using an FLDENV, FRSTOR, or FXRSTOR (Pentium III processor only) instruction, the processor examines the incoming tag and classifies the location only as empty or non-empty. Thus, tag values of 00, 01, and 10 are interpreted by the processor to indicate a non-empty location. The tag value of 11 is interpreted by the processor to indicate an empty location. Subsequent operations on a non-empty register always examine the value in the register, not the value in its tag. The FSTENV, FSAVE, and FXSAVE (Pentium III processor only) instructions examine the non-empty registers and put the correct values in the tags before storing the tag word.

The corresponding tag for a 16-bit IA-32 math coprocessor is checked before each register access to determine the class of operand in the register; the tag is updated after every change to a register so that the tag always reflects the most recent status of the register. Software can load a tag with a value that disagrees with the contents of a register (for example, the register contains a valid value, but the tag says special). Here, the 16-bit IA-32 math coprocessors honor the tag and do not examine the register.

Software written to run on a 16-bit IA-32 math coprocessor may not operate correctly on a 16-bit x87 FPU, if it uses the FLDENV, FRSTOR, or FXRSTOR instructions to change tags to values (other than to empty) that are different from actual register contents.

The encoding in the tag word for the 32-bit x87 FPUs for unsupported data formats (including pseudo-zero and unnormal) is special (10B), to comply with IEEE Standard 754. The encoding in the 16-bit IA-32 math coprocessors for pseudo-zero and unnormal is valid (00B) and the encoding for other unsupported data formats is special (10B). Code that recognizes the pseudo-zero or unnormal format as valid must therefore be changed if it is ported to a 32-bit x87 FPU.

### 22.18.5 Data Types

This section discusses the differences of data types for the various x87 FPUs and math coprocessors.

#### 22.18.5.1 NaNs

The 32-bit x87 FPUs distinguish between signaling NaNs (SNaNs) and quiet NaNs (QNaNs). These x87 FPUs only generate QNaNs and normally do not generate an exception upon encountering a QNaN. An invalid-operation exception (#I) is generated only upon encountering a SNaN, except for the FCOM, FIST, and FBSTP instructions, which also generates an invalid-operation exceptions for a QNaNs. This behavior matches IEEE Standard 754.

The 16-bit IA-32 math coprocessors only generate one kind of NaN (the equivalent of a QNaN), but the raise an invalid-operation exception upon encountering any kind of NaN.

When porting software written to run on a 16-bit IA-32 math coprocessor to a 32-bit x87 FPU, uninitialized memory locations that contain QNaNs should be changed to SNaNs to cause the x87 FPU or math coprocessor to fault when uninitialized memory locations are referenced.

### 22.18.5.2 Pseudo-zero, Pseudo-NaN, Pseudo-infinity, and Unnormal Formats

The 32-bit x87 FPUs neither generate nor support the pseudo-zero, pseudo-NaN, pseudo-infinity, and unnormal formats. Whenever they encounter them in an arithmetic operation, they raise an invalid-operation exception. The 16-bit IA-32 math coprocessors define and support special handling for these formats. Support for these formats was dropped to conform with IEEE Standard 754 for Binary Floating-Point Arithmetic.

This change should not impact software ported from 16-bit IA-32 math coprocessors to 32-bit x87 FPUs. The 32-bit x87 FPUs do not generate these formats, and therefore will not encounter them unless software explicitly loads them in the data registers. The only affect may be in how software handles the tags in the tag word (see also: Section 22.18.4, “x87 FPU Tag Word”).

## 22.18.6 Floating-Point Exceptions

This section identifies the implementation differences in exception handling for floating-point instructions in the various x87 FPUs and math coprocessors.

### 22.18.6.1 Denormal Operand Exception (#D)

When the denormal operand exception is masked, the 32-bit x87 FPUs automatically normalize denormalized numbers when possible; whereas, the 16-bit IA-32 math coprocessors return a denormal result. A program written to run on a 16-bit IA-32 math coprocessor that uses the denormal exception solely to normalize denormalized operands is redundant when run on the 32-bit x87 FPUs. If such a program is run on 32-bit x87 FPUs, performance can be improved by masking the denormal exception. Floating-point programs run faster when the FPU performs normalization of denormalized operands.

The denormal operand exception is not raised for transcendental instructions and the FEXTRACT instruction on the 16-bit IA-32 math coprocessors. This exception is raised for these instructions on the 32-bit x87 FPUs. The exception handlers ported to these latter processors need to be changed only if the handlers gives special treatment to different opcodes.

### 22.18.6.2 Numeric Overflow Exception (#O)

On the 32-bit x87 FPUs, when the numeric overflow exception is masked and the rounding mode is set to chop (toward 0), the result is the largest positive or smallest negative number. The 16-bit IA-32 math coprocessors do not signal the overflow exception when the masked response is not  $\infty$ ; that is, they signal overflow only when the rounding control is not set to round to 0. If rounding is set to chop (toward 0), the result is positive or negative  $\infty$ . Under the most common rounding modes, this difference has no impact on existing software.

If rounding is toward 0 (chop), a program on a 32-bit x87 FPU produces, under overflow conditions, a result that is different in the least significant bit of the significand, compared to the result on a 16-bit IA-32 math coprocessor. The reason for this difference is IEEE Standard 754 compatibility.

When the overflow exception is not masked, the precision exception is flagged on the 32-bit x87 FPUs. When the result is stored in the stack, the significand is rounded according to the precision control (PC) field of the FPU control word or according to the opcode. On the 16-bit IA-32 math coprocessors, the precision exception is not flagged and the significand is not rounded. The impact on existing software is that if the result is stored on the stack, a program running on a 32-bit x87 FPU produces a different result under overflow conditions than on a 16-bit IA-32 math coprocessor. The difference is apparent only to the exception handler. This difference is for IEEE Standard 754 compatibility.

### 22.18.6.3 Numeric Underflow Exception (#U)

When the underflow exception is masked on the 32-bit x87 FPUs, the underflow exception is signaled when both the result is tiny and denormalization results in a loss of accuracy. When the underflow exception is unmasked and the instruction is supposed to store the result on the stack, the significand is rounded to the appropriate precision (according to the PC flag in the FPU control word, for those instructions controlled by PC, otherwise to extended precision), after adjusting the exponent.

When the underflow exception is masked on the 16-bit IA-32 math coprocessors and rounding is toward 0, the underflow exception flag is raised on a tiny result, regardless of loss of accuracy. When the underflow exception is not masked and the destination is the stack, the significand is not rounded, but instead is left as is.

When the underflow exception is masked, this difference has no impact on existing software. The underflow exception occurs less often when rounding is toward 0.

When the underflow exception not masked. A program running on a 32-bit x87 FPU produces a different result during underflow conditions than on a 16-bit IA-32 math coprocessor if the result is stored on the stack. The difference is only in the least significant bit of the significand and is apparent only to the exception handler.

### 22.18.6.4 Exception Precedence

There is no difference in the precedence of the denormal-operand exception on the 32-bit x87 FPUs, whether it be masked or not. When the denormal-operand exception is not masked on the 16-bit IA-32 math coprocessors, it takes precedence over all other exceptions. This difference causes no impact on existing software, but some unneeded normalization of denormalized operands is prevented on the Intel486 processor and Intel 387 math coprocessor.

### 22.18.6.5 CS and EIP For FPU Exceptions

On the Intel 32-bit x87 FPUs, the values from the CS and EIP registers saved for floating-point exceptions point to any prefixes that come before the floating-point instruction. On the 8087 math coprocessor, the saved CS and IP registers points to the floating-point instruction.

### 22.18.6.6 FPU Error Signals

The floating-point error signals to the P6 family, Pentium, and Intel486 processors do not pass through an interrupt controller; an INT# signal from an Intel 387, Intel 287 or 8087 math coprocessors does. If an 8086 processor uses another exception for the 8087 interrupt, both exception vectors should call the floating-point-error exception handler. Some instructions in a floating-point-error exception handler may need to be deleted if they use the interrupt controller. The P6 family, Pentium, and Intel486 processors have signals that, with the addition of external logic, support reporting for emulation of the interrupt mechanism used in many personal computers.

On the P6 family, Pentium, and Intel486 processors, an undefined floating-point opcode will cause an invalid-opcode exception (#UD, interrupt vector 6). Undefined floating-point opcodes, like legal floating-point opcodes, cause a device not available exception (#NM, interrupt vector 7) when either the TS or EM flag in control register CR0 is set. The P6 family, Pentium, and Intel486 processors do not check for floating-point error conditions on encountering an undefined floating-point opcode.

### 22.18.6.7 Assertion of the FERR# Pin

When using the MS-DOS compatibility mode for handing floating-point exceptions, the FERR# pin must be connected to an input to an external interrupt controller. An external interrupt is then generated when the FERR# output drives the input to the interrupt controller and the interrupt controller in turn drives the INTR pin on the processor.

For the P6 family and Intel386 processors, an unmasked floating-point exception always causes the FERR# pin to be asserted upon completion of the instruction that caused the exception. For the Pentium and Intel486 processors, an unmasked floating-point exception may cause the FERR# pin to be asserted either at the end of the instruction causing the exception or immediately before execution of the next floating-point instruction. (Note that the next floating-point instruction would not be executed until the pending unmasked exception has been handled.)

See Appendix D, “Guidelines for Writing x87 FPU Extension Handlers,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1*, for a complete description of the required mechanism for handling floating-point exceptions using the MS-DOS compatibility mode.

Using FERR# and IGNNE# to handle floating-point exception is deprecated by modern operating systems; this approach also limits newer processors to operate with one logical processor active.

### 22.18.6.8 Invalid Operation Exception On Denormals

An invalid-operation exception is not generated on the 32-bit x87 FPUs upon encountering a denormal value when executing a FSQRT, FDIV, or FPREM instruction or upon conversion to BCD or to integer. The operation proceeds by first normalizing the value. On the 16-bit IA-32 math coprocessors, upon encountering this situation, the invalid-operation exception is generated. This difference has no impact on existing software. Software running on the 32-bit x87 FPUs continues to execute in cases where the 16-bit IA-32 math coprocessors trap. The reason for this change was to eliminate an exception from being raised.

### 22.18.6.9 Alignment Check Exceptions (#AC)

If alignment checking is enabled, a misaligned data operand on the P6 family, Pentium, and Intel486 processors causes an alignment check exception (#AC) when a program or procedure is running at privilege-level 3, except for the stack portion of the FSAVE/FNSAVE, FXSAVE, FRSTOR, and FXRSTOR instructions.

### 22.18.6.10 Segment Not Present Exception During FLDENV

On the Intel486 processor, when a segment not present exception (#NP) occurs in the middle of an FLDENV instruction, it can happen that part of the environment is loaded and part not. In such cases, the FPU control word is left with a value of 007FH. The P6 family and Pentium processors ensure the internal state is correct at all times by attempting to read the first and last bytes of the environment before updating the internal state.

### 22.18.6.11 Device Not Available Exception (#NM)

The device-not-available exception (#NM, interrupt 7) will occur in the P6 family, Pentium, and Intel486 processors as described in Section 2.5, “Control Registers,” Table 2-2, and Chapter 6, “Interrupt 7—Device Not Available Exception (#NM).”

### 22.18.6.12 Coprocessor Segment Overrun Exception

The coprocessor segment overrun exception (interrupt 9) does not occur in the P6 family, Pentium, and Intel486 processors. In situations where the Intel 387 math coprocessor would cause an interrupt 9, the P6 family, Pentium, and Intel486 processors simply abort the instruction. To avoid undetected segment overruns, it is recommended that the floating-point save area be placed in the same page as the TSS. This placement will prevent the FPU environment from being lost if a page fault occurs during the execution of an FLDENV, FRSTOR, or FXRSTOR instruction while the operating system is performing a task switch.

### 22.18.6.13 General Protection Exception (#GP)

A general-protection exception (#GP, interrupt 13) occurs if the starting address of a floating-point operand falls outside a segment’s size. An exception handler should be included to report these programming errors.

### 22.18.6.14 Floating-Point Error Exception (#MF)

In real mode and protected mode (not including virtual-8086 mode), interrupt vector 16 must point to the floating-point exception handler. In virtual 8086 mode, the virtual-8086 monitor can be programmed to accommodate a different location of the interrupt vector for floating-point exceptions.

## 22.18.7 Changes to Floating-Point Instructions

This section identifies the differences in floating-point instructions for the various Intel FPU and math coprocessor architectures, the reason for the differences, and their impact on software.

### 22.18.7.1 FDIV, FPREM, and FSQRT Instructions

The 32-bit x87 FPUs support operations on denormalized operands and, when detected, an underflow exception can occur, for compatibility with the IEEE Standard 754. The 16-bit IA-32 math coprocessors do not operate on denormalized operands or return underflow results. Instead, they generate an invalid-operation exception when they detect an underflow condition. An existing underflow exception handler will require change only if it gives different treatment to different opcodes. Also, it is possible that fewer invalid-operation exceptions will occur.

### 22.18.7.2 FSCALE Instruction

With the 32-bit x87 FPUs, the range of the scaling operand is not restricted. If  $(0 < |ST(1)| < 1)$ , the scaling factor is 0; therefore,  $ST(0)$  remains unchanged. If the rounded result is not exact or if there was a loss of accuracy (masked underflow), the precision exception is signaled. With the 16-bit IA-32 math coprocessors, the range of the scaling operand is restricted. If  $(0 < |ST(1)| < 1)$ , the result is undefined and no exception is signaled. The impact of this difference on existing software is that different results are delivered on the 32-bit and 16-bit FPUs and math coprocessors when  $(0 < |ST(1)| < 1)$ .

### 22.18.7.3 FPREM1 Instruction

The 32-bit x87 FPUs compute a partial remainder according to IEEE Standard 754. This instruction does not exist on the 16-bit IA-32 math coprocessors. The availability of the FPREM1 instruction has no impact on existing software.

### 22.18.7.4 FPREM Instruction

On the 32-bit x87 FPUs, the condition code flags C0, C3, C1 in the status word correctly reflect the three low-order bits of the quotient following execution of the FPREM instruction. On the 16-bit IA-32 math coprocessors, the quotient bits are incorrect when performing a reduction of  $(64^N + M)$  when  $(N \geq 1)$  and  $M$  is 1 or 2. This difference does not affect existing software; software that works around the bug should not be affected.

### 22.18.7.5 FUCOM, FUCOMP, and FUCOMPP Instructions

When executing the FUCOM, FUCOMP, and FUCOMPP instructions, the 32-bit x87 FPUs perform unordered compare according to IEEE Standard 754. These instructions do not exist on the 16-bit IA-32 math coprocessors. The availability of these new instructions has no impact on existing software.

### 22.18.7.6 FPTAN Instruction

On the 32-bit x87 FPUs, the range of the operand for the FPTAN instruction is much less restricted ( $|ST(0)| < 2^{63}$ ) than on earlier math coprocessors. The instruction reduces the operand internally using an internal  $\pi/4$  constant that is more accurate. The range of the operand is restricted to  $(|ST(0)| < \pi/4)$  on the 16-bit IA-32 math coprocessors; the operand must be reduced to this range using FPREM. This change has no impact on existing software.

### 22.18.7.7 Stack Overflow

On the 32-bit x87 FPUs, if an FPU stack overflow occurs when the invalid-operation exception is masked, the FPU returns the real, integer, or BCD-integer indefinite value to the destination operand, depending on the instruction being executed. On the 16-bit IA-32 math coprocessors, the original operand remains unchanged following a stack overflow, but it is loaded into register  $ST(1)$ . This difference has no impact on existing software.

### 22.18.7.8 FSIN, FCOS, and FSINCOS Instructions

On the 32-bit x87 FPUs, these instructions perform three common trigonometric functions. These instructions do not exist on the 16-bit IA-32 math coprocessors. The availability of these instructions has no impact on existing software, but using them provides a performance upgrade.

### 22.18.7.9 FPATAN Instruction

On the 32-bit x87 FPUs, the range of operands for the FPATAN instruction is unrestricted. On the 16-bit IA-32 math coprocessors, the absolute value of the operand in register ST(0) must be smaller than the absolute value of the operand in register ST(1). This difference has impact on existing software.

### 22.18.7.10 F2XM1 Instruction

The 32-bit x87 FPUs support a wider range of operands ( $-1 < ST(0) < +1$ ) for the F2XM1 instruction. The supported operand range for the 16-bit IA-32 math coprocessors is ( $0 \leq ST(0) \leq 0.5$ ). This difference has no impact on existing software.

### 22.18.7.11 FLD Instruction

On the 32-bit x87 FPUs, when using the FLD instruction to load an extended-real value, a denormal-operand exception is not generated because the instruction is not arithmetic. The 16-bit IA-32 math coprocessors do report a denormal-operand exception in this situation. This difference does not affect existing software.

On the 32-bit x87 FPUs, loading a denormal value that is in single- or double-real format causes the value to be converted to extended-real format. Loading a denormal value on the 16-bit IA-32 math coprocessors causes the value to be converted to an unnormal. If the next instruction is FEXTRACT or FXAM, the 32-bit x87 FPUs will give a different result than the 16-bit IA-32 math coprocessors. This change was made for IEEE Standard 754 compatibility.

On the 32-bit x87 FPUs, loading an SNaN that is in single- or double-real format causes the FPU to generate an invalid-operation exception. The 16-bit IA-32 math coprocessors do not raise an exception when loading a signaling NaN. The invalid-operation exception handler for 16-bit math coprocessor software needs to be updated to handle this condition when porting software to 32-bit FPUs. This change was made for IEEE Standard 754 compatibility.

### 22.18.7.12 FEXTRACT Instruction

On the 32-bit x87 FPUs, if the operand is 0 for the FEXTRACT instruction, the divide-by-zero exception is reported and  $-\infty$  is delivered to register ST(1). If the operand is  $+\infty$ , no exception is reported. If the operand is 0 on the 16-bit IA-32 math coprocessors, 0 is delivered to register ST(1) and no exception is reported. If the operand is  $+\infty$ , the invalid-operation exception is reported. These differences have no impact on existing software. Software usually bypasses 0 and  $\infty$ . This change is due to the IEEE Standard 754 recommendation to fully support the “logb” function.

### 22.18.7.13 Load Constant Instructions

On 32-bit x87 FPUs, rounding control is in effect for the load constant instructions. Rounding control is not in effect for the 16-bit IA-32 math coprocessors. Results for the FLDPI, FLDLN2, FLDLG2, and FLDL2E instructions are the same as for the 16-bit IA-32 math coprocessors when rounding control is set to round to nearest or round to  $+\infty$ . They are the same for the FLDL2T instruction when rounding control is set to round to nearest, round to  $-\infty$ , or round to zero. Results are different from the 16-bit IA-32 math coprocessors in the least significant bit of the mantissa if rounding control is set to round to  $-\infty$  or round to 0 for the FLDPI, FLDLN2, FLDLG2, and FLDL2E instructions; they are different for the FLDL2T instruction if round to  $+\infty$  is specified. These changes were implemented for compatibility with IEEE Standard 754 for Floating-Point Arithmetic recommendations.

### 22.18.7.14 FSETPM Instruction

With the 32-bit x87 FPUs, the FSETPM instruction is treated as NOP (no operation). This instruction informs the Intel 287 math coprocessor that the processor is in protected mode. This change has no impact on existing software. The 32-bit x87 FPUs handle all addressing and exception-pointer information, whether in protected mode or not.

### 22.18.7.15 FXAM Instruction

With the 32-bit x87 FPUs, if the FPU encounters an empty register when executing the FXAM instruction, it not generate combinations of C0 through C3 equal to 1101 or 1111. The 16-bit IA-32 math coprocessors may generate these combinations, among others. This difference has no impact on existing software; it provides a performance upgrade to provide repeatable results.

### 22.18.7.16 FSAVE and FSTENV Instructions

With the 32-bit x87 FPUs, the address of a memory operand pointer stored by FSAVE or FSTENV is undefined if the previous floating-point instruction did not refer to memory

## 22.18.8 Transcendental Instructions

The floating-point results of the P6 family and Pentium processors for transcendental instructions in the core range may differ from the Intel486 processors by about 2 or 3 ulps (see "Transcendental Instruction Accuracy" in Chapter 8, "Programming with the x87 FPU," of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1*). Condition code flag C1 of the status word may differ as a result. The exact threshold for underflow and overflow will vary by a few ulps. The P6 family and Pentium processors' results will have a worst case error of less than 1 ulp when rounding to the nearest-even and less than 1.5 ulps when rounding in other modes. The transcendental instructions are guaranteed to be monotonic, with respect to the input operands, throughout the domain supported by the instruction.

Transcendental instructions may generate different results in the round-up flag (C1) on the 32-bit x87 FPUs. The round-up flag is undefined for these instructions on the 16-bit IA-32 math coprocessors. This difference has no impact on existing software.

## 22.18.9 Obsolete Instructions

The 8087 math coprocessor instructions FENI and FDISI and the Intel 287 math coprocessor instruction FSETPM are treated as integer NOP instructions in the 32-bit x87 FPUs. If these opcodes are detected in the instruction stream, no specific operation is performed and no internal states are affected.

## 22.18.10 WAIT/FWAIT Prefix Differences

On the Intel486 processor, when a WAIT/FWAIT instruction precedes a floating-point instruction (one which itself automatically synchronizes with the previous floating-point instruction), the WAIT/FWAIT instruction is treated as a no-op. Pending floating-point exceptions from a previous floating-point instruction are processed not on the WAIT/FWAIT instruction but on the floating-point instruction following the WAIT/FWAIT instruction. In such a case, the report of a floating-point exception may appear one instruction later on the Intel486 processor than on a P6 family or Pentium FPU, or on Intel 387 math coprocessor.

## 22.18.11 Operands Split Across Segments and/or Pages

On the P6 family, Pentium, and Intel486 processor FPUs, when the first half of an operand to be written is inside a page or segment and the second half is outside, a memory fault can cause the first half to be stored but not the second half. In this situation, the Intel 387 math coprocessor stores nothing.

### 22.18.12 FPU Instruction Synchronization

On the 32-bit x87 FPUs, all floating-point instructions are automatically synchronized; that is, the processor automatically waits until the previous floating-point instruction has completed before completing the next floating-point instruction. No explicit WAIT/FWAIT instructions are required to assure this synchronization. For the 8087 math coprocessors, explicit waits are required before each floating-point instruction to ensure synchronization. Although 8087 programs having explicit WAIT instructions execute perfectly on the 32-bit IA-32 processors without reassembly, these WAIT instructions are unnecessary.

## 22.19 SERIALIZING INSTRUCTIONS

Certain instructions have been defined to serialize instruction execution to ensure that modifications to flags, registers and memory are completed before the next instruction is executed (or in P6 family processor terminology “committed to machine state”). Because the P6 family processors use branch-prediction and out-of-order execution techniques to improve performance, instruction execution is not generally serialized until the results of an executed instruction are committed to machine state (see Chapter 2, “Intel® 64 and IA-32 Architectures,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1*).

As a result, at places in a program or task where it is critical to have execution completed for all previous instructions before executing the next instruction (for example, at a branch, at the end of a procedure, or in multiprocessor dependent code), it is useful to add a serializing instruction. See Section 8.3, “Serializing Instructions,” for more information on serializing instructions.

## 22.20 FPU AND MATH COPROCESSOR INITIALIZATION

Table 9-1 shows the states of the FPUs in the P6 family, Pentium, Intel486 processors and of the Intel 387 math coprocessor and Intel 287 coprocessor following a power-up, reset, or INIT, or following the execution of an FINIT/FNINIT instruction. The following is some additional compatibility information concerning the initialization of x87 FPUs and math coprocessors.

### 22.20.1 Intel® 387 and Intel® 287 Math Coprocessor Initialization

Following an Intel386 processor reset, the processor identifies its coprocessor type (Intel® 287 or Intel® 387 DX math coprocessor) by sampling its ERROR# input some time after the falling edge of RESET# signal and before execution of the first floating-point instruction. The Intel 287 coprocessor keeps its ERROR# output in inactive state after hardware reset; the Intel 387 coprocessor keeps its ERROR# output in active state after hardware reset.

Upon hardware reset or execution of the FINIT/FNINIT instruction, the Intel 387 math coprocessor signals an error condition. The P6 family, Pentium, and Intel486 processors, like the Intel 287 coprocessor, do not.

### 22.20.2 Intel486 SX Processor and Intel 487 SX Math Coprocessor Initialization

When initializing an Intel486 SX processor and an Intel 487 SX math coprocessor, the initialization routine should check the presence of the math coprocessor and should set the FPU related flags (EM, MP, and NE) in control register CR0 accordingly (see Section 2.5, “Control Registers,” for a complete description of these flags). Table 22-2 gives the recommended settings for these flags when the math coprocessor is present. The FSTCW instruction will give a value of FFFFH for the Intel486 SX microprocessor and 037FH for the Intel 487 SX math coprocessor.

**Table 22-2. Recommended Values of the EM, MP, and NE Flags for Intel486 SX Microprocessor/Intel 487 SX Math Coprocessor System**

CRO Flags	Intel486 SX Processor Only	Intel 487 SX Math Coprocessor Present
EM	1	0
MP	0	1
NE	1	0, for MS-DOS* systems 1, for user-defined exception handler

The EM and MP flags in register CRO are interpreted as shown in Table 22-3.

**Table 22-3. EM and MP Flag Interpretation**

EM	MP	Interpretation
0	0	Floating-point instructions are passed to FPU; WAIT/FWAIT and other waiting-type instructions ignore TS.
0	1	Floating-point instructions are passed to FPU; WAIT/FWAIT and other waiting-type instructions test TS.
1	0	Floating-point instructions trap to emulator; WAIT/FWAIT and other waiting-type instructions ignore TS.
1	1	Floating-point instructions trap to emulator; WAIT/FWAIT and other waiting-type instructions test TS.

Following is an example code sequence to initialize the system and check for the presence of Intel486 SX processor/Intel 487 SX math coprocessor.

```
fninit
fstcw mem_loc
mov ax, mem_loc
cmp ax, 037fh
jz Intel487_SX_Math_CoProcessor_present ;ax=037fh
jmp Intel486_SX_microprocessor_present ;ax=ffffh
```

If the Intel 487 SX math coprocessor is not present, the following code can be run to set the CRO register for the Intel486 SX processor.

```
mov eax, cr0
and eax, ffffffffh ;make MP=0
or eax, 0024h ;make EM=1, NE=1
mov cr0, eax
```

This initialization will cause any floating-point instruction to generate a device not available exception (#NH), interrupt 7. The software emulation will then take control to execute these instructions. This code is not required if an Intel 487 SX math coprocessor is present in the system. In that case, the typical initialization routine for the Intel486 SX microprocessor will be adequate.

Also, when designing an Intel486 SX processor based system with an Intel 487 SX math coprocessor, timing loops should be independent of clock speed and clocks per instruction. One way to attain this is to implement these loops in hardware and not in software (for example, BIOS).

## 22.21 CONTROL REGISTERS

The following sections identify the new control registers and control register flags and fields that were introduced to the 32-bit IA-32 in various processor families. See Figure 2-7 for the location of these flags and fields in the control registers.

The Pentium III processor introduced one new control flag in control register CR4:

- OSXMMEXCPT (bit 10) — The OS will set this bit if it supports unmasked SIMD floating-point exceptions.

The Pentium II processor introduced one new control flag in control register CR4:

- OSFXSR (bit 9) — The OS supports saving and restoring the Pentium III processor state during context switches.

The Pentium Pro processor introduced three new control flags in control register CR4:

- PAE (bit 5) — Physical address extension. Enables paging mechanism to reference extended physical addresses when set; restricts physical addresses to 32 bits when clear (see also: Section 22.22.1.1, “Physical Memory Addressing Extension”).
- PGE (bit 7) — Page global enable. Inhibits flushing of frequently-used or shared pages on CR3 writes (see also: Section 22.22.1.2, “Global Pages”).
- PCE (bit 8) — Performance-monitoring counter enable. Enables execution of the RDPMC instruction at any protection level.

The content of CR4 is 0H following a hardware reset.

Control register CR4 was introduced in the Pentium processor. This register contains flags that enable certain new extensions provided in the Pentium processor:

- VME — Virtual-8086 mode extensions. Enables support for a virtual interrupt flag in virtual-8086 mode (see Section 20.3, “Interrupt and Exception Handling in Virtual-8086 Mode”).
- PVI — Protected-mode virtual interrupts. Enables support for a virtual interrupt flag in protected mode (see Section 20.4, “Protected-Mode Virtual Interrupts”).
- TSD — Time-stamp disable. Restricts the execution of the RDTSC instruction to procedures running at privileged level 0.
- DE — Debugging extensions. Causes an undefined opcode (#UD) exception to be generated when debug registers DR4 and DR5 are references for improved performance (see Section 22.23.3, “Debug Registers DR4 and DR5”).
- PSE — Page size extensions. Enables 4-MByte pages with 32-bit paging when set (see Section 4.3, “32-Bit Paging”).
- MCE — Machine-check enable. Enables the machine-check exception, allowing exception handling for certain hardware error conditions (see Chapter 15, “Machine-Check Architecture”).

The Intel486 processor introduced five new flags in control register CR0:

- NE — Numeric error. Enables the normal mechanism for reporting floating-point numeric errors.
- WP — Write protect. Write-protects read-only pages against supervisor-mode accesses.
- AM — Alignment mask. Controls whether alignment checking is performed. Operates in conjunction with the AC (Alignment Check) flag.
- NW — Not write-through. Enables write-throughs and cache invalidation cycles when clear and disables invalidation cycles and write-throughs that hit in the cache when set.
- CD — Cache disable. Enables the internal cache when clear and disables the cache when set.

The Intel486 processor introduced two new flags in control register CR3:

- PCD — Page-level cache disable. The state of this flag is driven on the PCD# pin during bus cycles that are not paged, such as interrupt acknowledge cycles, when paging is enabled. The PCD# pin is used to control caching in an external cache on a cycle-by-cycle basis.
- PWT — Page-level write-through. The state of this flag is driven on the PWT# pin during bus cycles that are not paged, such as interrupt acknowledge cycles, when paging is enabled. The PWT# pin is used to control write through in an external cache on a cycle-by-cycle basis.

## 22.22 MEMORY MANAGEMENT FACILITIES

The following sections describe the new memory management facilities available in the various IA-32 processors and some compatibility differences.

### 22.22.1 New Memory Management Control Flags

The Pentium Pro processor introduced three new memory management features: physical memory addressing extension, the global bit in page-table entries, and general support for larger page sizes. These features are only available when operating in protected mode.

#### 22.22.1.1 Physical Memory Addressing Extension

The new PAE (physical address extension) flag in control register CR4, bit 5, may enable additional address lines on the processor, allowing extended physical addresses. This option can only be used when paging is enabled, using a new page-table mechanism provided to support the larger physical address range (see Section 4.1, "Paging Modes and Control Bits").

#### 22.22.1.2 Global Pages

The new PGE (page global enable) flag in control register CR4, bit 7, provides a mechanism for preventing frequently used pages from being flushed from the translation lookaside buffer (TLB). When this flag is set, frequently used pages (such as pages containing kernel procedures or common data tables) can be marked global by setting the global flag in a page-directory or page-table entry.

On a task switch or a write to control register CR3 (which normally causes the TLBs to be flushed), the entries in the TLB marked global are not flushed. Marking pages global in this manner prevents unnecessary reloading of the TLB due to TLB misses on frequently used pages. See Section 4.10, "Caching Translation Information" for a detailed description of this mechanism.

#### 22.22.1.3 Larger Page Sizes

The P6 family processors support large page sizes. For 32-bit paging, this facility is enabled with the PSE (page size extension) flag in control register CR4, bit 4. When this flag is set, the processor supports either 4-KByte or 4-MByte page sizes. PAE paging and IA-32e paging support 2-MByte pages regardless of the value of CR4.PSE (see Section 4.4, "PAE Paging" and Section 4.5, "IA-32e Paging"). See Chapter 4, "Paging," for more information about large page sizes.

### 22.22.2 CD and NW Cache Control Flags

The CD and NW flags in control register CRO were introduced in the Intel486 processor. In the P6 family and Pentium processors, these flags are used to implement a writeback strategy for the data cache; in the Intel486 processor, they implement a write-through strategy. See Table 11-5 for a comparison of these bits on the P6 family, Pentium, and Intel486 processors. For complete information on caching, see Chapter 11, "Memory Cache Control."

### 22.22.3 Descriptor Types and Contents

Operating-system code that manages space in descriptor tables often contains an invalid value in the access-rights field of descriptor-table entries to identify unused entries. Access rights values of 80H and 00H remain invalid for the P6 family, Pentium, Intel486, Intel386, and Intel 286 processors. Other values that were invalid on the Intel 286 processor may be valid on the 32-bit processors because uses for these bits have been defined.

## 22.22.4 Changes in Segment Descriptor Loads

On the Intel386 processor, loading a segment descriptor always causes a locked read and write to set the accessed bit of the descriptor. On the P6 family, Pentium, and Intel486 processors, the locked read and write occur only if the bit is not already set.

## 22.23 DEBUG FACILITIES

The P6 family and Pentium processors include extensions to the Intel486 processor debugging support for breakpoints. To use the new breakpoint features, it is necessary to set the DE flag in control register CR4.

### 22.23.1 Differences in Debug Register DR6

It is not possible to write a 1 to reserved bit 12 in debug status register DR6 on the P6 family and Pentium processors; however, it is possible to write a 1 in this bit on the Intel486 processor. See Table 9-1 for the different setting of this register following a power-up or hardware reset.

### 22.23.2 Differences in Debug Register DR7

The P6 family and Pentium processors determines the type of breakpoint access by the R/W0 through R/W3 fields in debug control register DR7 as follows:

- 00 Break on instruction execution only.
- 01 Break on data writes only.
- 10 Undefined if the DE flag in control register CR4 is cleared; break on I/O reads or writes but not instruction fetches if the DE flag in control register CR4 is set.
- 11 Break on data reads or writes but not instruction fetches.

On the P6 family and Pentium processors, reserved bits 11, 12, 14 and 15 are hard-wired to 0. On the Intel486 processor, however, bit 12 can be set. See Table 9-1 for the different settings of this register following a power-up or hardware reset.

### 22.23.3 Debug Registers DR4 and DR5

Although the DR4 and DR5 registers are documented as reserved, previous generations of processors aliased references to these registers to debug registers DR6 and DR7, respectively. When debug extensions are not enabled (the DE flag in control register CR4 is cleared), the P6 family and Pentium processors remain compatible with existing software by allowing these aliased references. When debug extensions are enabled (the DE flag is set), attempts to reference registers DR4 or DR5 will result in an invalid-opcode exception (#UD).

## 22.24 RECOGNITION OF BREAKPOINTS

For the Pentium processor, it is recommended that debuggers execute the LGDT instruction before returning to the program being debugged to ensure that breakpoints are detected. This operation does not need to be performed on the P6 family, Intel486, or Intel386 processors.

The implementation of test registers on the Intel486 processor used for testing the cache and TLB has been redesigned using MSRs on the P6 family and Pentium processors. (Note that MSRs used for this function are different on the P6 family and Pentium processors.) The MOV to and from test register instructions generate invalid-opcode exceptions (#UD) on the P6 family processors.

## 22.25 EXCEPTIONS AND/OR EXCEPTION CONDITIONS

This section describes the new exceptions and exception conditions added to the 32-bit IA-32 processors and implementation differences in existing exception handling. See Chapter 6, “Interrupt and Exception Handling,” for a detailed description of the IA-32 exceptions.

The Pentium III processor introduced new state with the XMM registers. Computations involving data in these registers can produce exceptions. A new MXCSR control/status register is used to determine which exception or exceptions have occurred. When an exception associated with the XMM registers occurs, an interrupt is generated.

- SIMD floating-point exception (#XF, interrupt 19) — New exceptions associated with the SIMD floating-point registers and resulting computations.

No new exceptions were added with the Pentium Pro and Pentium II processors. The set of available exceptions is the same as for the Pentium processor. However, the following exception condition was added to the IA-32 with the Pentium Pro processor:

- Machine-check exception (#MC, interrupt 18) — New exception conditions. Many exception conditions have been added to the machine-check exception and a new architecture has been added for handling and reporting on hardware errors. See Chapter 15, “Machine-Check Architecture,” for a detailed description of the new conditions.

The following exceptions and/or exception conditions were added to the IA-32 with the Pentium processor:

- Machine-check exception (#MC, interrupt 18) — New exception. This exception reports parity and other hardware errors. It is a model-specific exception and may not be implemented or implemented differently in future processors. The MCE flag in control register CR4 enables the machine-check exception. When this bit is clear (which it is at reset), the processor inhibits generation of the machine-check exception.
- General-protection exception (#GP, interrupt 13) — New exception condition added. An attempt to write a 1 to a reserved bit position of a special register causes a general-protection exception to be generated.
- Page-fault exception (#PF, interrupt 14) — New exception condition added. When a 1 is detected in any of the reserved bit positions of a page-table entry, page-directory entry, or page-directory pointer during address translation, a page-fault exception is generated.

The following exception was added to the Intel486 processor:

- Alignment-check exception (#AC, interrupt 17) — New exception. Reports unaligned memory references when alignment checking is being performed.

The following exceptions and/or exception conditions were added to the Intel386 processor:

- Divide-error exception (#DE, interrupt 0)
  - Change in exception handling. Divide-error exceptions on the Intel386 processors always leave the saved CS:IP value pointing to the instruction that failed. On the 8086 processor, the CS:IP value points to the next instruction.
  - Change in exception handling. The Intel386 processors can generate the largest negative number as a quotient for the IDIV instruction (80H and 8000H). The 8086 processor generates a divide-error exception instead.
- Invalid-opcode exception (#UD, interrupt 6) — New exception condition added. Improper use of the LOCK instruction prefix can generate an invalid-opcode exception.
- Page-fault exception (#PF, interrupt 14) — New exception condition added. If paging is enabled in a 16-bit program, a page-fault exception can be generated as follows. Paging can be used in a system with 16-bit tasks if all tasks use the same page directory. Because there is no place in a 16-bit TSS to store the PDBR register, switching to a 16-bit task does not change the value of the PDBR register. Tasks ported from the Intel 286 processor should be given 32-bit TSSs so they can make full use of paging.
- General-protection exception (#GP, interrupt 13) — New exception condition added. The Intel386 processor sets a limit of 15 bytes on instruction length. The only way to violate this limit is by putting redundant prefixes before an instruction. A general-protection exception is generated if the limit on instruction length is violated. The 8086 processor has no instruction length limit.

## 22.25.1 Machine-Check Architecture

The Pentium Pro processor introduced a new architecture to the IA-32 for handling and reporting on machine-check exceptions. This machine-check architecture (described in detail in Chapter 15, “Machine-Check Architecture”) greatly expands the ability of the processor to report on internal hardware errors.

## 22.25.2 Priority of Exceptions

The priority of exceptions are broken down into several major categories:

1. Traps on the previous instruction
2. External interrupts
3. Faults on fetching the next instruction
4. Faults in decoding the next instruction
5. Faults on executing an instruction

There are no changes in the priority of these major categories between the different processors, however, exceptions within these categories are implementation dependent and may change from processor to processor.

## 22.25.3 Exception Conditions of Legacy SIMD Instructions Operating on MMX Registers

MMX instructions and a subset of SSE, SSE2, SSSE3 instructions operate on MMX registers. The exception conditions of these instructions are described in the following tables.

**Table 22-4. Exception Conditions for Legacy SIMD/MMX Instructions with FP Exception and 16-Byte Alignment**

Exception	Real	Virtual 8086	Protected and Compatibility	64-bit	Cause of Exception
Invalid Opcode, #UD	X	X	X	X	If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 0.
	X	X	X	X	If CR0.EM[bit 2] = 1. If CR4.OSFXSR[bit 9] = 0.
	X	X	X	X	If preceded by a LOCK prefix (FOH)
	X	X	X	X	If any corresponding CPUID feature flag is '0'
#MF	X	X	X	X	If there is a pending X87 FPU exception
#NM	X	X	X	X	If CR0.TS[bit 3]=1
Stack, SS(0)			X		For an illegal address in the SS segment
				X	If a memory address referencing the SS segment is in a non-canonical form
General Protection, #GP(0)	X	X	X	X	Legacy SSE: Memory operand is not 16-byte aligned
			X		For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
				X	If the memory address is in a non-canonical form.
	X	X			If any part of the operand lies outside the effective address space from 0 to FFFFH
#PF(fault-code)		X	X	X	For a page fault
#XM	X	X	X	X	If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 1
Applicable Instructions	CVTPD2PI, CVTTPD2PI				

**Table 22-5. Exception Conditions for Legacy SIMD/MMX Instructions with XMM and FP Exception**

Exception	Real	Virtual 80x86	Protected and Compatibility	64-bit	Cause of Exception
Invalid Opcode, #UD	X	X	X	X	If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 0.
	X	X	X	X	If CR0.EM[bit 2] = 1. If CR4.OSFXSR[bit 9] = 0.
	X	X	X	X	If preceded by a LOCK prefix (FOH)
	X	X	X	X	If any corresponding CPUID feature flag is '0'
#MF	X	X	X	X	If there is a pending X87 FPU exception
#NM	X	X	X	X	If CR0.TS[bit 3]=1
Stack, SS(0)			X		For an illegal address in the SS segment
				X	If a memory address referencing the SS segment is in a non-canonical form
General Protection, #GP(0)			X		For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
				X	If the memory address is in a non-canonical form.
	X	X			If any part of the operand lies outside the effective address space from 0 to FFFFH
#PF(fault-code)		X	X	X	For a page fault
Alignment Check #AC(0)		X	X	X	If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
SIMD Floating-point Exception, #XM	X	X	X	X	If an unmasked SIMD floating-point exception and CR4.OSXMMEXCPT[bit 10] = 1
Applicable Instructions	CVTPI2PS, CVTPS2PI, CVTTPS2PI				

Table 22-6. Exception Conditions for Legacy SIMD/MMX Instructions with XMM and without FP Exception

Exception	Real	Virtual 80x86	Protected and Compatibility	64-bit	Cause of Exception
Invalid Opcode, #UD	X	X	X	X	If CRO.EM[bit 2] = 1. If CR4.OSFXSR[bit 9] = 0.
	X	X	X	X	If preceded by a LOCK prefix (F0H)
	X	X	X	X	If any corresponding CPUID feature flag is '0'
#MF <sup>1</sup>	X	X	X	X	If there is a pending X87 FPU exception
#NM	X	X	X	X	If CRO.TS[bit 3]=1
Stack, SS(0)			X		For an illegal address in the SS segment
				X	If a memory address referencing the SS segment is in a non-canonical form
General Protection, #GP(0)			X		For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
				X	If the memory address is in a non-canonical form.
	X	X			If any part of the operand lies outside the effective address space from 0 to FFFFH
#PF(fault-code)		X	X	X	For a page fault
Alignment Check #AC(0)		X	X	X	If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
Applicable Instructions	CVTPI2PD				

**NOTES:**

1. Applies to "CVTPI2PD xmm, mm" but not "CVTPI2PD xmm, m64".

**Table 22-7. Exception Conditions for SIMD/MMX Instructions with Memory Reference**

Exception	Real	Virtual 80x86	Protected and Compatibility	64-bit	Cause of Exception
Invalid Opcode, #UD	X	X	X	X	If CR0.EM[bit 2] = 1.
	X	X	X	X	If preceded by a LOCK prefix (FOH)
	X	X	X	X	If any corresponding CPUID feature flag is '0'
#MF	X	X	X	X	If there is a pending X87 FPU exception
#NM	X	X	X	X	If CR0.TS[bit 3]=1
Stack, SS(0)			X		For an illegal address in the SS segment
				X	If a memory address referencing the SS segment is in a non-canonical form
General Protection, #GP(0)			X		For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
				X	If the memory address is in a non-canonical form.
	X	X			If any part of the operand lies outside the effective address space from 0 to FFFFH
#PF(fault-code)		X	X	X	For a page fault
Alignment Check #AC(0)		X	X	X	If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
Applicable Instructions	PABSB, PABSD, PABSW, PACKSSWB, PACKSSDW, PACKUSWB, PADDB, PADDD, PADDQ, PADDW, PADDSB, PADDSD, PADDUSB, PADDUSW, PALIGNR, PAND, PANDN, PAVGB, PAVGW, PCMPEQB, PCMPEQD, PCMPEQW, PCMPGTB, PCMPGTD, PCMPGTW, PHADDD, PHADDW, PHADDSW, PHSUBD, PHSUBW, PHSUBSW, PINSRW, PMADDUBSW, PMADDWD, PMAXS, PMAXSUB, PMINSW, PMINUB, PMULHRW, PMULHUW, PMULHW, PMULLW, PMULUDQ, PSADB, PSHUFB, PSHUFW, PSIGNB, PSIGND, PSIGNW, PSLW, PSLD, PSLQ, PSRAD, PSRAW, PSRLW, PSRLD, PSRLQ, PSUBB, PSUBD, PSUBQ, PSUBW, PSUBSB, PSUBSW, PSUBUSB, PSUBUSW, PUNPCKHBW, PUNPCKHWD, PUNPCKHDQ, PUNPCKLBW, PUNPCKLWD, PUNPCKLDQ, PXOR				

Table 22-8. Exception Conditions for Legacy SIMD/MMX Instructions without FP Exception

Exception	Real	Virtual 80x86	Protected and Compatibility	64-bit	Cause of Exception
Invalid Opcode, #UD	X	X	X	X	If CRO.EM[bit 2] = 1. If ModR/M.mod != 11b <sup>1</sup>
	X	X	X	X	If preceded by a LOCK prefix (FOH)
	X	X	X	X	If any corresponding CPUID feature flag is '0'
#MF	X	X	X	X	If there is a pending X87 FPU exception
#NM	X	X	X	X	If CRO.TS[bit 3]=1
Stack, SS(0)			X		For an illegal address in the SS segment
				X	If a memory address referencing the SS segment is in a non-canonical form
#GP(0)			X		For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments. If the destination operand is in a non-writable segment. <sup>2</sup> If the DS, ES, FS, or GS register contains a NULL segment selector. <sup>3</sup>
				X	If the memory address is in a non-canonical form.
	X	X			If any part of the operand lies outside the effective address space from 0 to FFFFH
#PF(fault-code)		X	X	X	For a page fault
#AC(0)		X	X	X	If alignment checking is enabled and an unaligned memory reference is made while the current privilege level is 3.
Applicable Instructions	MASKMOVQ, MOVNTQ, "MOVQ (mmreg)"				

**NOTES:**

1. Applies to MASKMOVQ only.
2. Applies to MASKMOVQ and MOVQ (mmreg) only.
3. Applies to MASKMOVQ only.

**Table 22-9. Exception Conditions for Legacy SIMD/MMX Instructions without Memory Reference**

Exception	Real	Virtual 80x86	Protected and Compatibility	64-bit	Cause of Exception
Invalid Opcode, #UD	X	X	X	X	If CR0.EM[bit 2] = 1.
	X	X	X	X	If preceded by a LOCK prefix (FOH)
	X	X	X	X	If any corresponding CPUID feature flag is '0'
#MF	X	X	X	X	If there is a pending X87 FPU exception
#NM			X	X	If CR0.TS[bit 3]=1
Applicable Instructions	PEXTRW, PMOVMASKB				

## 22.26 INTERRUPTS

The following differences in handling interrupts are found among the IA-32 processors.

### 22.26.1 Interrupt Propagation Delay

External hardware interrupts may be recognized on different instruction boundaries on the P6 family, Pentium, Intel486, and Intel386 processors, due to the superscaler designs of the P6 family and Pentium processors. Therefore, the EIP pushed onto the stack when servicing an interrupt may be different for the P6 family, Pentium, Intel486, and Intel386 processors.

### 22.26.2 NMI Interrupts

After an NMI interrupt is recognized by the P6 family, Pentium, Intel486, Intel386, and Intel 286 processors, the NMI interrupt is masked until the first IRET instruction is executed, unlike the 8086 processor.

### 22.26.3 IDT Limit

The LIDT instruction can be used to set a limit on the size of the IDT. A double-fault exception (#DF) is generated if an interrupt or exception attempts to read a vector beyond the limit. Shutdown then occurs on the 32-bit IA-32 processors if the double-fault handler vector is beyond the limit. (The 8086 processor does not have a shutdown mode nor a limit.)

## 22.27 ADVANCED PROGRAMMABLE INTERRUPT CONTROLLER (APIC)

The Advanced Programmable Interrupt Controller (APIC), referred to in this book as the **local APIC**, was introduced into the IA-32 processors with the Pentium processor (beginning with the 735/90 and 815/100 models) and is included in the Pentium 4, Intel Xeon, and P6 family processors. The features and functions of the local APIC are derived from the Intel 82489DX external APIC, which was used with the Intel486 and early Pentium processors. Additional refinements of the local APIC architecture were incorporated in the Pentium 4 and Intel Xeon processors.

### 22.27.1 Software Visible Differences Between the Local APIC and the 82489DX

The following features in the local APIC features differ from those found in the 82489DX external APIC:

- When the local APIC is disabled by clearing the APIC software enable/disable flag in the spurious-interrupt vector MSR, the state of its internal registers are unaffected, except that the mask bits in the LVT are all set to block local interrupts to the processor. Also, the local APIC ceases accepting IPIs except for INIT, SMI, NMI, and start-up IPIs. In the 82489DX, when the local unit is disabled, all the internal registers including the IRR, ISR and TMR are cleared and the mask bits in the LVT are set. In this state, the 82489DX local unit will accept only the reset deassert message.
- In the local APIC, NMI and INIT (except for INIT deassert) are always treated as edge triggered interrupts, even if programmed otherwise. In the 82489DX, these interrupts are always level triggered.
- In the local APIC, IPIs generated through the ICR are always treated as edge triggered (except INIT Deassert). In the 82489DX, the ICR can be used to generate either edge or level triggered IPIs.
- In the local APIC, the logical destination register supports 8 bits; in the 82489DX, it supports 32 bits.
- In the local APIC, the APIC ID register is 4 bits wide; in the 82489DX, it is 8 bits wide.
- The remote read delivery mode provided in the 82489DX and local APIC for Pentium processors is not supported in the local APIC in the Pentium 4, Intel Xeon, and P6 family processors.
- For the 82489DX, in the lowest priority delivery mode, all the target local APICs specified by the destination field participate in the lowest priority arbitration. For the local APIC, only those local APICs which have free interrupt slots will participate in the lowest priority arbitration.

### 22.27.2 New Features Incorporated in the Local APIC for the P6 Family and Pentium Processors

The local APIC in the Pentium and P6 family processors have the following new features not found in the 82489DX external APIC.

- Cluster addressing is supported in logical destination mode.
- Focus processor checking can be enabled/disabled.
- Interrupt input signal polarity can be programmed for the LINT0 and LINT1 pins.
- An SMI IPI is supported through the ICR and I/O redirection table.
- An error status register is incorporated into the LVT to log and report APIC errors.

In the P6 family processors, the local APIC incorporates an additional LVT register to handle performance monitoring counter interrupts.

### 22.27.3 New Features Incorporated in the Local APIC of the Pentium 4 and Intel Xeon Processors

The local APIC in the Pentium 4 and Intel Xeon processors has the following new features not found in the P6 family and Pentium processors and in the 82489DX.

- The local APIC ID is extended to 8 bits.
- An thermal sensor register is incorporated into the LVT to handle thermal sensor interrupts.
- The the ability to deliver lowest-priority interrupts to a focus processor is no longer supported.
- The flat cluster logical destination mode is not supported.

## 22.28 TASK SWITCHING AND TSS

This section identifies the implementation differences of task switching, additions to the TSS and the handling of TSSs and TSS segment selectors.

## 22.28.1 P6 Family and Pentium Processor TSS

When the virtual mode extensions are enabled (by setting the VME flag in control register CR4), the TSS in the P6 family and Pentium processors contain an interrupt redirection bit map, which is used in virtual-8086 mode to redirect interrupts back to an 8086 program.

## 22.28.2 TSS Selector Writes

During task state saves, the Intel486 processor writes 2-byte segment selectors into a 32-bit TSS, leaving the upper 16 bits undefined. For performance reasons, the P6 family and Pentium processors write 4-byte segment selectors into the TSS, with the upper 2 bytes being 0. For compatibility reasons, code should not depend on the value of the upper 16 bits of the selector in the TSS.

## 22.28.3 Order of Reads/Writes to the TSS

The order of reads and writes into the TSS is processor dependent. The P6 family and Pentium processors may generate different page-fault addresses in control register CR2 in the same TSS area than the Intel486 and Intel386 processors, if a TSS crosses a page boundary (which is not recommended).

## 22.28.4 Using A 16-Bit TSS with 32-Bit Constructs

Task switches using 16-bit TSSs should be used only for pure 16-bit code. Any new code written using 32-bit constructs (operands, addressing, or the upper word of the EFLAGS register) should use only 32-bit TSSs. This is due to the fact that the 32-bit processors do not save the upper 16 bits of EFLAGS to a 16-bit TSS. A task switch back to a 16-bit task that was executing in virtual mode will never re-enable the virtual mode, as this flag was not saved in the upper half of the EFLAGS value in the TSS. Therefore, it is strongly recommended that any code using 32-bit constructs use a 32-bit TSS to ensure correct behavior in a multitasking environment.

## 22.28.5 Differences in I/O Map Base Addresses

The Intel486 processor considers the TSS segment to be a 16-bit segment and wraps around the 64K boundary. Any I/O accesses check for permission to access this I/O address at the I/O base address plus the I/O offset. If the I/O map base address exceeds the specified limit of 0DFFFH, an I/O access will wrap around and obtain the permission for the I/O address at an incorrect location within the TSS. A TSS limit violation does not occur in this situation on the Intel486 processor. However, the P6 family and Pentium processors consider the TSS to be a 32-bit segment and a limit violation occurs when the I/O base address plus the I/O offset is greater than the TSS limit. By following the recommended specification for the I/O base address to be less than 0DFFFH, the Intel486 processor will not wrap around and access incorrect locations within the TSS for I/O port validation and the P6 family and Pentium processors will not experience general-protection exceptions (#GP). Figure 22-1 demonstrates the different areas accessed by the Intel486 and the P6 family and Pentium processors.

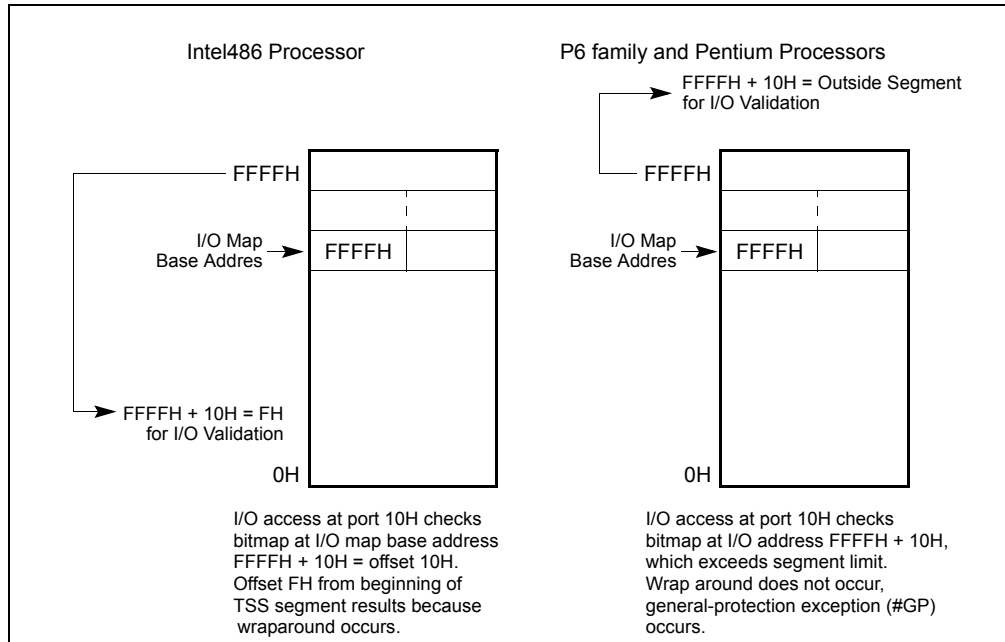

Figure 22-1. I/O Map Base Address Differences

## 22.29 CACHE MANAGEMENT

The P6 family processors include two levels of internal caches: L1 (level 1) and L2 (level 2). The L1 cache is divided into an instruction cache and a data cache; the L2 cache is a general-purpose cache. See Section 11.1, "Internal Caches, TLBs, and Buffers," for a description of these caches. (Note that although the Pentium II processor L2 cache is physically located on a separate chip in the cassette, it is considered an internal cache.)

The Pentium processor includes separate level 1 instruction and data caches. The data cache supports a writeback (or alternatively write-through, on a line by line basis) policy for memory updates.

The Intel486 processor includes a single level 1 cache for both instructions and data.

The meaning of the CD and NW flags in control register CR0 have been redefined for the P6 family and Pentium processors. For these processors, the recommended value (00B) enables writeback for the data cache of the Pentium processor and for the L1 data cache and L2 cache of the P6 family processors. In the Intel486 processor, setting these flags to (00B) enables write-through for the cache.

External system hardware can force the Pentium processor to disable caching or to use the write-through cache policy should that be required. In the P6 family processors, the MTRRs can be used to override the CD and NW flags (see Table 11-6).

The P6 family and Pentium processors support page-level cache management in the same manner as the Intel486 processor by using the PCD and PWT flags in control register CR3, the page-directory entries, and the page-table entries. The Intel486 processor, however, is not affected by the state of the PWT flag since the internal cache of the Intel486 processor is a write-through cache.

### 22.29.1 Self-Modifying Code with Cache Enabled

On the Intel486 processor, a write to an instruction in the cache will modify it in both the cache and memory. If the instruction was prefetched before the write, however, the old version of the instruction could be the one executed. To prevent this problem, it is necessary to flush the instruction prefetch unit of the Intel486 processor by coding a jump instruction immediately after any write that modifies an instruction. The P6 family and Pentium processors, however, check whether a write may modify an instruction that has been prefetched for execution. This check is based on the linear address of the instruction. If the linear address of an instruction is found to be present in the

prefetch queue, the P6 family and Pentium processors flush the prefetch queue, eliminating the need to code a jump instruction after any writes that modify an instruction.

Because the linear address of the write is checked against the linear address of the instructions that have been prefetched, special care must be taken for self-modifying code to work correctly when the physical addresses of the instruction and the written data are the same, but the linear addresses differ. In such cases, it is necessary to execute a serializing operation to flush the prefetch queue after the write and before executing the modified instruction. See Section 8.3, “Serializing Instructions,” for more information on serializing instructions.

### NOTE

The check on linear addresses described above is not in practice a concern for compatibility. Applications that include self-modifying code use the same linear address for modifying and fetching the instruction. System software, such as a debugger, that might possibly modify an instruction using a different linear address than that used to fetch the instruction must execute a serializing operation, such as IRET, before the modified instruction is executed.

## 22.29.2 Disabling the L3 Cache

A unified third-level (L3) cache in processors based on Intel NetBurst microarchitecture (see Section 11.1, “Internal Caches, TLBs, and Buffers”) provides the third-level cache disable flag, bit 6 of the IA32\_MISC\_ENABLE MSR. The third-level cache disable flag allows the L3 cache to be disabled and enabled, independently of the L1 and L2 caches (see Section 11.5.4, “Disabling and Enabling the L3 Cache”). The third-level cache disable flag applies only to processors based on Intel NetBurst microarchitecture. Processors with L3 and based on other microarchitectures do not support the third-level cache disable flag.

## 22.30 PAGING

This section identifies enhancements made to the paging mechanism and implementation differences in the paging mechanism for various IA-32 processors.

### 22.30.1 Large Pages

The Pentium processor extended the memory management/paging facilities of the IA-32 to allow large (4 MBytes) pages sizes (see Section 4.3, “32-Bit Paging”). The first P6 family processor (the Pentium Pro processor) added a 2 MByte page size to the IA-32 in conjunction with the physical address extension (PAE) feature (see Section 4.4, “PAE Paging”).

The availability of large pages with 32-bit paging on any IA-32 processor can be determined via feature bit 3 (PSE) of register EDX after the CPUID instruction has been execution with an argument of 1. (Large pages are always available with PAE paging and IA-32e paging.) Intel processors that do not support the CPUID instruction support only 32-bit paging and do not support page size enhancements. (See “CPUID—CPU Identification” in Chapter 3, “Instruction Set Reference, A-M,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2A*, and AP-485, *Intel Processor Identification and the CPUID Instruction*, for more information on the CPUID instruction.)

### 22.30.2 PCD and PWT Flags

The PCD and PWT flags were introduced to the IA-32 in the Intel486 processor to control the caching of pages:

- PCD (page-level cache disable) flag—Controls caching on a page-by-page basis.
- PWT (page-level write-through) flag—Controls the write-through/writeback caching policy on a page-by-page basis. Since the internal cache of the Intel486 processor is a write-through cache, it is not affected by the state of the PWT flag.

### 22.30.3 Enabling and Disabling Paging

Paging is enabled and disabled by loading a value into control register CR0 that modifies the PG flag. For backward and forward compatibility with all IA-32 processors, Intel recommends that the following operations be performed when enabling or disabling paging:

1. Execute a MOV CR0, REG instruction to either set (enable paging) or clear (disable paging) the PG flag.
2. Execute a near JMP instruction.

The sequence bounded by the MOV and JMP instructions should be identity mapped (that is, the instructions should reside on a page whose linear and physical addresses are identical).

For the P6 family processors, the MOV CR0, REG instruction is serializing, so the jump operation is not required. However, for backwards compatibility, the JMP instruction should still be included.

## 22.31 STACK OPERATIONS

This section identifies the differences in the stack mechanism for the various IA-32 processors.

### 22.31.1 Selector Pushes and Pops

When pushing a segment selector onto the stack, the Pentium 4, Intel Xeon, P6 family, and Intel486 processors decrement the ESP register by the operand size and then write 2 bytes. If the operand size is 32-bits, the upper two bytes of the write are not modified. The Pentium processor decrements the ESP register by the operand size and determines the size of the write by the operand size. If the operand size is 16-bits, the upper two bytes are written as 0s.

When popping a segment selector from the stack, the Pentium 4, Intel Xeon, P6 family, and Intel486 processors read 2 bytes and increment the ESP register by the operand size of the instruction. The Pentium processor determines the size of the read from the operand size and increments the ESP register by the operand size.

It is possible to align a 32-bit selector push or pop such that the operation generates an exception on a Pentium processor and not on an Pentium 4, Intel Xeon, P6 family, or Intel486 processor. This could occur if the third and/or fourth byte of the operation lies beyond the limit of the segment or if the third and/or fourth byte of the operation is located on a non-present or inaccessible page.

For a POP-to-memory instruction that meets the following conditions:

- The stack segment size is 16-bit.
- Any 32-bit addressing form with the SIB byte specifying ESP as the base register.
- The initial stack pointer is FFFCH (32-bit operand) or FFFEh (16-bit operand) and will wrap around to 0h as a result of the POP operation.

The result of the memory write is implementation-specific. For example, in P6 family processors, the result of the memory write is SS:0h plus any scaled index and displacement. In Pentium processors, the result of the memory write may be either a stack fault (real mode or protected mode with stack segment size of 64 KByte), or write to SS:10000h plus any scaled index and displacement (protected mode and stack segment size exceeds 64 KByte).

### 22.31.2 Error Code Pushes

The Intel486 processor implements the error code pushed on the stack as a 16-bit value. When pushed onto a 32-bit stack, the Intel486 processor only pushes 2 bytes and updates ESP by 4. The P6 family and Pentium processors' error code is a full 32 bits with the upper 16 bits set to zero. The P6 family and Pentium processors, therefore, push 4 bytes and update ESP by 4. Any code that relies on the state of the upper 16 bits may produce inconsistent results.

### 22.31.3 Fault Handling Effects on the Stack

During the handling of certain instructions, such as CALL and PUSHA, faults may occur in different sequences for the different processors. For example, during far calls, the Intel486 processor pushes the old CS and EIP before a possible branch fault is resolved. A branch fault is a fault from a branch instruction occurring from a segment limit or access rights violation. If a branch fault is taken, the Intel486 and P6 family processors will have corrupted memory below the stack pointer. However, the ESP register is backed up to make the instruction restartable. The P6 family processors issue the branch before the pushes. Therefore, if a branch fault does occur, these processors do not corrupt memory below the stack pointer. This implementation difference, however, does not constitute a compatibility problem, as only values at or above the stack pointer are considered to be valid. Other operations that encounter faults may also corrupt memory below the stack pointer and this behavior may vary on different implementations.

### 22.31.4 Interlevel RET/IRET From a 16-Bit Interrupt or Call Gate

If a call or interrupt is made from a 32-bit stack environment through a 16-bit gate, only 16 bits of the old ESP can be pushed onto the stack. On the subsequent RET/IRET, the 16-bit ESP is popped but the full 32-bit ESP is updated since control is being resumed in a 32-bit stack environment. The Intel486 processor writes the SS selector into the upper 16 bits of ESP. The P6 family and Pentium processors write zeros into the upper 16 bits.

## 22.32 MIXING 16- AND 32-BIT SEGMENTS

The features of the 16-bit Intel 286 processor are an object-code compatible subset of those of the 32-bit IA-32 processors. The D (default operation size) flag in segment descriptors indicates whether the processor treats a code or data segment as a 16-bit or 32-bit segment; the B (default stack size) flag in segment descriptors indicates whether the processor treats a stack segment as a 16-bit or 32-bit segment.

The segment descriptors used by the Intel 286 processor are supported by the 32-bit IA-32 processors if the Intel-reserved word (highest word) of the descriptor is clear. On the 32-bit IA-32 processors, this word includes the upper bits of the base address and the segment limit.

The segment descriptors for data segments, code segments, local descriptor tables (there are no descriptors for global descriptor tables), and task gates are the same for the 16- and 32-bit processors. Other 16-bit descriptors (TSS segment, call gate, interrupt gate, and trap gate) are supported by the 32-bit processors.

The 32-bit processors also have descriptors for TSS segments, call gates, interrupt gates, and trap gates that support the 32-bit architecture. Both kinds of descriptors can be used in the same system.

For those segment descriptors common to both 16- and 32-bit processors, clear bits in the reserved word cause the 32-bit processors to interpret these descriptors exactly as an Intel 286 processor does, that is:

- Base Address — The upper 8 bits of the 32-bit base address are clear, which limits base addresses to 24 bits.
- Limit — The upper 4 bits of the limit field are clear, restricting the value of the limit field to 64 KBytes.
- Granularity bit — The G (granularity) flag is clear, indicating the value of the 16-bit limit is interpreted in units of 1 byte.
- Big bit — In a data-segment descriptor, the B flag is clear in the segment descriptor used by the 32-bit processors, indicating the segment is no larger than 64 KBytes.
- Default bit — In a code-segment descriptor, the D flag is clear, indicating 16-bit addressing and operands are the default. In a stack-segment descriptor, the D flag is clear, indicating use of the SP register (instead of the ESP register) and a 64-KByte maximum segment limit.

For information on mixing 16- and 32-bit code in applications, see Chapter 21, "Mixing 16-Bit and 32-Bit Code."

## 22.33 SEGMENT AND ADDRESS WRAPAROUND

This section discusses differences in segment and address wraparound between the P6 family, Pentium, Intel486, Intel386, Intel 286, and 8086 processors.

### 22.33.1 Segment Wraparound

On the 8086 processor, an attempt to access a memory operand that crosses offset 65,535 or 0FFFFH or offset 0 (for example, moving a word to offset 65,535 or pushing a word when the stack pointer is set to 1) causes the offset to wrap around modulo 65,536 or 010000H. With the Intel 286 processor, any base and offset combination that addresses beyond 16 MBytes wraps around to the 1 MByte of the address space. The P6 family, Pentium, Intel486, and Intel386 processors in real-address mode generate an exception in these cases:

- A general-protection exception (#GP) if the segment is a data segment (that is, if the CS, DS, ES, FS, or GS register is being used to address the segment).
- A stack-fault exception (#SS) if the segment is a stack segment (that is, if the SS register is being used).

An exception to this behavior occurs when a stack access is data aligned, and the stack pointer is pointing to the last aligned piece of data that size at the top of the stack (ESP is FFFFFFFCH). When this data is popped, no segment limit violation occurs and the stack pointer will wrap around to 0.

The address space of the P6 family, Pentium, and Intel486 processors may wraparound at 1 MByte in real-address mode. An external A20M# pin forces wraparound if enabled. On Intel 8086 processors, it is possible to specify addresses greater than 1 MByte. For example, with a selector value FFFFH and an offset of FFFFH, the effective address would be 10FFEFH (1 MByte plus 65519 bytes). The 8086 processor, which can form addresses up to 20 bits long, truncates the uppermost bit, which “wraps” this address to FFEFH. However, the P6 family, Pentium, and Intel486 processors do not truncate this bit if A20M# is not enabled.

If a stack operation wraps around the address limit, shutdown occurs. (The 8086 processor does not have a shutdown mode or a limit.)

The behavior when executing near the limit of a 4-GByte selector (limit=0xFFFFFFFF) is different between the Pentium Pro and the Pentium 4 family of processors. On the Pentium Pro, instructions which cross the limit -- for example, a two byte instruction such as INC EAX that is encoded as 0xFF 0xC0 starting exactly at the limit faults for a segment violation (a one byte instruction at 0xFFFFFFFF does not cause an exception). Using the Pentium 4 microprocessor family, neither of these situations causes a fault.

Segment wraparound and the functionality of A20M# is used primarily by older operating systems and not used by modern operating systems. On newer Intel 64 processors, A20M# may be absent.

## 22.34 STORE BUFFERS AND MEMORY ORDERING

The Pentium 4, Intel Xeon, and P6 family processors provide a store buffer for temporary storage of writes (stores) to memory (see Section 11.10, “Store Buffer”). Writes stored in the store buffer(s) are always written to memory in program order, with the exception of “fast string” store operations (see Section 8.2.4, “Fast-String Operation and Out-of-Order Stores”).

The Pentium processor has two store buffers, one corresponding to each of the pipelines. Writes in these buffers are always written to memory in the order they were generated by the processor core.

It should be noted that only memory writes are buffered and I/O writes are not. The Pentium 4, Intel Xeon, P6 family, Pentium, and Intel486 processors do not synchronize the completion of memory writes on the bus and instruction execution after a write. An I/O, locked, or serializing instruction needs to be executed to synchronize writes with the next instruction (see Section 8.3, “Serializing Instructions”).

The Pentium 4, Intel Xeon, and P6 family processors use processor ordering to maintain consistency in the order that data is read (loaded) and written (stored) in a program and the order the processor actually carries out the reads and writes. With this type of ordering, reads can be carried out speculatively and in any order, reads can pass buffered writes, and writes to memory are always carried out in program order. (See Section 8.2, “Memory Ordering,” for more information about processor ordering.) The Pentium III processor introduced a new instruction to serialize writes and make them globally visible. Memory ordering issues can arise between a producer and a consumer of data. The SFENCE instruction provides a performance-efficient way of ensuring ordering between routines that produce weakly-ordered results and routines that consume this data.

No re-ordering of reads occurs on the Pentium processor, except under the condition noted in Section 8.2.1, “Memory Ordering in the Intel® Pentium® and Intel486™ Processors,” and in the following paragraph describing the Intel486 processor.

Specifically, the store buffers are flushed before the IN instruction is executed. No reads (as a result of cache miss) are reordered around previously generated writes sitting in the store buffers. The implication of this is that the store buffers will be flushed or emptied before a subsequent bus cycle is run on the external bus.

On both the Intel486 and Pentium processors, under certain conditions, a memory read will go onto the external bus before the pending memory writes in the buffer even though the writes occurred earlier in the program execution. A memory read will only be reordered in front of all writes pending in the buffers if all writes pending in the buffers are cache hits and the read is a cache miss. Under these conditions, the Intel486 and Pentium processors will not read from an external memory location that needs to be updated by one of the pending writes.

During a locked bus cycle, the Intel486 processor will always access external memory, it will never look for the location in the on-chip cache. All data pending in the Intel486 processor's store buffers will be written to memory before a locked cycle is allowed to proceed to the external bus. Thus, the locked bus cycle can be used for eliminating the possibility of reordering read cycles on the Intel486 processor. The Pentium processor does check its cache on a read-modify-write access and, if the cache line has been modified, writes the contents back to memory before locking the bus. The P6 family processors write to their cache on a read-modify-write operation (if the access does not split across a cache line) and does not write back to system memory. If the access does split across a cache line, it locks the bus and accesses system memory.

I/O reads are never reordered in front of buffered memory writes on an IA-32 processor. This ensures an update of all memory locations before reading the status from an I/O device.

## 22.35 BUS LOCKING

The Intel 286 processor performs the bus locking differently than the Intel P6 family, Pentium, Intel486, and Intel386 processors. Programs that use forms of memory locking specific to the Intel 286 processor may not run properly when run on later processors.

A locked instruction is guaranteed to lock only the area of memory defined by the destination operand, but may lock a larger memory area. For example, typical 8086 and Intel 286 configurations lock the entire physical memory space. Programmers should not depend on this.

On the Intel 286 processor, the LOCK prefix is sensitive to IOPL. If the CPL is greater than the IOPL, a general-protection exception (#GP) is generated. On the Intel386 DX, Intel486, and Pentium, and P6 family processors, no check against IOPL is performed.

The Pentium processor automatically asserts the LOCK# signal when acknowledging external interrupts. After signaling an interrupt request, an external interrupt controller may use the data bus to send the interrupt vector to the processor. After receiving the interrupt request signal, the processor asserts LOCK# to insure that no other data appears on the data bus until the interrupt vector is received. This bus locking does not occur on the P6 family processors.

## 22.36 BUS HOLD

Unlike the 8086 and Intel 286 processors, but like the Intel386 and Intel486 processors, the P6 family and Pentium processors respond to requests for control of the bus from other potential bus masters, such as DMA controllers, between transfers of parts of an unaligned operand, such as two words which form a doubleword. Unlike the Intel386 processor, the P6 family, Pentium and Intel486 processors respond to bus hold during reset initialization.

## 22.37 MODEL-SPECIFIC EXTENSIONS TO THE IA-32

Certain extensions to the IA-32 are specific to a processor or family of IA-32 processors and may not be implemented or implemented in the same way in future processors. The following sections describe these model-specific extensions. The CPUID instruction indicates the availability of some of the model-specific features.

### 22.37.1 Model-Specific Registers

The Pentium processor introduced a set of model-specific registers (MSRs) for use in controlling hardware functions and performance monitoring. To access these MSRs, two new instructions were added to the IA-32 architecture: read MSR (RDMSR) and write MSR (WRMSR). The MSRs in the Pentium processor are not guaranteed to be duplicated or provided in the next generation IA-32 processors.

The P6 family processors greatly increased the number of MSRs available to software. See Chapter 35, “Model-Specific Registers (MSRs),” for a complete list of the available MSRs. The new registers control the debug extensions, the performance counters, the machine-check exception capability, the machine-check architecture, and the MTRRs. These registers are accessible using the RDMSR and WRMSR instructions. Specific information on some of these new MSRs is provided in the following sections. As with the Pentium processor MSR, the P6 family processor MSRs are not guaranteed to be duplicated or provided in the next generation IA-32 processors.

### 22.37.2 RDMSR and WRMSR Instructions

The RDMSR (read model-specific register) and WRMSR (write model-specific register) instructions recognize a much larger number of model-specific registers in the P6 family processors. (See “RDMSR—Read from Model Specific Register” and “WRMSR—Write to Model Specific Register” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volumes 2A, 2B & 2C* for more information.)

### 22.37.3 Memory Type Range Registers

Memory type range registers (MTRRs) are a new feature introduced into the IA-32 in the Pentium Pro processor. MTRRs allow the processor to optimize memory operations for different types of memory, such as RAM, ROM, frame buffer memory, and memory-mapped I/O.

MTRRs are MSRs that contain an internal map of how physical address ranges are mapped to various types of memory. The processor uses this internal memory map to determine the cacheability of various physical memory locations and the optimal method of accessing memory locations. For example, if a memory location is specified in an MTRR as write-through memory, the processor handles accesses to this location as follows. It reads data from that location in lines and caches the read data or maps all writes to that location to the bus and updates the cache to maintain cache coherency. In mapping the physical address space with MTRRs, the processor recognizes five types of memory: uncacheable (UC), uncacheable, speculatable, write-combining (WC), write-through (WT), write-protected (WP), and writeback (WB).

Earlier IA-32 processors (such as the Intel486 and Pentium processors) used the KEN# (cache enable) pin and external logic to maintain an external memory map and signal cacheable accesses to the processor. The MTRR mechanism simplifies hardware designs by eliminating the KEN# pin and the external logic required to drive it.

See Chapter 9, “Processor Management and Initialization,” and Chapter 35, “Model-Specific Registers (MSRs),” for more information on the MTRRs.

### 22.37.4 Machine-Check Exception and Architecture

The Pentium processor introduced a new exception called the machine-check exception (#MC, interrupt 18). This exception is used to detect hardware-related errors, such as a parity error on a read cycle.

The P6 family processors extend the types of errors that can be detected and that generate a machine-check exception. It also provides a new machine-check architecture for recording information about a machine-check error and provides extended recovery capability.

The machine-check architecture provides several banks of reporting registers for recording machine-check errors. Each bank of registers is associated with a specific hardware unit in the processor. The primary focus of the machine checks is on bus and interconnect operations; however, checks are also made of translation lookaside buffer (TLB) and cache operations.

The machine-check architecture can correct some errors automatically and allow for reliable restart of instruction execution. It also collects sufficient information for software to use in correcting other machine errors not corrected by hardware.

See Chapter 15, “Machine-Check Architecture,” for more information on the machine-check exception and the machine-check architecture.

### 22.37.5 Performance-Monitoring Counters

The P6 family and Pentium processors provide two performance-monitoring counters for use in monitoring internal hardware operations. The number of performance monitoring counters and associated programming interfaces may be implementation specific for Pentium 4 processors, Pentium M processors. Later processors may have implemented these as part of an architectural performance monitoring feature. The architectural and non-architectural performance monitoring interfaces for different processor families are described in Chapter 18, “Performance Monitoring,”. Chapter 19, “Performance Monitoring Events,” lists all the events that can be counted for architectural performance monitoring events and non-architectural events. The counters are set up, started, and stopped using two MSR and the RDMSR and WRMSR instructions. For the P6 family processors, the current count for a particular counter can be read using the new RDPMC instruction.

The performance-monitoring counters are useful for debugging programs, optimizing code, diagnosing system failures, or refining hardware designs. See Chapter 18, “Performance Monitoring,” for more information on these counters.

## 22.38 TWO WAYS TO RUN INTEL 286 PROCESSOR TASKS

When porting 16-bit programs to run on 32-bit IA-32 processors, there are two approaches to consider:

- Porting an entire 16-bit software system to a 32-bit processor, complete with the old operating system, loader, and system builder. Here, all tasks will have 16-bit TSSs. The 32-bit processor is being used as if it were a faster version of the 16-bit processor.
- Porting selected 16-bit applications to run in a 32-bit processor environment with a 32-bit operating system, loader, and system builder. Here, the TSSs used to represent 286 tasks should be changed to 32-bit TSSs. It is possible to mix 16 and 32-bit TSSs, but the benefits are small and the problems are great. All tasks in a 32-bit software system should have 32-bit TSSs. It is not necessary to change the 16-bit object modules themselves; TSSs are usually constructed by the operating system, by the loader, or by the system builder. See Chapter 21, “Mixing 16-Bit and 32-Bit Code,” for more detailed information about mixing 16-bit and 32-bit code.

Because the 32-bit processors use the contents of the reserved word of 16-bit segment descriptors, 16-bit programs that place values in this word may not run correctly on the 32-bit processors.

### 23.1 OVERVIEW

This chapter describes the basics of virtual machine architecture and an overview of the virtual-machine extensions (VMX) that support virtualization of processor hardware for multiple software environments.

Information about VMX instructions is provided in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B*. Other aspects of VMX and system programming considerations are described in chapters of *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3B*.

### 23.2 VIRTUAL MACHINE ARCHITECTURE

Virtual-machine extensions define processor-level support for virtual machines on IA-32 processors. Two principal classes of software are supported:

- **Virtual-machine monitors (VMM)** — A VMM acts as a host and has full control of the processor(s) and other platform hardware. A VMM presents guest software (see next paragraph) with an abstraction of a virtual processor and allows it to execute directly on a logical processor. A VMM is able to retain selective control of processor resources, physical memory, interrupt management, and I/O.
- **Guest software** — Each virtual machine (VM) is a guest software environment that supports a stack consisting of operating system (OS) and application software. Each operates independently of other virtual machines and uses on the same interface to processor(s), memory, storage, graphics, and I/O provided by a physical platform. The software stack acts as if it were running on a platform with no VMM. Software executing in a virtual machine must operate with reduced privilege so that the VMM can retain control of platform resources.

### 23.3 INTRODUCTION TO VMX OPERATION

Processor support for virtualization is provided by a form of processor operation called VMX operation. There are two kinds of VMX operation: VMX root operation and VMX non-root operation. In general, a VMM will run in VMX root operation and guest software will run in VMX non-root operation. Transitions between VMX root operation and VMX non-root operation are called VMX transitions. There are two kinds of VMX transitions. Transitions into VMX non-root operation are called VM entries. Transitions from VMX non-root operation to VMX root operation are called VM exits.

Processor behavior in VMX root operation is very much as it is outside VMX operation. The principal differences are that a set of new instructions (the VMX instructions) is available and that the values that can be loaded into certain control registers are limited (see Section 23.8).

Processor behavior in VMX non-root operation is restricted and modified to facilitate virtualization. Instead of their ordinary operation, certain instructions (including the new VMCALL instruction) and events cause VM exits to the VMM. Because these VM exits replace ordinary behavior, the functionality of software in VMX non-root operation is limited. It is this limitation that allows the VMM to retain control of processor resources.

There is no software-visible bit whose setting indicates whether a logical processor is in VMX non-root operation. This fact may allow a VMM to prevent guest software from determining that it is running in a virtual machine.

Because VMX operation places restrictions even on software running with current privilege level (CPL) 0, guest software can run at the privilege level for which it was originally designed. This capability may simplify the development of a VMM.

## 23.4 LIFE CYCLE OF VMM SOFTWARE

Figure 23-1 illustrates the life cycle of a VMM and its guest software as well as the interactions between them. The following items summarize that life cycle:

- Software enters VMX operation by executing a VMXON instruction.
- Using VM entries, a VMM can then enter guests into virtual machines (one at a time). The VMM effects a VM entry using instructions VMLAUNCH and VMRESUME; it regains control using VM exits.
- VM exits transfer control to an entry point specified by the VMM. The VMM can take action appropriate to the cause of the VM exit and can then return to the virtual machine using a VM entry.
- Eventually, the VMM may decide to shut itself down and leave VMX operation. It does so by executing the VMXOFF instruction.

Figure 23-1. Interaction of a Virtual-Machine Monitor and Guests

## 23.5 VIRTUAL-MACHINE CONTROL STRUCTURE

VMX non-root operation and VMX transitions are controlled by a data structure called a virtual-machine control structure (VMCS).

Access to the VMCS is managed through a component of processor state called the VMCS pointer (one per logical processor). The value of the VMCS pointer is the 64-bit address of the VMCS. The VMCS pointer is read and written using the instructions VMPTRST and VMPTRLD. The VMM configures a VMCS using the VMREAD, VMWRITE, and VMCLEAR instructions.

A VMM could use a different VMCS for each virtual machine that it supports. For a virtual machine with multiple logical processors (virtual processors), the VMM could use a different VMCS for each virtual processor.

## 23.6 DISCOVERING SUPPORT FOR VMX

Before system software enters into VMX operation, it must discover the presence of VMX support in the processor. System software can determine whether a processor supports VMX operation using CPUID. If CPUID.1:ECX.VMX[bit 5] = 1, then VMX operation is supported. See Chapter 3, “Instruction Set Reference, A-M” of *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2A*.

The VMX architecture is designed to be extensible so that future processors in VMX operation can support additional features not present in first-generation implementations of the VMX architecture. The availability of extensible VMX features is reported to software using a set of VMX capability MSRs (see Appendix A, “VMX Capability Reporting Facility”).

## 23.7 ENABLING AND ENTERING VMX OPERATION

Before system software can enter VMX operation, it enables VMX by setting `CR4.VMXE[bit 13] = 1`. VMX operation is then entered by executing the `VMXON` instruction. `VMXON` causes an invalid-opcode exception (`#UD`) if executed with `CR4.VMXE = 0`. Once in VMX operation, it is not possible to clear `CR4.VMXE` (see Section 23.8). System software leaves VMX operation by executing the `VMXOFF` instruction. `CR4.VMXE` can be cleared outside of VMX operation after executing of `VMXOFF`.

`VMXON` is also controlled by the `IA32_FEATURE_CONTROL` MSR (MSR address 3AH). This MSR is cleared to zero when a logical processor is reset. The relevant bits of the MSR are:

- **Bit 0 is the lock bit.** If this bit is clear, `VMXON` causes a general-protection exception. If the lock bit is set, `WRMSR` to this MSR causes a general-protection exception; the MSR cannot be modified until a power-up reset condition. System BIOS can use this bit to provide a setup option for BIOS to disable support for VMX. To enable VMX support in a platform, BIOS must set bit 1, bit 2, or both (see below), as well as the lock bit.
- **Bit 1 enables VMXON in SMX operation.** If this bit is clear, execution of `VMXON` in SMX operation causes a general-protection exception. Attempts to set this bit on logical processors that do not support both VMX operation (see Section 23.6) and SMX operation (see Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*) cause general-protection exceptions.
- **Bit 2 enables VMXON outside SMX operation.** If this bit is clear, execution of `VMXON` outside SMX operation causes a general-protection exception. Attempts to set this bit on logical processors that do not support VMX operation (see Section 23.6) cause general-protection exceptions.

### NOTE

A logical processor is in SMX operation if `GETSEC[SEXIT]` has not been executed since the last execution of `GETSEC[SENTER]`. A logical processor is outside SMX operation if `GETSEC[SENTER]` has not been executed or if `GETSEC[SEXIT]` was executed after the last execution of `GETSEC[SENTER]`. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

Before executing `VMXON`, software should allocate a naturally aligned 4-KByte region of memory that a logical processor may use to support VMX operation.<sup>1</sup> This region is called the **VMXON region**. The address of the VMXON region (the VMXON pointer) is provided in an operand to `VMXON`. Section 24.11.5, “VMXON Region,” details how software should initialize and access the VMXON region.

## 23.8 RESTRICTIONS ON VMX OPERATION

VMX operation places restrictions on processor operation. These are detailed below:

- In VMX operation, processors may fix certain bits in `CR0` and `CR4` to specific values and not support other values. `VMXON` fails if any of these bits contains an unsupported value (see “VMXON—Enter VMX Operation” in Chapter 30). Any attempt to set one of these bits to an unsupported value while in VMX operation (including VMX root operation) using any of the `CLTS`, `LMSW`, or `MOV CR` instructions causes a general-protection exception. VM entry or VM exit cannot set any of these bits to an unsupported value.<sup>2</sup>

### NOTES

The first processors to support VMX operation require that the following bits be 1 in VMX operation: `CR0.PE`, `CR0.NE`, `CR0.PG`, and `CR4.VMXE`. The restrictions on `CR0.PE` and `CR0.PG` imply that VMX operation is supported only in paged protected mode (including IA-32e mode). Therefore, guest software cannot be run in unpagged protected mode or in real-address mode. See Section 31.2,

1. Future processors may require that a different amount of memory be reserved. If so, this fact is reported to software using the VMX capability-reporting mechanism.
2. Software should consult the VMX capability MSRs `IA32_VMX_CR0_FIXED0` and `IA32_VMX_CR0_FIXED1` to determine how bits in `CR0` are set. (see Appendix A.7). For `CR4`, software should consult the VMX capability MSRs `IA32_VMX_CR4_FIXED0` and `IA32_VMX_CR4_FIXED1` (see Appendix A.8).

“Supporting Processor Operating Modes in Guest Environments,” for a discussion of how a VMM might support guest software that expects to run in unpagged protected mode or in real-address mode.

Later processors support a VM-execution control called “unrestricted guest” (see Section 24.6.2). If this control is 1, CRO.PE and CRO.PG may be 0 in VMX non-root operation (even if the capability MSR IA32\_VMX\_CR0\_FIXED0 reports otherwise).<sup>1</sup> Such processors allow guest software to run in unpagged protected mode or in real-address mode.

- VMXON fails if a logical processor is in A20M mode (see “VMXON—Enter VMX Operation” in Chapter 30). Once the processor is in VMX operation, A20M interrupts are blocked. Thus, it is impossible to be in A20M mode in VMX operation.
- The INIT signal is blocked whenever a logical processor is in VMX root operation. It is not blocked in VMX non-root operation. Instead, INITs cause VM exits (see Section 25.2, “Other Causes of VM Exits”).

---

1. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “unrestricted guest” VM-execution control were 0. See Section 24.6.2.

### 24.1 OVERVIEW

A logical processor uses **virtual-machine control data structures (VMCSs)** while it is in VMX operation. These manage transitions into and out of VMX non-root operation (VM entries and VM exits) as well as processor behavior in VMX non-root operation. This structure is manipulated by the new instructions VMCLEAR, VMPTRLD, VMREAD, and VMWRITE.

A VMM can use a different VMCS for each virtual machine that it supports. For a virtual machine with multiple logical processors (virtual processors), the VMM can use a different VMCS for each virtual processor.

A logical processor associates a region in memory with each VMCS. This region is called the **VMCS region**.<sup>1</sup> Software references a specific VMCS using the 64-bit physical address of the region (a **VMCS pointer**). VMCS pointers must be aligned on a 4-KByte boundary (bits 11:0 must be zero). These pointers must not set bits beyond the processor's physical-address width.<sup>2,3</sup>

A logical processor may maintain a number of VMCSs that are **active**. The processor may optimize VMX operation by maintaining the state of an active VMCS in memory, on the processor, or both. At any given time, at most one of the active VMCSs is the **current** VMCS. (This document frequently uses the term "the VMCS" to refer to the current VMCS.) The VMLAUNCH, VMREAD, VMRESUME, and VMWRITE instructions operate only on the current VMCS.

The following items describe how a logical processor determines which VMCSs are active and which is current:

- The memory operand of the VMPTRLD instruction is the address of a VMCS. After execution of the instruction, that VMCS is both active and current on the logical processor. Any other VMCS that had been active remains so, but no other VMCS is current.
- The VMCS link pointer field in the current VMCS (see Section 24.4.2) is itself the address of a VMCS. If VM entry is performed successfully with the 1-setting of the "VMCS shadowing" VM-execution control, the VMCS referenced by the VMCS link pointer field becomes active on the logical processor. The identity of the current VMCS does not change.
- The memory operand of the VMCLEAR instruction is also the address of a VMCS. After execution of the instruction, that VMCS is neither active nor current on the logical processor. If the VMCS had been current on the logical processor, the logical processor no longer has a current VMCS.

The VMPTRST instruction stores the address of the logical processor's current VMCS into a specified memory location (it stores the value FFFFFFFF\_FFFFFFFFH if there is no current VMCS).

The **launch state** of a VMCS determines which VM-entry instruction should be used with that VMCS: the VMLAUNCH instruction requires a VMCS whose launch state is "clear"; the VMRESUME instruction requires a VMCS whose launch state is "launched". A logical processor maintains a VMCS's launch state in the corresponding VMCS region. The following items describe how a logical processor manages the launch state of a VMCS:

- If the launch state of the current VMCS is "clear", successful execution of the VMLAUNCH instruction changes the launch state to "launched".
- The memory operand of the VMCLEAR instruction is the address of a VMCS. After execution of the instruction, the launch state of that VMCS is "clear".
- There are no other ways to modify the launch state of a VMCS (it cannot be modified using VMWRITE) and there is no direct way to discover it (it cannot be read using VMREAD).

---

1. The amount of memory required for a VMCS region is at most 4 KBytes. The exact size is implementation specific and can be determined by consulting the VMX capability MSR IA32\_VMX\_BASIC to determine the size of the VMCS region (see Appendix A.1).

2. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

3. If IA32\_VMX\_BASIC[48] is read as 1, these pointers must not set any bits in the range 63:32; see Appendix A.1.

Figure 24-1 illustrates the different states of a VMCS. It uses “X” to refer to the VMCS and “Y” to refer to any other VMCS. Thus: “VMPTRLD X” always makes X current and active; “VMPTRLD Y” always makes X not current (because it makes Y current); VMLAUNCH makes the launch state of X “launched” if X was current and its launch state was “clear”; and VMCLEAR X always makes X inactive and not current and makes its launch state “clear”.

The figure does not illustrate operations that do not modify the VMCS state relative to these parameters (e.g., execution of VMPTRLD X when X is already current). Note that VMCLEAR X makes X “inactive, not current, and clear,” even if X’s current state is not defined (e.g., even if X has not yet been initialized). See Section 24.11.3.

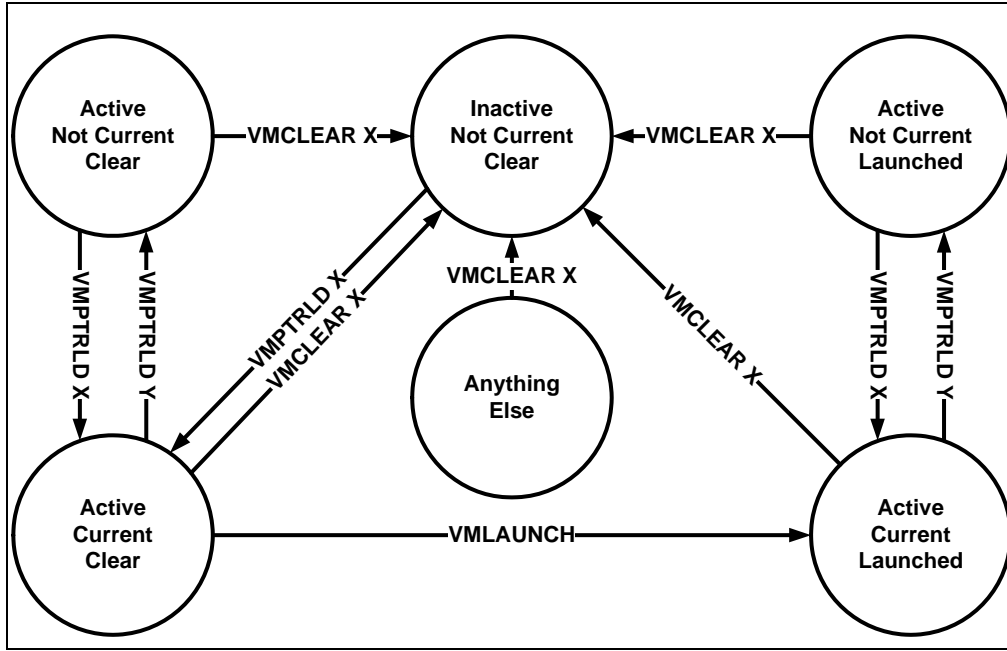

Figure 24-1. States of VMCS X

Because a shadow VMCS (see Section 24.10) cannot be used for VM entry, the launch state of a shadow VMCS is not meaningful. Figure 24-1 does not illustrate all the ways in which a shadow VMCS may be made active.

## 24.2 FORMAT OF THE VMCS REGION

A VMCS region comprises up to 4-KBytes.<sup>1</sup> The format of a VMCS region is given in Table 24-1.

Table 24-1. Format of the VMCS Region

Byte Offset	Contents
0	Bits 30:0: VMCS revision identifier Bit 31: shadow-VMCS indicator (see Section 24.10)
4	VMX-abort indicator
8	VMCS data (implementation-specific format)

The first 4 bytes of the VMCS region contain the **VMCS revision identifier** at bits 30:0.<sup>2</sup> Processors that maintain VMCS data in different formats (see below) use different VMCS revision identifiers. These identifiers enable soft-

1. The exact size is implementation specific and can be determined by consulting the VMX capability MSR IA32\_VMX\_BASIC to determine the size of the VMCS region (see Appendix A.1).

ware to avoid using a VMCS region formatted for one processor on a processor that uses a different format.<sup>1</sup> Bit 31 of this 4-byte region indicates whether the VMCS is a shadow VMCS (see Section 24.10).

Software should write the VMCS revision identifier to the VMCS region before using that region for a VMCS. The VMCS revision identifier is never written by the processor; VMPTRLD fails if its operand references a VMCS region whose VMCS revision identifier differs from that used by the processor. (VMPTRLD also fails if the shadow-VMCS indicator is 1 and the processor does not support the 1-setting of the “VMCS shadowing” VM-execution control; see Section 24.6.2) Software can discover the VMCS revision identifier that a processor uses by reading the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1).

Software should clear or set the shadow-VMCS indicator depending on whether the VMCS is to be an ordinary VMCS or a shadow VMCS (see Section 24.10). VMPTRLD fails if the shadow-VMCS indicator is set and the processor does not support the 1-setting of the “VMCS shadowing” VM-execution control. Software can discover support for this setting by reading the VMX capability MSR IA32\_VMX\_PROCBASED\_CTLS2 (see Appendix A.3.3).

The next 4 bytes of the VMCS region are used for the **VMX-abort indicator**. The contents of these bits do not control processor operation in any way. A logical processor writes a non-zero value into these bits if a VMX abort occurs (see Section 27.7). Software may also write into this field.

The remainder of the VMCS region is used for **VMCS data** (those parts of the VMCS that control VMX non-root operation and the VMX transitions). The format of these data is implementation-specific. VMCS data are discussed in Section 24.3 through Section 24.9. To ensure proper behavior in VMX operation, software should maintain the VMCS region and related structures (enumerated in Section 24.11.4) in writeback cacheable memory. Future implementations may allow or require a different memory type<sup>2</sup>. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1).

## 24.3 ORGANIZATION OF VMCS DATA

The VMCS data are organized into six logical groups:

- **Guest-state area.** Processor state is saved into the guest-state area on VM exits and loaded from there on VM entries.
- **Host-state area.** Processor state is loaded from the host-state area on VM exits.
- **VM-execution control fields.** These fields control processor behavior in VMX non-root operation. They determine in part the causes of VM exits.
- **VM-exit control fields.** These fields control VM exits.
- **VM-entry control fields.** These fields control VM entries.
- **VM-exit information fields.** These fields receive information on VM exits and describe the cause and the nature of VM exits. On some processors, these fields are read-only.<sup>3</sup>

The VM-execution control fields, the VM-exit control fields, and the VM-entry control fields are sometimes referred to collectively as VMX controls.

---

2. Earlier versions of this manual specified that the VMCS revision identifier was a 32-bit field. For all processors produced prior to this change, bit 31 of the VMCS revision identifier was 0.

1. Logical processors that use the same VMCS revision identifier use the same size for VMCS regions.

2. Alternatively, software may map any of these regions or structures with the UC memory type. Doing so is strongly discouraged unless necessary as it will cause the performance of transitions using those structures to suffer significantly. In addition, the processor will continue to use the memory type reported in the VMX capability MSR IA32\_VMX\_BASIC with exceptions noted in Appendix A.1.

3. Software can discover whether these fields can be written by reading the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6).

## 24.4 GUEST-STATE AREA

This section describes fields contained in the guest-state area of the VMCS. As noted earlier, processor state is loaded from these fields on every VM entry (see Section 26.3.2) and stored into these fields on every VM exit (see Section 27.3).

### 24.4.1 Guest Register State

The following fields in the guest-state area correspond to processor registers:

- Control registers CR0, CR3, and CR4 (64 bits each; 32 bits on processors that do not support Intel 64 architecture).
- Debug register DR7 (64 bits; 32 bits on processors that do not support Intel 64 architecture).
- RSP, RIP, and RFLAGS (64 bits each; 32 bits on processors that do not support Intel 64 architecture).<sup>1</sup>
- The following fields for each of the registers CS, SS, DS, ES, FS, GS, LDTR, and TR:
  - Selector (16 bits).
  - Base address (64 bits; 32 bits on processors that do not support Intel 64 architecture). The base-address fields for CS, SS, DS, and ES have only 32 architecturally-defined bits; nevertheless, the corresponding VMCS fields have 64 bits on processors that support Intel 64 architecture.
  - Segment limit (32 bits). The limit field is always a measure in bytes.
  - Access rights (32 bits). The format of this field is given in Table 24-2 and detailed as follows:
    - The low 16 bits correspond to bits 23:8 of the upper 32 bits of a 64-bit segment descriptor. While bits 19:16 of code-segment and data-segment descriptors correspond to the upper 4 bits of the segment limit, the corresponding bits (bits 11:8) are reserved in this VMCS field.
    - Bit 16 indicates an **unusable segment**. Attempts to use such a segment fault except in 64-bit mode. In general, a segment register is unusable if it has been loaded with a null selector.<sup>2</sup>
    - Bits 31:17 are reserved.

**Table 24-2. Format of Access Rights**

Bit Position(s)	Field
3:0	Segment type
4	S — Descriptor type (0 = system; 1 = code or data)
6:5	DPL — Descriptor privilege level
7	P — Segment present
11:8	Reserved
12	AVL — Available for use by system software

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.
2. There are a few exceptions to this statement. For example, a segment with a non-null selector may be unusable following a task switch that fails after its commit point; see “Interrupt 10—Invalid TSS Exception (#TS)” in Section 6.14, “Exception and Interrupt Handling in 64-bit Mode,” of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*. In contrast, the TR register is usable after processor reset despite having a null selector; see Table 10-1 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

Table 24-2. Format of Access Rights (Contd.)

Bit Position(s)	Field
13	Reserved (except for CS) L — 64-bit mode active (for CS only)
14	D/B — Default operation size (0 = 16-bit segment; 1 = 32-bit segment)
15	G — Granularity
16	Segment unusable (0 = usable; 1 = unusable)
31:17	Reserved

The base address, segment limit, and access rights compose the “hidden” part (or “descriptor cache”) of each segment register. These data are included in the VMCS because it is possible for a segment register’s descriptor cache to be inconsistent with the segment descriptor in memory (in the GDT or the LDT) referenced by the segment register’s selector.

The value of the DPL field for SS is always equal to the logical processor’s current privilege level (CPL).<sup>1</sup>

- The following fields for each of the registers GDTR and IDTR:
  - Base address (64 bits; 32 bits on processors that do not support Intel 64 architecture).
  - Limit (32 bits). The limit fields contain 32 bits even though these fields are specified as only 16 bits in the architecture.
- The following MSRs:
  - IA32\_DEBUGCTL (64 bits)
  - IA32\_SYSENTER\_CS (32 bits)
  - IA32\_SYSENTER\_ESP and IA32\_SYSENTER\_EIP (64 bits; 32 bits on processors that do not support Intel 64 architecture)
  - IA32\_PERF\_GLOBAL\_CTRL (64 bits). This field is supported only on processors that support the 1-setting of the “load IA32\_PERF\_GLOBAL\_CTRL” VM-entry control.
  - IA32\_PAT (64 bits). This field is supported only on processors that support either the 1-setting of the “load IA32\_PAT” VM-entry control or that of the “save IA32\_PAT” VM-exit control.
  - IA32\_EFER (64 bits). This field is supported only on processors that support either the 1-setting of the “load IA32\_EFER” VM-entry control or that of the “save IA32\_EFER” VM-exit control.
- The register SMBASE (32 bits). This register contains the base address of the logical processor’s SMRAM image.

## 24.4.2 Guest Non-Register State

In addition to the register state described in Section 24.4.1, the guest-state area includes the following fields that characterize guest state but which do not correspond to processor registers:

- **Activity state** (32 bits). This field identifies the logical processor’s activity state. When a logical processor is executing instructions normally, it is in the **active state**. Execution of certain instructions and the occurrence of certain events may cause a logical processor to transition to an **inactive state** in which it ceases to execute instructions.

The following activity states are defined:<sup>2</sup>

- 0: **Active**. The logical processor is executing instructions normally.

1. In protected mode, CPL is also associated with the RPL field in the CS selector. However, the RPL fields are not meaningful in real-address mode or in virtual-8086 mode.

2. Execution of the MWAIT instruction may put a logical processor into an inactive state. However, this VMCS field never reflects this state. See Section 27.1.

- 1: **HLT**. The logical processor is inactive because it executed the HLT instruction.
- 2: **Shutdown**. The logical processor is inactive because it incurred a **triple fault**<sup>1</sup> or some other serious error.
- 3: **Wait-for-SIPI**. The logical processor is inactive because it is waiting for a startup-IPI (SIPI).

Future processors may include support for other activity states. Software should read the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6) to determine what activity states are supported.

- **Interruptibility state** (32 bits). The IA-32 architecture includes features that permit certain events to be blocked for a period of time. This field contains information about such blocking. Details and the format of this field are given in Table 24-3.

**Table 24-3. Format of Interruptibility State**

Bit Position(s)	Bit Name	Notes
0	Blocking by STI	See the “STI—Set Interrupt Flag” section in Chapter 4 of the <i>Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B</i> . Execution of STI with RFLAGS.IF = 0 blocks interrupts (and, optionally, other events) for one instruction after its execution. Setting this bit indicates that this blocking is in effect.
1	Blocking by MOV SS	See the “MOV—Move a Value from the Stack” from Chapter 3 of the <i>Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2A</i> , and “POP—Pop a Value from the Stack” from Chapter 4 of the <i>Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B</i> , and Section 6.8.3 in the <i>Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A</i> . Execution of a MOV to SS or a POP to SS blocks interrupts for one instruction after its execution. In addition, certain debug exceptions are inhibited between a MOV to SS or a POP to SS and a subsequent instruction. Setting this bit indicates that the blocking of all these events is in effect. This document uses the term “blocking by MOV SS,” but it applies equally to POP SS.
2	Blocking by SMI	See Section 34.2. System-management interrupts (SMIs) are disabled while the processor is in system-management mode (SMM). Setting this bit indicates that blocking of SMIs is in effect.
3	Blocking by NMI	See Section 6.7.1 in the <i>Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A</i> and Section 34.8. Delivery of a non-maskable interrupt (NMI) or a system-management interrupt (SMI) blocks subsequent NMIs until the next execution of IRET. See Section 25.3 for how this behavior of IRET may change in VMX non-root operation. Setting this bit indicates that blocking of NMIs is in effect. Clearing this bit does not imply that NMIs are not (temporarily) blocked for other reasons. If the “virtual NMIs” VM-execution control (see Section 24.6.1) is 1, this bit does not control the blocking of NMIs. Instead, it refers to “virtual-NMI blocking” (the fact that guest software is not ready for an NMI).
31:4	Reserved	VM entry will fail if these bits are not 0. See Section 26.3.1.5.

- **Pending debug exceptions** (64 bits; 32 bits on processors that do not support Intel 64 architecture). IA-32 processors may recognize one or more debug exceptions without immediately delivering them.<sup>2</sup> This field contains information about such exceptions. This field is described in Table 24-4.

---

1. A triple fault occurs when a logical processor encounters an exception while attempting to deliver a double fault.

2. For example, execution of a MOV to SS or a POP to SS may inhibit some debug exceptions for one instruction. See Section 6.8.3 of *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*. In addition, certain events incident to an instruction (for example, an INIT signal) may take priority over debug traps generated by that instruction. See Table 6-2 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

**Table 24-4. Format of Pending-Debug-Exceptions**

Bit Position(s)	Bit Name	Notes
3:0	B3 - B0	When set, each of these bits indicates that the corresponding breakpoint condition was met. Any of these bits may be set even if the corresponding enabling bit in DR7 is not set.
11:4	Reserved	VM entry fails if these bits are not 0. See Section 26.3.1.5.
12	Enabled breakpoint	When set, this bit indicates that at least one data or I/O breakpoint was met and was enabled in DR7.
13	Reserved	VM entry fails if this bit is not 0. See Section 26.3.1.5.
14	BS	When set, this bit indicates that a debug exception would have been triggered by single-step execution mode.
63:15	Reserved	VM entry fails if these bits are not 0. See Section 26.3.1.5. Bits 63:32 exist only on processors that support Intel 64 architecture.

- **VMCS link pointer** (64 bits). This field is included for future expansion. Software should set this field to FFFFFFFF\_FFFFFFFFH to avoid VM-entry failures (see Section 26.3.1.5).
- **VMX-preemption timer value** (32 bits). This field is supported only on processors that support the 1-setting of the “activate VMX-preemption timer” VM-execution control. This field contains the value that the VMX-preemption timer will use following the next VM entry with that setting. See Section 25.5.1 and Section 26.6.4.
- **Page-directory-pointer-table entries** (PDPTes; 64 bits each). These four (4) fields (PDPTE0, PDPTE1, PDPTE2, and PDPTE3) are supported only on processors that support the 1-setting of the “enable EPT” VM-execution control. They correspond to the PDPTes referenced by CR3 when PAE paging is in use (see Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*). They are used only if the “enable EPT” VM-execution control is 1.
- **Guest interrupt status** (16 bits). This field is supported only on processors that support the 1-setting of the “virtual-interrupt delivery” VM-execution control. It characterizes part of the guest’s virtual-APIC state and does not correspond to any processor or APIC registers. It comprises two 8-bit subfields:
  - **Requesting virtual interrupt (RVI)**. This is the low byte of the guest interrupt status. The processor treats this value as the vector of the highest priority virtual interrupt that is requesting service. (The value 0 implies that there is no such interrupt.)
  - **Servicing virtual interrupt (SVI)**. This is the high byte of the guest interrupt status. The processor treats this value as the vector of the highest priority virtual interrupt that is in service. (The value 0 implies that there is no such interrupt.)

See Chapter 29 for more information on the use of this field.

## 24.5 HOST-STATE AREA

This section describes fields contained in the host-state area of the VMCS. As noted earlier, processor state is loaded from these fields on every VM exit (see Section 27.5).

All fields in the host-state area correspond to processor registers:

- CR0, CR3, and CR4 (64 bits each; 32 bits on processors that do not support Intel 64 architecture).
- RSP and RIP (64 bits each; 32 bits on processors that do not support Intel 64 architecture).
- Selector fields (16 bits each) for the segment registers CS, SS, DS, ES, FS, GS, and TR. There is no field in the host-state area for the LDTR selector.
- Base-address fields for FS, GS, TR, GDTR, and IDTR (64 bits each; 32 bits on processors that do not support Intel 64 architecture).
- The following MSRs:

- IA32\_SYSENTER\_CS (32 bits)
- IA32\_SYSENTER\_ESP and IA32\_SYSENTER\_EIP (64 bits; 32 bits on processors that do not support Intel 64 architecture).
- IA32\_PERF\_GLOBAL\_CTRL (64 bits). This field is supported only on processors that support the 1-setting of the “load IA32\_PERF\_GLOBAL\_CTRL” VM-exit control.
- IA32\_PAT (64 bits). This field is supported only on processors that support either the 1-setting of the “load IA32\_PAT” VM-exit control.
- IA32\_EFER (64 bits). This field is supported only on processors that support either the 1-setting of the “load IA32\_EFER” VM-exit control.

In addition to the state identified here, some processor state components are loaded with fixed values on every VM exit; there are no fields corresponding to these components in the host-state area. See Section 27.5 for details of how state is loaded on VM exits.

## 24.6 VM-EXECUTION CONTROL FIELDS

The VM-execution control fields govern VMX non-root operation. These are described in Section 24.6.1 through Section 24.6.8.

### 24.6.1 Pin-Based VM-Execution Controls

The pin-based VM-execution controls constitute a 32-bit vector that governs the handling of asynchronous events (for example: interrupts).<sup>1</sup> Table 24-5 lists the controls. See Chapter 27 for how these controls affect processor behavior in VMX non-root operation.

**Table 24-5. Definitions of Pin-Based VM-Execution Controls**

Bit Position(s)	Name	Description
0	External-interrupt exiting	If this control is 1, external interrupts cause VM exits. Otherwise, they are delivered normally through the guest interrupt-descriptor table (IDT). If this control is 1, the value of RFLAGS.IF does not affect interrupt blocking.
3	NMI exiting	If this control is 1, non-maskable interrupts (NMIs) cause VM exits. Otherwise, they are delivered normally using descriptor 2 of the IDT. This control also determines interactions between IRET and blocking by NMI (see Section 25.3).
5	Virtual NMIs	If this control is 1, NMIs are never blocked and the “blocking by NMI” bit (bit 3) in the interruptibility-state field indicates “virtual-NMI blocking” (see Table 24-3). This control also interacts with the “NMI-window exiting” VM-execution control (see Section 24.6.2).
6	Activate VMX-preemption timer	If this control is 1, the VMX-preemption timer counts down in VMX non-root operation; see Section 25.5.1. A VM exit occurs when the timer counts down to zero; see Section 25.2.
7	Process posted interrupts	If this control is 1, the processor treats interrupts with the posted-interrupt notification vector (see Section 24.6.8) specially, updating the virtual-APIC page with posted-interrupt requests (see Section 29.6).

All other bits in this field are reserved, some to 0 and some to 1. Software should consult the VMX capability MSRs IA32\_VMX\_PINBASED\_CTLs and IA32\_VMX\_TRUE\_PINBASED\_CTLs (see Appendix A.3.1) to determine how to set reserved bits. Failure to set reserved bits properly causes subsequent VM entries to fail (see Section 26.2.1.1).

The first processors to support the virtual-machine extensions supported only the 1-settings of bits 1, 2, and 4. The VMX capability MSR IA32\_VMX\_PINBASED\_CTLs will always report that these bits must be 1. Logical processors that support the 0-settings of any of these bits will support the VMX capability MSR

1. Some asynchronous events cause VM exits regardless of the settings of the pin-based VM-execution controls (see Section 25.2).

IA32\_VMX\_TRUE\_PINBASED\_CTLMSR MSR, and software should consult this MSR to discover support for the 0- settings of these bits. Software that is not aware of the functionality of any one of these bits should set that bit to 1.

## 24.6.2 Processor-Based VM-Execution Controls

The processor-based VM-execution controls constitute two 32-bit vectors that govern the handling of synchronous events, mainly those caused by the execution of specific instructions.<sup>1</sup> These are the **primary processor-based VM-execution controls** and the **secondary processor-based VM-execution controls**.

Table 24-6 lists the primary processor-based VM-execution controls. See Chapter 27 for more details of how these controls affect processor behavior in VMX non-root operation.

**Table 24-6. Definitions of Primary Processor-Based VM-Execution Controls**

Bit Position(s)	Name	Description
2	Interrupt-window exiting	If this control is 1, a VM exit occurs at the beginning of any instruction if RFLAGS.IF = 1 and there are no other blocking of interrupts (see Section 24.4.2).
3	Use TSC offsetting	This control determines whether executions of RDTSC, executions of RDTSCP, and executions of RDMSR that read from the IA32_TIME_STAMP_COUNTER MSR return a value modified by the TSC offset field (see Section 24.6.5 and Section 25.3).
7	HLT exiting	This control determines whether executions of HLT cause VM exits.
9	INVLPG exiting	This determines whether executions of INVLPG cause VM exits.
10	MWAIT exiting	This control determines whether executions of MWAIT cause VM exits.
11	RDPMC exiting	This control determines whether executions of RDPMC cause VM exits.
12	RDTSR exiting	This control determines whether executions of RDTSR and RDTSCP cause VM exits.
15	CR3-load exiting	In conjunction with the CR3-target controls (see Section 24.6.7), this control determines whether executions of MOV to CR3 cause VM exits. See Section 25.1.3. The first processors to support the virtual-machine extensions supported only the 1-setting of this control.
16	CR3-store exiting	This control determines whether executions of MOV from CR3 cause VM exits. The first processors to support the virtual-machine extensions supported only the 1-setting of this control.
19	CR8-load exiting	This control determines whether executions of MOV to CR8 cause VM exits.
20	CR8-store exiting	This control determines whether executions of MOV from CR8 cause VM exits.
21	Use TPR shadow	Setting this control to 1 enables TPR virtualization and other APIC-virtualization features. See Chapter 29.
22	NMI-window exiting	If this control is 1, a VM exit occurs at the beginning of any instruction if there is no virtual-NMI blocking (see Section 24.4.2).
23	MOV-DR exiting	This control determines whether executions of MOV DR cause VM exits.
24	Unconditional I/O exiting	This control determines whether executions of I/O instructions (IN, INS/INSB/INSw/INSD, OUT, and OUTS/OUTSB/OUTSw/OUTSD) cause VM exits.
25	Use I/O bitmaps	This control determines whether I/O bitmaps are used to restrict executions of I/O instructions (see Section 24.6.4 and Section 25.1.3). For this control, "0" means "do not use I/O bitmaps" and "1" means "use I/O bitmaps." If the I/O bitmaps are used, the setting of the "unconditional I/O exiting" control is ignored.
27	Monitor trap flag	If this control is 1, the monitor trap flag debugging feature is enabled. See Section 25.5.2.

1. Some instructions cause VM exits regardless of the settings of the processor-based VM-execution controls (see Section 25.1.2), as do task switches (see Section 25.2).

**Table 24-6. Definitions of Primary Processor-Based VM-Execution Controls (Contd.)**

Bit Position(s)	Name	Description
28	Use MSR bitmaps	This control determines whether MSR bitmaps are used to control execution of the RDMSR and WRMSR instructions (see Section 24.6.9 and Section 25.1.3). For this control, “0” means “do not use MSR bitmaps” and “1” means “use MSR bitmaps.” If the MSR bitmaps are not used, all executions of the RDMSR and WRMSR instructions cause VM exits.
29	MONITOR exiting	This control determines whether executions of MONITOR cause VM exits.
30	PAUSE exiting	This control determines whether executions of PAUSE cause VM exits.
31	Activate secondary controls	This control determines whether the secondary processor-based VM-execution controls are used. If this control is 0, the logical processor operates as if all the secondary processor-based VM-execution controls were also 0.

All other bits in this field are reserved, some to 0 and some to 1. Software should consult the VMX capability MSRs IA32\_VMX\_PROCBASED\_CTL5 and IA32\_VMX\_TRUE\_PROCBASED\_CTL5 (see Appendix A.3.2) to determine how to set reserved bits. Failure to set reserved bits properly causes subsequent VM entries to fail (see Section 26.2.1.1).

The first processors to support the virtual-machine extensions supported only the 1-settings of bits 1, 4–6, 8, 13–16, and 26. The VMX capability MSR IA32\_VMX\_PROCBASED\_CTL5 will always report that these bits must be 1. Logical processors that support the 0-settings of any of these bits will support the VMX capability MSR IA32\_VMX\_TRUE\_PROCBASED\_CTL5 MSR, and software should consult this MSR to discover support for the 0-settings of these bits. Software that is not aware of the functionality of any one of these bits should set that bit to 1.

Bit 31 of the primary processor-based VM-execution controls determines whether the secondary processor-based VM-execution controls are used. If that bit is 0, VM entry and VMX non-root operation function as if all the secondary processor-based VM-execution controls were 0. Processors that support only the 0-setting of bit 31 of the primary processor-based VM-execution controls do not support the secondary processor-based VM-execution controls.

Table 24-7 lists the secondary processor-based VM-execution controls. See Chapter 27 for more details of how these controls affect processor behavior in VMX non-root operation.

**Table 24-7. Definitions of Secondary Processor-Based VM-Execution Controls**

Bit Position(s)	Name	Description
0	Virtualize APIC accesses	If this control is 1, the logical processor treats specially accesses to the page with the APIC-access address. See Section 29.4.
1	Enable EPT	If this control is 1, extended page tables (EPT) are enabled. See Section 28.2.
2	Descriptor-table exiting	This control determines whether executions of LGDT, LIDT, LLDT, LTR, SGDT, SIDT, SLDT, and STR cause VM exits.
3	Enable RDTSCP	If this control is 0, any execution of RDTSCP causes an invalid-opcode exception (#UD).
4	Virtualize x2APIC mode	If this control is 1, the logical processor treats specially RDMSR and WRMSR to APIC MSRs (in the range 800H–8FFH). See Section 29.5.
5	Enable VPID	If this control is 1, cached translations of linear addresses are associated with a virtual-processor identifier (VPID). See Section 28.1.
6	WBINVD exiting	This control determines whether executions of WBINVD cause VM exits.
7	Unrestricted guest	This control determines whether guest software may run in unpagged protected mode or in real-address mode.
8	APIC-register virtualization	If this control is 1, the logical processor virtualizes certain APIC accesses. See Section 29.4 and Section 29.5.
9	Virtual-interrupt delivery	This controls enables the evaluation and delivery of pending virtual interrupts as well as the emulation of writes to the APIC registers that control interrupt prioritization.
10	PAUSE-loop exiting	This control determines whether a series of executions of PAUSE can cause a VM exit (see Section 24.6.13 and Section 25.1.3).

**Table 24-7. Definitions of Secondary Processor-Based VM-Execution Controls (Contd.)**

Bit Position(s)	Name	Description
11	RDRAND exiting	This control determines whether executions of RDRAND cause VM exits.
12	Enable INVPCID	If this control is 0, any execution of INVPCID causes an invalid-opcode exception (#UD).
13	Enable VM functions	Setting this control to 1 enables use of the VMFUNC instruction in VMX non-root operation. See Section 25.5.5.
14	VMCS shadowing	If this control is 1, executions of VMREAD and VMWRITE in VMX non-root operation may access a shadow VMCS (instead of causing VM exits). See Section 24.10 and Section 30.3.
18	EPT-violation #VE	If this control is 1, EPT violations may cause virtualization exceptions (#VE) instead of VM exits. See Section 25.5.6.

All other bits in this field are reserved to 0. Software should consult the VMX capability MSR IA32\_VMX\_PROCBASED\_CTLX2 (see Appendix A.3.3) to determine which bits may be set to 1. Failure to clear reserved bits causes subsequent VM entries to fail (see Section 26.2.1.1).

### 24.6.3 Exception Bitmap

The **exception bitmap** is a 32-bit field that contains one bit for each exception. When an exception occurs, its vector is used to select a bit in this field. If the bit is 1, the exception causes a VM exit. If the bit is 0, the exception is delivered normally through the IDT, using the descriptor corresponding to the exception's vector.

Whether a page fault (exception with vector 14) causes a VM exit is determined by bit 14 in the exception bitmap as well as the error code produced by the page fault and two 32-bit fields in the VMCS (the **page-fault error-code mask** and **page-fault error-code match**). See Section 25.2 for details.

### 24.6.4 I/O-Bitmap Addresses

The VM-execution control fields include the 64-bit physical addresses of **I/O bitmaps** A and B (each of which are 4 KBytes in size). I/O bitmap A contains one bit for each I/O port in the range 0000H through 7FFFH; I/O bitmap B contains bits for ports in the range 8000H through FFFFH.

A logical processor uses these bitmaps if and only if the “use I/O bitmaps” control is 1. If the bitmaps are used, execution of an I/O instruction causes a VM exit if any bit in the I/O bitmaps corresponding to a port it accesses is 1. See Section 25.1.3 for details. If the bitmaps are used, their addresses must be 4-KByte aligned.

### 24.6.5 Time-Stamp Counter Offset

VM-execution control fields include a 64-bit **TSC-offset** field. If the “RDTSC exiting” control is 0 and the “use TSC offsetting” control is 1, this field controls executions of the RDTSC and RDTSCP instructions. It also controls executions of the RDMSR instruction that read from the IA32\_TIME\_STAMP\_COUNTER MSR. For all of these, the signed value of the TSC offset is combined with the contents of the time-stamp counter (using signed addition) and the sum is reported to guest software in EDX:EAX. See Chapter 27 for a detailed treatment of the behavior of RDTSC, RDTSCP, and RDMSR in VMX non-root operation.

### 24.6.6 Guest/Host Masks and Read Shadows for CR0 and CR4

VM-execution control fields include **guest/host masks** and **read shadows** for the CR0 and CR4 registers. These fields control executions of instructions that access those registers (including CLTS, LMSW, MOV CR, and SMSW). They are 64 bits on processors that support Intel 64 architecture and 32 bits on processors that do not.

In general, bits set to 1 in a guest/host mask correspond to bits “owned” by the host:

- Guest attempts to set them (using CLTS, LMSW, or MOV to CR) to values differing from the corresponding bits in the corresponding read shadow cause VM exits.
- Guest reads (using MOV from CR or SMSW) return values for these bits from the corresponding read shadow.

Bits cleared to 0 correspond to bits “owned” by the guest; guest attempts to modify them succeed and guest reads return values for these bits from the control register itself.

See Chapter 27 for details regarding how these fields affect VMX non-root operation.

## 24.6.7 CR3-Target Controls

The VM-execution control fields include a set of 4 **CR3-target values** and a **CR3-target count**. The CR3-target values each have 64 bits on processors that support Intel 64 architecture and 32 bits on processors that do not. The CR3-target count has 32 bits on all processors.

An execution of MOV to CR3 in VMX non-root operation does not cause a VM exit if its source operand matches one of these values. If the CR3-target count is  $n$ , only the first  $n$  CR3-target values are considered; if the CR3-target count is 0, MOV to CR3 always causes a VM exit

There are no limitations on the values that can be written for the CR3-target values. VM entry fails (see Section 26.2) if the CR3-target count is greater than 4.

Future processors may support a different number of CR3-target values. Software should read the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6) to determine the number of values supported.

## 24.6.8 Controls for APIC Virtualization

There are three mechanisms by which software accesses registers of the logical processor’s local APIC:

- If the local APIC is in xAPIC mode, it can perform memory-mapped accesses to addresses in the 4-KByte page referenced by the physical address in the IA32\_APIC\_BASE MSR (see Section 10.4.4, “Local APIC Status and Location” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* and *Intel® 64 Architecture Processor Topology Enumeration*).<sup>1</sup>
- If the local APIC is in x2APIC mode, it can access the local APIC’s registers using the RDMSR and WRMSR instructions (see *Intel® 64 Architecture Processor Topology Enumeration*).
- In 64-bit mode, it can access the local APIC’s task-priority register (TPR) using the MOV CR8 instruction.

There are five processor-based VM-execution controls (see Section 24.6.2) that control such accesses. There are “use TPR shadow”, “virtualize APIC accesses”, “virtualize x2APIC mode”, “virtual-interrupt delivery”, and “APIC-register virtualization”. These controls interact with the following fields:

- **APIC-access address** (64 bits). This field contains the physical address of the 4-KByte **APIC-access page**. If the “virtualize APIC accesses” VM-execution control is 1, access to this page may cause VM exits or be virtualized by the processor. See Section 29.4.

The APIC-access address exists only on processors that support the 1-setting of the “virtualize APIC accesses” VM-execution control.

- **Virtual-APIC address** (64 bits). This field contains the physical address of the 4-KByte **virtual-APIC page**. The processor uses the virtual-APIC page to virtualize certain accesses to APIC registers and to manage virtual interrupts; see Chapter 29.

Depending on the setting of the controls indicated earlier, the virtual-APIC page may be accessed by the following operations:

- The MOV CR8 instructions (see Section 29.3).
- Accesses to the APIC-access page if, in addition, the “virtualize APIC accesses” VM-execution control is 1 (see Section 29.4).
- The RDMSR and WRMSR instructions if, in addition, the value of ECX is in the range 800H–8FFH (indicating an APIC MSR) and the “virtualize x2APIC mode” VM-execution control is 1 (see Section 29.5).

If the “use TPR shadow” VM-execution control is 1, VM entry ensures that the virtual-APIC address is 4-KByte aligned. The virtual-APIC address exists only on processors that support the 1-setting of the “use TPR shadow” VM-execution control.

---

1. If the local APIC does not support x2APIC mode, it is always in xAPIC mode.

- **TPR threshold** (32 bits). Bits 3:0 of this field determine the threshold below which bits 7:4 of VTPR (see Section 29.1.1) cannot fall. If the “virtual-interrupt delivery” VM-execution control is 0, a VM exit occurs after an operation (e.g., an execution of MOV to CR8) that reduces the value of those bits below the TPR threshold. See Section 29.1.2.

The TPR threshold exists only on processors that support the 1-setting of the “use TPR shadow” VM-execution control.

- **EOI-exit bitmap** (4 fields; 64 bits each). These fields are supported only on processors that support the 1-setting of the “virtual-interrupt delivery” VM-execution control. They are used to determine which virtualized writes to the APIC’s EOI register cause VM exits:
  - EOI\_EXIT0 contains bits for vectors from 0 (bit 0) to 63 (bit 63).
  - EOI\_EXIT1 contains bits for vectors from 64 (bit 0) to 127 (bit 63).
  - EOI\_EXIT2 contains bits for vectors from 128 (bit 0) to 191 (bit 63).
  - EOI\_EXIT3 contains bits for vectors from 192 (bit 0) to 255 (bit 63).

See Section 29.1.4 for more information on the use of this field.

- **Posted-interrupt notification vector** (16 bits). This field is supported only on processors that support the 1-setting of the “process posted interrupts” VM-execution control. Its low 8 bits contain the interrupt vector that is used to notify a logical processor that virtual interrupts have been posted. See Section 29.6 for more information on the use of this field.
- **Posted-interrupt descriptor address** (64 bits). This field is supported only on processors that support the 1-setting of the “process posted interrupts” VM-execution control. It is the physical address of a 64-byte aligned posted interrupt descriptor. See Section 29.6 for more information on the use of this field.

## 24.6.9 MSR-Bitmap Address

On processors that support the 1-setting of the “use MSR bitmaps” VM-execution control, the VM-execution control fields include the 64-bit physical address of four contiguous **MSR bitmaps**, which are each 1-KByte in size. This field does not exist on processors that do not support the 1-setting of that control. The four bitmaps are:

- **Read bitmap for low MSRs** (located at the MSR-bitmap address). This contains one bit for each MSR address in the range 00000000H to 00001FFFH. The bit determines whether an execution of RDMSR applied to that MSR causes a VM exit.
- **Read bitmap for high MSRs** (located at the MSR-bitmap address plus 1024). This contains one bit for each MSR address in the range C0000000H to C0001FFFH. The bit determines whether an execution of RDMSR applied to that MSR causes a VM exit.
- **Write bitmap for low MSRs** (located at the MSR-bitmap address plus 2048). This contains one bit for each MSR address in the range 00000000H to 00001FFFH. The bit determines whether an execution of WRMSR applied to that MSR causes a VM exit.
- **Write bitmap for high MSRs** (located at the MSR-bitmap address plus 3072). This contains one bit for each MSR address in the range C0000000H to C0001FFFH. The bit determines whether an execution of WRMSR applied to that MSR causes a VM exit.

A logical processor uses these bitmaps if and only if the “use MSR bitmaps” control is 1. If the bitmaps are used, an execution of RDMSR or WRMSR causes a VM exit if the value of RCX is in neither of the ranges covered by the bitmaps or if the appropriate bit in the MSR bitmaps (corresponding to the instruction and the RCX value) is 1. See Section 25.1.3 for details. If the bitmaps are used, their address must be 4-KByte aligned.

## 24.6.10 Executive-VMCS Pointer

The executive-VMCS pointer is a 64-bit field used in the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM). SMM VM exits save this field as described in Section 34.15.2. VM entries that return from SMM use this field as described in Section 34.15.4.

### 24.6.11 Extended-Page-Table Pointer (EPTP)

The **extended-page-table pointer** (EPTP) contains the address of the base of EPT PML4 table (see Section 28.2.2), as well as other EPT configuration information. The format of this field is shown in Table 24-8.

**Table 24-8. Format of Extended-Page-Table Pointer**

Bit Position(s)	Field
2:0	EPT paging-structure memory type (see Section 28.2.5): 0 = Uncacheable (UC) 6 = Write-back (WB) Other values are reserved. <sup>1</sup>
5:3	This value is 1 less than the EPT page-walk length (see Section 28.2.2)
6	Setting this control to 1 enables accessed and dirty flags for EPT (see Section 28.2.4) <sup>2</sup>
11:7	Reserved
N-1:12	Bits N-1:12 of the physical address of the 4-KByte aligned EPT PML4 table <sup>3</sup>
63:N	Reserved

**NOTES:**

1. Software should read the VMX capability MSR IA32\_VMX\_EPT\_VPID\_CAP (see Appendix A.10) to determine what EPT paging-structure memory types are supported.
2. Not all processors support accessed and dirty flags for EPT. Software should read the VMX capability MSR IA32\_VMX\_EPT\_VPID\_CAP (see Appendix A.10) to determine whether the processor supports this feature.
3. N is the physical-address width supported by the logical processor. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

The EPTP exists only on processors that support the 1-setting of the “enable EPT” VM-execution control.

### 24.6.12 Virtual-Processor Identifier (VPID)

The **virtual-processor identifier** (VPID) is a 16-bit field. It exists only on processors that support the 1-setting of the “enable VPID” VM-execution control. See Section 28.1 for details regarding the use of this field.

### 24.6.13 Controls for PAUSE-Loop Exiting

On processors that support the 1-setting of the “PAUSE-loop exiting” VM-execution control, the VM-execution control fields include the following 32-bit fields:

- **PLE\_Gap.** Software can configure this field as an upper bound on the amount of time between two successive executions of PAUSE in a loop.
- **PLE\_Window.** Software can configure this field as an upper bound on the amount of time a guest is allowed to execute in a PAUSE loop.

These fields measure time based on a counter that runs at the same rate as the timestamp counter (TSC). See Section 25.1.3 for more details regarding PAUSE-loop exiting.

### 24.6.14 VM-Function Controls

The **VM-function controls** constitute a 64-bit vector that governs use of the VMFUNC instruction in VMX non-root operation. This field is supported only on processors that support the 1-settings of both the “activate secondary

controls” primary processor-based VM-execution control and the “enable VM functions” secondary processor-based VM-execution control.

Table 24-9 lists the VM-function controls. See Section 25.5.5 for more details of how these controls affect processor behavior in VMX non-root operation.

**Table 24-9. Definitions of VM-Function Controls**

Bit Position(s)	Name	Description
0	EPTP switching	The EPTP-switching VM function changes the EPT pointer to a value chosen from the EPTP list. See Section 25.5.5.3.

All other bits in this field are reserved to 0. Software should consult the VMX capability MSR IA32\_VMX\_VMFUNC (see Appendix A.11) to determine which bits are reserved. Failure to clear reserved bits causes subsequent VM entries to fail (see Section 26.2.1.1).

Processors that support the 1-setting of the “EPTP switching” VM-function control also support a 64-bit field called the **EPTP-list address**. This field contains the physical address of the 4-KByte **EPTP list**. The EPTP list comprises 512 8-Byte entries (each an EPTP value) and is used by the EPTP-switching VM function (see Section 25.5.5.3).

### 24.6.15 VMCS Shadowing Bitmap Addresses

On processors that support the 1-setting of the “VMCS shadowing” VM-execution control, the VM-execution control fields include the 64-bit physical addresses of the **VMREAD bitmap** and the **VMWRITE bitmap**. Each bitmap is 4 KBytes in size and thus contains 32 KBits. The addresses are the **VMREAD-bitmap address** and the **VMWRITE-bitmap address**.

If the “VMCS shadowing” VM-execution control is 1, executions of VMREAD and VMWRITE may consult these bitmaps (see Section 24.10 and Section 30.3).

### 24.6.16 Controls for Virtualization Exceptions

On processors that support the 1-setting of the “EPT-violation #VE” VM-execution control, the VM-execution control fields include the following:

- **Virtualization-exception information address** (64 bits). This field contains the physical address of the **virtualization-exception information area**. When a logical processor encounters a virtualization exception, it saves virtualization-exception information at the virtualization-exception information address; see Section 25.5.6.2.
- **EPTP index** (16 bits). When an EPT violation causes a virtualization exception, the processor writes the value of this field to the virtualization-exception information area. The EPTP-switching VM function updates this field (see Section 25.5.5.3).

## 24.7 VM-EXIT CONTROL FIELDS

The VM-exit control fields govern the behavior of VM exits. They are discussed in Section 24.7.1 and Section 24.7.2.

### 24.7.1 VM-Exit Controls

The **VM-exit controls** constitute a 32-bit vector that governs the basic operation of VM exits. Table 24-10 lists the controls supported. See Chapter 27 for complete details of how these controls affect VM exits.

All other bits in this field are reserved, some to 0 and some to 1. Software should consult the VMX capability MSRs IA32\_VMX\_EXIT\_CTLS and IA32\_VMX\_TRUE\_EXIT\_CTLS (see Appendix A.4) to determine how it should set the reserved bits. Failure to set reserved bits properly causes subsequent VM entries to fail (see Section 26.2.1.2).

**Table 24-10. Definitions of VM-Exit Controls**

Bit Position(s)	Name	Description
2	Save debug controls	This control determines whether DR7 and the IA32_DEBUGCTL MSR are saved on VM exit. The first processors to support the virtual-machine extensions supported only the 1-setting of this control.
9	Host address-space size	On processors that support Intel 64 architecture, this control determines whether a logical processor is in 64-bit mode after the next VM exit. Its value is loaded into CS.L, IA32_EFER.LME, and IA32_EFER.LMA on every VM exit. <sup>1</sup> This control must be 0 on processors that do not support Intel 64 architecture.
12	Load IA32_PERF_GLOBAL_CTRL	This control determines whether the IA32_PERF_GLOBAL_CTRL MSR is loaded on VM exit.
15	Acknowledge interrupt on exit	This control affects VM exits due to external interrupts: <ul style="list-style-type: none"> <li>▪ If such a VM exit occurs and this control is 1, the logical processor acknowledges the interrupt controller, acquiring the interrupt’s vector. The vector is stored in the VM-exit interruption-information field, which is marked valid.</li> <li>▪ If such a VM exit occurs and this control is 0, the interrupt is not acknowledged and the VM-exit interruption-information field is marked invalid.</li> </ul>
18	Save IA32_PAT	This control determines whether the IA32_PAT MSR is saved on VM exit.
19	Load IA32_PAT	This control determines whether the IA32_PAT MSR is loaded on VM exit.
20	Save IA32_EFER	This control determines whether the IA32_EFER MSR is saved on VM exit.
21	Load IA32_EFER	This control determines whether the IA32_EFER MSR is loaded on VM exit.
22	Save VMX-preemption timer value	This control determines whether the value of the VMX-preemption timer is saved on VM exit.

**NOTES:**

1. Since Intel 64 architecture specifies that IA32\_EFER.LMA is always set to the logical-AND of CRO.PG and IA32\_EFER.LME, and since CRO.PG is always 1 in VMX operation, IA32\_EFER.LMA is always identical to IA32\_EFER.LME in VMX operation.

The first processors to support the virtual-machine extensions supported only the 1-settings of bits 0–8, 10, 11, 13, 14, 16, and 17. The VMX capability MSR IA32\_VMX\_EXIT\_CTLS always reports that these bits must be 1. Logical processors that support the 0-settings of any of these bits will support the VMX capability MSR IA32\_VMX\_TRUE\_EXIT\_CTLS MSR, and software should consult this MSR to discover support for the 0-settings of these bits. Software that is not aware of the functionality of any one of these bits should set that bit to 1.

### 24.7.2 VM-Exit Controls for MSRs

A VMM may specify lists of MSRs to be stored and loaded on VM exits. The following VM-exit control fields determine how MSRs are stored on VM exits:

- **VM-exit MSR-store count** (32 bits). This field specifies the number of MSRs to be stored on VM exit. It is recommended that this count not exceed 512 bytes.<sup>1</sup> Otherwise, unpredictable processor behavior (including a machine check) may result during VM exit.
- **VM-exit MSR-store address** (64 bits). This field contains the physical address of the VM-exit MSR-store area. The area is a table of entries, 16 bytes per entry, where the number of entries is given by the VM-exit MSR-store count. The format of each entry is given in Table 24-11. If the VM-exit MSR-store count is not zero, the address

1. Future implementations may allow more MSRs to be stored reliably. Software should consult the VMX capability MSR IA32\_VMX\_MISC to determine the number supported (see Appendix A.6).

must be 16-byte aligned.

**Table 24-11. Format of an MSR Entry**

Bit Position(s)	Contents
31:0	MSR index
63:32	Reserved
127:64	MSR data

See Section 27.4 for how this area is used on VM exits.

The following VM-exit control fields determine how MSRs are loaded on VM exits:

- **VM-exit MSR-load count** (32 bits). This field contains the number of MSRs to be loaded on VM exit. It is recommended that this count not exceed 512 bytes. Otherwise, unpredictable processor behavior (including a machine check) may result during VM exit.<sup>1</sup>
- **VM-exit MSR-load address** (64 bits). This field contains the physical address of the VM-exit MSR-load area. The area is a table of entries, 16 bytes per entry, where the number of entries is given by the VM-exit MSR-load count (see Table 24-11). If the VM-exit MSR-load count is not zero, the address must be 16-byte aligned.

See Section 27.6 for how this area is used on VM exits.

## 24.8 VM-ENTRY CONTROL FIELDS

The VM-entry control fields govern the behavior of VM entries. They are discussed in Sections 24.8.1 through 24.8.3.

### 24.8.1 VM-Entry Controls

The **VM-entry controls** constitute a 32-bit vector that governs the basic operation of VM entries. Table 24-12 lists the controls supported. See Chapter 24 for how these controls affect VM entries.

**Table 24-12. Definitions of VM-Entry Controls**

Bit Position(s)	Name	Description
2	Load debug controls	This control determines whether DR7 and the IA32_DEBUGCTL MSR are loaded on VM exit. The first processors to support the virtual-machine extensions supported only the 1-setting of this control.
9	IA-32e mode guest	On processors that support Intel 64 architecture, this control determines whether the logical processor is in IA-32e mode after VM entry. Its value is loaded into IA32_EFER.LMA as part of VM entry. <sup>1</sup> This control must be 0 on processors that do not support Intel 64 architecture.
10	Entry to SMM	This control determines whether the logical processor is in system-management mode (SMM) after VM entry. This control must be 0 for any VM entry from outside SMM.
11	Deactivate dual-monitor treatment	If set to 1, the default treatment of SMIs and SMM is in effect after the VM entry (see Section 34.15.7). This control must be 0 for any VM entry from outside SMM.
13	Load IA32_PERF_GLOBAL_CTRL	This control determines whether the IA32_PERF_GLOBAL_CTRL MSR is loaded on VM entry.
14	Load IA32_PAT	This control determines whether the IA32_PAT MSR is loaded on VM entry.
15	Load IA32_EFER	This control determines whether the IA32_EFER MSR is loaded on VM entry.

1. Future implementations may allow more MSRs to be loaded reliably. Software should consult the VMX capability MSR IA32\_VMX\_MISC to determine the number supported (see Appendix A.6).

**NOTES:**

1. Bit 5 of the IA32\_VMX\_MISC MSR is read as 1 on any logical processor that supports the 1-setting of the “unrestricted guest” VM-execution control. If it is read as 1, every VM exit stores the value of IA32\_EFER.LMA into the “IA-32e mode guest” VM-entry control (see Section 27.2).

All other bits in this field are reserved, some to 0 and some to 1. Software should consult the VMX capability MSRs IA32\_VMX\_ENTRY\_CTLS and IA32\_VMX\_TRUE\_ENTRY\_CTLS (see Appendix A.5) to determine how it should set the reserved bits. Failure to set reserved bits properly causes subsequent VM entries to fail (see Section 26.2.1.3).

The first processors to support the virtual-machine extensions supported only the 1-settings of bits 0–8 and 12. The VMX capability MSR IA32\_VMX\_ENTRY\_CTLS always reports that these bits must be 1. Logical processors that support the 0-settings of any of these bits will support the VMX capability MSR IA32\_VMX\_TRUE\_ENTRY\_CTLS MSR, and software should consult this MSR to discover support for the 0-settings of these bits. Software that is not aware of the functionality of any one of these bits should set that bit to 1.

### 24.8.2 VM-Entry Controls for MSRs

A VMM may specify a list of MSRs to be loaded on VM entries. The following VM-entry control fields manage this functionality:

- **VM-entry MSR-load count** (32 bits). This field contains the number of MSRs to be loaded on VM entry. It is recommended that this count not exceed 512 bytes. Otherwise, unpredictable processor behavior (including a machine check) may result during VM entry.<sup>1</sup>
- **VM-entry MSR-load address** (64 bits). This field contains the physical address of the VM-entry MSR-load area. The area is a table of entries, 16 bytes per entry, where the number of entries is given by the VM-entry MSR-load count. The format of entries is described in Table 24-11. If the VM-entry MSR-load count is not zero, the address must be 16-byte aligned.

See Section 26.4 for details of how this area is used on VM entries.

### 24.8.3 VM-Entry Controls for Event Injection

VM entry can be configured to conclude by delivering an event through the IDT (after all guest state and MSRs have been loaded). This process is called **event injection** and is controlled by the following three VM-entry control fields:

- **VM-entry interruption-information field** (32 bits). This field provides details about the event to be injected. Table 24-13 describes the field.

**Table 24-13. Format of the VM-Entry Interruption-Information Field**

Bit Position(s)	Content
7:0	Vector of interrupt or exception
10:8	Interruption type: 0: External interrupt 1: Reserved 2: Non-maskable interrupt (NMI) 3: Hardware exception 4: Software interrupt 5: Privileged software exception 6: Software exception 7: Other event
11	Deliver error code (0 = do not deliver; 1 = deliver)
30:12	Reserved

1. Future implementations may allow more MSRs to be loaded reliably. Software should consult the VMX capability MSR IA32\_VMX\_MISC to determine the number supported (see Appendix A.6).

**Table 24-13. Format of the VM-Entry Interruption-Information Field (Contd.)**

Bit Position(s)	Content
31	Valid

- The **vector** (bits 7:0) determines which entry in the IDT is used or which other event is injected.
- The **interruption type** (bits 10:8) determines details of how the injection is performed. In general, a VMM should use the type **hardware exception** for all exceptions other than breakpoint exceptions (#BP; generated by INT3) and overflow exceptions (#OF; generated by INTO); it should use the type **software exception** for #BP and #OF. The type **other event** is used for injection of events that are not delivered through the IDT.
- For exceptions, the **deliver-error-code bit** (bit 11) determines whether delivery pushes an error code on the guest stack.
- VM entry injects an event if and only if the **valid bit** (bit 31) is 1. The valid bit in this field is cleared on every VM exit (see Section 27.2).
- **VM-entry exception error code** (32 bits). This field is used if and only if the valid bit (bit 31) and the deliver-error-code bit (bit 11) are both set in the VM-entry interruption-information field.
- **VM-entry instruction length** (32 bits). For injection of events whose type is software interrupt, software exception, or privileged software exception, this field is used to determine the value of RIP that is pushed on the stack.

See Section 26.5 for details regarding the mechanics of event injection, including the use of the interruption type and the VM-entry instruction length.

VM exits clear the valid bit (bit 31) in the VM-entry interruption-information field.

## 24.9 VM-EXIT INFORMATION FIELDS

The VMCS contains a section of fields that contain information about the most recent VM exit.

On some processors, attempts to write to these fields with VMWRITE fail (see “VMWRITE—Write Field to Virtual-Machine Control Structure” in Chapter 30).<sup>1</sup>

### 24.9.1 Basic VM-Exit Information

The following VM-exit information fields provide basic information about a VM exit:

- **Exit reason** (32 bits). This field encodes the reason for the VM exit and has the structure given in Table 24-14.

**Table 24-14. Format of Exit Reason**

Bit Position(s)	Contents
15:0	Basic exit reason
27:16	Reserved (cleared to 0)
28	Pending MTF VM exit
29	VM exit from VMX root operation
30	Reserved (cleared to 0)
31	VM-entry failure (0 = true VM exit; 1 = VM-entry failure)

1. Software can discover whether these fields can be written by reading the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6).

- Bits 15:0 provide basic information about the cause of the VM exit (if bit 31 is clear) or of the VM-entry failure (if bit 31 is set). Appendix C enumerates the basic exit reasons.
- Bit 28 is set only by an SMM VM exit (see Section 34.15.2) that took priority over an MTF VM exit (see Section 25.5.2) that would have occurred had the SMM VM exit not occurred. See Section 34.15.2.3.
- Bit 29 is set if and only if the processor was in VMX root operation at the time the VM exit occurred. This can happen only for SMM VM exits. See Section 34.15.2.
- Because some VM-entry failures load processor state from the host-state area (see Section 26.7), software must be able to distinguish such cases from true VM exits. Bit 31 is used for that purpose.
- **Exit qualification** (64 bits; 32 bits on processors that do not support Intel 64 architecture). This field contains additional information about the cause of VM exits due to the following: debug exceptions; page-fault exceptions; start-up IPIs (SIPIs); task switches; INVEPT; INVLPG; INVVPID; LGDT; LIDT; LLDT; LTR; SGDT; SIDT; SLDT; STR; VMCLEAR; VMPTRLD; VMPTRST; VMREAD; VMWRITE; VMXON; control-register accesses; MOV DR; I/O instructions; and MWAIT. The format of the field depends on the cause of the VM exit. See Section 27.2.1 for details.
- **Guest-linear address** (64 bits; 32 bits on processors that do not support Intel 64 architecture). This field is used in the following cases:
  - VM exits due to attempts to execute LMSW with a memory operand.
  - VM exits due to attempts to execute INS or OUTS.
  - VM exits due to system-management interrupts (SMIs) that arrive immediately after retirement of I/O instructions.
  - Certain VM exits due to EPT violations
 See Section 27.2.1 and Section 34.15.2.3 for details of when and how this field is used.
- **Guest-physical address** (64 bits). This field is used VM exits due to EPT violations and EPT misconfigurations. See Section 27.2.1 for details of when and how this field is used.

## 24.9.2 Information for VM Exits Due to Vectored Events

Event-specific information is provided for VM exits due to the following vectored events: exceptions (including those generated by the instructions INT3, INTO, BOUND, and UD2); external interrupts that occur while the “acknowledge interrupt on exit” VM-exit control is 1; and non-maskable interrupts (NMIs). This information is provided in the following fields:

- **VM-exit interruption information** (32 bits). This field receives basic information associated with the event causing the VM exit. Table 24-15 describes this field.

**Table 24-15. Format of the VM-Exit Interruption-Information Field**

Bit Position(s)	Content
7:0	Vector of interrupt or exception
10:8	Interruption type: 0: External interrupt 1: Not used 2: Non-maskable interrupt (NMI) 3: Hardware exception 4 – 5: Not used 6: Software exception 7: Not used
11	Error code valid (0 = invalid; 1 = valid)
12	NMI unblocking due to IRET
30:13	Reserved (cleared to 0)
31	Valid

- **VM-exit interruption error code** (32 bits). For VM exits caused by hardware exceptions that would have delivered an error code on the stack, this field receives that error code.

Section 27.2.2 provides details of how these fields are saved on VM exits.

### 24.9.3 Information for VM Exits That Occur During Event Delivery

Additional information is provided for VM exits that occur during event delivery in VMX non-root operation.<sup>1</sup> This information is provided in the following fields:

- **IDT-vectoring information** (32 bits). This field receives basic information associated with the event that was being delivered when the VM exit occurred. Table 24-16 describes this field.

**Table 24-16. Format of the IDT-Vectoring Information Field**

Bit Position(s)	Content
7:0	Vector of interrupt or exception
10:8	Interruption type: 0: External interrupt 1: Not used 2: Non-maskable interrupt (NMI) 3: Hardware exception 4: Software interrupt 5: Privileged software exception 6: Software exception 7: Not used
11	Error code valid (0 = invalid; 1 = valid)
12	Undefined
30:13	Reserved (cleared to 0)
31	Valid

- **IDT-vectoring error code** (32 bits). For VM exits that occur during delivery of hardware exceptions that would have delivered an error code on the stack, this field receives that error code.

See Section 27.2.3 provides details of how these fields are saved on VM exits.

### 24.9.4 Information for VM Exits Due to Instruction Execution

The following fields are used for VM exits caused by attempts to execute certain instructions in VMX non-root operation:

- **VM-exit instruction length** (32 bits). For VM exits resulting from instruction execution, this field receives the length in bytes of the instruction whose execution led to the VM exit.<sup>2</sup> See Section 27.2.4 for details of when and how this field is used.
- **VM-exit instruction information** (32 bits). This field is used for VM exits due to attempts to execute `INS`, `INVEPT`, `INVVPID`, `LIDT`, `LGDT`, `LLDT`, `LTR`, `OUTS`, `SIDT`, `SGDT`, `SLDT`, `STR`, `VMCLEAR`, `VMPTRLD`, `VMPTRST`, `VMREAD`, `VMWRITE`, or `VMXON`.<sup>3</sup> The format of the field depends on the cause of the VM exit. See Section 27.2.4 for details.

1. This includes cases in which the event delivery was caused by event injection as part of VM entry; see Section 26.5.1.2.

2. This field is also used for VM exits that occur during the delivery of a software interrupt or software exception.

3. Whether the processor provides this information on VM exits due to attempts to execute `INS` or `OUTS` can be determined by consulting the VMX capability MSR `IA32_VMX_BASIC` (see Appendix A.1).

The following fields (64 bits each; 32 bits on processors that do not support Intel 64 architecture) are used only for VM exits due to SMIs that arrive immediately after retirement of I/O instructions. They provide information about that I/O instruction:

- **I/O RCX**. The value of RCX before the I/O instruction started.
- **I/O RSI**. The value of RSI before the I/O instruction started.
- **I/O RDI**. The value of RDI before the I/O instruction started.
- **I/O RIP**. The value of RIP before the I/O instruction started (the RIP that addressed the I/O instruction).

## 24.9.5 VM-Instruction Error Field

The 32-bit **VM-instruction error field** does not provide information about the most recent VM exit. In fact, it is not modified on VM exits. Instead, it provides information about errors encountered by a non-faulting execution of one of the VMX instructions.

## 24.10 VMCS TYPES: ORDINARY AND SHADOW

Every VMCS is either an **ordinary VMCS** or a **shadow VMCS**. A VMCS's type is determined by the shadow-VMCS indicator in the VMCS region (this is the value of bit 31 of the first 4 bytes of the VMCS region; see Table 24-1): 0 indicates an ordinary VMCS, while 1 indicates a shadow VMCS. Shadow VMCSs are supported only on processors that support the 1-setting of the "VMCS shadowing" VM-execution control (see Section 24.6.2).

A shadow VMCS differs from an ordinary VMCS in two ways:

- An ordinary VMCS can be used for VM entry but a shadow VMCS cannot. Attempts to perform VM entry when the current VMCS is a shadow VMCS fail (see Section 26.1).
- The VMREAD and VMWRITE instructions can be used in VMX non-root operation to access a shadow VMCS but not an ordinary VMCS. This fact results from the following:
  - If the "VMCS shadowing" VM-execution control is 0, execution of the VMREAD and VMWRITE instructions in VMX non-root operation always cause VM exits (see Section 25.1.3).
  - If the "VMCS shadowing" VM-execution control is 1, execution of the VMREAD and VMWRITE instructions in VMX non-root operation can access the VMCS referenced by the VMCS link pointer (see Section 30.3).
  - If the "VMCS shadowing" VM-execution control is 1, VM entry ensures that any VMCS referenced by the VMCS link pointer is a shadow VMCS (see Section 26.3.1.5).

In VMX root operation, both types of VMCSs can be accessed with the VMREAD and VMWRITE instructions.

Software should not modify the shadow-VMCS indicator in the VMCS region of a VMCS that is active. Doing so may cause the VMCS to become corrupted (see Section 24.11.1). Before modifying the shadow-VMCS indicator, software should execute VMCLEAR for the VMCS to ensure that it is not active.

## 24.11 SOFTWARE USE OF THE VMCS AND RELATED STRUCTURES

This section details guidelines that software should observe when using a VMCS and related structures. It also provides descriptions of consequences for failing to follow guidelines.

### 24.11.1 Software Use of Virtual-Machine Control Structures

To ensure proper processor behavior, software should observe certain guidelines when using an active VMCS.

No VMCS should ever be active on more than one logical processor. If a VMCS is to be "migrated" from one logical processor to another, the first logical processor should execute VMCLEAR for the VMCS (to make it inactive on that logical processor and to ensure that all VMCS data are in memory) before the other logical processor executes VMPTRLD for the VMCS (to make it active on the second logical processor).<sup>1</sup> A VMCS that is made active on more than one logical processor may become **corrupted** (see below).

Software should not modify the shadow-VMCS indicator (see Table 24-1) in the VMCS region of a VMCS that is active. Doing so may cause the VMCS to become corrupted. Before modifying the shadow-VMCS indicator, software should execute VMCLEAR for the VMCS to ensure that it is not active.

Software should use the VMREAD and VMWRITE instructions to access the different fields in the current VMCS (see Section 24.11.2). Software should never access or modify the VMCS data of an active VMCS using ordinary memory operations, in part because the format used to store the VMCS data is implementation-specific and not architecturally defined, and also because a logical processor may maintain some VMCS data of an active VMCS on the processor and not in the VMCS region. The following items detail some of the hazards of accessing VMCS data using ordinary memory operations:

- Any data read from a VMCS with an ordinary memory read does not reliably reflect the state of the VMCS. Results may vary from time to time or from logical processor to logical processor.
- Writing to a VMCS with an ordinary memory write is not guaranteed to have a deterministic effect on the VMCS. Doing so may cause the VMCS to become corrupted (see below).

(Software can avoid these hazards by removing any linear-address mappings to a VMCS region before executing a VMPTRLD for that region and by not remapping it until after executing VMCLEAR for that region.)

If a logical processor leaves VMX operation, any VMCSs active on that logical processor may be corrupted (see below). To prevent such corruption of a VMCS that may be used either after a return to VMX operation or on another logical processor, software should execute VMCLEAR for that VMCS before executing the VMXOFF instruction or removing power from the processor (e.g., as part of a transition to the S3 and S4 power states).

This section has identified operations that may cause a VMCS to become corrupted. These operations may cause the VMCS's data to become undefined. Behavior may be unpredictable if that VMCS used subsequently on any logical processor. The following items detail some hazards of VMCS corruption:

- VM entries may fail for unexplained reasons or may load undesired processor state.
- The processor may not correctly support VMX non-root operation as documented in Chapter 27 and may generate unexpected VM exits.
- VM exits may load undesired processor state, save incorrect state into the VMCS, or cause the logical processor to transition to a shutdown state.

### 24.11.2 VMREAD, VMWRITE, and Encodings of VMCS Fields

Every field of the VMCS is associated with a 32-bit value that is its **encoding**. The encoding is provided in an operand to VMREAD and VMWRITE when software wishes to read or write that field. These instructions fail if given, in 64-bit mode, an operand that sets an encoding bit beyond bit 32. See Chapter 30 for a description of these instructions.

The structure of the 32-bit encodings of the VMCS components is determined principally by the width of the fields and their function in the VMCS. See Table 24-17.

**Table 24-17. Structure of VMCS Component Encoding**

Bit Position(s)	Contents
0	Access type (0 = full; 1 = high); must be full for 16-bit, 32-bit, and natural-width fields
9:1	Index
11:10	Type: 0: control 1: VM-exit information 2: guest state 3: host state

1. As noted in Section 24.1, execution of the VMPTRLD instruction makes a VMCS is active. In addition, VM entry makes active any shadow VMCS referenced by the VMCS link pointer in the current VMCS. If a shadow VMCS is made active by VM entry, it is necessary to execute VMCLEAR for that VMCS before allowing that VMCS to become active on another logical processor.

**Table 24-17. Structure of VMCS Component Encoding (Contd.)**

Bit Position(s)	Contents
12	Reserved (must be 0)
14:13	Width: 0: 16-bit 1: 64-bit 2: 32-bit 3: natural-width
31:15	Reserved (must be 0)

The following items detail the meaning of the bits in each encoding:

- **Field width.** Bits 14:13 encode the width of the field.
  - A value of 0 indicates a 16-bit field.
  - A value of 1 indicates a 64-bit field.
  - A value of 2 indicates a 32-bit field.
  - A value of 3 indicates a **natural-width** field. Such fields have 64 bits on processors that support Intel 64 architecture and 32 bits on processors that do not.

Fields whose encodings use value 1 are specially treated to allow 32-bit software access to all 64 bits of the field. Such access is allowed by defining, for each such field, an encoding that allows direct access to the high 32 bits of the field. See below.
- **Field type.** Bits 11:10 encode the type of VMCS field: control, guest-state, host-state, or VM-exit information. (The last category also includes the VM-instruction error field.)
- **Index.** Bits 9:1 distinguish components with the same field width and type.
- **Access type.** Bit 0 must be 0 for all fields except for 64-bit fields (those with field-width 1; see above). A VMREAD or VMWRITE using an encoding with this bit cleared to 0 accesses the entire field. For a 64-bit field with field-width 1, a VMREAD or VMWRITE using an encoding with this bit set to 1 accesses only the high 32 bits of the field.

Appendix B gives the encodings of all fields in the VMCS.

The following describes the operation of VMREAD and VMWRITE based on processor mode, VMCS-field width, and access type:

- 16-bit fields:
  - A VMREAD returns the value of the field in bits 15:0 of the destination operand; other bits of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 15:0 of the source operand into the VMCS field; other bits of the source operand are not used.
- 32-bit fields:
  - A VMREAD returns the value of the field in bits 31:0 of the destination operand; in 64-bit mode, bits 63:32 of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 31:0 of the source operand into the VMCS field; in 64-bit mode, bits 63:32 of the source operand are not used.
- 64-bit fields and natural-width fields using the full access type outside IA-32e mode.
  - A VMREAD returns the value of bits 31:0 of the field in its destination operand; bits 63:32 of the field are ignored.
  - A VMWRITE writes the value of its source operand to bits 31:0 of the field and clears bits 63:32 of the field.
- 64-bit fields and natural-width fields using the full access type in 64-bit mode (only on processors that support Intel 64 architecture).

- A VMREAD returns the value of the field in bits 63:0 of the destination operand
- A VMWRITE writes the value of bits 63:0 of the source operand into the VMCS field.
- 64-bit fields using the high access type.
  - A VMREAD returns the value of bits 63:32 of the field in bits 31:0 of the destination operand; in 64-bit mode, bits 63:32 of the destination operand are cleared to 0.
  - A VMWRITE writes the value of bits 31:0 of the source operand to bits 63:32 of the field; in 64-bit mode, bits 63:32 of the source operand are not used.

Software seeking to read a 64-bit field outside IA-32e mode can use VMREAD with the full access type (reading bits 31:0 of the field) and VMREAD with the high access type (reading bits 63:32 of the field); the order of the two VMREAD executions is not important. Software seeking to modify a 64-bit field outside IA-32e mode should first use VMWRITE with the full access type (establishing bits 31:0 of the field while clearing bits 63:32) and then use VMWRITE with the high access type (establishing bits 63:32 of the field).

### 24.11.3 Initializing a VMCS

Software should initialize fields in a VMCS (using VMWRITE) before using the VMCS for VM entry. Failure to do so may result in unpredictable behavior; for example, a VM entry may fail for unexplained reasons, or a successful transition (VM entry or VM exit) may load processor state with unexpected values.

It is not necessary to initialize fields that the logical processor will not use. (For example, it is not necessary to initialize the MSR-bitmap address if the “use MSR bitmaps” VM-execution control is 0.)

A processor maintains some VMCS information that cannot be modified with the VMWRITE instruction; this includes a VMCS’s launch state (see Section 24.1). Such information may be stored in the VMCS data portion of a VMCS region. Because the format of this information is implementation-specific, there is no way for software to know, when it first allocates a region of memory for use as a VMCS region, how the processor will determine this information from the contents of the memory region.

In addition to its other functions, the VMCLEAR instruction initializes any implementation-specific information in the VMCS region referenced by its operand. To avoid the uncertainties of implementation-specific behavior, software should execute VMCLEAR on a VMCS region before making the corresponding VMCS active with VMPTRLD for the first time. (Figure 24-1 illustrates how execution of VMCLEAR puts a VMCS into a well-defined state.)

The following software usage is consistent with these limitations:

- VMCLEAR should be executed for a VMCS before it is used for VM entry for the first time.
- VMLAUNCH should be used for the first VM entry using a VMCS after VMCLEAR has been executed for that VMCS.
- VMRESUME should be used for any subsequent VM entry using a VMCS (until the next execution of VMCLEAR for the VMCS).

It is expected that, in general, VMRESUME will have lower latency than VMLAUNCH. Since “migrating” a VMCS from one logical processor to another requires use of VMCLEAR (see Section 24.11.1), which sets the launch state of the VMCS to “clear”, such migration requires the next VM entry to be performed using VMLAUNCH. Software developers can avoid the performance cost of increased VM-entry latency by avoiding unnecessary migration of a VMCS from one logical processor to another.

### 24.11.4 Software Access to Related Structures

In addition to data in the VMCS region itself, VMX non-root operation can be controlled by data structures that are referenced by pointers in a VMCS (for example, the I/O bitmaps). While the pointers to these data structures are parts of the VMCS, the data structures themselves are not. They are not accessible using VMREAD and VMWRITE but by ordinary memory writes.

Software should ensure that each such data structure is modified only when no logical processor with a current VMCS that references it is in VMX non-root operation. Doing otherwise may lead to unpredictable behavior (including behaviors identified in Section 24.11.1).

### 24.11.5 VMXON Region

Before executing VMXON, software allocates a region of memory (called the VMXON region)<sup>1</sup> that the logical processor uses to support VMX operation. The physical address of this region (the VMXON pointer) is provided in an operand to VMXON. The VMXON pointer is subject to the limitations that apply to VMCS pointers:

- The VMXON pointer must be 4-KByte aligned (bits 11:0 must be zero).
- The VMXON pointer must not set any bits beyond the processor's physical-address width.<sup>2,3</sup>

Before executing VMXON, software should write the VMCS revision identifier (see Section 24.2) to the VMXON region. (Specifically, it should write the 31-bit VMCS revision identifier to bits 30:0 of the first 4 bytes of the VMXON region; bit 31 should be cleared to 0.) It need not initialize the VMXON region in any other way. Software should use a separate region for each logical processor and should not access or modify the VMXON region of a logical processor between execution of VMXON and VMXOFF on that logical processor. Doing otherwise may lead to unpredictable behavior (including behaviors identified in Section 24.11.1).

- 
1. The amount of memory required for the VMXON region is the same as that required for a VMCS region. This size is implementation specific and can be determined by consulting the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1).
  2. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  3. If IA32\_VMX\_BASIC[48] is read as 1, the VMXON pointer must not set any bits in the range 63:32; see Appendix A.1.

In a virtualized environment using VMX, the guest software stack typically runs on a logical processor in VMX non-root operation. This mode of operation is similar to that of ordinary processor operation outside of the virtualized environment. This chapter describes the differences between VMX non-root operation and ordinary processor operation with special attention to causes of VM exits (which bring a logical processor from VMX non-root operation to root operation). The differences between VMX non-root operation and ordinary processor operation are described in the following sections:

- Section 25.1, “Instructions That Cause VM Exits”
- Section 25.2, “Other Causes of VM Exits”
- Section 25.3, “Changes to Instruction Behavior in VMX Non-Root Operation”
- Section 25.4, “Other Changes in VMX Non-Root Operation”
- Section 25.5, “Features Specific to VMX Non-Root Operation”
- Section 25.6, “Unrestricted Guests”

Chapter 26, “VM Entries,” describes the data control structures that govern VMX non-root operation. Chapter 26, “VM Entries,” describes the operation of VM entries by which the processor transitions from VMX root operation to VMX non-root operation. Chapter 25, “VMX Non-Root Operation,” describes the operation of VM exits by which the processor transitions from VMX non-root operation to VMX root operation.

Chapter 28, “VMX Support for Address Translation,” describes two features that support address translation in VMX non-root operation. Chapter 29, “APIC Virtualization and Virtual Interrupts,” describes features that support virtualization of interrupts and the Advanced Programmable Interrupt Controller (APIC) in VMX non-root operation.

## 25.1 INSTRUCTIONS THAT CAUSE VM EXITS

Certain instructions may cause VM exits if executed in VMX non-root operation. Unless otherwise specified, such VM exits are “fault-like,” meaning that the instruction causing the VM exit does not execute and no processor state is updated by the instruction. Section 27.1 details architectural state in the context of a VM exit.

Section 25.1.1 defines the prioritization between faults and VM exits for instructions subject to both. Section 25.1.2 identifies instructions that cause VM exits whenever they are executed in VMX non-root operation (and thus can never be executed in VMX non-root operation). Section 25.1.3 identifies instructions that cause VM exits depending on the settings of certain VM-execution control fields (see Section 24.6).

### 25.1.1 Relative Priority of Faults and VM Exits

The following principles describe the ordering between existing faults and VM exits:

- Certain exceptions have priority over VM exits. These include invalid-opcode exceptions, faults based on privilege level,<sup>1</sup> and general-protection exceptions that are based on checking I/O permission bits in the task-state segment (TSS). For example, execution of RDMSR with CPL = 3 generates a general-protection exception and not a VM exit.<sup>2</sup>
- Faults incurred while fetching instruction operands have priority over VM exits that are conditioned based on the contents of those operands (see LMSW in Section 25.1.3).
- VM exits caused by execution of the INS and OUTS instructions (resulting either because the “unconditional I/O exiting” VM-execution control is 1 or because the “use I/O bitmaps control is 1) have priority over the following faults:

1. These include faults generated by attempts to execute, in virtual-8086 mode, privileged instructions that are not recognized in that mode.
2. MOV DR is an exception to this rule; see Section 25.1.3.

- A general-protection fault due to the relevant segment (ES for INS; DS for OUTS unless overridden by an instruction prefix) being unusable
- A general-protection fault due to an offset beyond the limit of the relevant segment
- An alignment-check exception
- Fault-like VM exits have priority over exceptions other than those mentioned above. For example, RDMSR of a non-existent MSR with CPL = 0 generates a VM exit and not a general-protection exception.

When Section 25.1.2 or Section 25.1.3 (below) identify an instruction execution that may lead to a VM exit, it is assumed that the instruction does not incur a fault that takes priority over a VM exit.

### 25.1.2 Instructions That Cause VM Exits Unconditionally

The following instructions cause VM exits when they are executed in VMX non-root operation: CPUID, GETSEC,<sup>1</sup> INVVD, and XSETBV. This is also true of instructions introduced with VMX, which include: INVEPT, INVVPID, VMCALL,<sup>2</sup> VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMRESUME, VMXOFF, and VMXON.

### 25.1.3 Instructions That Cause VM Exits Conditionally

Certain instructions cause VM exits in VMX non-root operation depending on the setting of the VM-execution controls. The following instructions can cause “fault-like” VM exits based on the conditions described:

- **CLTS.** The CLTS instruction causes a VM exit if the bits in position 3 (corresponding to CR0.TS) are set in both the CR0 guest/host mask and the CR0 read shadow.
- **HLT.** The HLT instruction causes a VM exit if the “HLT exiting” VM-execution control is 1.
- **IN, INS/INSB/INSW/INSD, OUT, OUTS/OUTSB/OUTSW/OUTSD.** The behavior of each of these instructions is determined by the settings of the “unconditional I/O exiting” and “use I/O bitmaps” VM-execution controls:
  - If both controls are 0, the instruction executes normally.
  - If the “unconditional I/O exiting” VM-execution control is 1 and the “use I/O bitmaps” VM-execution control is 0, the instruction causes a VM exit.
  - If the “use I/O bitmaps” VM-execution control is 1, the instruction causes a VM exit if it attempts to access an I/O port corresponding to a bit set to 1 in the appropriate I/O bitmap (see Section 24.6.4). If an I/O operation “wraps around” the 16-bit I/O-port space (accesses ports FFFFH and 0000H), the I/O instruction causes a VM exit (the “unconditional I/O exiting” VM-execution control is ignored if the “use I/O bitmaps” VM-execution control is 1).

See Section 25.1.1 for information regarding the priority of VM exits relative to faults that may be caused by the INS and OUTS instructions.

- **INVLPG.** The INVLPG instruction causes a VM exit if the “INVLPG exiting” VM-execution control is 1.
- **INVPCID.** The INVPCID instruction causes a VM exit if the “INVLPG exiting” and “enable INVPCID” VM-execution controls are both 1.<sup>3</sup>
- **LGDT, LIDT, LLDT, LTR, SGDT, SIDT, SLDT, STR.** These instructions cause VM exits if the “descriptor-table exiting” VM-execution control is 1.<sup>4</sup>

---

1. An execution of GETSEC in VMX non-root operation causes a VM exit if CR4.SMXE[Bit 14] = 1 regardless of the value of CPL or RAX. An execution of GETSEC causes an invalid-opcode exception (#UD) if CR4.SMXE[Bit 14] = 0.

2. Under the dual-monitor treatment of SMIs and SMM, executions of VMCALL cause SMM VM exits in VMX root operation outside SMM. See Section 34.15.2.

3. “Enable INVPCID” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable INVPCID” VM-execution control were 0. See Section 24.6.2.

4. “Descriptor-table exiting” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “descriptor-table exiting” VM-execution control were 0. See Section 24.6.2.

- **LMSW.** In general, the LMSW instruction causes a VM exit if it would write, for any bit set in the low 4 bits of the CR0 guest/host mask, a value different than the corresponding bit in the CR0 read shadow. LMSW never clears bit 0 of CR0 (CR0.PE); thus, LMSW causes a VM exit if either of the following are true:
  - The bits in position 0 (corresponding to CR0.PE) are set in both the CR0 guest/mask and the source operand, and the bit in position 0 is clear in the CR0 read shadow.
  - For any bit position in the range 3:1, the bit in that position is set in the CR0 guest/mask and the values of the corresponding bits in the source operand and the CR0 read shadow differ.
- **MONITOR.** The MONITOR instruction causes a VM exit if the “MONITOR exiting” VM-execution control is 1.
- **MOV from CR3.** The MOV from CR3 instruction causes a VM exit if the “CR3-store exiting” VM-execution control is 1. The first processors to support the virtual-machine extensions supported only the 1-setting of this control.
- **MOV from CR8.** The MOV from CR8 instruction causes a VM exit if the “CR8-store exiting” VM-execution control is 1.
- **MOV to CR0.** The MOV to CR0 instruction causes a VM exit unless the value of its source operand matches, for the position of each bit set in the CR0 guest/host mask, the corresponding bit in the CR0 read shadow. (If every bit is clear in the CR0 guest/host mask, MOV to CR0 cannot cause a VM exit.)
- **MOV to CR3.** The MOV to CR3 instruction causes a VM exit unless the “CR3-load exiting” VM-execution control is 0 or the value of its source operand is equal to one of the CR3-target values specified in the VMCS. If the CR3-target count in  $n$ , only the first  $n$  CR3-target values are considered; if the CR3-target count is 0, MOV to CR3 always causes a VM exit.

The first processors to support the virtual-machine extensions supported only the 1-setting of the “CR3-load exiting” VM-execution control. These processors always consult the CR3-target controls to determine whether an execution of MOV to CR3 causes a VM exit.

- **MOV to CR4.** The MOV to CR4 instruction causes a VM exit unless the value of its source operand matches, for the position of each bit set in the CR4 guest/host mask, the corresponding bit in the CR4 read shadow.
- **MOV to CR8.** The MOV to CR8 instruction causes a VM exit if the “CR8-load exiting” VM-execution control is 1.
- **MOV DR.** The MOV DR instruction causes a VM exit if the “MOV-DR exiting” VM-execution control is 1. Such VM exits represent an exception to the principles identified in Section 25.1.1 in that they take priority over the following: general-protection exceptions based on privilege level; and invalid-opcode exceptions that occur because CR4.DE=1 and the instruction specified access to DR4 or DR5.
- **MWAIT.** The MWAIT instruction causes a VM exit if the “MWAIT exiting” VM-execution control is 1. If this control is 0, the behavior of the MWAIT instruction may be modified (see Section 25.3).
- **PAUSE.** The behavior of each of this instruction depends on CPL and the settings of the “PAUSE exiting” and “PAUSE-loop exiting” VM-execution controls:<sup>1</sup>
  - CPL = 0.

- If the “PAUSE exiting” and “PAUSE-loop exiting” VM-execution controls are both 0, the PAUSE instruction executes normally.
- If the “PAUSE exiting” VM-execution control is 1, the PAUSE instruction causes a VM exit (the “PAUSE-loop exiting” VM-execution control is ignored if CPL = 0 and the “PAUSE exiting” VM-execution control is 1).
- If the “PAUSE exiting” VM-execution control is 0 and the “PAUSE-loop exiting” VM-execution control is 1, the following treatment applies.

The processor determines the amount of time between this execution of PAUSE and the previous execution of PAUSE at CPL 0. If this amount of time exceeds the value of the VM-execution control field PLE\_Gap, the processor considers this execution to be the first execution of PAUSE in a loop. (It also does so for the first execution of PAUSE at CPL 0 after VM entry.)

---

1. “PAUSE-loop exiting” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “PAUSE-loop exiting” VM-execution control were 0. See Section 24.6.2.

Otherwise, the processor determines the amount of time since the most recent execution of PAUSE that was considered to be the first in a loop. If this amount of time exceeds the value of the VM-execution control field PLE\_Window, a VM exit occurs.

For purposes of these computations, time is measured based on a counter that runs at the same rate as the timestamp counter (TSC).

- CPL > 0.
  - If the “PAUSE exiting” VM-execution control is 0, the PAUSE instruction executes normally.
  - If the “PAUSE exiting” VM-execution control is 1, the PAUSE instruction causes a VM exit.

The “PAUSE-loop exiting” VM-execution control is ignored if CPL > 0.

- **RDMSR.** The RDMSR instruction causes a VM exit if any of the following are true:
  - The “use MSR bitmaps” VM-execution control is 0.
  - The value of ECX is not in the ranges 00000000H – 00001FFFH and C0000000H – C0001FFFH.
  - The value of ECX is in the range 00000000H – 00001FFFH and bit *n* in read bitmap for low MSRs is 1, where *n* is the value of ECX.
  - The value of ECX is in the range C0000000H – C0001FFFH and bit *n* in read bitmap for high MSRs is 1, where *n* is the value of ECX & 00001FFFH.

See Section 24.6.9 for details regarding how these bitmaps are identified.

- **RDPMC.** The RDPMC instruction causes a VM exit if the “RDPMC exiting” VM-execution control is 1.
- **RDRAND.** The RDRAND instruction causes a VM exit if the “RDRAND exiting” VM-execution control is 1.<sup>1</sup>
- **RD TSC.** The RD TSC instruction causes a VM exit if the “RD TSC exiting” VM-execution control is 1.
- **RD TSCP.** The RD TSCP instruction causes a VM exit if the “RD TSC exiting” and “enable RD TSCP” VM-execution controls are both 1.<sup>2</sup>
- **RSM.** The RSM instruction causes a VM exit if executed in system-management mode (SMM).<sup>3</sup>
- **VMREAD.** The VMREAD instruction causes a VM exit if any of the following are true:
  - The “VMCS shadowing” VM-execution control is 0.<sup>4</sup>
  - Bits 63:15 (bits 31:15 outside 64-bit mode) of the register source operand are not all 0.
  - Bit *n* in VMREAD bitmap is 1, where *n* is the value of bits 14:0 of the register source operand. See Section 24.6.15 for details regarding how the VMREAD bitmap is identified.

If the VMREAD instruction does not cause a VM exit, it reads from the VMCS referenced by the VMCS link pointer. See Chapter 30, “VMREAD—Read Field from Virtual-Machine Control Structure” for details of the operation of the VMREAD instruction.

- **VMWRITE.** The VMWRITE instruction causes a VM exit if any of the following are true:
  - The “VMCS shadowing” VM-execution control is 0.
  - Bits 63:15 (bits 31:15 outside 64-bit mode) of the register source operand are not all 0.
  - Bit *n* in VMWRITE bitmap is 1, where *n* is the value of bits 14:0 of the register source operand. See Section 24.6.15 for details regarding how the VMWRITE bitmap is identified.

---

1. “RDRAND exiting” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “RDRAND exiting” VM-execution control were 0. See Section 24.6.2.

2. “Enable RD TSCP” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable RD TSCP” VM-execution control were 0. See Section 24.6.2.

3. Execution of the RSM instruction outside SMM causes an invalid-opcode exception regardless of whether the processor is in VMX operation. It also does so in VMX root operation in SMM; see Section 34.15.3.

4. “VMCS shadowing” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “VMCS shadowing” VM-execution control were 0. See Section 24.6.2.

If the VMWRITE instruction does not cause a VM exit, it writes to the VMCS referenced by the VMCS link pointer. See Chapter 30, “VMWRITE—Write Field to Virtual-Machine Control Structure” for details of the operation of the VMWRITE instruction.

- **WBINVD.** The WBINVD instruction causes a VM exit if the “WBINVD exiting” VM-execution control is 1.<sup>1</sup>
- **WRMSR.** The WRMSR instruction causes a VM exit if any of the following are true:
  - The “use MSR bitmaps” VM-execution control is 0.
  - The value of ECX is not in the ranges 00000000H – 00001FFFH and C0000000H – C0001FFFH.
  - The value of ECX is in the range 00000000H – 00001FFFH and bit *n* in write bitmap for low MSRs is 1, where *n* is the value of ECX.
  - The value of ECX is in the range C0000000H – C0001FFFH and bit *n* in write bitmap for high MSRs is 1, where *n* is the value of ECX & 00001FFFH.

See Section 24.6.9 for details regarding how these bitmaps are identified.

## 25.2 OTHER CAUSES OF VM EXITS

In addition to VM exits caused by instruction execution, the following events can cause VM exits:

- **Exceptions.** Exceptions (faults, traps, and aborts) cause VM exits based on the exception bitmap (see Section 24.6.3). If an exception occurs, its vector (in the range 0–31) is used to select a bit in the exception bitmap. If the bit is 1, a VM exit occurs; if the bit is 0, the exception is delivered normally through the guest IDT. This use of the exception bitmap applies also to exceptions generated by the instructions INT3, INTO, BOUND, and UD2. Page faults (exceptions with vector 14) are specially treated. When a page fault occurs, a processor consults (1) bit 14 of the exception bitmap; (2) the error code produced with the page fault [PFEC]; (3) the page-fault error-code mask field [PFEC\_MASK]; and (4) the page-fault error-code match field [PFEC\_MATCH]. It checks if PFEC & PFEC\_MASK = PFEC\_MATCH. If there is equality, the specification of bit 14 in the exception bitmap is followed (for example, a VM exit occurs if that bit is set). If there is inequality, the meaning of that bit is reversed (for example, a VM exit occurs if that bit is clear). Thus, if software desires VM exits on all page faults, it can set bit 14 in the exception bitmap to 1 and set the page-fault error-code mask and match fields each to 00000000H. If software desires VM exits on no page faults, it can set bit 14 in the exception bitmap to 1, the page-fault error-code mask field to 00000000H, and the page-fault error-code match field to FFFFFFFFH.
- **Triple fault.** A VM exit occurs if the logical processor encounters an exception while attempting to call the double-fault handler and that exception itself does not cause a VM exit due to the exception bitmap. This applies to the case in which the double-fault exception was generated within VMX non-root operation, the case in which the double-fault exception was generated during event injection by VM entry, and to the case in which VM entry is injecting a double-fault exception.
- **External interrupts.** An external interrupt causes a VM exit if the “external-interrupt exiting” VM-execution control is 1. Otherwise, the interrupt is delivered normally through the IDT. (If a logical processor is in the shutdown state or the wait-for-SIPI state, external interrupts are blocked. The interrupt is not delivered through the IDT and no VM exit occurs.)
- **Non-maskable interrupts (NMIs).** An NMI causes a VM exit if the “NMI exiting” VM-execution control is 1. Otherwise, it is delivered using descriptor 2 of the IDT. (If a logical processor is in the wait-for-SIPI state, NMIs are blocked. The NMI is not delivered through the IDT and no VM exit occurs.)
- **INIT signals.** INIT signals cause VM exits. A logical processor performs none of the operations normally associated with these events. Such exits do not modify register state or clear pending events as they would outside of VMX operation. (If a logical processor is in the wait-for-SIPI state, INIT signals are blocked. They do not cause VM exits in this case.)
- **Start-up IPIs (SIPIs). SIPIs cause VM exits.** If a logical processor is not in the wait-for-SIPI activity state when a SIPI arrives, no VM exit occurs and the SIPI is discarded. VM exits due to SIPIs do not perform any of

1. “WBINVD exiting” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “WBINVD exiting” VM-execution control were 0. See Section 24.6.2.

the normal operations associated with those events: they do not modify register state as they would outside of VMX operation. (If a logical processor is not in the wait-for-SIPI state, SIPIs are blocked. They do not cause VM exits in this case.)

- **Task switches.** Task switches are not allowed in VMX non-root operation. Any attempt to effect a task switch in VMX non-root operation causes a VM exit. See Section 25.4.2.
- **System-management interrupts (SMIs).** If the logical processor is using the dual-monitor treatment of SMIs and system-management mode (SMM), SMIs cause SMM VM exits. See Section 34.15.2.<sup>1</sup>
- **VMX-preemption timer.** A VM exit occurs when the timer counts down to zero. See Section 25.5.1 for details of operation of the VMX-preemption timer.

Debug-trap exceptions and higher priority events take priority over VM exits caused by the VMX-preemption timer. VM exits caused by the VMX-preemption timer take priority over VM exits caused by the “NMI-window exiting” VM-execution control and lower priority events.

These VM exits wake a logical processor from the same inactive states as would a non-maskable interrupt. Specifically, they wake a logical processor from the shutdown state and from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the wait-for-SIPI state.

In addition, there are controls that cause VM exits based on the readiness of guest software to receive interrupts:

- If the “interrupt-window exiting” VM-execution control is 1, a VM exit occurs before execution of any instruction if RFLAGS.IF = 1 and there is no blocking of events by STI or by MOV SS (see Table 24-3). Such a VM exit occurs immediately after VM entry if the above conditions are true (see Section 26.6.5).

Non-maskable interrupts (NMIs) and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over external interrupts and lower priority events.

These VM exits wake a logical processor from the same inactive states as would an external interrupt. Specifically, they wake a logical processor from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the shutdown state or the wait-for-SIPI state.

- If the “NMI-window exiting” VM-execution control is 1, a VM exit occurs before execution of any instruction if there is no virtual-NMI blocking and there is no blocking of events by MOV SS (see Table 24-3). (A logical processor may also prevent such a VM exit if there is blocking of events by STI.) Such a VM exit occurs immediately after VM entry if the above conditions are true (see Section 26.6.6).

VM exits caused by the VMX-preemption timer and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over non-maskable interrupts (NMIs) and lower priority events.

These VM exits wake a logical processor from the same inactive states as would an NMI. Specifically, they wake a logical processor from the shutdown state and from the states entered using the HLT and MWAIT instructions. These VM exits do not occur if the logical processor is in the wait-for-SIPI state.

## 25.3 CHANGES TO INSTRUCTION BEHAVIOR IN VMX NON-ROOT OPERATION

The behavior of some instructions is changed in VMX non-root operation. Some of these changes are determined by the settings of certain VM-execution control fields. The following items detail such changes:

- **CLTS.** Behavior of the CLTS instruction is determined by the bits in position 3 (corresponding to CR0.TS) in the CR0 guest/host mask and the CR0 read shadow:
  - If bit 3 in the CR0 guest/host mask is 0, CLTS clears CR0.TS normally (the value of bit 3 in the CR0 read shadow is irrelevant in this case), unless CR0.TS is fixed to 1 in VMX operation (see Section 23.8), in which case CLTS causes a general-protection exception.
  - If bit 3 in the CR0 guest/host mask is 1 and bit 3 in the CR0 read shadow is 0, CLTS completes but does not change the contents of CR0.TS.
  - If the bits in position 3 in the CR0 guest/host mask and the CR0 read shadow are both 1, CLTS causes a VM exit.

1. Under the dual-monitor treatment of SMIs and SMM, SMIs also cause SMM VM exits if they occur in VMX root operation outside SMM. If the processor is using the default treatment of SMIs and SMM, SMIs are delivered as described in Section 34.14.1.

- **INVPCID.** Behavior of the INVPCID instruction is determined first by the setting of the “enable INVPCID” VM-execution control:<sup>1</sup>
  - If the “enable INVPCID” VM-execution control is 0, INVPCID causes an invalid-opcode exception (#UD).
  - If the “enable INVPCID” VM-execution control is 1, treatment is based on the setting of the “INVLPG exiting” VM-execution control:
    - If the “INVLPG exiting” VM-execution control is 0, INVPCID operates normally.
    - If the “INVLPG exiting” VM-execution control is 1, INVPCID causes a VM exit.
- **IRET.** Behavior of IRET with regard to NMI blocking (see Table 24-3) is determined by the settings of the “NMI exiting” and “virtual NMIs” VM-execution controls:
  - If the “NMI exiting” VM-execution control is 0, IRET operates normally and unblocks NMIs. (If the “NMI exiting” VM-execution control is 0, the “virtual NMIs” control must be 0; see Section 26.2.1.1.)
  - If the “NMI exiting” VM-execution control is 1, IRET does not affect blocking of NMIs. If, in addition, the “virtual NMIs” VM-execution control is 1, the logical processor tracks virtual-NMI blocking. In this case, IRET removes any virtual-NMI blocking.

The unblocking of NMIs or virtual NMIs specified above occurs even if IRET causes a fault.

- **LMSW.** Outside of VMX non-root operation, LMSW loads its source operand into CR0[3:0], but it does not clear CR0.PE if that bit is set. In VMX non-root operation, an execution of LMSW that does not cause a VM exit (see Section 25.1.3) leaves unmodified any bit in CR0[3:0] corresponding to a bit set in the CR0 guest/host mask. An attempt to set any other bit in CR0[3:0] to a value not supported in VMX operation (see Section 23.8) causes a general-protection exception. Attempts to clear CR0.PE are ignored without fault.
- **MOV from CR0.** The behavior of MOV from CR0 is determined by the CR0 guest/host mask and the CR0 read shadow. For each position corresponding to a bit clear in the CR0 guest/host mask, the destination operand is loaded with the value of the corresponding bit in CR0. For each position corresponding to a bit set in the CR0 guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CR0 read shadow. Thus, if every bit is cleared in the CR0 guest/host mask, MOV from CR0 reads normally from CR0; if every bit is set in the CR0 guest/host mask, MOV from CR0 returns the value of the CR0 read shadow.
 

Depending on the contents of the CR0 guest/host mask and the CR0 read shadow, bits may be set in the destination that would never be set when reading directly from CR0.
- **MOV from CR3.** If the “enable EPT” VM-execution control is 1 and an execution of MOV from CR3 does not cause a VM exit (see Section 25.1.3), the value loaded from CR3 is a guest-physical address; see Section 28.2.1.
- **MOV from CR4.** The behavior of MOV from CR4 is determined by the CR4 guest/host mask and the CR4 read shadow. For each position corresponding to a bit clear in the CR4 guest/host mask, the destination operand is loaded with the value of the corresponding bit in CR4. For each position corresponding to a bit set in the CR4 guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CR4 read shadow. Thus, if every bit is cleared in the CR4 guest/host mask, MOV from CR4 reads normally from CR4; if every bit is set in the CR4 guest/host mask, MOV from CR4 returns the value of the CR4 read shadow.
 

Depending on the contents of the CR4 guest/host mask and the CR4 read shadow, bits may be set in the destination that would never be set when reading directly from CR4.
- **MOV from CR8.** If the MOV from CR8 instruction does not cause a VM exit (see Section 25.1.3), its behavior is modified if the “use TPR shadow” VM-execution control is 1; see Section 29.3.
- **MOV to CR0.** An execution of MOV to CR0 that does not cause a VM exit (see Section 25.1.3) leaves unmodified any bit in CR0 corresponding to a bit set in the CR0 guest/host mask. Treatment of attempts to modify other bits in CR0 depends on the setting of the “unrestricted guest” VM-execution control:<sup>2</sup>
  - If the control is 0, MOV to CR0 causes a general-protection exception if it attempts to set any bit in CR0 to a value not supported in VMX operation (see Section 23.8).

1. “Enable INVPCID” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable INVPCID” VM-execution control were 0. See Section 24.6.2.

2. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “unrestricted guest” VM-execution control were 0. See Section 24.6.2.

- If the control is 1, MOV to CR0 causes a general-protection exception if it attempts to set any bit in CR0 other than bit 0 (PE) or bit 31 (PG) to a value not supported in VMX operation. It remains the case, however, that MOV to CR0 causes a general-protection exception if it would result in  $CR0.PE = 0$  and  $CR0.PG = 1$  or if it would result in  $CR0.PG = 1$ ,  $CR4.PAE = 0$ , and  $IA32\_EFER.LME = 1$ .
- **MOV to CR3.** If the “enable EPT” VM-execution control is 1 and an execution of MOV to CR3 does not cause a VM exit (see Section 25.1.3), the value loaded into CR3 is treated as a guest-physical address; see Section 28.2.1.
  - If PAE paging is not being used, the instruction does not use the guest-physical address to access memory and it does not cause it to be translated through EPT.<sup>1</sup>
  - If PAE paging is being used, the instruction translates the guest-physical address through EPT and uses the result to load the four (4) page-directory-pointer-table entries (PDPTes). The instruction does not use the guest-physical addresses the PDPTes to access memory and it does not cause them to be translated through EPT.
- **MOV to CR4.** An execution of MOV to CR4 that does not cause a VM exit (see Section 25.1.3) leaves unmodified any bit in CR4 corresponding to a bit set in the CR4 guest/host mask. Such an execution causes a general-protection exception if it attempts to set any bit in CR4 (not corresponding to a bit set in the CR4 guest/host mask) to a value not supported in VMX operation (see Section 23.8).
- **MOV to CR8.** If the MOV to CR8 instruction does not cause a VM exit (see Section 25.1.3), its behavior is modified if the “use TPR shadow” VM-execution control is 1; see Section 29.3.
- **MWAIT.** Behavior of the MWAIT instruction (which always causes an invalid-opcode exception—#UD—if  $CPL > 0$ ) is determined by the setting of the “MWAIT exiting” VM-execution control:
  - If the “MWAIT exiting” VM-execution control is 1, MWAIT causes a VM exit.
  - If the “MWAIT exiting” VM-execution control is 0, MWAIT does not cause the processor to enter an implementation-dependent optimized state if (1)  $ECX[0] = 1$ ; and (2) either (a) the “interrupt-window exiting” VM-execution control is 0; or (b) the logical processor has recognized a pending virtual interrupt (see Section 29.2.1). Instead, control passes to the instruction following the MWAIT instruction.
- **RDMSR.** Section 25.1.3 identifies when executions of the RDMSR instruction cause VM exits. If such an execution causes neither a fault due to  $CPL > 0$  nor a VM exit, the instruction’s behavior may be modified for certain values of ECX:
  - If ECX contains 10H (indicating the IA32\_TIME\_STAMP\_COUNTER MSR), the value returned by the instruction is determined by the setting of the “use TSC offsetting” VM-execution control as well as the TSC offset:
    - If the control is 0, the instruction operates normally, loading EAX:EDX with the value of the IA32\_TIME\_STAMP\_COUNTER MSR.
    - If the control is 1, the instruction loads EAX:EDX with the sum (using signed addition) of the value of the IA32\_TIME\_STAMP\_COUNTER MSR and the value of the TSC offset (interpreted as a signed value).

The 1-setting of the “use TSC-offsetting” VM-execution control does not effect executions of RDMSR if ECX contains 6E0H (indicating the IA32\_TSC\_DEADLINE MSR). Such executions return the APIC-timer deadline relative to the actual timestamp counter without regard to the TSC offset.
  - If ECX is in the range 800H–8FFH (indicating an APIC MSR), instruction behavior may be modified if the “virtualize x2APIC mode” VM-execution control is 1; see Section 29.5.<sup>2</sup>
- **RDTSC.** Behavior of the RDTSC instruction is determined by the settings of the “RDTSC exiting” and “use TSC offsetting” VM-execution controls as well as the TSC offset:
  - If both controls are 0, RDTSC operates normally.

---

1. A logical processor uses PAE paging if  $CR0.PG = 1$ ,  $CR4.PAE = 1$  and  $IA32\_EFER.LMA = 0$ . See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

2. “Virtualize x2APIC mode” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “virtualize x2APIC mode” VM-execution control were 0. See Section 24.6.2.

- If the “RDTSC exiting” VM-execution control is 0 and the “use TSC offsetting” VM-execution control is 1, RDTSC loads EAX:EDX with the sum (using signed addition) of the value of the IA32\_TIME\_STAMP\_COUNTER MSR and the value of the TSC offset (interpreted as a signed value).
- If the “RDTSC exiting” VM-execution control is 1, RDTSC causes a VM exit.
- **RDTSCP.** Behavior of the RDTSCP instruction is determined first by the setting of the “enable RDTSCP” VM-execution control:<sup>1</sup>
  - If the “enable RDTSCP” VM-execution control is 0, RDTSCP causes an invalid-opcode exception (#UD).
  - If the “enable RDTSCP” VM-execution control is 1, treatment is based on the settings of the “RDTSC exiting” and “use TSC offsetting” VM-execution controls as well as the TSC offset:
    - If both controls are 0, RDTSCP operates normally.
    - If the “RDTSC exiting” VM-execution control is 0 and the “use TSC offsetting” VM-execution control is 1, RDTSCP loads EAX:EDX with the sum (using signed addition) of the value of the IA32\_TIME\_STAMP\_COUNTER MSR and the value of the TSC offset (interpreted as a signed value); it also loads ECX with the value of bits 31:0 of the IA32\_TSC\_AUX MSR.
    - If the “RDTSC exiting” VM-execution control is 1, RDTSCP causes a VM exit.
- **SMSW.** The behavior of SMSW is determined by the CR0 guest/host mask and the CR0 read shadow. For each position corresponding to a bit clear in the CR0 guest/host mask, the destination operand is loaded with the value of the corresponding bit in CR0. For each position corresponding to a bit set in the CR0 guest/host mask, the destination operand is loaded with the value of the corresponding bit in the CR0 read shadow. Thus, if every bit is cleared in the CR0 guest/host mask, MOV from CR0 reads normally from CR0; if every bit is set in the CR0 guest/host mask, MOV from CR0 returns the value of the CR0 read shadow.

Note the following: (1) for any memory destination or for a 16-bit register destination, only the low 16 bits of the CR0 guest/host mask and the CR0 read shadow are used (bits 63:16 of a register destination are left unchanged); (2) for a 32-bit register destination, only the low 32 bits of the CR0 guest/host mask and the CR0 read shadow are used (bits 63:32 of the destination are cleared); and (3) depending on the contents of the CR0 guest/host mask and the CR0 read shadow, bits may be set in the destination that would never be set when reading directly from CR0.
- **WRMSR.** Section 25.1.3 identifies when executions of the WRMSR instruction cause VM exits. If such an execution neither a fault due to CPL > 0 nor a VM exit, the instruction’s behavior may be modified for certain values of ECX:
  - If ECX contains 79H (indicating IA32\_BIOS\_UPDT\_TRIG MSR), no microcode update is loaded, and control passes to the next instruction. This implies that microcode updates cannot be loaded in VMX non-root operation.
  - If ECX contains 808H (indicating the TPR MSR), 80BH (the EOI MSR), or 83FH (self-IPI MSR), instruction behavior may be modified if the “virtualize x2APIC mode” VM-execution control is 1; see Section 29.5.<sup>2</sup>

## 25.4 OTHER CHANGES IN VMX NON-ROOT OPERATION

Treatments of event blocking and of task switches differ in VMX non-root operation as described in the following sections.

### 25.4.1 Event Blocking

Event blocking is modified in VMX non-root operation as follows:

- 
1. “Enable RDTSCP” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable RDTSCP” VM-execution control were 0. See Section 24.6.2.
  2. “Virtualize x2APIC mode” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “virtualize x2APIC mode” VM-execution control were 0. See Section 24.6.2.

- If the “external-interrupt exiting” VM-execution control is 1, RFLAGS.IF does not control the blocking of external interrupts. In this case, an external interrupt that is not blocked for other reasons causes a VM exit (even if RFLAGS.IF = 0).
- If the “external-interrupt exiting” VM-execution control is 1, external interrupts may or may not be blocked by STI or by MOV SS (behavior is implementation-specific).
- If the “NMI exiting” VM-execution control is 1, non-maskable interrupts (NMIs) may or may not be blocked by STI or by MOV SS (behavior is implementation-specific).

## 25.4.2 Treatment of Task Switches

Task switches are not allowed in VMX non-root operation. Any attempt to effect a task switch in VMX non-root operation causes a VM exit. However, the following checks are performed (in the order indicated), possibly resulting in a fault, before there is any possibility of a VM exit due to task switch:

1. If a task gate is being used, appropriate checks are made on its P bit and on the proper values of the relevant privilege fields. The following cases detail the privilege checks performed:
  - a. If CALL, INT  $n$ , or JMP accesses a task gate in IA-32e mode, a general-protection exception occurs.
  - b. If CALL, INT  $n$ , INT3, INTO, or JMP accesses a task gate outside IA-32e mode, privilege-levels checks are performed on the task gate but, if they pass, privilege levels are not checked on the referenced task-state segment (TSS) descriptor.
  - c. If CALL or JMP accesses a TSS descriptor directly in IA-32e mode, a general-protection exception occurs.
  - d. If CALL or JMP accesses a TSS descriptor directly outside IA-32e mode, privilege levels are checked on the TSS descriptor.
  - e. If a non-maskable interrupt (NMI), an exception, or an external interrupt accesses a task gate in the IDT in IA-32e mode, a general-protection exception occurs.
  - f. If a non-maskable interrupt (NMI), an exception other than breakpoint exceptions (#BP) and overflow exceptions (#OF), or an external interrupt accesses a task gate in the IDT outside IA-32e mode, no privilege checks are performed.
  - g. If IRET is executed with RFLAGS.NT = 1 in IA-32e mode, a general-protection exception occurs.
  - h. If IRET is executed with RFLAGS.NT = 1 outside IA-32e mode, a TSS descriptor is accessed directly and no privilege checks are made.
2. Checks are made on the new TSS selector (for example, that is within GDT limits).
3. The new TSS descriptor is read. (A page fault results if a relevant GDT page is not present).
4. The TSS descriptor is checked for proper values of type (depends on type of task switch), P bit, S bit, and limit.

Only if checks 1–4 all pass (do not generate faults) might a VM exit occur. However, the ordering between a VM exit due to a task switch and a page fault resulting from accessing the old TSS or the new TSS is implementation-specific. Some processors may generate a page fault (instead of a VM exit due to a task switch) if accessing either TSS would cause a page fault. Other processors may generate a VM exit due to a task switch even if accessing either TSS would cause a page fault.

If an attempt at a task switch through a task gate in the IDT causes an exception (before generating a VM exit due to the task switch) and that exception causes a VM exit, information about the event whose delivery that accessed the task gate is recorded in the IDT-vectoring information fields and information about the exception that caused the VM exit is recorded in the VM-exit interruption-information fields. See Section 27.2. The fact that a task gate was being accessed is not recorded in the VMCS.

If an attempt at a task switch through a task gate in the IDT causes VM exit due to the task switch, information about the event whose delivery accessed the task gate is recorded in the IDT-vectoring fields of the VMCS. Since the cause of such a VM exit is a task switch and not an interruption, the valid bit for the VM-exit interruption information field is 0. See Section 27.2.

## 25.5 FEATURES SPECIFIC TO VMX NON-ROOT OPERATION

Some VM-execution controls support features that are specific to VMX non-root operation. These are the VMX-preemption timer (Section 25.5.1) and the monitor trap flag (Section 25.5.2), translation of guest-physical addresses (Section 25.5.3), VM functions (Section 25.5.5), and virtualization exceptions (Section 25.5.6).

### 25.5.1 VMX-Preemption Timer

If the last VM entry was performed with the 1-setting of “activate VMX-preemption timer” VM-execution control, the **VMX-preemption timer** counts down (from the value loaded by VM entry; see Section 26.6.4) in VMX non-root operation. When the timer counts down to zero, it stops counting down and a VM exit occurs (see Section 25.2).

The VMX-preemption timer counts down at rate proportional to that of the timestamp counter (TSC). Specifically, the timer counts down by 1 every time bit X in the TSC changes due to a TSC increment. The value of X is in the range 0–31 and can be determined by consulting the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6).

The VMX-preemption timer operates in the C-states C0, C1, and C2; it also operates in the shutdown and wait-for-SIPI states. If the timer counts down to zero in any state other than the wait-for SIPI state, the logical processor transitions to the C0 C-state and causes a VM exit; the timer does not cause a VM exit if it counts down to zero in the wait-for-SIPI state. The timer is not decremented in C-states deeper than C2.

Treatment of the timer in the case of system management interrupts (SMIs) and system-management mode (SMM) depends on whether the treatment of SMIs and SMM:

- If the default treatment of SMIs and SMM (see Section 34.14) is active, the VMX-preemption timer counts across an SMI to VMX non-root operation, subsequent execution in SMM, and the return from SMM via the RSM instruction. However, the timer can cause a VM exit only from VMX non-root operation. If the timer expires during SMI, in SMM, or during RSM, a timer-induced VM exit occurs immediately after RSM with its normal priority unless it is blocked based on activity state (Section 25.2).
- If the dual-monitor treatment of SMIs and SMM (see Section 34.15) is active, transitions into and out of SMM are VM exits and VM entries, respectively. The treatment of the VMX-preemption timer by those transitions is mostly the same as for ordinary VM exits and VM entries; Section 34.15.2 and Section 34.15.4 detail some differences.

### 25.5.2 Monitor Trap Flag

The **monitor trap flag** is a debugging feature that causes VM exits to occur on certain instruction boundaries in VMX non-root operation. Such VM exits are called **MTF VM exits**. An MTF VM exit may occur on an instruction boundary in VMX non-root operation as follows:

- If the “monitor trap flag” VM-execution control is 1 and VM entry is injecting a vectored event (see Section 26.5.1), an MTF VM exit is pending on the instruction boundary before the first instruction following the VM entry.
- If VM entry is injecting a pending MTF VM exit (see Section 26.5.2), an MTF VM exit is pending on the instruction boundary before the first instruction following the VM entry. This is the case even if the “monitor trap flag” VM-execution control is 0.
- If the “monitor trap flag” VM-execution control is 1, VM entry is not injecting an event, and a pending event (e.g., debug exception or interrupt) is delivered before an instruction can execute, an MTF VM exit is pending on the instruction boundary following delivery of the event (or any nested exception).
- Suppose that the “monitor trap flag” VM-execution control is 1, VM entry is not injecting an event, and the first instruction following VM entry is a REP-prefixed string instruction:
  - If the first iteration of the instruction causes a fault, an MTF VM exit is pending on the instruction boundary following delivery of the fault (or any nested exception).
  - If the first iteration of the instruction does not cause a fault, an MTF VM exit is pending on the instruction boundary after that iteration.

- Suppose that the “monitor trap flag” VM-execution control is 1, VM entry is not injecting an event, and the first instruction following VM entry is **not** a REP-prefixed string instruction:
  - If the instruction causes a fault, an MTF VM exit is pending on the instruction boundary following delivery of the fault (or any nested exception).<sup>1</sup>
  - If the instruction does not cause a fault, an MTF VM exit is pending on the instruction boundary following execution of that instruction. If the instruction is INT3 or INTO, this boundary follows delivery of any software exception. If the instruction is INT *n*, this boundary follows delivery of a software interrupt. If the instruction is HLT, the MTF VM exit will be from the HLT activity state.

No MTF VM exit occurs if another VM exit occurs before reaching the instruction boundary on which an MTF VM exit would be pending (e.g., due to an exception or triple fault).

An MTF VM exit occurs on the instruction boundary on which it is pending unless a higher priority event takes precedence or the MTF VM exit is blocked due to the activity state:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over MTF VM exits. MTF VM exits take priority over debug-trap exceptions and lower priority events.
- No MTF VM exit occurs if the processor is in either the shutdown activity state or wait-for-SIPI activity state. If a non-maskable interrupt subsequently takes the logical processor out of the shutdown activity state without causing a VM exit, an MTF VM exit is pending after delivery of that interrupt.

### 25.5.3 Translation of Guest-Physical Addresses Using EPT

The extended page-table mechanism (EPT) is a feature that can be used to support the virtualization of physical memory. When EPT is in use, certain physical addresses are treated as guest-physical addresses and are not used to access memory directly. Instead, guest-physical addresses are translated by traversing a set of EPT paging structures to produce physical addresses that are used to access memory.

Details of the EPT are given in Section 28.2.

### 25.5.4 APIC Virtualization

APIC virtualization is a collection of features that can be used to support the virtualization of interrupts and the Advanced Programmable Interrupt Controller (APIC). When APIC virtualization is enabled, the processor emulates many accesses to the APIC, tracks the state of the virtual APIC, and delivers virtual interrupts — all in VMX non-root operation without a VM exit.

Details of the APIC virtualization are given in Chapter 29.

### 25.5.5 VM Functions

A **VM function** is an operation provided by the processor that can be invoked from VMX non-root operation without a VM exit. VM functions are enabled and configured by the settings of different fields in the VMCS. Software in VMX non-root operation invokes a VM function with the **VMFUNC** instruction; the value of EAX selects the specific VM function being invoked.

Section 25.5.5.1 explains how VM functions are enabled. Section 25.5.5.2 specifies the behavior of the VMFUNC instruction. Section 25.5.5.3 describes a specific VM function called **EPTP switching**.

#### 25.5.5.1 Enabling VM Functions

Software enables VM functions generally by setting the “enable VM functions” VM-execution control. A specific VM function is enabled by setting the corresponding VM-function control.

---

1. This item includes the cases of an invalid opcode exception—#UD—generated by the UD2 instruction and a BOUND-range exceeded exception—#BR—generated by the BOUND instruction.

Suppose, for example, that software wants to enable EPTP switching (VM function 0; see Section 24.6.14). To do so, it must set the “activate secondary controls” VM-execution control (bit 31 of the primary processor-based VM-execution controls), the “enable VM functions” VM-execution control (bit 13 of the secondary processor-based VM-execution controls) and the “EPTP switching” VM-function control (bit 0 of the VM-function controls).

### 25.5.5.2 General Operation of the VMFUNC Instruction

The VMFUNC instruction causes an invalid-opcode exception (#UD) if the “enable VM functions” VM-execution controls is 0<sup>1</sup> or the value of EAX is greater than 63 (only VM functions 0–63 can be enable). Otherwise, the instruction causes a VM exit if the bit at position EAX is 0 in the VM-function controls (the selected VM function is not enabled). If such a VM exit occurs, the basic exit reason used is 59 (3BH), indicating “VMFUNC”, and the length of the VMFUNC instruction is saved into the VM-exit instruction-length field. If the instruction causes neither an invalid-opcode exception nor a VM exit due to a disabled VM function, it performs the functionality of the VM function specified by the value in EAX.

Individual VM functions may perform additional fault checking (e.g., one might cause a general-protection exception if  $CPL > 0$ ). In addition, specific VM functions may include checks that might result in a VM exit. If such a VM exit occurs, VM-exit information is saved as described in the previous paragraph. The specification of a VM function may indicate that additional VM-exit information is provided.

The specific behavior of the EPTP-switching VM function (including checks that result in VM exits) is given in Section 25.5.5.3.

### 25.5.5.3 EPTP Switching

EPTP switching is VM function 0. This VM function allows software in VMX non-root operation to load a new value for the EPT pointer (EPTP), thereby establishing a different EPT paging-structure hierarchy (see Section 28.2 for details of the operation of EPT). Software is limited to selecting from a list of potential EPTP values configured in advance by software in VMX root operation.

Specifically, the value of ECX is used to select an entry from the EPTP list, the 4-KByte structure referenced by the EPTP-list address (see Section 24.6.14; because this structure contains 512 8-Byte entries, VMFUNC causes a VM exit if  $ECX \geq 512$ ). If the selected entry is a valid EPTP value (it would not cause VM entry to fail; see Section 26.2.1.1), it is stored in the EPTP field of the current VMCS and is used for subsequent accesses using guest-physical addresses. The following pseudocode provides details:

```

IF ECX ≥ 512
    THEN VM exit;
ELSE
    tent_EPTP ← 8 bytes from EPTP-list address + 8 * ECX;
    IF tent_EPTP is not a valid EPTP value (would cause VM entry to fail if in EPTP)
        THEN VMexit;
    ELSE
        write tent_EPTP to the EPTP field in the current VMCS;
        use tent_EPTP as the new EPTP value for address translation;
        IF processor supports the 1-setting of the “EPT-violation #VE” VM-execution control
            THEN
                write ECX[15:0] to EPTP-index field in current VMCS;
                use ECX[15:0] as EPTP index for subsequent EPT-violation virtualization exceptions (see Section 25.5.6.2);
        FI;
    FI;
FI;

```

Execution of the EPTP-switching VM function does not modify the state of any registers; no flags are modified.

---

1. “Enable VM functions” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable VM functions” VM-execution control were 0. See Section 24.6.2.

As noted in Section 25.5.5.2, an execution of the EPTP-switching VM function that causes a VM exit (as specified above), uses the basic exit reason 59, indicating “VMFUNC”. The length of the VMFUNC instruction is saved into the VM-exit instruction-length field. No additional VM-exit information is provided.

An execution of VMFUNC loads EPTP from the EPTP list (and thus does not cause a fault or VM exit) is called an **EPTP-switching VMFUNC**. After an EPTP-switching VMFUNC, control passes to the next instruction. The logical processor starts creating and using guest-physical and combined mappings associated with the new value of bits 51:12 of EPTP; the combined mappings created and used are associated with the current VPID and PCID (these are not changed by VMFUNC).<sup>1</sup> If the “enable VPID” VM-execution control is 0, an EPTP-switching VMFUNC invalidates combined mappings associated with VPID 0000H (for all PCIDs and for all EP4TA values, where EP4TA is the value of bits 51:12 of EPTP).

Because an EPTP-switching VMFUNC may change the translation of guest-physical addresses, it may affect use of the guest-physical address in CR3. The EPTP-switching VMFUNC cannot itself cause a VM exit due to an EPT violation or an EPT misconfiguration due to the translation of that guest-physical address through the new EPT paging structures. The following items provide details that apply if CR0.PG = 1:

- If 32-bit paging or IA-32e paging is in use (either CR4.PAE = 0 or IA32\_EFER.LMA = 1), the next memory access with a linear address uses the translation of the guest-physical address in CR3 through the new EPT paging structures. As a result, this access may cause a VM exit due to an EPT violation or an EPT misconfiguration encountered during that translation.
- If PAE paging is in use (CR4.PAE = 1 and IA32\_EFER.LMA = 0), an EPTP-switching VMFUNC **does not** load the four page-directory-pointer-table entries (PDPTes) from the guest-physical address in CR3. The logical processor continues to use the four guest-physical addresses already present in the PDPTes. The guest-physical address in CR3 is not translated through the new EPT paging structures (until some operation that would load the PDPTes).

The EPTP-switching VMFUNC cannot itself cause a VM exit due to an EPT violation or an EPT misconfiguration encountered during the translation of a guest-physical address in any of the PDPTes. A subsequent memory access with a linear address uses the translation of the guest-physical address in the appropriate PDPTE through the new EPT paging structures. As a result, such an access may cause a VM exit due to an EPT violation or an EPT misconfiguration encountered during that translation.

If an EPTP-switching VMFUNC establishes an EPTP value that enables accessed and dirty flags for EPT (by setting bit 6), subsequent memory accesses may fail to set those flags as specified if there has been no appropriate execution of INVEPT since the last use of an EPTP value that does not enable accessed and dirty flags for EPT (because bit 6 is clear) and that is identical to the new value on bits 51:12.

If the processor supports the 1-setting of the “EPT-violation #VE” VM-execution control, an EPTP-switching VMFUNC loads the value in ECX[15:0] into to EPTP-index field in current VMCS. Subsequent EPT-violation virtualization exceptions will save this value into the virtualization-exception information area (see Section 25.5.6.2);

## 25.5.6 Virtualization Exceptions

A **virtualization exception** is a new processor exception. It uses vector 20 and is abbreviated #VE.

A virtualization exception can occur only in VMX non-root operation. Virtualization exceptions occur only with certain settings of certain VM-execution controls. Generally, these settings imply that certain conditions that would normally cause VM exits instead cause virtualization exceptions

In particular, the 1-setting of the “EPT-violation #VE” VM-execution control causes some EPT violations to generate virtualization exceptions instead of VM exits. Section 25.5.6.1 provides the details of how the processor determines whether an EPT violation causes a virtualization exception or a VM exit.

When the processor encounters a virtualization exception, it saves information about the exception to the virtualization-exception information area; see Section 25.5.6.2.

After saving virtualization-exception information, the processor delivers a virtualization exception as it would any other exception; see Section 25.5.6.3 for details.

---

1. If the “enable VPID” VM-execution control is 0, the current VPID is 0000H; if CR4.PCIDE = 0, the current PCID is 000H.

### 25.5.6.1 Convertible EPT Violations

If the “EPT-violation #VE” VM-execution control is 0 (e.g., on processors that do not support this feature), EPT violations always cause VM exits. If instead the control is 1, certain EPT violations may be converted to cause virtualization exceptions instead; such EPT violations are **convertible**.

The values of certain EPT paging-structure entries determine which EPT violations are convertible. Specifically, bit 63 of certain EPT paging-structure entries may be defined to mean **suppress #VE**:

- If bits 2:0 of an EPT paging-structure entry are all 0, the entry is **not present**. If the processor encounters such an entry while translating a guest-physical address, it causes an EPT violation. The EPT violation is convertible if and only if bit 63 of the entry is 0.
- If bits 2:0 of an EPT paging-structure entry are not all 0, the following cases apply:
  - If the value of the EPT paging-structure entry is not supported, the entry is **misconfigured**. If the processor encounters such an entry while translating a guest-physical address, it causes an EPT misconfiguration (not an EPT violation). EPT misconfigurations always cause VM exits.
  - If the value of the EPT paging-structure entry is supported, the following cases apply:
    - If bit 7 of the entry is 1, or if the entry is an EPT PTE, the entry maps a page. If the processor uses such an entry to translate a guest-physical address, and if an access to that address causes an EPT violation, the EPT violation is convertible if and only if bit 63 of the entry is 0.
    - If bit 7 of the entry is 0 and the entry is not an EPT PTE, the entry references another EPT paging structure. The processor does not use the value of bit 63 of the entry to determine whether any subsequent EPT violation is convertible.

If an access to a guest-physical address causes an EPT violation, bit 63 of exactly one of the EPT paging-structure entries used to translate that address is used to determine whether the EPT violation is convertible: either a entry that is not present (if the guest-physical address does not translate to a physical address) or an entry that maps a page (if it does).

A convertible EPT violation instead causes a virtualization exception if the following all hold:

- CRO.PE = 1;
- the logical processor is not in the process of delivering an event through the IDT; and
- the 32 bits at offset 4 in the virtualization-exception information area are all 0.

Delivery of virtualization exceptions writes the value FFFFFFFFH to offset 4 in the virtualization-exception information area (see Section 25.5.6.2). Thus, once a virtualization exception occurs, another can occur only if software clears this field.

### 25.5.6.2 Virtualization-Exception Information

Virtualization exceptions save data into the virtualization-exception information area (see Section 24.6.16). Table 25-1 enumerates the data saved and the format of the area.

**Table 25-1. Format of the Virtualization-Exception Information Area**

Byte Offset	Contents
0	The 32-bit value that would have been saved into the VMCS as an exit reason had a VM exit occurred instead of the virtualization exception. For EPT violations, this value is 48 (00000030H)
4	FFFFFFFFH
8	The 64-bit value that would have been saved into the VMCS as an exit qualification had a VM exit occurred instead of the virtualization exception
16	The 64-bit value that would have been saved into the VMCS as a guest-linear address had a VM exit occurred instead of the virtualization exception

**Table 25-1. Format of the Virtualization-Exception Information Area (Contd.)**

Byte Offset	Contents
24	The 64-bit value that would have been saved into the VMCS as a guest-physical address had a VM exit occurred instead of the virtualization exception
32	The current 16-bit value of the EPTP index VM-execution control (see Section 24.6.16 and Section 25.5.5.3)

### 25.5.6.3 Delivery of Virtualization Exceptions

After saving virtualization-exception information, the processor treats a virtualization exception as it does other exceptions:

- If bit 20 (#VE) is 1 in the exception bitmap in the VMCS, a virtualization exception causes a VM exit (see below). If the bit is 0, the virtualization exception is delivered using gate descriptor 20 in the IDT.
- Virtualization exceptions produce no error code. Delivery of a virtualization exception pushes no error code on the stack.
- With respect to double faults, virtualization exceptions have the same severity as page faults. If delivery of a virtualization exception encounters a nested fault that is either contributory or a page fault, a double fault (#DF) is generated. See Chapter 6, “Interrupt 8—Double Fault Exception (#DF)” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

It is not possible for a virtualization exception to be encountered while delivering another exception (see Section 25.5.6.1).

If a virtualization exception causes a VM exit directly (because bit 20 is 1 in the exception bitmap), information about the exception is saved normally in the VM-exit interruption information field in the VMCS (see Section 27.2.2). Specifically, the event is reported as a hardware exception with vector 20 and no error code. Bit 12 of the field (NMI unblocking due to IRET) is set normally.

If a virtualization exception causes a VM exit indirectly (because bit 20 is 0 in the exception bitmap and delivery of the exception generates an event that causes a VM exit), information about the exception is saved normally in the IDT-vectoring information field in the VMCS (see Section 27.2.3). Specifically, the event is reported as a hardware exception with vector 20 and no error code.

## 25.6 UNRESTRICTED GUESTS

The first processors to support VMX operation require CR0.PE and CR0.PG to be 1 in VMX operation (see Section 23.8). This restriction implies that guest software cannot be run in unpagged protected mode or in real-address mode. Later processors support a VM-execution control called “unrestricted guest”.<sup>1</sup> If this control is 1, CR0.PE and CR0.PG may be 0 in VMX non-root operation. Such processors allow guest software to run in unpagged protected mode or in real-address mode. The following items describe the behavior of such software:

- The MOV CR0 instructions does not cause a general-protection exception simply because it would set either CR0.PE and CR0.PG to 0. See Section 25.3 for details.
- A logical processor treats the values of CR0.PE and CR0.PG in VMX non-root operation just as it does outside VMX operation. Thus, if CR0.PE = 0, the processor operates as it does normally in real-address mode (for example, it uses the 16-bit **interrupt table** to deliver interrupts and exceptions). If CR0.PG = 0, the processor operates as it does normally when paging is disabled.
- Processor operation is modified by the fact that the processor is in VMX non-root operation and by the settings of the VM-execution controls just as it is in protected mode or when paging is enabled. Instructions, interrupts, and exceptions that cause VM exits in protected mode or when paging is enabled also do so in real-address mode or when paging is disabled. The following examples should be noted:

1. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “unrestricted guest” VM-execution control were 0. See Section 24.6.2.

- If CR0.PG = 0, page faults do not occur and thus cannot cause VM exits.
- If CR0.PE = 0, invalid-TSS exceptions do not occur and thus cannot cause VM exits.
- If CR0.PE = 0, the following instructions cause invalid-opcode exceptions and do not cause VM exits: INVEPT, INVVPID, LLDT, LTR, SLDT, STR, VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMREAD, VMRESUME, VMWRITE, VMXOFF, and VMXON.
- If CR0.PG = 0, each linear address is passed directly to the EPT mechanism for translation to a physical address.<sup>1</sup> The guest memory type passed on to the EPT mechanism is WB (writeback).

---

1. As noted in Section 26.2.1.1, the “enable EPT” VM-execution control must be 1 if the “unrestricted guest” VM-execution control is 1.

Software can enter VMX non-root operation using either of the VM-entry instructions VMLAUNCH and VMRESUME. VMLAUNCH can be used only with a VMCS whose launch state is clear and VMRESUME can be used only with a VMCS whose the launch state is launched. VMLAUNCH should be used for the first VM entry after VMCLEAR; VMRESUME should be used for subsequent VM entries with the same VMCS.

Each VM entry performs the following steps in the order indicated:

1. Basic checks are performed to ensure that VM entry can commence (Section 26.1).
2. The control and host-state areas of the VMCS are checked to ensure that they are proper for supporting VMX non-root operation and that the VMCS is correctly configured to support the next VM exit (Section 26.2).
3. The following may be performed in parallel or in any order (Section 26.3):
  - The guest-state area of the VMCS is checked to ensure that, after the VM entry completes, the state of the logical processor is consistent with IA-32 and Intel 64 architectures.
  - Processor state is loaded from the guest-state area and based on controls in the VMCS.
  - Address-range monitoring is cleared.
4. MSRs are loaded from the VM-entry MSR-load area (Section 26.4).
5. If VMLAUNCH is being executed, the launch state of the VMCS is set to “launched.”
6. An event may be injected in the guest context (Section 26.5).

Steps 1–4 above perform checks that may cause VM entry to fail. Such failures occur in one of the following three ways:

- Some of the checks in Section 26.1 may generate ordinary faults (for example, an invalid-opcode exception). Such faults are delivered normally.
- Some of the checks in Section 26.1 and all the checks in Section 26.2 cause control to pass to the instruction following the VM-entry instruction. The failure is indicated by setting RFLAGS.ZF<sup>1</sup> (if there is a current VMCS) or RFLAGS.CF (if there is no current VMCS). If there is a current VMCS, an error number indicating the cause of the failure is stored in the VM-instruction error field. See Chapter 30 for the error numbers.
- The checks in Section 26.3 and Section 26.4 cause processor state to be loaded from the host-state area of the VMCS (as would be done on a VM exit). Information about the failure is stored in the VM-exit information fields. See Section 26.7 for details.

EFLAGS.TF = 1 causes a VM-entry instruction to generate a single-step debug exception only if failure of one of the checks in Section 26.1 and Section 26.2 causes control to pass to the following instruction. A VM-entry does not generate a single-step debug exception in any of the following cases: (1) the instruction generates a fault; (2) failure of one of the checks in Section 26.3 or in loading MSRs causes processor state to be loaded from the host-state area of the VMCS; or (3) the instruction passes all checks in Section 26.1, Section 26.2, and Section 26.3 and there is no failure in loading MSRs.

Section 34.15 describes the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM). Under this treatment, code running in SMM returns using VM entries instead of the RSM instruction. A VM entry **returns from SMM** if it is executed in SMM and the “entry to SMM” VM-entry control is 0. VM entries that return from SMM differ from ordinary VM entries in ways that are detailed in Section 34.15.4.

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For IA-32 processors, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.

## 26.1 BASIC VM-ENTRY CHECKS

Before a VM entry commences, the current state of the logical processor is checked in the following order:

1. If the logical processor is in virtual-8086 mode or compatibility mode, an invalid-opcode exception is generated.
2. If the current privilege level (CPL) is not zero, a general-protection exception is generated.
3. If there is no current VMCS, RFLAGS.CF is set to 1 and control passes to the next instruction.
4. If there is a current VMCS but the current VMCS is a shadow VMCS (see Section 24.10), RFLAGS.CF is set to 1 and control passes to the next instruction.
5. If there is a current VMCS that is not a shadow VMCS, the following conditions are evaluated in order; any of these cause VM entry to fail:
  - a. if there is MOV-SS blocking (see Table 24-3)
  - b. if the VM entry is invoked by VMLAUNCH and the VMCS launch state is not clear
  - c. if the VM entry is invoked by VMRESUME and the VMCS launch state is not launched

If any of these checks fail, RFLAGS.ZF is set to 1 and control passes to the next instruction. An error number indicating the cause of the failure is stored in the VM-instruction error field. See Chapter 30 for the error numbers.

## 26.2 CHECKS ON VMX CONTROLS AND HOST-STATE AREA

If the checks in Section 26.1 do not cause VM entry to fail, the control and host-state areas of the VMCS are checked to ensure that they are proper for supporting VMX non-root operation, that the VMCS is correctly configured to support the next VM exit, and that, after the next VM exit, the processor's state is consistent with the Intel 64 and IA-32 architectures.

VM entry fails if any of these checks fail. When such failures occur, control is passed to the next instruction, RFLAGS.ZF is set to 1 to indicate the failure, and the VM-instruction error field is loaded with an error number that indicates whether the failure was due to the controls or the host-state area (see Chapter 30).

These checks may be performed in any order. Thus, an indication by error number of one cause (for example, host state) does not imply that there are not also other errors. Different processors may thus give different error numbers for the same VMCS. Some checks prevent establishment of settings (or combinations of settings) that are currently reserved. Future processors may allow such settings (or combinations) and may not perform the corresponding checks. The correctness of software should not rely on VM-entry failures resulting from the checks documented in this section.

The checks on the controls and the host-state area are presented in Section 26.2.1 through Section 26.2.4. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the host-state area.

### 26.2.1 Checks on VMX Controls

This section identifies VM-entry checks on the VMX control fields.

#### 26.2.1.1 VM-Execution Control Fields

VM entries perform the following checks on the VM-execution control fields:<sup>1</sup>

- Reserved bits in the pin-based VM-execution controls must be set properly. Software may consult the VMX capability MSR to determine the proper settings (see Appendix A.3.1).

---

1. If the "activate secondary controls" primary processor-based VM-execution control is 0, VM entry operates as if each secondary processor-based VM-execution control were 0.

- Reserved bits in the primary processor-based VM-execution controls must be set properly. Software may consult the VMX capability MSR to determine the proper settings (see Appendix A.3.2).
- If the “activate secondary controls” primary processor-based VM-execution control is 1, reserved bits in the secondary processor-based VM-execution controls must be cleared. Software may consult the VMX capability MSR to determine which bits are reserved (see Appendix A.3.3).  
If the “activate secondary controls” primary processor-based VM-execution control is 0 (or if the processor does not support the 1-setting of that control), no checks are performed on the secondary processor-based VM-execution controls. The logical processor operates as if all the secondary processor-based VM-execution controls were 0.
- The CR3-target count must not be greater than 4. Future processors may support a different number of CR3-target values. Software should read the VMX capability MSR IA32\_VMX\_MISC to determine the number of values supported (see Appendix A.6).
- If the “use I/O bitmaps” VM-execution control is 1, bits 11:0 of each I/O-bitmap address must be 0. Neither address should set any bits beyond the processor’s physical-address width.<sup>1,2</sup>
- If the “use MSR bitmaps” VM-execution control is 1, bits 11:0 of the MSR-bitmap address must be 0. The address should not set any bits beyond the processor’s physical-address width.<sup>3</sup>
- If the “use TPR shadow” VM-execution control is 1, the virtual-APIC address must satisfy the following checks:
  - Bits 11:0 of the address must be 0.
  - The address should not set any bits beyond the processor’s physical-address width.<sup>4</sup>

If all of the above checks are satisfied and the “use TPR shadow” VM-execution control is 1, bytes 3:1 of VTPR (see Section 29.1.1) may be cleared (behavior may be implementation-specific).

The clearing of these bytes may occur even if the VM entry fails. This is true either if the failure causes control to pass to the instruction following the VM-entry instruction or if it causes processor state to be loaded from the host-state area of the VMCS.

- If the “use TPR shadow” VM-execution control is 1 and the “virtual-interrupt delivery” VM-execution control is 0, bits 31:4 of the TPR threshold VM-execution control field must be 0.<sup>5</sup>
- The following check is performed if the “use TPR shadow” VM-execution control is 1 and the “virtualize APIC accesses” and “virtual-interrupt delivery” VM-execution controls are both 0: the value of bits 3:0 of the TPR threshold VM-execution control field should not be greater than the value of bits 7:4 of VTPR (see Section 29.1.1).
- If the “NMI exiting” VM-execution control is 0, the “virtual NMIs” VM-execution control must be 0.
- If the “virtual NMIs” VM-execution control is 0, the “NMI-window exiting” VM-execution control must be 0.
- If the “virtualize APIC-accesses” VM-execution control is 1, the APIC-access address must satisfy the following checks:
  - Bits 11:0 of the address must be 0.
  - The address should not set any bits beyond the processor’s physical-address width.<sup>6</sup>
- If the “use TPR shadow” VM-execution control is 0, the following VM-execution controls must also be 0: “virtualize x2APIC mode”, “APIC-register virtualization”, and “virtual-interrupt delivery”.<sup>7</sup>

---

1. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

2. If IA32\_VMX\_BASIC[48] is read as 1, these addresses must not set any bits in the range 63:32; see Appendix A.1.

3. If IA32\_VMX\_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix A.1.

4. If IA32\_VMX\_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix A.1.

5. “Virtual-interrupt delivery” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “virtual-interrupt delivery” VM-execution control were 0. See Section 24.6.2.

6. If IA32\_VMX\_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix A.1.

7. “Virtualize x2APIC mode” and “APIC-register virtualization” are secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if these controls were 0. See Section 24.6.2.

- If the “virtualize x2APIC mode” VM-execution control is 1, the “virtualize APIC accesses” VM-execution control must be 0.
- If the “virtual-interrupt delivery” VM-execution control is 1, the “external-interrupt exiting” VM-execution control must be 1.
- If the “process posted interrupts” VM-execution control is 1, the following must be true:<sup>1</sup>
  - The “virtual-interrupt delivery” VM-execution control is 1.
  - The “acknowledge interrupt on exit” VM-exit control is 1.
  - The posted-interrupt notification vector has a value in the range 0–255 (bits 15:8 are all 0).
  - Bits 5:0 of the posted-interrupt descriptor address are all 0.
  - The posted-interrupt descriptor address does not set any bits beyond the processor’s physical-address width.<sup>2</sup>
- If the “enable VPID” VM-execution control is 1, the value of the VPID VM-execution control field must not be 0000H.<sup>3</sup>
- If the “enable EPT” VM-execution control is 1, the EPTP VM-execution control field (see Table 24-8 in Section 24.6.11) must satisfy the following checks:<sup>4</sup>
  - The EPT memory type (bits 2:0) must be a value supported by the processor as indicated in the IA32\_VMX\_EPT\_VPID\_CAP MSR (see Appendix A.10).
  - Bits 5:3 (1 less than the EPT page-walk length) must be 3, indicating an EPT page-walk length of 4; see Section 28.2.2.
  - Bit 6 (enable bit for accessed and dirty flags for EPT) must be 0 if bit 21 of the IA32\_VMX\_EPT\_VPID\_CAP MSR (see Appendix A.10) is read as 0, indicating that the processor does not support accessed and dirty flags for EPT.
  - Reserved bits 11:7 and 63:N (where N is the processor’s physical-address width) must all be 0.
  - If the “unrestricted guest” VM-execution control is 1, the “enable EPT” VM-execution control must also be 1.<sup>5</sup>
- If the “enable VM functions” processor-based VM-execution control is 1, reserved bits in the VM-function controls must be clear.<sup>6</sup> Software may consult the VMX capability MSRs to determine which bits are reserved (see Appendix A.11). In addition, the following check is performed based on the setting of bits in the VM-function controls (see Section 24.6.14):
  - If “EPTP switching” VM-function control is 1, the “enable EPT” VM-execution control must also be 1. In addition, the EPTP-list address must satisfy the following checks:
    - Bits 11:0 of the address must be 0.
    - The address must not set any bits beyond the processor’s physical-address width.

If the “enable VM functions” processor-based VM-execution control is 0, no checks are performed on the VM-function controls.
- If the “VMCS shadowing” VM-execution control is 1, the VMREAD-bitmap and VMWRITE-bitmap addresses must each satisfy the following checks:<sup>7</sup>

1. “Process posted interrupts” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “process posted interrupts” VM-execution control were 0. See Section 24.6.2.
2. If IA32\_VMX\_BASIC[48] is read as 1, this address must not set any bits in the range 63:32; see Appendix A.1.
3. “Enable VPID” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “enable VPID” VM-execution control were 0. See Section 24.6.2.
4. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “enable EPT” VM-execution control were 0. See Section 24.6.2.
5. “Unrestricted guest” and “enable EPT” are both secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if both these controls were 0. See Section 24.6.2.
6. “Enable VM functions” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “enable VM functions” VM-execution control were 0. See Section 24.6.2.

- Bits 11:0 of the address must be 0.
- The address must not set any bits beyond the processor's physical-address width.
- If the "EPT-violation #VE" VM-execution control is 1, the virtualization-exception information address must satisfy the following checks:<sup>1</sup>
  - Bits 11:0 of the address must be 0.
  - The address must not set any bits beyond the processor's physical-address width.

### 26.2.1.2 VM-Exit Control Fields

VM entries perform the following checks on the VM-exit control fields.

- Reserved bits in the VM-exit controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix A.4).
- If "activate VMX-preemption timer" VM-execution control is 0, the "save VMX-preemption timer value" VM-exit control must also be 0.
- The following checks are performed for the VM-exit MSR-store address if the VM-exit MSR-store count field is non-zero:
  - The lower 4 bits of the VM-exit MSR-store address must be 0. The address should not set any bits beyond the processor's physical-address width.<sup>2</sup>
  - The address of the last byte in the VM-exit MSR-store area should not set any bits beyond the processor's physical-address width. The address of this last byte is VM-exit MSR-store address + (MSR count \* 16) – 1. (The arithmetic used for the computation uses more bits than the processor's physical-address width.)

If IA32\_VMX\_BASIC[48] is read as 1, neither address should set any bits in the range 63:32; see Appendix A.1.
- The following checks are performed for the VM-exit MSR-load address if the VM-exit MSR-load count field is non-zero:
  - The lower 4 bits of the VM-exit MSR-load address must be 0. The address should not set any bits beyond the processor's physical-address width.
  - The address of the last byte in the VM-exit MSR-load area should not set any bits beyond the processor's physical-address width. The address of this last byte is VM-exit MSR-load address + (MSR count \* 16) – 1. (The arithmetic used for the computation uses more bits than the processor's physical-address width.)

If IA32\_VMX\_BASIC[48] is read as 1, neither address should set any bits in the range 63:32; see Appendix A.1.

### 26.2.1.3 VM-Entry Control Fields

VM entries perform the following checks on the VM-entry control fields.

- Reserved bits in the VM-entry controls must be set properly. Software may consult the VMX capability MSRs to determine the proper settings (see Appendix A.5).
- Fields relevant to VM-entry event injection must be set properly. These fields are the VM-entry interruption-information field (see Table 24-13 in Section 24.8.3), the VM-entry exception error code, and the VM-entry

---

7. "VMCS shadowing" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "VMCS shadowing" VM-execution control were 0. See Section 24.6.2.

1. "EPT-violation #VE" is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the "EPT-violation #VE" VM-execution control were 0. See Section 24.6.2.

2. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

instruction length. If the valid bit (bit 31) in the VM-entry interruption-information field is 1, the following must hold:

- The field's interruption type (bits 10:8) is not set to a reserved value. Value 1 is reserved on all logical processors; value 7 (other event) is reserved on logical processors that do not support the 1-setting of the "monitor trap flag" VM-execution control.
  - The field's vector (bits 7:0) is consistent with the interruption type:
    - If the interruption type is non-maskable interrupt (NMI), the vector is 2.
    - If the interruption type is hardware exception, the vector is at most 31.
    - If the interruption type is other event, the vector is 0 (pending MTF VM exit).
  - The field's deliver-error-code bit (bit 11) is 1 if and only if (1) either (a) the "unrestricted guest" VM-execution control is 0; or (b) bit 0 (corresponding to CRO.PE) is set in the CRO field in the guest-state area; (2) the interruption type is hardware exception; and (3) the vector indicates an exception that would normally deliver an error code (8 = #DF; 10 = TS; 11 = #NP; 12 = #SS; 13 = #GP; 14 = #PF; or 17 = #AC).
  - Reserved bits in the field (30:12) are 0.
  - If the deliver-error-code bit (bit 11) is 1, bits 31:15 of the VM-entry exception error-code field are 0.
  - If the interruption type is software interrupt, software exception, or privileged software exception, the VM-entry instruction-length field is in the range 1–15.
  - The following checks are performed for the VM-entry MSR-load address if the VM-entry MSR-load count field is non-zero:
    - The lower 4 bits of the VM-entry MSR-load address must be 0. The address should not set any bits beyond the processor's physical-address width.<sup>1</sup>
    - The address of the last byte in the VM-entry MSR-load area should not set any bits beyond the processor's physical-address width. The address of this last byte is VM-entry MSR-load address + (MSR count \* 16) – 1. (The arithmetic used for the computation uses more bits than the processor's physical-address width.)
- If IA32\_VMX\_BASIC[48] is read as 1, neither address should set any bits in the range 63:32; see Appendix A.1.
- If the processor is not in SMM, the "entry to SMM" and "deactivate dual-monitor treatment" VM-entry controls must be 0.
  - The "entry to SMM" and "deactivate dual-monitor treatment" VM-entry controls cannot both be 1.

## 26.2.2 Checks on Host Control Registers and MSRs

The following checks are performed on fields in the host-state area that correspond to control registers and MSRs:

- The CRO field must not set any bit to a value not supported in VMX operation (see Section 23.8).<sup>2</sup>
- The CR4 field must not set any bit to a value not supported in VMX operation (see Section 23.8).
- On processors that support Intel 64 architecture, the CR3 field must be such that bits 63:52 and bits in the range 51:32 beyond the processor's physical-address width must be 0.<sup>3,4</sup>
- On processors that support Intel 64 architecture, the IA32\_SYSENTER\_ESP field and the IA32\_SYSENTER\_EIP field must each contain a canonical address.

- 
1. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  2. The bits corresponding to CRO.NW (bit 29) and CRO.CD (bit 30) are never checked because the values of these bits are not changed by VM exit; see Section 27.5.1.
  3. Software can determine a processor's physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  4. Bit 63 of the CR3 field in the host-state area must be 0. This is true even though, if CR4.PCIDE = 1, bit 63 of the source operand to MOV to CR3 is used to determine whether cached translation information is invalidated.

- If the “load IA32\_PERF\_GLOBAL\_CTRL” VM-exit control is 1, bits reserved in the IA32\_PERF\_GLOBAL\_CTRL MSR must be 0 in the field for that register (see Figure 18-3).
- If the “load IA32\_PAT” VM-exit control is 1, the value of the field for the IA32\_PAT MSR must be one that could be written by WRMSR without fault at CPL 0. Specifically, each of the 8 bytes in the field must have one of the values 0 (UC), 1 (WC), 4 (WT), 5 (WP), 6 (WB), or 7 (UC-).
- If the “load IA32\_EFER” VM-exit control is 1, bits reserved in the IA32\_EFER MSR must be 0 in the field for that register. In addition, the values of the LMA and LME bits in the field must each be that of the “host address-space size” VM-exit control.

### 26.2.3 Checks on Host Segment and Descriptor-Table Registers

The following checks are performed on fields in the host-state area that correspond to segment and descriptor-table registers:

- In the selector field for each of CS, SS, DS, ES, FS, GS and TR, the RPL (bits 1:0) and the TI flag (bit 2) must be 0.
- The selector fields for CS and TR cannot be 0000H.
- The selector field for SS cannot be 0000H if the “host address-space size” VM-exit control is 0.
- On processors that support Intel 64 architecture, the base-address fields for FS, GS, GDTR, IDTR, and TR must contain canonical addresses.

### 26.2.4 Checks Related to Address-Space Size

On processors that support Intel 64 architecture, the following checks related to address-space size are performed on VMX controls and fields in the host-state area:

- If the logical processor is outside IA-32e mode (if IA32\_EFER.LMA = 0) at the time of VM entry, the following must hold:
  - The “IA-32e mode guest” VM-entry control is 0.
  - The “host address-space size” VM-exit control is 0.
- If the logical processor is in IA-32e mode (if IA32\_EFER.LMA = 1) at the time of VM entry, the “host address-space size” VM-exit control must be 1.
- If the “host address-space size” VM-exit control is 0, the following must hold:
  - The “IA-32e mode guest” VM-entry control is 0.
  - Bit 17 of the CR4 field (corresponding to CR4.PCIDE) is 0.
  - Bits 63:32 in the RIP field is 0.
- If the “host address-space size” VM-exit control is 1, the following must hold:
  - Bit 5 of the CR4 field (corresponding to CR4.PAE) is 1.
  - The RIP field contains a canonical address.

On processors that do not support Intel 64 architecture, checks are performed to ensure that the “IA-32e mode guest” VM-entry control and the “host address-space size” VM-exit control are both 0.

## 26.3 CHECKING AND LOADING GUEST STATE

If all checks on the VMX controls and the host-state area pass (see Section 26.2), the following operations take place concurrently: (1) the guest-state area of the VMCS is checked to ensure that, after the VM entry completes, the state of the logical processor is consistent with IA-32 and Intel 64 architectures; (2) processor state is loaded from the guest-state area or as specified by the VM-entry control fields; and (3) address-range monitoring is cleared.

Because the checking and the loading occur concurrently, a failure may be discovered only after some state has been loaded. For this reason, the logical processor responds to such failures by loading state from the host-state area, as it would for a VM exit. See Section 26.7.

## 26.3.1 Checks on the Guest State Area

This section describes checks performed on fields in the guest-state area. These checks may be performed in any order. Some checks prevent establishment of settings (or combinations of settings) that are currently reserved. Future processors may allow such settings (or combinations) and may not perform the corresponding checks. The correctness of software should not rely on VM-entry failures resulting from the checks documented in this section.

The following subsections reference fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

### 26.3.1.1 Checks on Guest Control Registers, Debug Registers, and MSRs

The following checks are performed on fields in the guest-state area corresponding to control registers, debug registers, and MSRs:

- The CR0 field must not set any bit to a value not supported in VMX operation (see Section 23.8). The following are exceptions:
  - Bit 0 (corresponding to CR0.PE) and bit 31 (PG) are not checked if the “unrestricted guest” VM-execution control is 1.<sup>1</sup>
  - Bit 29 (corresponding to CR0.NW) and bit 30 (CD) are never checked because the values of these bits are not changed by VM entry; see Section 26.3.2.1.
- If bit 31 in the CR0 field (corresponding to PG) is 1, bit 0 in that field (PE) must also be 1.<sup>2</sup>
- The CR4 field must not set any bit to a value not supported in VMX operation (see Section 23.8).
- If the “load debug controls” VM-entry control is 1, bits reserved in the IA32\_DEBUGCTL MSR must be 0 in the field for that register. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus performed this check unconditionally.
- The following checks are performed on processors that support Intel 64 architecture:
  - If the “IA-32e mode guest” VM-entry control is 1, bit 31 in the CR0 field (corresponding to CR0.PG) and bit 5 in the CR4 field (corresponding to CR4.PAE) must each be 1.<sup>3</sup>
  - If the “IA-32e mode guest” VM-entry control is 0, bit 17 in the CR4 field (corresponding to CR4.PCIDE) must each be 0.
  - The CR3 field must be such that bits 63:52 and bits in the range 51:32 beyond the processor’s physical-address width are 0.<sup>4,5</sup>
  - If the “load debug controls” VM-entry control is 1, bits 63:32 in the DR7 field must be 0. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus performed this check unconditionally (if they supported Intel 64 architecture).
  - The IA32\_SYSENTER\_ESP field and the IA32\_SYSENTER\_EIP field must each contain a canonical address.

- 
1. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “unrestricted guest” VM-execution control were 0. See Section 24.6.2.
  2. If the capability MSR IA32\_VMX\_CR0\_FIXED0 reports that CR0.PE must be 1 in VMX operation, bit 0 in the CR0 field must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
  3. If the capability MSR IA32\_VMX\_CR0\_FIXED0 reports that CR0.PG must be 1 in VMX operation, bit 31 in the CR0 field must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
  4. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  5. Bit 63 of the CR3 field in the guest-state area must be 0. This is true even though, if CR4.PCIDE = 1, bit 63 of the source operand to MOV to CR3 is used to determine whether cached translation information is invalidated.

- If the “load IA32\_PERF\_GLOBAL\_CTRL” VM-entry control is 1, bits reserved in the IA32\_PERF\_GLOBAL\_CTRL MSR must be 0 in the field for that register (see Figure 18-3).
- If the “load IA32\_PAT” VM-entry control is 1, the value of the field for the IA32\_PAT MSR must be one that could be written by WRMSR without fault at CPL 0. Specifically, each of the 8 bytes in the field must have one of the values 0 (UC), 1 (WC), 4 (WT), 5 (WP), 6 (WB), or 7 (UC-).
- If the “load IA32\_EFER” VM-entry control is 1, the following checks are performed on the field for the IA32\_EFER MSR :
  - Bits reserved in the IA32\_EFER MSR must be 0.
  - Bit 10 (corresponding to IA32\_EFER.LMA) must equal the value of the “IA-32e mode guest” VM-exit control. It must also be identical to bit 8 (LME) if bit 31 in the CRO field (corresponding to CRO.PG) is 1.<sup>1</sup>

### 26.3.1.2 Checks on Guest Segment Registers

This section specifies the checks on the fields for CS, SS, DS, ES, FS, GS, TR, and LDTR. The following terms are used in defining these checks:

- The guest will be **virtual-8086** if the VM flag (bit 17) is 1 in the RFLAGS field in the guest-state area.
- The guest will be **IA-32e mode** if the “IA-32e mode guest” VM-entry control is 1. (This is possible only on processors that support Intel 64 architecture.)
- Any one of these registers is said to be **usable** if the unusable bit (bit 16) is 0 in the access-rights field for that register.

The following are the checks on these fields:

- Selector fields.
  - TR. The TI flag (bit 2) must be 0.
  - LDTR. If LDTR is usable, the TI flag (bit 2) must be 0.
  - SS. If the guest will not be virtual-8086 and the “unrestricted guest” VM-execution control is 0, the RPL (bits 1:0) must equal the RPL of the selector field for CS.<sup>2</sup>
- Base-address fields.
  - CS, SS, DS, ES, FS, GS. If the guest will be virtual-8086, the address must be the selector field shifted left 4 bits (multiplied by 16).
  - The following checks are performed on processors that support Intel 64 architecture:
    - TR, FS, GS. The address must be canonical.
    - LDTR. If LDTR is usable, the address must be canonical.
    - CS. Bits 63:32 of the address must be zero.
    - SS, DS, ES. If the register is usable, bits 63:32 of the address must be zero.
- Limit fields for CS, SS, DS, ES, FS, GS. If the guest will be virtual-8086, the field must be 0000FFFFH.
- Access-rights fields.
  - CS, SS, DS, ES, FS, GS.
    - If the guest will be virtual-8086, the field must be 000000F3H. This implies the following:
      - Bits 3:0 (Type) must be 3, indicating an expand-up read/write accessed data segment.
      - Bit 4 (S) must be 1.
      - Bits 6:5 (DPL) must be 3.

---

1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PG must be 1 in VMX operation, bit 31 in the CRO field must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

2. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “unrestricted guest” VM-execution control were 0. See Section 24.6.2.

- Bit 7 (P) must be 1.
- Bits 11:8 (reserved), bit 12 (software available), bit 13 (reserved/L), bit 14 (D/B), bit 15 (G), bit 16 (unusable), and bits 31:17 (reserved) must all be 0.
- If the guest will not be virtual-8086, the different sub-fields are considered separately:
  - Bits 3:0 (Type).
    - CS. The values allowed depend on the setting of the “unrestricted guest” VM-execution control:
      - If the control is 0, the Type must be 9, 11, 13, or 15 (accessed code segment).
      - If the control is 1, the Type must be either 3 (read/write accessed expand-up data segment) or one of 9, 11, 13, and 15 (accessed code segment).
    - SS. If SS is usable, the Type must be 3 or 7 (read/write, accessed data segment).
    - DS, ES, FS, GS. The following checks apply if the register is usable:
      - Bit 0 of the Type must be 1 (accessed).
      - If bit 3 of the Type is 1 (code segment), then bit 1 of the Type must be 1 (readable).
  - Bit 4 (S). If the register is CS or if the register is usable, S must be 1.
  - Bits 6:5 (DPL).
    - CS.
      - If the Type is 3 (read/write accessed expand-up data segment), the DPL must be 0. The Type can be 3 only if the “unrestricted guest” VM-execution control is 1.
      - If the Type is 9 or 11 (non-conforming code segment), the DPL must equal the DPL in the access-rights field for SS.
      - If the Type is 13 or 15 (conforming code segment), the DPL cannot be greater than the DPL in the access-rights field for SS.
    - SS.
      - If the “unrestricted guest” VM-execution control is 0, the DPL must equal the RPL from the selector field.
      - The DPL must be 0 either if the Type in the access-rights field for CS is 3 (read/write accessed expand-up data segment) or if bit 0 in the CR0 field (corresponding to CR0.PE) is 0.<sup>1</sup>
    - DS, ES, FS, GS. The DPL cannot be less than the RPL in the selector field if (1) the “unrestricted guest” VM-execution control is 0; (2) the register is usable; and (3) the Type in the access-rights field is in the range 0 – 11 (data segment or non-conforming code segment).
  - Bit 7 (P). If the register is CS or if the register is usable, P must be 1.
  - Bits 11:8 (reserved). If the register is CS or if the register is usable, these bits must all be 0.
  - Bit 14 (D/B). For CS, D/B must be 0 if the guest will be IA-32e mode and the L bit (bit 13) in the access-rights field is 1.
  - Bit 15 (G). The following checks apply if the register is CS or if the register is usable:
    - If any bit in the limit field in the range 11:0 is 0, G must be 0.
    - If any bit in the limit field in the range 31:20 is 1, G must be 1.
  - Bits 31:17 (reserved). If the register is CS or if the register is usable, these bits must all be 0.
- TR. The different sub-fields are considered separately:

---

1. The following apply if either the “unrestricted guest” VM-execution control or bit 31 of the primary processor-based VM-execution controls is 0: (1) bit 0 in the CR0 field must be 1 if the capability MSR IA32\_VMX\_CR0\_FIXED0 reports that CR0.PE must be 1 in VMX operation; and (2) the Type in the access-rights field for CS cannot be 3.

- Bits 3:0 (Type).
    - If the guest will not be IA-32e mode, the Type must be 3 (16-bit busy TSS) or 11 (32-bit busy TSS).
    - If the guest will be IA-32e mode, the Type must be 11 (64-bit busy TSS).
  - Bit 4 (S). S must be 0.
  - Bit 7 (P). P must be 1.
  - Bits 11:8 (reserved). These bits must all be 0.
  - Bit 15 (G).
    - If any bit in the limit field in the range 11:0 is 0, G must be 0.
    - If any bit in the limit field in the range 31:20 is 1, G must be 1.
  - Bit 16 (Unusable). The unusable bit must be 0.
  - Bits 31:17 (reserved). These bits must all be 0.
- LDTR. The following checks on the different sub-fields apply only if LDTR is usable:
- Bits 3:0 (Type). The Type must be 2 (LDT).
  - Bit 4 (S). S must be 0.
  - Bit 7 (P). P must be 1.
  - Bits 11:8 (reserved). These bits must all be 0.
  - Bit 15 (G).
    - If any bit in the limit field in the range 11:0 is 0, G must be 0.
    - If any bit in the limit field in the range 31:20 is 1, G must be 1.
  - Bits 31:17 (reserved). These bits must all be 0.

### 26.3.1.3 Checks on Guest Descriptor-Table Registers

The following checks are performed on the fields for GDTR and IDTR:

- On processors that support Intel 64 architecture, the base-address fields must contain canonical addresses.
- Bits 31:16 of each limit field must be 0.

### 26.3.1.4 Checks on Guest RIP and RFLAGS

The following checks are performed on fields in the guest-state area corresponding to RIP and RFLAGS:

- RIP. The following checks are performed on processors that support Intel 64 architecture:
  - Bits 63:32 must be 0 if the “IA-32e mode guest” VM-entry control is 0 or if the L bit (bit 13) in the access-rights field for CS is 0.
  - If the processor supports  $N < 64$  linear-address bits, bits 63:N must be identical if the “IA-32e mode guest” VM-entry control is 1 and the L bit in the access-rights field for CS is 1.<sup>1</sup> (No check applies if the processor supports 64 linear-address bits.)
- RFLAGS.
  - Reserved bits 63:22 (bits 31:22 on processors that do not support Intel 64 architecture), bit 15, bit 5 and bit 3 must be 0 in the field, and reserved bit 1 must be 1.
  - The VM flag (bit 17) must be 0 either if the “IA-32e mode guest” VM-entry control is 1 or if bit 0 in the CRO field (corresponding to CR0.PE) is 0.<sup>2</sup>

---

1. Software can determine the number N by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

- The IF flag (RFLAGS[bit 9]) must be 1 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) is external interrupt.

### 26.3.1.5 Checks on Guest Non-Register State

The following checks are performed on fields in the guest-state area corresponding to non-register state:

- Activity state.
  - The activity-state field must contain a value in the range 0 – 3, indicating an activity state supported by the implementation (see Section 24.4.2). Future processors may include support for other activity states. Software should read the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6) to determine what activity states are supported.
  - The activity-state field must not indicate the HLT state if the DPL (bits 6:5) in the access-rights field for SS is not 0.<sup>1</sup>
  - The activity-state field must indicate the active state if the interruptibility-state field indicates blocking by either MOV-SS or by STI (if either bit 0 or bit 1 in that field is 1).
  - If the valid bit (bit 31) in the VM-entry interruption-information field is 1, the interruption to be delivered (as defined by interruption type and vector) must not be one that would normally be blocked while a logical processor is in the activity state corresponding to the contents of the activity-state field. The following items enumerate the interruptions (as specified in the VM-entry interruption-information field) whose injection is allowed for the different activity states:
    - Active. Any interruption is allowed.
    - HLT. The only events allowed are the following:
      - Those with interruption type external interrupt or non-maskable interrupt (NMI).
      - Those with interruption type hardware exception and vector 1 (debug exception) or vector 18 (machine-check exception).
      - Those with interruption type other event and vector 0 (pending MTF VM exit).
 See Table 24-13 in Section 24.8.3 for details regarding the format of the VM-entry interruption-information field.
    - Shutdown. Only NMIs and machine-check exceptions are allowed.
    - Wait-for-SIPI. No interruptions are allowed.
  - The activity-state field must not indicate the wait-for-SIPI state if the “entry to SMM” VM-entry control is 1.
- Interruptibility state.
  - The reserved bits (bits 31:4) must be 0.
  - The field cannot indicate blocking by both STI and MOV SS (bits 0 and 1 cannot both be 1).
  - Bit 0 (blocking by STI) must be 0 if the IF flag (bit 9) is 0 in the RFLAGS field.
  - Bit 0 (blocking by STI) and bit 1 (blocking by MOV-SS) must both be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 0, indicating external interrupt.
  - Bit 1 (blocking by MOV-SS) must be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 2, indicating non-maskable interrupt (NMI).
  - Bit 2 (blocking by SMI) must be 0 if the processor is not in SMM.
  - Bit 2 (blocking by SMI) must be 1 if the “entry to SMM” VM-entry control is 1.

---

2. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PE must be 1 in VMX operation, bit 0 in the CRO field must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

1. As noted in Section 24.4.1, SS.DPL corresponds to the logical processor’s current privilege level (CPL).

- A processor may require bit 0 (blocking by STI) to be 0 if the valid bit (bit 31) in the VM-entry interruption-information field is 1 and the interruption type (bits 10:8) in that field has value 2, indicating NMI. Other processors may not make this requirement.
- Bit 3 (blocking by NMI) must be 0 if the “virtual NMIs” VM-execution control is 1, the valid bit (bit 31) in the VM-entry interruption-information field is 1, and the interruption type (bits 10:8) in that field has value 2 (indicating NMI).

### NOTE

If the “virtual NMIs” VM-execution control is 0, there is no requirement that bit 3 be 0 if the valid bit in the VM-entry interruption-information field is 1 and the interruption type in that field has value 2.

- Pending debug exceptions.
  - Bits 11:4, bit 13, and bits 63:15 (bits 31:15 on processors that do not support Intel 64 architecture) must be 0.
  - The following checks are performed if any of the following holds: (1) the interruptibility-state field indicates blocking by STI (bit 0 in that field is 1); (2) the interruptibility-state field indicates blocking by MOV SS (bit 1 in that field is 1); or (3) the activity-state field indicates HLT:
    - Bit 14 (BS) must be 1 if the TF flag (bit 8) in the RFLAGS field is 1 and the BTF flag (bit 1) in the IA32\_DEBUGCTL field is 0.
    - Bit 14 (BS) must be 0 if the TF flag (bit 8) in the RFLAGS field is 0 or the BTF flag (bit 1) in the IA32\_DEBUGCTL field is 1.
- VMCS link pointer. The following checks apply if the field contains a value other than FFFFFFFF\_FFFFFFFFH:
  - Bits 11:0 must be 0.
  - Bits beyond the processor’s physical-address width must be 0.<sup>1,2</sup>
  - The 4 bytes located in memory referenced by the value of the field (as a physical address) must satisfy the following:
    - Bits 30:0 must contain the processor’s VMCS revision identifier (see Section 24.2).<sup>3</sup>
    - Bit 31 must contain the setting of the “VMCS shadowing” VM-execution control.<sup>4</sup> This implies that the referenced VMCS is a shadow VMCS (see Section 24.10) if and only if the “VMCS shadowing” VM-execution control is 1.
  - If the processor is not in SMM or the “entry to SMM” VM-entry control is 1, the field must not contain the current VMCS pointer.
  - If the processor is in SMM and the “entry to SMM” VM-entry control is 0, the field must differ from the executive-VMCS pointer.

#### 26.3.1.6 Checks on Guest Page-Directory-Pointer-Table Entries

If CR0.PG = 1, CR4.PAE = 1, and IA32\_EFER.LMA = 0, the logical processor also uses **PAE paging** (see Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*).<sup>5</sup> When PAE paging is in use, the physical address in CR3 references a table of **page-directory-pointer-table entries** (PDPTEs). A MOV to CR3 when PAE paging is in use checks the validity of the PDPTEs.

- 
1. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  2. If IA32\_VMX\_BASIC[48] is read as 1, this field must not set any bits in the range 63:32; see Appendix A.1.
  3. Earlier versions of this manual specified that the VMCS revision identifier was a 32-bit field. For all processors produced prior to this change, bit 31 of the VMCS revision identifier was 0.
  4. “VMCS shadowing” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “VMCS shadowing” VM-execution control were 0. See Section 24.6.2.

A VM entry is to a guest that uses PAE paging if (1) bit 31 (corresponding to CR0.PG) is set in the CR0 field in the guest-state area; (2) bit 5 (corresponding to CR4.PAE) is set in the CR4 field; and (3) the “IA-32e mode guest” VM-entry control is 0. Such a VM entry checks the validity of the PDPTes:

- If the “enable EPT” VM-execution control is 0, VM entry checks the validity of the PDPTes referenced by the CR3 field in the guest-state area if either (1) PAE paging was not in use before the VM entry; or (2) the value of CR3 is changing as a result of the VM entry. VM entry may check their validity even if neither (1) nor (2) hold.<sup>1</sup>
- If the “enable EPT” VM-execution control is 1, VM entry checks the validity of the PDPTe fields in the guest-state area (see Section 24.4.2).

A VM entry to a guest that does not use PAE paging does not check the validity of any PDPTes.

A VM entry that checks the validity of the PDPTes uses the same checks that are used when CR3 is loaded with MOV to CR3 when PAE paging is in use.<sup>2</sup> If MOV to CR3 would cause a general-protection exception due to the PDPTes that would be loaded (e.g., because a reserved bit is set), the VM entry fails.

## 26.3.2 Loading Guest State

Processor state is updated on VM entries in the following ways:

- Some state is loaded from the guest-state area.
- Some state is determined by VM-entry controls.
- The page-directory pointers are loaded based on the values of certain control registers.

This loading may be performed in any order and in parallel with the checking of VMCS contents (see Section 26.3.1).

The loading of guest state is detailed in Section 26.3.2.1 to Section 26.3.2.4. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

In addition to the state loading described in this section, VM entries may load MSRs from the VM-entry MSR-load area (see Section 26.4). This loading occurs only after the state loading described in this section and the checking of VMCS contents described in Section 26.3.1.

### 26.3.2.1 Loading Guest Control Registers, Debug Registers, and MSRs

The following items describe how guest control registers, debug registers, and MSRs are loaded on VM entry:

- CR0 is loaded from the CR0 field with the exception of the following bits, which are never modified on VM entry: ET (bit 4); reserved bits 15:6, 17, and 28:19; NW (bit 29) and CD (bit 30).<sup>3</sup> The values of these bits in the CR0 field are ignored.
- CR3 and CR4 are loaded from the CR3 field and the CR4 field, respectively.
- If the “load debug controls” VM-execution control is 1, DR7 is loaded from the DR7 field with the exception that bit 12 and bits 15:14 are always 0 and bit 10 is always 1. The values of these bits in the DR7 field are ignored. The first processors to support the virtual-machine extensions supported only the 1-setting of the “load debug controls” VM-execution control and thus always loaded DR7 from the DR7 field.

---

5. On processors that support Intel 64 architecture, the physical-address extension may support more than 36 physical-address bits. Software can determine the number physical-address bits supported by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

1. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “enable EPT” VM-execution control were 0. See Section 24.6.2.

2. This implies that (1) bits 11:9 in each PDPTe are ignored; and (2) if bit 0 (present) is clear in one of the PDPTes, bits 63:1 of that PDPTe are ignored.

3. Bits 15:6, bit 17, and bit 28:19 of CR0 and CR0.ET are unchanged by executions of MOV to CR0. Bits 15:6, bit 17, and bit 28:19 of CR0 are always 0 and CR0.ET is always 1.

- The following describes how some MSR fields are loaded using fields in the guest-state area:
  - If the “load debug controls” VM-execution control is 1, the IA32\_DEBUGCTL MSR is loaded from the IA32\_DEBUGCTL field. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus always loaded the IA32\_DEBUGCTL MSR from the IA32\_DEBUGCTL field.
  - The IA32\_SYSENTER\_CS MSR is loaded from the IA32\_SYSENTER\_CS field. Since this field has only 32 bits, bits 63:32 of the MSR are cleared to 0.
  - The IA32\_SYSENTER\_ESP and IA32\_SYSENTER\_EIP MSRs are loaded from the IA32\_SYSENTER\_ESP field and the IA32\_SYSENTER\_EIP field, respectively. On processors that do not support Intel 64 architecture, these fields have only 32 bits; bits 63:32 of the MSRs are cleared to 0.
  - The following are performed on processors that support Intel 64 architecture:
    - The MSRs FS.base and GS.base are loaded from the base-address fields for FS and GS, respectively (see Section 26.3.2.2).
    - If the “load IA32\_EFER” VM-entry control is 0, bits in the IA32\_EFER MSR are modified as follows:
      - IA32\_EFER.LMA is loaded with the setting of the “IA-32e mode guest” VM-entry control.
      - If CRO is being loaded so that CRO.PG = 1, IA32\_EFER.LME is also loaded with the setting of the “IA-32e mode guest” VM-entry control.<sup>1</sup> Otherwise, IA32\_EFER.LME is unmodified.

See below for the case in which the “load IA32\_EFER” VM-entry control is 1

  - If the “load IA32\_PERF\_GLOBAL\_CTRL” VM-entry control is 1, the IA32\_PERF\_GLOBAL\_CTRL MSR is loaded from the IA32\_PERF\_GLOBAL\_CTRL field.
  - If the “load IA32\_PAT” VM-entry control is 1, the IA32\_PAT MSR is loaded from the IA32\_PAT field.
  - If the “load IA32\_EFER” VM-entry control is 1, the IA32\_EFER MSR is loaded from the IA32\_EFER field.

With the exception of FS.base and GS.base, any of these MSRs is subsequently overwritten if it appears in the VM-entry MSR-load area. See Section 26.4.

- The SMBASE register is unmodified by all VM entries except those that return from SMM.

### 26.3.2.2 Loading Guest Segment Registers and Descriptor-Table Registers

For each of CS, SS, DS, ES, FS, GS, TR, and LDTR, fields are loaded from the guest-state area as follows:

- The unusable bit is loaded from the access-rights field. This bit can never be set for TR (see Section 26.3.1.2). If it is set for one of the other registers, the following apply:
  - For each of CS, SS, DS, ES, FS, and GS, uses of the segment cause faults (general-protection exception or stack-fault exception) outside 64-bit mode, just as they would had the segment been loaded using a null selector. This bit does not cause accesses to fault in 64-bit mode.
  - If this bit is set for LDTR, uses of LDTR cause general-protection exceptions in all modes, just as they would had LDTR been loaded using a null selector.

If this bit is clear for any of CS, SS, DS, ES, FS, GS, TR, and LDTR, a null selector value does not cause a fault (general-protection exception or stack-fault exception).
- TR. The selector, base, limit, and access-rights fields are loaded.
- CS.
  - The following fields are always loaded: selector, base address, limit, and (from the access-rights field) the L, D, and G bits.
  - For the other fields, the unusable bit of the access-rights field is consulted:
    - If the unusable bit is 0, all of the access-rights field is loaded.
    - If the unusable bit is 1, the remainder of CS access rights are undefined after VM entry.

---

1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PG must be 1 in VMX operation, VM entry must be loading CRO so that CRO.PG = 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

- SS, DS, ES, FS, GS, and LDTR.
  - The selector fields are loaded.
  - For the other fields, the unusable bit of the corresponding access-rights field is consulted:
    - If the unusable bit is 0, the base-address, limit, and access-rights fields are loaded.
    - If the unusable bit is 1, the base address, the segment limit, and the remainder of the access rights are undefined after VM entry with the following exceptions:
      - Bits 3:0 of the base address for SS are cleared to 0.
      - SS.DPL is always loaded from the SS access-rights field. This will be the current privilege level (CPL) after the VM entry completes.
      - SS.B is always set to 1.
      - The base addresses for FS and GS are loaded from the corresponding fields in the VMCS. On processors that support Intel 64 architecture, the values loaded for base addresses for FS and GS are also manifest in the FS.base and GS.base MSRs.
      - On processors that support Intel 64 architecture, the base address for LDTR is set to an undefined but canonical value.
      - On processors that support Intel 64 architecture, bits 63:32 of the base addresses for SS, DS, and ES are cleared to 0.

GDTR and IDTR are loaded using the base and limit fields.

### 26.3.2.3 Loading Guest RIP, RSP, and RFLAGS

RSP, RIP, and RFLAGS are loaded from the RSP field, the RIP field, and the RFLAGS field, respectively. The following items regard the upper 32 bits of these fields on VM entries that are not to 64-bit mode:

- Bits 63:32 of RSP are undefined outside 64-bit mode. Thus, a logical processor may ignore the contents of bits 63:32 of the RSP field on VM entries that are not to 64-bit mode.
- As noted in Section 26.3.1.4, bits 63:32 of the RIP and RFLAGS fields must be 0 on VM entries that are not to 64-bit mode.

### 26.3.2.4 Loading Page-Directory-Pointer-Table Entries

As noted in Section 26.3.1.6, the logical processor uses PAE paging if bit 5 in CR4 (CR4.PAE) is 1 and IA32\_EFER.LMA is 0. A VM entry to a guest that uses PAE paging loads the PDPTEs into internal, non-architectural registers based on the setting of the “enable EPT” VM-execution control:

- If the control is 0, the PDPTEs are loaded from the page-directory-pointer table referenced by the physical address in the value of CR3 being loaded by the VM entry (see Section 26.3.2.1). The values loaded are treated as physical addresses in VMX non-root operation.
- If the control is 1, the PDPTEs are loaded from corresponding fields in the guest-state area (see Section 24.4.2). The values loaded are treated as guest-physical addresses in VMX non-root operation.

### 26.3.2.5 Updating Non-Register State

Section 28.3 describes how the VMX architecture controls how a logical processor manages information in the TLBs and paging-structure caches. The following items detail how VM entries invalidate cached mappings:

- If the “enable VPID” VM-execution control is 0, the logical processor invalidates linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP).
- VM entries are not required to invalidate any guest-physical mappings, nor are they required to invalidate any linear mappings or combined mappings if the “enable VPID” VM-execution control is 1.

If the “virtual-interrupt delivery” VM-execution control is 1, VM entry loads the values of RVI and SVI from the guest interrupt-status field in the VMCS (see Section 24.4.2). After doing so, the logical processor first causes PPR virtualization (Section 29.1.3) and then evaluates pending virtual interrupts (Section 29.2.1).

If a virtual interrupt is recognized, it may be delivered in VMX non-root operation immediately after VM entry (including any specified event injection) completes; see Section 26.6.5. See Section 29.2.2 for details regarding the delivery of virtual interrupts.

### 26.3.3 Clearing Address-Range Monitoring

The Intel 64 and IA-32 architectures allow software to monitor a specified address range using the MONITOR and MWAIT instructions. See Section 8.10.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*. VM entries clear any address-range monitoring that may be in effect.

## 26.4 LOADING MSRS

VM entries may load MSRs from the VM-entry MSR-load area (see Section 24.8.2). Specifically each entry in that area (up to the number specified in the VM-entry MSR-load count) is processed in order by loading the MSR indexed by bits 31:0 with the contents of bits 127:64 as they would be written by WRMSR.<sup>1</sup>

Processing of an entry fails in any of the following cases:

- The value of bits 31:0 is either C0000100H (the IA32\_FS\_BASE MSR) or C0000101 (the IA32\_GS\_BASE MSR).
- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be written only in system-management mode (SMM) and the VM entry did not commence in SMM. (IA32\_SMM\_MONITOR\_CTL is an MSR that can be written only in SMM.)
- The value of bits 31:0 indicates an MSR that cannot be loaded on VM entries for model-specific reasons. A processor may prevent loading of certain MSRs even if they can normally be written by WRMSR. Such model-specific behavior is documented in Chapter 35.
- Bits 63:32 are not all 0.
- An attempt to write bits 127:64 to the MSR indexed by bits 31:0 of the entry would cause a general-protection exception if executed via WRMSR with CPL = 0.<sup>2</sup>

The VM entry fails if processing fails for any entry. The logical processor responds to such failures by loading state from the host-state area, as it would for a VM exit. See Section 26.7.

If any MSR is being loaded in such a way that would architecturally require a TLB flush, the TLBs are updated so that, after VM entry, the logical processor will not use any translations that were cached before the transition.

## 26.5 EVENT INJECTION

If the valid bit in the VM-entry interruption-information field (see Section 24.8.3) is 1, VM entry causes an event to be delivered (or made pending) after all components of guest state have been loaded (including MSRs) and after the VM-execution control fields have been established.

- If the interruption type in the field is 0 (external interrupt), 2 (non-maskable interrupt); 3 (hardware exception), 4 (software interrupt), 5 (privileged software exception), or 6 (software exception), the event is delivered as described in Section 26.5.1.

---

1. Because attempts to modify the value of IA32\_EFER.LMA by WRMSR are ignored, attempts to modify it using the VM-entry MSR-load area are also ignored.

2. If CR0.PG = 1, WRMSR to the IA32\_EFER MSR causes a general-protection exception if it would modify the LME bit. If VM entry has established CR0.PG = 1, the IA32\_EFER MSR should not be included in the VM-entry MSR-load area for the purpose of modifying the LME bit.

- If the interruption type in the field is 7 (other event) and the vector field is 0, an MTF VM exit is pending after VM entry. See Section 26.5.2.

## 26.5.1 Vectored-Event Injection

VM entry delivers an injected vectored event within the guest context established by VM entry. This means that delivery occurs after all components of guest state have been loaded (including MSRs) and after the VM-execution control fields have been established.<sup>1</sup> The event is delivered using the vector in that field to select a descriptor in the IDT. Since event injection occurs after loading IDTR from the guest-state area, this is the guest IDT.

Section 26.5.1.1 provides details of vectored-event injection. In general, the event is delivered exactly as if it had been generated normally.

If event delivery encounters a nested exception (for example, a general-protection exception because the vector indicates a descriptor beyond the IDT limit), the exception bitmap is consulted using the vector of that exception:

- If the bit for the nested exception is 0, the nested exception is delivered normally. If the nested exception is benign, it is delivered through the IDT. If it is contributory or a page fault, a double fault may be generated, depending on the nature of the event whose delivery encountered the nested exception. See Chapter 6, “Interrupt 8—Double Fault Exception (#DF)” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.<sup>2</sup>
- If the bit for the nested exception is 1, a VM exit occurs. Section 26.5.1.2 details cases in which event injection causes a VM exit.

### 26.5.1.1 Details of Vectored-Event Injection

The event-injection process is controlled by the contents of the VM-entry interruption information field (format given in Table 24-13), the VM-entry exception error-code field, and the VM-entry instruction-length field. The following items provide details of the process:

- The value pushed on the stack for RFLAGS is generally that which was loaded from the guest-state area. The value pushed for the RF flag is not modified based on the type of event being delivered. However, the pushed value of RFLAGS may be modified if a software interrupt is being injected into a guest that will be in virtual-8086 mode (see below). After RFLAGS is pushed on the stack, the value in the RFLAGS register is modified as is done normally when delivering an event through the IDT.
- The instruction pointer that is pushed on the stack depends on the type of event and whether nested exceptions occur during its delivery. The term **current guest RIP** refers to the value to be loaded from the guest-state area. The value pushed is determined as follows:<sup>3</sup>
  - If VM entry successfully injects (with no nested exception) an event with interruption type external interrupt, NMI, or hardware exception, the current guest RIP is pushed on the stack.
  - If VM entry successfully injects (with no nested exception) an event with interruption type software interrupt, privileged software exception, or software exception, the current guest RIP is incremented by the VM-entry instruction length before being pushed on the stack.
  - If VM entry encounters an exception while injecting an event and that exception does not cause a VM exit, the current guest RIP is pushed on the stack regardless of event type or VM-entry instruction length. If the encountered exception does cause a VM exit that saves RIP, the saved RIP is current guest RIP.
- If the deliver-error-code bit (bit 11) is set in the VM-entry interruption-information field, the contents of the VM-entry exception error-code field is pushed on the stack as an error code would be pushed during delivery of an exception.

1. This does not imply that injection of an exception or interrupt will cause a VM exit due to the settings of VM-execution control fields (such as the exception bitmap) that would cause a VM exit if the event had occurred in VMX non-root operation. In contrast, a nested exception encountered during event delivery may cause a VM exit; see Section 26.5.1.1.

2. Hardware exceptions with the following unused vectors are considered benign: 15 and 21–31. A hardware exception with vector 20 is considered benign unless the processor supports the 1-setting of the “EPT-violation #VE” VM-execution control; in that case, it has the same severity as page faults.

3. While these items refer to RIP, the width of the value pushed (16 bits, 32 bits, or 64 bits) is determined normally.

- DR6, DR7, and the IA32\_DEBUGCTL MSR are not modified by event injection, even if the event has vector 1 (normal deliveries of debug exceptions, which have vector 1, do update these registers).
- If VM entry is injecting a software interrupt and the guest will be in virtual-8086 mode (RFLAGS.VM = 1), no general-protection exception can occur due to RFLAGS.IOPL < 3. A VM monitor should check RFLAGS.IOPL before injecting such an event and, if desired, inject a general-protection exception instead of a software interrupt.
- If VM entry is injecting a software interrupt and the guest will be in virtual-8086 mode with virtual-8086 mode extensions (RFLAGS.VM = CR4.VME = 1), event delivery is subject to VME-based interrupt redirection based on the software interrupt redirection bitmap in the task-state segment (TSS) as follows:
  - If bit  $n$  in the bitmap is clear (where  $n$  is the number of the software interrupt), the interrupt is directed to an 8086 program interrupt handler: the processor uses a 16-bit interrupt-vector table (IVT) located at linear address zero. If the value of RFLAGS.IOPL is less than 3, the following modifications are made to the value of RFLAGS that is pushed on the stack: IOPL is set to 3, and IF is set to the value of VIF.
  - If bit  $n$  in the bitmap is set (where  $n$  is the number of the software interrupt), the interrupt is directed to a protected-mode interrupt handler. (In other words, the injection is treated as described in the next item.) In this case, the software interrupt does not invoke such a handler if RFLAGS.IOPL < 3 (a general-protection exception occurs instead). However, as noted above, RFLAGS.IOPL cannot cause an injected software interrupt to cause such an exception. Thus, in this case, the injection invokes a protected-mode interrupt handler independent of the value of RFLAGS.IOPL.

Injection of events of other types are not subject to this redirection.

- If VM entry is injecting a software interrupt (not redirected as described above) or software exception, privilege checking is performed on the IDT descriptor being accessed as would be the case for executions of INT  $n$ , INT3, or INTO (the descriptor's DPL cannot be less than CPL). There is no checking of RFLAGS.IOPL, even if the guest will be in virtual-8086 mode. Failure of this check may lead to a nested exception. Injection of an event with interruption type external interrupt, NMI, hardware exception, and privileged software exception, or with interruption type software interrupt and being redirected as described above, do not perform these checks.
- If VM entry is injecting a non-maskable interrupt (NMI) and the “virtual NMIs” VM-execution control is 1, virtual-NMI blocking is in effect after VM entry.
- The transition causes a last-branch record to be logged if the LBR bit is set in the IA32\_DEBUGCTL MSR. This is true even for events such as debug exceptions, which normally clear the LBR bit before delivery.
- The last-exception record MSRs (LERs) may be updated based on the setting of the LBR bit in the IA32\_DEBUGCTL MSR. Events such as debug exceptions, which normally clear the LBR bit before they are delivered, and therefore do not normally update the LERs, may do so as part of VM-entry event injection.
- If injection of an event encounters a nested exception that does not itself cause a VM exit, the value of the EXT bit (bit 0) in any error code pushed on the stack is determined as follows:
  - If event being injected has interruption type external interrupt, NMI, hardware exception, or privileged software exception and encounters a nested exception (but does not produce a double fault), the error code for the first such exception encountered sets the EXT bit.
  - If event being injected is a software interrupt or an software exception and encounters a nested exception (but does not produce a double fault), the error code for the first such exception encountered clears the EXT bit.
  - If event delivery encounters a nested exception and delivery of that exception encounters another exception (but does not produce a double fault), the error code for that exception sets the EXT bit. If a double fault is produced, the error code for the double fault is 0000H (the EXT bit is clear).

### 26.5.1.2 VM Exits During Event Injection

An event being injected never causes a VM exit directly regardless of the settings of the VM-execution controls. For example, setting the “NMI exiting” VM-execution control to 1 does not cause a VM exit due to injection of an NMI.

However, the event-delivery process may lead to a VM exit:

- If the vector in the VM-entry interruption-information field identifies a task gate in the IDT, the attempted task switch may cause a VM exit just as it would had the injected event occurred during normal execution in VMX non-root operation (see Section 25.4.2).
- If event delivery encounters a nested exception, a VM exit may occur depending on the contents of the exception bitmap (see Section 25.2).
- If event delivery generates a double-fault exception (due to a nested exception); the logical processor encounters another nested exception while attempting to call the double-fault handler; and that exception does not cause a VM exit due to the exception bitmap; then a VM exit occurs due to triple fault (see Section 25.2).
- If event delivery injects a double-fault exception and encounters a nested exception that does not cause a VM exit due to the exception bitmap, then a VM exit occurs due to triple fault (see Section 25.2).
- If the “virtualize APIC accesses” VM-execution control is 1 and event delivery generates an access to the APIC-access page, that access is treated as described in Section 29.4 and may cause a VM exit.<sup>1</sup>

If the event-delivery process does cause a VM exit, the processor state before the VM exit is determined just as it would be had the injected event occurred during normal execution in VMX non-root operation. If the injected event directly accesses a task gate that cause a VM exit or if the first nested exception encountered causes a VM exit, information about the injected event is saved in the IDT-vectoring information field (see Section 27.2.3).

### 26.5.1.3 Event Injection for VM Entries to Real-Address Mode

If VM entry is loading CR0.PE with 0, any injected vectored event is delivered as would normally be done in real-address mode.<sup>2</sup> Specifically, VM entry uses the vector provided in the VM-entry interruption-information field to select a 4-byte entry from an interrupt-vector table at the linear address in IDTR.base. Further details are provided in Section 15.1.4 in Volume 3A of the *IA-32 Intel® Architecture Software Developer’s Manual*.

Because bit 11 (deliver error code) in the VM-entry interruption-information field must be 0 if CR0.PE will be 0 after VM entry (see Section 26.2.1.3), vectored events injected with CR0.PE = 0 do not push an error code on the stack. This is consistent with event delivery in real-address mode.

If event delivery encounters a fault (due to a violation of IDTR.limit or of SS.limit), the fault is treated as if it had occurred during event delivery in VMX non-root operation. Such a fault may lead to a VM exit as discussed in Section 26.5.1.2.

### 26.5.2 Injection of Pending MTF VM Exits

If the interruption type in the VM-entry interruption-information field is 7 (other event) and the vector field is 0, VM entry causes an MTF VM exit to be pending on the instruction boundary following VM entry. This is the case even if the “monitor trap flag” VM-execution control is 0. See Section 25.5.2 for the treatment of pending MTF VM exits.

## 26.6 SPECIAL FEATURES OF VM ENTRY

This section details a variety of features of VM entry. It uses the following terminology: a VM entry is **vectoring** if the valid bit (bit 31) of the VM-entry interruption information field is 1 and the interruption type in the field is 0 (external interrupt), 2 (non-maskable interrupt); 3 (hardware exception), 4 (software interrupt), 5 (privileged software exception), or 6 (software exception).

- 
1. “Virtualize APIC accesses” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “virtualize APIC accesses” VM-execution control were 0. See Section 24.6.2.
  2. If the capability MSR IA32\_VMX\_CR0\_FIXED0 reports that CR0.PE must be 1 in VMX operation, VM entry must be loading CR0.PE with 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

## 26.6.1 Interruptibility State

The interruptibility-state field in the guest-state area (see Table 24-3) contains bits that control blocking by STI, blocking by MOV SS, and blocking by NMI. This field impacts event blocking after VM entry as follows:

- If the VM entry is vectoring, there is no blocking by STI or by MOV SS following the VM entry, regardless of the contents of the interruptibility-state field.
- If the VM entry is not vectoring, the following apply:
  - Events are blocked by STI if and only if bit 0 in the interruptibility-state field is 1. This blocking is cleared after the guest executes one instruction or incurs an exception (including a debug exception made pending by VM entry; see Section 26.6.3).
  - Events are blocked by MOV SS if and only if bit 1 in the interruptibility-state field is 1. This may affect the treatment of pending debug exceptions; see Section 26.6.3. This blocking is cleared after the guest executes one instruction or incurs an exception (including a debug exception made pending by VM entry).
- The blocking of non-maskable interrupts (NMIs) is determined as follows:
  - If the “virtual NMIs” VM-execution control is 0, NMIs are blocked if and only if bit 3 (blocking by NMI) in the interruptibility-state field is 1. If the “NMI exiting” VM-execution control is 0, execution of the IRET instruction removes this blocking (even if the instruction generates a fault). If the “NMI exiting” control is 1, IRET does not affect this blocking.
  - The following items describe the use of bit 3 (blocking by NMI) in the interruptibility-state field if the “virtual NMIs” VM-execution control is 1:
    - The bit’s value does not affect the blocking of NMIs after VM entry. NMIs are not blocked in VMX non-root operation (except for ordinary blocking for other reasons, such as by the MOV SS instruction, the wait-for-SIPI state, etc.)
    - The bit’s value determines whether there is virtual-NMI blocking after VM entry. If the bit is 1, virtual-NMI blocking is in effect after VM entry. If the bit is 0, there is no virtual-NMI blocking after VM entry unless the VM entry is injecting an NMI (see Section 26.5.1.1). Execution of IRET removes virtual-NMI blocking (even if the instruction generates a fault).

If the “NMI exiting” VM-execution control is 0, the “virtual NMIs” control must be 0; see Section 26.2.1.1.
- Blocking of system-management interrupts (SMIs) is determined as follows:
  - If the VM entry was not executed in system-management mode (SMM), SMI blocking is unchanged by VM entry.
  - If the VM entry was executed in SMM, SMIs are blocked after VM entry if and only if the bit 2 in the interruptibility-state field is 1.

## 26.6.2 Activity State

The activity-state field in the guest-state area controls whether, after VM entry, the logical processor is active or in one of the inactive states identified in Section 24.4.2. The use of this field is determined as follows:

- If the VM entry is vectoring, the logical processor is in the active state after VM entry. While the consistency checks described in Section 26.3.1.5 on the activity-state field do apply in this case, the contents of the activity-state field do not determine the activity state after VM entry.
- If the VM entry is not vectoring, the logical processor ends VM entry in the activity state specified in the guest-state area. If VM entry ends with the logical processor in an inactive activity state, the VM entry generates any special bus cycle that is normally generated when that activity state is entered from the active state. If VM entry would end with the logical processor in the shutdown state and the logical processor is in SMX operation,<sup>1</sup> an Intel<sup>®</sup> TXT shutdown condition occurs. The error code used is 0000H, indicating “legacy shutdown.” See *Intel<sup>®</sup> Trusted Execution Technology Preliminary Architecture Specification*.

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENDER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel<sup>®</sup> 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

- Some activity states unconditionally block certain events. The following blocking is in effect after any VM entry that puts the processor in the indicated state:
  - The active state blocks start-up IPIs (SIPIs). SIPIs that arrive while a logical processor is in the active state and in VMX non-root operation are discarded and do not cause VM exits.
  - The HLT state blocks start-up IPIs (SIPIs). SIPIs that arrive while a logical processor is in the HLT state and in VMX non-root operation are discarded and do not cause VM exits.
  - The shutdown state blocks external interrupts and SIPIs. External interrupts that arrive while a logical processor is in the shutdown state and in VMX non-root operation do not cause VM exits even if the “external-interrupt exiting” VM-execution control is 1. SIPIs that arrive while a logical processor is in the shutdown state and in VMX non-root operation are discarded and do not cause VM exits.
  - The wait-for-SIPI state blocks external interrupts, non-maskable interrupts (NMIs), INIT signals, and system-management interrupts (SMIs). Such events do not cause VM exits if they arrive while a logical processor is in the wait-for-SIPI state and in VMX non-root operation do not cause VM exits regardless of the settings of the pin-based VM-execution controls.

### 26.6.3 Delivery of Pending Debug Exceptions after VM Entry

The pending debug exceptions field in the guest-state area indicates whether there are debug exceptions that have not yet been delivered (see Section 24.4.2). This section describes how these are treated on VM entry.

There are no pending debug exceptions after VM entry if any of the following are true:

- The VM entry is vectoring with one of the following interruption types: external interrupt, non-maskable interrupt (NMI), hardware exception, or privileged software exception.
- The interruptibility-state field does not indicate blocking by MOV SS and the VM entry is vectoring with either of the following interruption type: software interrupt or software exception.
- The VM entry is not vectoring and the activity-state field indicates either shutdown or wait-for-SIPI.

If none of the above hold, the pending debug exceptions field specifies the debug exceptions that are pending for the guest. There are **valid pending debug exceptions** if either the BS bit (bit 14) or the enable-breakpoint bit (bit 12) is 1. If there are valid pending debug exceptions, they are handled as follows:

- If the VM entry is not vectoring, the pending debug exceptions are treated as they would had they been encountered normally in guest execution:
  - If the logical processor is not blocking such exceptions (the interruptibility-state field indicates no blocking by MOV SS), a debug exception is delivered after VM entry (see below).
  - If the logical processor is blocking such exceptions (due to blocking by MOV SS), the pending debug exceptions are held pending or lost as would normally be the case.
- If the VM entry is vectoring (with interruption type software interrupt or software exception and with blocking by MOV SS), the following items apply:
  - For injection of a software interrupt or of a software exception with vector 3 (#BP) or vector 4 (#OF), the pending debug exceptions are treated as they would had they been encountered normally in guest execution if the corresponding instruction (INT3 or INTO) were executed after a MOV SS that encountered a debug trap.
  - For injection of a software exception with a vector other than 3 and 4, the pending debug exceptions may be lost or they may be delivered after injection (see below).

If there are no valid pending debug exceptions (as defined above), no pending debug exceptions are delivered after VM entry.

If a pending debug exception is delivered after VM entry, it has the priority of “traps on the previous instruction” (see Section 6.9 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*). Thus, INIT signals and system-management interrupts (SMIs) take priority of such an exception, as do VM exits induced by the TPR threshold (see Section 26.6.7) and pending MTF VM exits (see Section 26.6.8). The exception takes priority over any pending non-maskable interrupt (NMI) or external interrupt and also over VM exits due to the 1-settings of the “interrupt-window exiting” and “NMI-window exiting” VM-execution controls.

A pending debug exception delivered after VM entry causes a VM exit if the bit 1 (#DB) is 1 in the exception bitmap. If it does not cause a VM exit, it updates DR6 normally.

## 26.6.4 VMX-Preemption Timer

If the “activate VMX-preemption timer” VM-execution control is 1, VM entry starts the VMX-preemption timer with the unsigned value in the VMX-preemption timer-value field.

It is possible for the VMX-preemption timer to expire during VM entry (e.g., if the value in the VMX-preemption timer-value field is zero). If this happens (and if the VM entry was not to the wait-for-SIPI state), a VM exit occurs with its normal priority after any event injection and before execution of any instruction following VM entry. For example, any pending debug exceptions established by VM entry (see Section 26.6.3) take priority over a timer-induced VM exit. (The timer-induced VM exit will occur after delivery of the debug exception, unless that exception or its delivery causes a different VM exit.)

See Section 25.5.1 for details of the operation of the VMX-preemption timer in VMX non-root operation, including the blocking and priority of the VM exits that it causes.

## 26.6.5 Interrupt-Window Exiting and Virtual-Interrupt Delivery

If “interrupt-window exiting” VM-execution control is 1, an open interrupt window may cause a VM exit immediately after VM entry (see Section 25.2 for details). If the “interrupt-window exiting” VM-execution control is 0 but the “virtual-interrupt delivery” VM-execution control is 1, a virtual interrupt may be delivered immediately after VM entry (see Section 26.3.2.5 and Section 29.2.1).

The following items detail the treatment of these events:

- These events occur after any event injection specified for VM entry.
- Non-maskable interrupts (NMIs) and higher priority events take priority over these events. These events take priority over external interrupts and lower priority events.
- These events wake the logical processor if it just entered the HLT state because of a VM entry (see Section 26.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state.

## 26.6.6 NMI-Window Exiting

The “NMI-window exiting” VM-execution control may cause a VM exit to occur immediately after VM entry (see Section 25.2 for details).

The following items detail the treatment of these VM exits:

- These VM exits follow event injection if such injection is specified for VM entry.
- Debug-trap exceptions (see Section 26.6.3) and higher priority events take priority over VM exits caused by this control. VM exits caused by this control take priority over non-maskable interrupts (NMIs) and lower priority events.
- VM exits caused by this control wake the logical processor if it just entered either the HLT state or the shutdown state because of a VM entry (see Section 26.6.2). They do not occur if the logical processor just entered the wait-for-SIPI state.

## 26.6.7 VM Exits Induced by the TPR Threshold

If the “use TPR shadow” and “virtualize APIC accesses” VM-execution controls are both 1 and the “virtual-interrupt delivery” VM-execution control is 0, a VM exit occurs immediately after VM entry if the value of bits 3:0 of the TPR threshold VM-execution control field is greater than the value of bits 7:4 of VTPR (see Section 29.1.1).<sup>1</sup>

---

1. “Virtualize APIC accesses” and “virtual-interrupt delivery” are secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if these controls were 0. See Section 24.6.2.

The following items detail the treatment of these VM exits:

- The VM exits are not blocked if RFLAGS.IF = 0 or by the setting of bits in the interruptibility-state field in guest-state area.
- The VM exits follow event injection if such injection is specified for VM entry.
- VM exits caused by this control take priority over system-management interrupts (SMIs), INIT signals, and lower priority events. They thus have priority over the VM exits described in Section 26.6.5, Section 26.6.6, and Section 26.6.8, as well as any interrupts or debug exceptions that may be pending at the time of VM entry.
- These VM exits wake the logical processor if it just entered the HLT state as part of a VM entry (see Section 26.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state. If such a VM exit is suppressed because the processor just entered the shutdown state, it occurs after the delivery of any event that cause the logical processor to leave the shutdown state while remaining in VMX non-root operation (e.g., due to an NMI that occurs while the “NMI-exiting” VM-execution control is 0).
- The basic exit reason is “TPR below threshold.”

### 26.6.8 Pending MTF VM Exits

As noted in Section 26.5.2, VM entry may cause an MTF VM exit to be pending immediately after VM entry. The following items detail the treatment of these VM exits:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over these VM exits. These VM exits take priority over debug-trap exceptions and lower priority events.
- These VM exits wake the logical processor if it just entered the HLT state because of a VM entry (see Section 26.6.2). They do not occur if the logical processor just entered the shutdown state or the wait-for-SIPI state.

### 26.6.9 VM Entries and Advanced Debugging Features

VM entries are not logged with last-branch records, do not produce branch-trace messages, and do not update the branch-trace store.

## 26.7 VM-ENTRY FAILURES DURING OR AFTER LOADING GUEST STATE

VM-entry failures due to the checks identified in Section 26.3.1 and failures during the MSR loading identified in Section 26.4 are treated differently from those that occur earlier in VM entry. In these cases, the following steps take place:

1. Information about the VM-entry failure is recorded in the VM-exit information fields:
  - Exit reason.
    - Bits 15:0 of this field contain the basic exit reason. It is loaded with a number indicating the general cause of the VM-entry failure. The following numbers are used:
      - 33. VM-entry failure due to invalid guest state. A VM entry failed one of the checks identified in Section 26.3.1.
      - 34. VM-entry failure due to MSR loading. A VM entry failed in an attempt to load MSRs (see Section 26.4).
      - 41. VM-entry failure due to machine-check event. A machine-check event occurred during VM entry (see Section 26.8).
    - Bit 31 is set to 1 to indicate a VM-entry failure.
    - The remainder of the field (bits 30:16) is cleared.
  - Exit qualification. This field is set based on the exit reason.
    - VM-entry failure due to invalid guest state. In most cases, the exit qualification is cleared to 0. The following non-zero values are used in the cases indicated:

1. Not used.
2. Failure was due to a problem loading the PDPTes (see Section 26.3.1.6).
3. Failure was due to an attempt to inject a non-maskable interrupt (NMI) into a guest that is blocking events through the STI blocking bit in the interruptibility-state field. Such failures are implementation-specific (see Section 26.3.1.5).
4. Failure was due to an invalid VMCS link pointer (see Section 26.3.1.5).

VM-entry checks on guest-state fields may be performed in any order. Thus, an indication by exit qualification of one cause does not imply that there are not also other errors. Different processors may give different exit qualifications for the same VMCS.

- VM-entry failure due to MSR loading. The exit qualification is loaded to indicate which entry in the VM-entry MSR-load area caused the problem (1 for the first entry, 2 for the second, etc.).

— All other VM-exit information fields are unmodified.

2. Processor state is loaded as would be done on a VM exit (see Section 27.5). If this results in  $[CR4.PAE \& CR0.PG \& \sim IA32\_EFER.LMA] = 1$ , page-directory-pointer-table entries (PDPTes) may be checked and loaded (see Section 27.5.4).
3. The state of blocking by NMI is what it was before VM entry.
4. MSRs are loaded as specified in the VM-exit MSR-load area (see Section 27.6).

Although this process resembles that of a VM exit, many steps taken during a VM exit do not occur for these VM-entry failures:

- Most VM-exit information fields are not updated (see step 1 above).
- The valid bit in the VM-entry interruption-information field is not cleared.
- The guest-state area is not modified.
- No MSRs are saved into the VM-exit MSR-store area.

## 26.8 MACHINE-CHECK EVENTS DURING VM ENTRY

If a machine-check event occurs during a VM entry, one of the following occurs:

- The machine-check event is handled as if it occurred before the VM entry:
  - If  $CR4.MCE = 0$ , operation of the logical processor depends on whether the logical processor is in SMX operation:<sup>1</sup>
    - If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs. The error code used is 000CH, indicating “unrecoverable machine-check condition.”
    - If the logical processor is outside SMX operation, it goes to the shutdown state.
  - If  $CR4.MCE = 1$ , a machine-check exception (#MC) is delivered through the IDT.
- The machine-check event is handled after VM entry completes:
  - If the VM entry ends with  $CR4.MCE = 0$ , operation of the logical processor depends on whether the logical processor is in SMX operation:
    - If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs with error code 000CH (unrecoverable machine-check condition).
    - If the logical processor is outside SMX operation, it goes to the shutdown state.
  - If the VM entry ends with  $CR4.MCE = 1$ , a machine-check exception (#MC) is generated:
    - If bit 18 (#MC) of the exception bitmap is 0, the exception is delivered through the guest IDT.

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENDER]. A logical processor is outside SMX operation if GETSEC[SENDER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENDER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

## VM ENTRIES

- If bit 18 of the exception bitmap is 1, the exception causes a VM exit.
- A VM-entry failure occurs as described in Section 26.7. The basic exit reason is 41, for “VM-entry failure due to machine-check event.”

The first option is not used if the machine-check event occurs after any guest state has been loaded. The second option is used only if VM entry is able to load all guest state.

VM exits occur in response to certain instructions and events in VMX non-root operation as detailed in Section 25.1 through Section 25.2. VM exits perform the following operations:

1. Information about the cause of the VM exit is recorded in the VM-exit information fields and VM-entry control fields are modified as described in Section 27.2.
2. Processor state is saved in the guest-state area (Section 27.3).
3. MSRs may be saved in the VM-exit MSR-store area (Section 27.4). This step is not performed for SMM VM exits that activate the dual-monitor treatment of SMIs and SMM.
4. The following may be performed in parallel and in any order (Section 27.5):
  - Processor state is loaded based in part on the host-state area and some VM-exit controls. This step is not performed for SMM VM exits that activate the dual-monitor treatment of SMIs and SMM. See Section 34.15.6 for information on how processor state is loaded by such VM exits.
  - Address-range monitoring is cleared.
5. MSRs may be loaded from the VM-exit MSR-load area (Section 27.6). This step is not performed for SMM VM exits that activate the dual-monitor treatment of SMIs and SMM.

VM exits are not logged with last-branch records, do not produce branch-trace messages, and do not update the branch-trace store.

Section 27.1 clarifies the nature of the architectural state before a VM exit begins. The steps described above are detailed in Section 27.2 through Section 27.6.

Section 34.15 describes the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM). Under this treatment, ordinary transitions to SMM are replaced by VM exits to a separate SMM monitor. Called **SMM VM exits**, these are caused by the arrival of an SMI or the execution of VMCALL in VMX root operation. SMM VM exits differ from other VM exits in ways that are detailed in Section 34.15.2.

## 27.1 ARCHITECTURAL STATE BEFORE A VM EXIT

This section describes the architectural state that exists before a VM exit, especially for VM exits caused by events that would normally be delivered through the IDT. Note the following:

- An exception causes a VM exit **directly** if the bit corresponding to that exception is set in the exception bitmap. A non-maskable interrupt (NMI) causes a VM exit directly if the “NMI exiting” VM-execution control is 1. An external interrupt causes a VM exit directly if the “external-interrupt exiting” VM-execution control is 1. A start-up IPI (SIPI) that arrives while a logical processor is in the wait-for-SIPI activity state causes a VM exit directly. INIT signals that arrive while the processor is not in the wait-for-SIPI activity state cause VM exits directly.
- An exception, NMI, external interrupt, or software interrupt causes a VM exit **indirectly** if it does not do so directly but delivery of the event causes a nested exception, double fault, task switch, APIC access (see Section 27.4), EPT violation, or EPT misconfiguration that causes a VM exit.
- An event **results** in a VM exit if it causes a VM exit (directly or indirectly).

The following bullets detail when architectural state is and is not updated in response to VM exits:

- If an event causes a VM exit directly, it does not update architectural state as it would have if it had it not caused the VM exit:
  - A debug exception does not update DR6, DR7.GD, or IA32\_DEBUGCTL.LBR. (Information about the nature of the debug exception is saved in the exit qualification field.)
  - A page fault does not update CR2. (The linear address causing the page fault is saved in the exit-qualification field.)
  - An NMI causes subsequent NMIs to be blocked, but only after the VM exit completes.

- An external interrupt does not acknowledge the interrupt controller and the interrupt remains pending, unless the “acknowledge interrupt on exit” VM-exit control is 1. In such a case, the interrupt controller is acknowledged and the interrupt is no longer pending.
  - The flags L0 – L3 in DR7 (bit 0, bit 2, bit 4, and bit 6) are not cleared when a task switch causes a VM exit.
  - If a task switch causes a VM exit, none of the following are modified by the task switch: old task-state segment (TSS); new TSS; old TSS descriptor; new TSS descriptor; RFLAGS.NT<sup>1</sup>; or the TR register.
  - No last-exception record is made if the event that would do so directly causes a VM exit.
  - If a machine-check exception causes a VM exit directly, this does not prevent machine-check MSRs from being updated. These are updated by the machine-check event itself and not the resulting machine-check exception.
  - If the logical processor is in an inactive state (see Section 24.4.2) and not executing instructions, some events may be blocked but others may return the logical processor to the active state. Unblocked events may cause VM exits.<sup>2</sup> If an unblocked event causes a VM exit directly, a return to the active state occurs only after the VM exit completes.<sup>3</sup> The VM exit generates any special bus cycle that is normally generated when the active state is entered from that activity state.
- MTF VM exits (see Section 25.5.2 and Section 26.6.8) are not blocked in the HLT activity state. If an MTF VM exit occurs in the HLT activity state, the logical processor returns to the active state only after the VM exit completes. MTF VM exits are blocked the shutdown state and the wait-for-SIPI state.
- If an event causes a VM exit indirectly, the event does update architectural state:
    - A debug exception updates DR6, DR7, and the IA32\_DEBUGCTL MSR. No debug exceptions are considered pending.
    - A page fault updates CR2.
    - An NMI causes subsequent NMIs to be blocked before the VM exit commences.
    - An external interrupt acknowledges the interrupt controller and the interrupt is no longer pending.
    - If the logical processor had been in an inactive state, it enters the active state and, before the VM exit commences, generates any special bus cycle that is normally generated when the active state is entered from that activity state.
    - There is no blocking by STI or by MOV SS when the VM exit commences.
    - Processor state that is normally updated as part of delivery through the IDT (CS, RIP, SS, RSP, RFLAGS) is not modified. However, the incomplete delivery of the event may write to the stack.
    - The treatment of last-exception records is implementation dependent:
      - Some processors make a last-exception record when beginning the delivery of an event through the IDT (before it can encounter a nested exception). Such processors perform this update even if the event encounters a nested exception that causes a VM exit (including the case where nested exceptions lead to a triple fault).
      - Other processors delay making a last-exception record until event delivery has reached some event handler successfully (perhaps after one or more nested exceptions). Such processors do not update the last-exception record if a VM exit or triple fault occurs before an event handler is reached.
  - If the “virtual NMIs” VM-execution control is 1, VM entry injects an NMI, and delivery of the NMI causes a nested exception, double fault, task switch, or APIC access that causes a VM exit, virtual-NMI blocking is in effect before the VM exit commences.

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.

2. If a VM exit takes the processor from an inactive state resulting from execution of a specific instruction (HLT or MWAIT), the value saved for RIP by that VM exit will reference the following instruction.

3. An exception is made if the logical processor had been inactive due to execution of MWAIT; in this case, it is considered to have become active before the VM exit.

- If a VM exit results from a fault, EPT violation, or EPT misconfiguration encountered during execution of IRET and the “NMI exiting” VM-execution control is 0, any blocking by NMI is cleared before the VM exit commences. However, the previous state of blocking by NMI may be recorded in the VM-exit interruption-information field; see Section 27.2.2.
- If a VM exit results from a fault, EPT violation, or EPT misconfiguration encountered during execution of IRET and the “virtual NMIs” VM-execution control is 1, virtual-NMI blocking is cleared before the VM exit commences. However, the previous state of virtual-NMI blocking may be recorded in the VM-exit interruption-information field; see Section 27.2.2.
- Suppose that a VM exit is caused directly by an x87 FPU Floating-Point Error (#MF) or by any of the following events if the event was unblocked due to (and given priority over) an x87 FPU Floating-Point Error: an INIT signal, an external interrupt, an NMI, an SMI; or a machine-check exception. In these cases, there is no blocking by STI or by MOV SS when the VM exit commences.
- Normally, a last-branch record may be made when an event is delivered through the IDT. However, if such an event results in a VM exit before delivery is complete, no last-branch record is made.
- If machine-check exception results in a VM exit, processor state is suspect and may result in suspect state being saved to the guest-state area. A VM monitor should consult the RIPV and EIPV bits in the IA32\_MCG\_STATUS MSR before resuming a guest that caused a VM exit resulting from a machine-check exception.
- If a VM exit results from a fault, APIC access (see Section 29.4), EPT violation, or EPT misconfiguration encountered while executing an instruction, data breakpoints due to that instruction may have been recognized and information about them may be saved in the pending debug exceptions field (see Section 27.3.4).
- The following VM exits are considered to happen after an instruction is executed:
  - VM exits resulting from debug traps (single-step, I/O breakpoints, and data breakpoints).
  - VM exits resulting from debug exceptions whose recognition was delayed by blocking by MOV SS.
  - VM exits resulting from some machine-check exceptions.
  - Trap-like VM exits due to execution of MOV to CR8 when the “CR8-load exiting” VM-execution control is 0 and the “use TPR shadow” VM-execution control is 1 (see Section 29.3). (Such VM exits can occur only from 64-bit mode and thus only on processors that support Intel 64 architecture.)
  - Trap-like VM exits due to execution of WRMSR when the “use MSR bitmaps” VM-execution control is 1; the value of ECX is in the range 800H–8FFH; and the bit corresponding to the ECX value in write bitmap for low MSRs is 0; and the “virtualize x2APIC mode” VM-execution control is 1. See Section 29.5.
  - VM exits caused by APIC-write emulation (see Section 29.4.3.2) that result from APIC accesses as part of instruction execution.

For these VM exits, the instruction’s modifications to architectural state complete before the VM exit occurs. Such modifications include those to the logical processor’s interruptibility state (see Table 24-3). If there had been blocking by MOV SS, POP SS, or STI before the instruction executed, such blocking is no longer in effect.

## 27.2 RECORDING VM-EXIT INFORMATION AND UPDATING VM-ENTRY CONTROL FIELDS

VM exits begin by recording information about the nature of and reason for the VM exit in the VM-exit information fields. Section 27.2.1 to Section 27.2.4 detail the use of these fields.

In addition to updating the VM-exit information fields, the valid bit (bit 31) is cleared in the VM-entry interruption-information field. If bit 5 of the IA32\_VMX\_MISC MSR (index 485H) is read as 1 (see Appendix A.6), the value of IA32\_EFER.LMA is stored into the “IA-32e mode guest” VM-entry control.<sup>1</sup>

---

1. Bit 5 of the IA32\_VMX\_MISC MSR is read as 1 on any logical processor that supports the 1-setting of the “unrestricted guest” VM-execution control.

## 27.2.1 Basic VM-Exit Information

Section 24.9.1 defines the basic VM-exit information fields. The following items detail their use.

- **Exit reason.**
  - Bits 15:0 of this field contain the basic exit reason. It is loaded with a number indicating the general cause of the VM exit. Appendix C lists the numbers used and their meaning.
  - The remainder of the field (bits 31:16) is cleared to 0 (certain SMM VM exits may set some of these bits; see Section 34.15.2.3).<sup>1</sup>
- **Exit qualification.** This field is saved for VM exits due to the following causes: debug exceptions; page-fault exceptions; start-up IPIs (SIPIs); system-management interrupts (SMIs) that arrive immediately after the retirement of I/O instructions; task switches; INVEPT; INVLPG; INVPCID; INVVPID; LGDT; LIDT; LLDT; LTR; SGDT; SIDT; SLDT; STR; VMCLEAR; VMPTRLD; VMPTRST; VMREAD; VMWRITE; VMXON; control-register accesses; MOV DR; I/O instructions; MWAIT; accesses to the APIC-access page (see Section 29.4); EPT violations; EOI virtualization (Section 29.1.4); and APIC-write emulation (see Section 29.4.3.3). For all other VM exits, this field is cleared. The following items provide details:
  - For a debug exception, the exit qualification contains information about the debug exception. The information has the format given in Table 27-1.

**Table 27-1. Exit Qualification for Debug Exceptions**

Bit Position(s)	Contents
3:0	B3 – B0. When set, each of these bits indicates that the corresponding breakpoint condition was met. Any of these bits may be set even if its corresponding enabling bit in DR7 is not set.
12:4	Reserved (cleared to 0).
13	BD. When set, this bit indicates that the cause of the debug exception is “debug register access detected.”
14	BS. When set, this bit indicates that the cause of the debug exception is either the execution of a single instruction (if RFLAGS.TF = 1 and IA32_DEBUGCTL.BTF = 0) or a taken branch (if RFLAGS.TF = DEBUGCTL.BTF = 1).
63:15	Reserved (cleared to 0). Bits 63:32 exist only on processors that support Intel 64 architecture.

- For a page-fault exception, the exit qualification contains the linear address that caused the page fault. On processors that support Intel 64 architecture, bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
- For a start-up IPI (SIPI), the exit qualification contains the SIPI vector information in bits 7:0. Bits 63:8 of the exit qualification are cleared to 0.
- For a task switch, the exit qualification contains details about the task switch, encoded as shown in Table 27-2.

1. Bit 13 of this field is set on certain VM-entry failures; see Section 26.7.

Table 27-2. Exit Qualification for Task Switch

Bit Position(s)	Contents
15:0	Selector of task-state segment (TSS) to which the guest attempted to switch
29:16	Reserved (cleared to 0)
31:30	Source of task switch initiation: 0: CALL instruction 1: IRET instruction 2: JMP instruction 3: Task gate in IDT
63:32	Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture.

- For INVLPG, the exit qualification contains the linear-address operand of the instruction.
  - On processors that support Intel 64 architecture, bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - If the INVLPG source operand specifies an unusable segment, the linear address specified in the exit qualification will match the linear address that the INVLPG would have used if no VM exit occurred. This address is not architecturally defined and may be implementation-specific.
- For INVEPT, INVPCID, INVVPID, LGDT, LIDT, LLDT, LTR, SGDT, SIDT, SLDT, STR, VMCLEAR, VMPTRLD, VMPTRST, VMREAD, VMWRITE, and VMXON, the exit qualification receives the value of the instruction's displacement field, which is sign-extended to 64 bits if necessary (32 bits on processors that do not support Intel 64 architecture). If the instruction has no displacement (for example, has a register operand), zero is stored into the exit qualification.

On processors that support Intel 64 architecture, an exception is made for RIP-relative addressing (used only in 64-bit mode). Such addressing causes an instruction to use an address that is the sum of the displacement field and the value of RIP that references the following instruction. In this case, the exit qualification is loaded with the sum of the displacement field and the appropriate RIP value.

In all cases, bits of this field beyond the instruction's address size are undefined. For example, suppose that the address-size field in the VM-exit instruction-information field (see Section 24.9.4 and Section 27.2.4) reports an  $n$ -bit address size. Then bits 63: $n$  (bits 31: $n$  on processors that do not support Intel 64 architecture) of the instruction displacement are undefined.

- For a control-register access, the exit qualification contains information about the access and has the format given in Table 27-3.

**Table 27-3. Exit Qualification for Control-Register Accesses**

Bit Positions	Contents
3:0	Number of control register (0 for CLTS and LMSW). Bit 3 is always 0 on processors that do not support Intel 64 architecture as they do not support CR8.
5:4	Access type: 0 = MOV to CR 1 = MOV from CR 2 = CLTS 3 = LMSW
6	LMSW operand type: 0 = register 1 = memory  For CLTS and MOV CR, cleared to 0
7	Reserved (cleared to 0)
11:8	For MOV CR, the general-purpose register: 0 = RAX 1 = RCX 2 = RDX 3 = RBX 4 = RSP 5 = RBP 6 = RSI 7 = RDI 8-15 represent R8-R15, respectively (used only on processors that support Intel 64 architecture)  For CLTS and LMSW, cleared to 0
15:12	Reserved (cleared to 0)
31:16	For LMSW, the LMSW source data For CLTS and MOV CR, cleared to 0
63:32	Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture.

- For MOV DR, the exit qualification contains information about the instruction and has the format given in Table 27-4.

Table 27-4. Exit Qualification for MOV DR

Bit Position(s)	Contents
2:0	Number of debug register
3	Reserved (cleared to 0)
4	Direction of access (0 = MOV to DR; 1 = MOV from DR)
7:5	Reserved (cleared to 0)
11:8	General-purpose register: 0 = RAX 1 = RCX 2 = RDX 3 = RBX 4 = RSP 5 = RBP 6 = RSI 7 = RDI 8 - 15 = R8 - R15, respectively
63:12	Reserved (cleared to 0)

- For an I/O instruction, the exit qualification contains information about the instruction and has the format given in Table 27-5.

Table 27-5. Exit Qualification for I/O Instructions

Bit Position(s)	Contents
2:0	Size of access: 0 = 1-byte 1 = 2-byte 3 = 4-byte  Other values not used
3	Direction of the attempted access (0 = OUT, 1 = IN)
4	String instruction (0 = not string; 1 = string)
5	REP prefixed (0 = not REP; 1 = REP)
6	Operand encoding (0 = DX, 1 = immediate)
15:7	Reserved (cleared to 0)
31:16	Port number (as specified in DX or in an immediate operand)
63:32	Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture.

- For MWAIT, the exit qualification contains a value that indicates whether address-range monitoring hardware was armed. The exit qualification is set either to 0 (if address-range monitoring hardware is not armed) or to 1 (if address-range monitoring hardware is armed).

- For an APIC-access VM exit resulting from a linear access or a guest-physical access to the APIC-access page (see Section 29.4), the exit qualification contains information about the access and has the format given in Table 27-6.<sup>1</sup>

**Table 27-6. Exit Qualification for APIC-Access VM Exits from Linear Accesses and Guest-Physical Accesses**

Bit Position(s)	Contents
11:0	<ul style="list-style-type: none"> <li>▪ If the APIC-access VM exit is due to a linear access, the offset of access within the APIC page.</li> <li>▪ Undefined if the APIC-access VM exit is due a guest-physical access</li> </ul>
15:12	<p>Access type:</p> <ul style="list-style-type: none"> <li>0 = linear access for a data read during instruction execution</li> <li>1 = linear access for a data write during instruction execution</li> <li>2 = linear access for an instruction fetch</li> <li>3 = linear access (read or write) during event delivery</li> <li>10 = guest-physical access during event delivery</li> <li>15 = guest-physical access for an instruction fetch or during instruction execution</li> </ul> <p>Other values not used</p>
63:16	Reserved (cleared to 0). Bits 63:32 exist only on processors that support Intel 64 architecture.

Such a VM exit that set bits 15:12 of the exit qualification to 0000b (data read during instruction execution) or 0001b (data write during instruction execution) set bit 12—which distinguishes data read from data write—to that which would have been stored in bit 1—W/R—of the page-fault error code had the access caused a page fault instead of an APIC-access VM exit. This implies the following:

- For an APIC-access VM exit caused by the CLFLUSH instruction, the access type is “data read during instruction execution.”
- For an APIC-access VM exit caused by the ENTER instruction, the access type is “data write during instruction execution.”
- For an APIC-access VM exit caused by the MASKMOVQ instruction or the MASKMOVDQU instruction, the access type is “data write during instruction execution.”
- For an APIC-access VM exit caused by the MONITOR instruction, the access type is “data read during instruction execution.”

Such a VM exit stores 1 for bit 31 for IDT-vectoring information field (see Section 27.2.3) if and only if it sets bits 15:12 of the exit qualification to 0011b (linear access during event delivery) or 1010b (guest-physical access during event delivery).

See Section 29.4.4 for further discussion of these instructions and APIC-access VM exits.

For APIC-access VM exits resulting from physical accesses, the APIC-access page (see Section 29.4.6), the exit qualification is undefined.

- For an EPT violation, the exit qualification contains information about the access causing the EPT violation and has the format given in Table 27-7.

1. The exit qualification is undefined if the access was part of the logging of a branch record or a precise-event-based-sampling (PEBS) record to the DS save area. It is recommended that software configure the paging structures so that no address in the DS save area translates to an address on the APIC-access page.

Table 27-7. Exit Qualification for EPT Violations

Bit Position(s)	Contents
0	Set if the access causing the EPT violation was a data read. <sup>1</sup>
1	Set if the access causing the EPT violation was a data write. <sup>1</sup>
2	Set if the access causing the EPT violation was an instruction fetch.
3	The logical-AND of bit 0 in the EPT paging-structures entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was readable). <sup>2</sup>
4	The logical-AND of bit 1 in the EPT paging-structures entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was writeable).
5	The logical-AND of bit 2 in the EPT paging-structures entries used to translate the guest-physical address of the access causing the EPT violation (indicates that the guest-physical address was executable).
6	Reserved (cleared to 0).
7	Set if the guest linear-address field is valid. The guest linear-address field is valid for all EPT violations except those resulting from an attempt to load the guest PDPTes as part of the execution of the MOV CR instruction.
8	If bit 7 is 1: <ul style="list-style-type: none"> <li>▪ Set if the access causing the EPT violation is to a guest-physical address that is the translation of a linear address.</li> <li>▪ Clear if the access causing the EPT violation is to a paging-structure entry as part of a page walk or the update of an accessed or dirty bit.</li> </ul> Reserved if bit 7 is 0 (cleared to 0).
11:9	Reserved (cleared to 0).
12	NMI unblocking due to IRET
63:13	Reserved (cleared to 0).

**NOTES:**

1. If accessed and dirty flags for EPT are enabled, processor accesses to guest paging-structure entries are treated as writes with regard to EPT violations (see Section 28.2.3.2). If such an access causes an EPT violation, the processor sets both bit 0 and bit 1 of the exit qualification.
2. Bits 5:3 are cleared to 0 if any of EPT paging-structures entries used to translate the guest-physical address of the access causing the EPT violation is not present (see Section 28.2.2).

An EPT violation that occurs during as a result of execution of a read-modify-write operation sets bit 1 (data write). Whether it also sets bit 0 (data read) is implementation-specific and, for a given implementation, may differ for different kinds of read-modify-write operations.

Bit 12 is undefined in any of the following cases:

- If the “NMI exiting” VM-execution control is 1 and the “virtual NMIs” VM-execution control is 0.
- If the VM exit sets the valid bit in the IDT-vectoring information field (see Section 27.2.3).

Otherwise, bit 12 is defined as follows:

- If the “virtual NMIs” VM-execution control is 0, the EPT violation was caused by a memory access as part of execution of the IRET instruction, and blocking by NMI (see Table 24-3) was in effect before execution of IRET, bit 12 is set to 1.

- If the “virtual NMIs” VM-execution control is 1, the EPT violation was caused by a memory access as part of execution of the IRET instruction, and virtual-NMI blocking was in effect before execution of IRET, bit 12 is set to 1.
- For all other relevant VM exits, bit 12 is cleared to 0.
- For VM exits caused as part of EOI virtualization (Section 29.1.4), bits 7:0 of the exit qualification are set to vector of the virtual interrupt that was dismissed by the EOI virtualization. Bits above bit 7 are cleared.
- For APIC-write VM exits (Section 29.4.3.3), bits 11:0 of the exit qualification are set to the page offset of the write access that caused the VM exit.<sup>1</sup> Bits above bit 11 are cleared.
- **Guest-linear address.** For some VM exits, this field receives a linear address that pertains to the VM exit. The field is set for different VM exits as follows:
  - VM exits due to attempts to execute LMSW with a memory operand. In these cases, this field receives the linear address of that operand. Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - VM exits due to attempts to execute INS or OUTS for which the relevant segment is usable (if the relevant segment is not usable, the value is undefined). (ES is always the relevant segment for INS; for OUTS, the relevant segment is DS unless overridden by an instruction prefix.) The linear address is the base address of relevant segment plus (E)DI (for INS) or (E)SI (for OUTS). Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - VM exits due to EPT violations that set bit 7 of the exit qualification (see Table 27-7; these are all EPT violations except those resulting from an attempt to load the PDPTEs as of execution of the MOV CR instruction). The linear address may translate to the guest-physical address whose access caused the EPT violation. Alternatively, translation of the linear address may reference a paging-structure entry whose access caused the EPT violation. Bits 63:32 are cleared if the logical processor was not in 64-bit mode before the VM exit.
  - For all other VM exits, the field is undefined.
- **Guest-physical address.** For a VM exit due to an EPT violation or an EPT misconfiguration, this field receives the guest-physical address that caused the EPT violation or EPT misconfiguration. For all other VM exits, the field is undefined.

## 27.2.2 Information for VM Exits Due to Vectored Events

Section 24.9.2 defines fields containing information for VM exits due to the following events: exceptions (including those generated by the instructions INT3, INTO, BOUND, and UD2); external interrupts that occur while the “acknowledge interrupt on exit” VM-exit control is 1; and non-maskable interrupts (NMIs). Such VM exits include those that occur on an attempt at a task switch that causes an exception before generating the VM exit due to the task switch that causes the VM exit.

The following items detail the use of these fields:

- **VM-exit interruption information** (format given in Table 24-15). The following items detail how this field is established for VM exits due to these events:
  - For an exception, bits 7:0 receive the exception vector (at most 31). For an NMI, bits 7:0 are set to 2. For an external interrupt, bits 7:0 receive the interrupt number.
  - Bits 10:8 are set to 0 (external interrupt), 2 (non-maskable interrupt), 3 (hardware exception), or 6 (software exception). Hardware exceptions comprise all exceptions except breakpoint exceptions (#BP; generated by INT3) and overflow exceptions (#OF; generated by INTO); these are software exceptions. BOUND-range exceeded exceptions (#BR; generated by BOUND) and invalid opcode exceptions (#UD) generated by UD2 are hardware exceptions.
  - Bit 11 is set to 1 if the VM exit is caused by a hardware exception that would have delivered an error code on the stack. This bit is always 0 if the VM exit occurred while the logical processor was in real-address

---

1. Execution of WRMSR with ECX = 83FH (self-IPI MSR) can lead to an APIC-write VM exit; the exit qualification for such an APIC-write VM exit is 3F0H.

mode (CRO.PE=0).<sup>1</sup> If bit 11 is set to 1, the error code is placed in the VM-exit interruption error code (see below).

- Bit 12 is undefined in any of the following cases:
  - If the “NMI exiting” VM-execution control is 1 and the “virtual NMIs” VM-execution control is 0.
  - If the VM exit sets the valid bit in the IDT-vectoring information field (see Section 27.2.3).
  - If the VM exit is due to a double fault (the interruption type is hardware exception and the vector is 8).

Otherwise, bit 12 is defined as follows:

- If the “virtual NMIs” VM-execution control is 0, the VM exit is due to a fault on the IRET instruction (other than a debug exception for an instruction breakpoint), and blocking by NMI (see Table 24-3) was in effect before execution of IRET, bit 12 is set to 1.
  - If the “virtual NMIs” VM-execution control is 1, the VM exit is due to a fault on the IRET instruction (other than a debug exception for an instruction breakpoint), and virtual-NMI blocking was in effect before execution of IRET, bit 12 is set to 1.
  - For all other relevant VM exits, bit 12 is cleared to 0.<sup>2</sup>
- Bits 30:13 are always set to 0.
  - Bit 31 is always set to 1.

For other VM exits (including those due to external interrupts when the “acknowledge interrupt on exit” VM-exit control is 0), the field is marked invalid (by clearing bit 31) and the remainder of the field is undefined.

- VM-exit interruption error code.
  - For VM exits that set both bit 31 (valid) and bit 11 (error code valid) in the VM-exit interruption-information field, this field receives the error code that would have been pushed on the stack had the event causing the VM exit been delivered normally through the IDT. The EXT bit is set in this field exactly when it would be set normally. For exceptions that occur during the delivery of double fault (if the IDT-vectoring information field indicates a double fault), the EXT bit is set to 1, assuming that (1) that the exception would produce an error code normally (if not incident to double-fault delivery) and (2) that the error code uses the EXT bit (not for page faults, which use a different format).
  - For other VM exits, the value of this field is undefined.

### 27.2.3 Information for VM Exits During Event Delivery

Section 24.9.3 defined fields containing information for VM exits that occur while delivering an event through the IDT and as a result of any of the following cases:<sup>3</sup>

- A fault occurs during event delivery and causes a VM exit (because the bit associated with the fault is set to 1 in the exception bitmap).
- A task switch is invoked through a task gate in the IDT. The VM exit occurs due to the task switch only after the initial checks of the task switch pass (see Section 25.4.2).
- Event delivery causes an APIC-access VM exit (see Section 29.4).
- An EPT violation or EPT misconfiguration that occurs during event delivery.

These fields are used for VM exits that occur during delivery of events injected as part of VM entry (see Section 26.5.1.2).

- 
1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CRO.PE must be 1 in VMX operation, a logical processor cannot be in real-address mode unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
  2. The conditions imply that, if the “NMI exiting” VM-execution control is 0 or the “virtual NMIs” VM-execution control is 1, bit 12 is always cleared to 0 by VM exits due to debug exceptions.
  3. This includes the case in which a VM exit occurs while delivering a software interrupt (INT  $n$ ) through the 16-bit IVT (interrupt vector table) that is used in virtual-8086 mode with virtual-machine extensions (if RFLAGS.VM = CR4.VME = 1).

A VM exit is not considered to occur during event delivery in any of the following circumstances:

- The original event causes the VM exit directly (for example, because the original event is a non-maskable interrupt (NMI) and the “NMI exiting” VM-execution control is 1).
- The original event results in a double-fault exception that causes the VM exit directly.
- The VM exit occurred as a result of fetching the first instruction of the handler invoked by the event delivery.
- The VM exit is caused by a triple fault.

The following items detail the use of these fields:

- IDT-vectoring information (format given in Table 24-16). The following items detail how this field is established for VM exits that occur during event delivery:
  - If the VM exit occurred during delivery of an exception, bits 7:0 receive the exception vector (at most 31). If the VM exit occurred during delivery of an NMI, bits 7:0 are set to 2. If the VM exit occurred during delivery of an external interrupt, bits 7:0 receive the interrupt number.
  - Bits 10:8 are set to indicate the type of event that was being delivered when the VM exit occurred: 0 (external interrupt), 2 (non-maskable interrupt), 3 (hardware exception), 4 (software interrupt), 5 (privileged software interrupt), or 6 (software exception).  
Hardware exceptions comprise all exceptions except breakpoint exceptions (#BP; generated by INT3) and overflow exceptions (#OF; generated by INTO); these are software exceptions. BOUND-range exceeded exceptions (#BR; generated by BOUND) and invalid opcode exceptions (#UD) generated by UD2 are hardware exceptions.  
Bits 10:8 may indicate privileged software interrupt if such an event was injected as part of VM entry.
  - Bit 11 is set to 1 if the VM exit occurred during delivery of a hardware exception that would have delivered an error code on the stack. This bit is always 0 if the VM exit occurred while the logical processor was in real-address mode (CR0.PE=0).<sup>1</sup> If bit 11 is set to 1, the error code is placed in the IDT-vectoring error code (see below).
  - Bit 12 is undefined.
  - Bits 30:13 are always set to 0.
  - Bit 31 is always set to 1.

For other VM exits, the field is marked invalid (by clearing bit 31) and the remainder of the field is undefined.

- IDT-vectoring error code.
  - For VM exits that set both bit 31 (valid) and bit 11 (error code valid) in the IDT-vectoring information field, this field receives the error code that would have been pushed on the stack by the event that was being delivered through the IDT at the time of the VM exit. The EXT bit is set in this field when it would be set normally.
  - For other VM exits, the value of this field is undefined.

## 27.2.4 Information for VM Exits Due to Instruction Execution

Section 24.9.4 defined fields containing information for VM exits that occur due to instruction execution. (The VM-exit instruction length is also used for VM exits that occur during the delivery of a software interrupt or software exception.) The following items detail their use.

- **VM-exit instruction length.** This field is used in the following cases:
  - For fault-like VM exits due to attempts to execute one of the following instructions that cause VM exits unconditionally (see Section 25.1.2) or based on the settings of VM-execution controls (see Section 25.1.3): CLTS, CPUID, GETSEC, HLT, IN, INS, INVLD, INVEPT, INVLPG, INVPCID, INVVPID, LGDT, LIDT, LLDT, LMSW, LTR, MONITOR, MOV CR, MOV DR, MWAIT, OUT, OUTS, PAUSE, RDMSR, RDPID, RDRAND, RDTSC,

1. If the capability MSR IA32\_VMX\_CR0\_FIXED0 reports that CR0.PE must be 1 in VMX operation, a logical processor cannot be in real-address mode unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

RDTSCP, RSM, SGDT, SIDT, SLDT, STR, VMCALL, VMCLEAR, VMLAUNCH, VMPTRLD, VMPTRST, VMREAD, VMRESUME, VMWRITE, VMXOFF, VMXON, WBINVD, WRMSR, and XSETBV.<sup>1</sup>

- For VM exits due to software exceptions (those generated by executions of INT3 or INTO).
- For VM exits due to faults encountered during delivery of a software interrupt, privileged software exception, or software exception.
- For VM exits due to attempts to effect a task switch via instruction execution. These are VM exits that produce an exit reason indicating task switch and either of the following:
  - An exit qualification indicating execution of CALL, IRET, or JMP instruction.
  - An exit qualification indicating a task gate in the IDT and an IDT-vectoring information field indicating that the task gate was encountered during delivery of a software interrupt, privileged software exception, or software exception.
- For APIC-access VM exits resulting from accesses (see Section 29.4) during delivery of a software interrupt, privileged software exception, or software exception.<sup>2</sup>
- For VM exits due executions of VMFUNC that fail because one of the following is true:
  - EAX indicates a VM function that is not enabled (the bit at position EAX is 0 in the VM-function controls; see Section 25.5.5.2).
  - EAX = 0 and either ECX ≥ 512 or the value of ECX selects an invalid tentative EPTP value (see Section 25.5.5.3).

In all the above cases, this field receives the length in bytes (1–15) of the instruction (including any instruction prefixes) whose execution led to the VM exit (see the next paragraph for one exception).

The cases of VM exits encountered during delivery of a software interrupt, privileged software exception, or software exception include those encountered during delivery of events injected as part of VM entry (see Section 26.5.1.2). If the original event was injected as part of VM entry, this field receives the value of the VM-entry instruction length.

All VM exits other than those listed in the above items leave this field undefined.

- **VM-exit instruction information.** For VM exits due to attempts to execute INS, INVEPT, INVPCID, INVVPID, LIDT, LGDT, LLDT, LTR, OUTS, RDRAND, SIDT, SGDT, SLDT, STR, VMCLEAR, VMPTRLD, VMPTRST, VMREAD, VMWRITE, or VMXON, this field receives information about the instruction that caused the VM exit. The format of the field depends on the identity of the instruction causing the VM exit:
  - For VM exits due to attempts to execute INS or OUTS, the field has the format is given in Table 27-8.<sup>3</sup>

---

1. This item applies only to fault-like VM exits. It does not apply to trap-like VM exits following executions of the MOV to CR8 instruction when the “use TPR shadow” VM-execution control is 1 or to those following executions of the WRMSR instruction when the “virtualize x2APIC mode” VM-execution control is 1.

2. The VM-exit instruction-length field is not defined following APIC-access VM exits resulting from physical accesses (see Section 29.4.6) even if encountered during delivery of a software interrupt, privileged software exception, or software exception.

**Table 27-8. Format of the VM-Exit Instruction-Information Field as Used for INS and OUTS**

Bit Position(s)	Content
6:0	Undefined.
9:7	Address size: 0: 16-bit 1: 32-bit 2: 64-bit (used only on processors that support Intel 64 architecture) Other values not used.
14:10	Undefined.
17:15	Segment register: 0: ES 1: CS 2: SS 3: DS 4: FS 5: GS Other values not used. Undefined for VM exits due to execution of INS.
31:18	Undefined.

— For VM exits due to attempts to execute INVEPT, INVPCID, or INVVPID, the field has the format is given in Table 27-9.

**Table 27-9. Format of the VM-Exit Instruction-Information Field as Used for INVEPT, INVPCID, and INVVPID**

Bit Position(s)	Content
1:0	Scaling: 0: no scaling 1: scale by 2 2: scale by 4 3: scale by 8 (used only on processors that support Intel 64 architecture) Undefined for instructions with no index register (bit 22 is set).
6:2	Undefined.
9:7	Address size: 0: 16-bit 1: 32-bit 2: 64-bit (used only on processors that support Intel 64 architecture) Other values not used.
10	Cleared to 0.
14:11	Undefined.
17:15	Segment register: 0: ES 1: CS 2: SS 3: DS 4: FS 5: GS Other values not used.

3. The format of the field was undefined for these VM exits on the first processors to support the virtual-machine extensions. Software can determine whether the format specified in Table 27-8 is used by consulting the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1).

**Table 27-9. Format of the VM-Exit Instruction-Information Field as Used for INVEPT, INVPCID, and INVPID (Contd.)**

Bit Position(s)	Content
21:18	IndexReg: 0 = RAX 1 = RCX 2 = RDX 3 = RBX 4 = RSP 5 = RBP 6 = RSI 7 = RDI 8-15 represent R8-R15, respectively (used only on processors that support Intel 64 architecture) Undefined for instructions with no index register (bit 22 is set).
22	IndexReg invalid (0 = valid; 1 = invalid)
26:23	BaseReg (encoded as IndexReg above) Undefined for memory instructions with no base register (bit 27 is set).
27	BaseReg invalid (0 = valid; 1 = invalid)
31:28	Reg2 (same encoding as IndexReg above)

— For VM exits due to attempts to execute LIDT, LGDT, SIDT, or SGDT, the field has the format is given in Table 27-10.

**Table 27-10. Format of the VM-Exit Instruction-Information Field as Used for LIDT, LGDT, SIDT, or SGDT**

Bit Position(s)	Content
1:0	Scaling: 0: no scaling 1: scale by 2 2: scale by 4 3: scale by 8 (used only on processors that support Intel 64 architecture) Undefined for instructions with no index register (bit 22 is set).
6:2	Undefined.
9:7	Address size: 0: 16-bit 1: 32-bit 2: 64-bit (used only on processors that support Intel 64 architecture) Other values not used.
10	Cleared to 0.
11	Operand size: 0: 16-bit 1: 32-bit Undefined for VM exits from 64-bit mode.
14:12	Undefined.
17:15	Segment register: 0: ES 1: CS 2: SS 3: DS 4: FS 5: GS Other values not used.

**Table 27-10. Format of the VM-Exit Instruction-Information Field as Used for LIDT, LGDT, SIDT, or SGDT (Contd.)**

Bit Position(s)	Content
21:18	IndexReg: 0 = RAX 1 = RCX 2 = RDX 3 = RBX 4 = RSP 5 = RBP 6 = RSI 7 = RDI 8-15 represent R8-R15, respectively (used only on processors that support Intel 64 architecture) Undefined for instructions with no index register (bit 22 is set).
22	IndexReg invalid (0 = valid; 1 = invalid)
26:23	BaseReg (encoded as IndexReg above) Undefined for instructions with no base register (bit 27 is set).
27	BaseReg invalid (0 = valid; 1 = invalid)
29:28	Instruction identity: 0: SGDT 1: SIDT 2: LGDT 3: LIDT
31:30	Undefined.

— For VM exits due to attempts to execute LLDT, LTR, SLDT, or STR, the field has the format is given in Table 27-11.

**Table 27-11. Format of the VM-Exit Instruction-Information Field as Used for LLDT, LTR, SLDT, and STR**

Bit Position(s)	Content
1:0	Scaling: 0: no scaling 1: scale by 2 2: scale by 4 3: scale by 8 (used only on processors that support Intel 64 architecture) Undefined for register instructions (bit 10 is set) and for memory instructions with no index register (bit 10 is clear and bit 22 is set).
2	Undefined.
6:3	Reg1: 0 = RAX 1 = RCX 2 = RDX 3 = RBX 4 = RSP 5 = RBP 6 = RSI 7 = RDI 8-15 represent R8-R15, respectively (used only on processors that support Intel 64 architecture) Undefined for memory instructions (bit 10 is clear).

**Table 27-11. Format of the VM-Exit Instruction-Information Field as Used for LLDT, LTR, SLDT, and STR (Contd.)**

Bit Position(s)	Content
9:7	Address size: 0: 16-bit 1: 32-bit 2: 64-bit (used only on processors that support Intel 64 architecture) Other values not used. Undefined for register instructions (bit 10 is set).
10	Mem/Reg (0 = memory; 1 = register).
14:11	Undefined.
17:15	Segment register: 0: ES 1: CS 2: SS 3: DS 4: FS 5: GS Other values not used. Undefined for register instructions (bit 10 is set).
21:18	IndexReg (encoded as Reg1 above) Undefined for register instructions (bit 10 is set) and for memory instructions with no index register (bit 10 is clear and bit 22 is set).
22	IndexReg invalid (0 = valid; 1 = invalid) Undefined for register instructions (bit 10 is set).
26:23	BaseReg (encoded as Reg1 above) Undefined for register instructions (bit 10 is set) and for memory instructions with no base register (bit 10 is clear and bit 27 is set).
27	BaseReg invalid (0 = valid; 1 = invalid) Undefined for register instructions (bit 10 is set).
29:28	Instruction identity: 0: SLDT 1: STR 2: LLDT 3: LTR
31:30	Undefined.

— For VM exits due to attempts to execute RDRAND, the field has the format is given in Table 27-12.

**Table 27-12. Format of the VM-Exit Instruction-Information Field as Used for RDRAND**

Bit Position(s)	Content
2:0	Undefined.
6:3	Destination register: 0 = RAX 1 = RCX 2 = RDX 3 = RBX 4 = RSP 5 = RBP 6 = RSI 7 = RDI 8-15 represent R8-R15, respectively (used only on processors that support Intel 64 architecture)
10:7	Undefined.
12:11	Operand size: 0: 16-bit 1: 32-bit 2: 64-bit The value 3 is not used.
31:13	Undefined.

- For VM exits due to attempts to execute VMCLEAR, VMPTRLD, VMPTRST, or VMXON, the field has the format is given in Table 27-13.

**Table 27-13. Format of the VM-Exit Instruction-Information Field as Used for VMCLEAR, VMPTRLD, VMPTRST, and VMXON**

Bit Position(s)	Content
1:0	Scaling: 0: no scaling 1: scale by 2 2: scale by 4 3: scale by 8 (used only on processors that support Intel 64 architecture) Undefined for instructions with no index register (bit 22 is set).
6:2	Undefined.
9:7	Address size: 0: 16-bit 1: 32-bit 2: 64-bit (used only on processors that support Intel 64 architecture) Other values not used.
10	Cleared to 0.
14:11	Undefined.
17:15	Segment register: 0: ES 1: CS 2: SS 3: DS 4: FS 5: GS Other values not used.

**Table 27-13. Format of the VM-Exit Instruction-Information Field as Used for VMCLEAR, VMPTRLD, VMPTRST, and VMXON (Contd.)**

Bit Position(s)	Content
21:18	IndexReg: 0 = RAX 1 = RCX 2 = RDX 3 = RBX 4 = RSP 5 = RBP 6 = RSI 7 = RDI 8-15 represent R8-R15, respectively (used only on processors that support Intel 64 architecture) Undefined for instructions with no index register (bit 22 is set).
22	IndexReg invalid (0 = valid; 1 = invalid)
26:23	BaseReg (encoded as IndexReg above) Undefined for instructions with no base register (bit 27 is set).
27	BaseReg invalid (0 = valid; 1 = invalid)
31:28	Undefined.

— For VM exits due to attempts to execute VMREAD or VMWRITE, the field has the format is given in Table 27-14.

**Table 27-14. Format of the VM-Exit Instruction-Information Field as Used for VMREAD and VMWRITE**

Bit Position(s)	Content
1:0	Scaling: 0: no scaling 1: scale by 2 2: scale by 4 3: scale by 8 (used only on processors that support Intel 64 architecture) Undefined for register instructions (bit 10 is set) and for memory instructions with no index register (bit 10 is clear and bit 22 is set).
2	Undefined.
6:3	Reg1: 0 = RAX 1 = RCX 2 = RDX 3 = RBX 4 = RSP 5 = RBP 6 = RSI 7 = RDI 8-15 represent R8-R15, respectively (used only on processors that support Intel 64 architecture) Undefined for memory instructions (bit 10 is clear).
9:7	Address size: 0: 16-bit 1: 32-bit 2: 64-bit (used only on processors that support Intel 64 architecture) Other values not used. Undefined for register instructions (bit 10 is set).
10	Mem/Reg (0 = memory; 1 = register).
14:11	Undefined.

**Table 27-14. Format of the VM-Exit Instruction-Information Field as Used for VMREAD and VMWRITE (Contd.)**

Bit Position(s)	Content
17:15	Segment register: 0: ES 1: CS 2: SS 3: DS 4: FS 5: GS  Other values not used. Undefined for register instructions (bit 10 is set).
21:18	IndexReg (encoded as Reg1 above)  Undefined for register instructions (bit 10 is set) and for memory instructions with no index register (bit 10 is clear and bit 22 is set).
22	IndexReg invalid (0 = valid; 1 = invalid)  Undefined for register instructions (bit 10 is set).
26:23	BaseReg (encoded as Reg1 above)  Undefined for register instructions (bit 10 is set) and for memory instructions with no base register (bit 10 is clear and bit 27 is set).
27	BaseReg invalid (0 = valid; 1 = invalid)  Undefined for register instructions (bit 10 is set).
31:28	Reg2 (same encoding as Reg1 above)

For all other VM exits, the field is undefined.

- **I/O RCX, I/O RSI, I/O RDI, I/O RIP.** These fields are undefined except for SMM VM exits due to system-management interrupts (SMIs) that arrive immediately after retirement of I/O instructions. See Section 34.15.2.3.

## 27.3 SAVING GUEST STATE

Each field in the guest-state area of the VMCS (see Section 24.4) is written with the corresponding component of processor state. On processors that support Intel 64 architecture, the full values of each natural-width field (see Section 24.11.2) is saved regardless of the mode of the logical processor before and after the VM exit.

In general, the state saved is that which was in the logical processor at the time the VM exit commences. See Section 27.1 for a discussion of which architectural updates occur at that time.

Section 27.3.1 through Section 27.3.4 provide details for how certain components of processor state are saved. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the guest-state area.

### 27.3.1 Saving Control Registers, Debug Registers, and MSRs

Contents of certain control registers, debug registers, and MSRs is saved as follows:

- The contents of CR0, CR3, CR4, and the IA32\_SYSENTER\_CS, IA32\_SYSENTER\_ESP, and IA32\_SYSENTER\_EIP MSRs are saved into the corresponding fields. Bits 63:32 of the IA32\_SYSENTER\_CS MSR are not saved. On processors that do not support Intel 64 architecture, bits 63:32 of the IA32\_SYSENTER\_ESP and IA32\_SYSENTER\_EIP MSRs are not saved.
- If the “save debug controls” VM-exit control is 1, the contents of DR7 and the IA32\_DEBUGCTL MSR are saved into the corresponding fields. The first processors to support the virtual-machine extensions supported only the 1-setting of this control and thus always saved data into these fields.

- If the “save IA32\_PAT” VM-exit control is 1, the contents of the IA32\_PAT MSR are saved into the corresponding field.
- If the “save IA32\_EFER” VM-exit control is 1, the contents of the IA32\_EFER MSR are saved into the corresponding field.
- The value of the SMBASE field is undefined after all VM exits except SMM VM exits. See Section 34.15.2.

### 27.3.2 Saving Segment Registers and Descriptor-Table Registers

For each segment register (CS, SS, DS, ES, FS, GS, LDTR, or TR), the values saved for the base-address, segment-limit, and access rights are based on whether the register was unusable (see Section 24.4.1) before the VM exit:

- If the register was unusable, the values saved into the following fields are undefined: (1) base address; (2) segment limit; and (3) bits 7:0 and bits 15:12 in the access-rights field. The following exceptions apply:
  - CS.
    - The base-address and segment-limit fields are saved.
    - The L, D, and G bits are saved in the access-rights field.
  - SS.
    - DPL is saved in the access-rights field.
    - On processors that support Intel 64 architecture, bits 63:32 of the value saved for the base address are always zero.
  - DS and ES. On processors that support Intel 64 architecture, bits 63:32 of the values saved for the base addresses are always zero.
  - FS and GS. The base-address field is saved.
  - LDTR. The value saved for the base address is always canonical.
- If the register was not unusable, the values saved into the following fields are those which were in the register before the VM exit: (1) base address; (2) segment limit; and (3) bits 7:0 and bits 15:12 in access rights.
- Bits 31:17 and 11:8 in the access-rights field are always cleared. Bit 16 is set to 1 if and only if the segment is unusable.

The contents of the GDTR and IDTR registers are saved into the corresponding base-address and limit fields.

### 27.3.3 Saving RIP, RSP, and RFLAGS

The contents of the RIP, RSP, and RFLAGS registers are saved as follows:

- The value saved in the RIP field is determined by the nature and cause of the VM exit:
  - If the VM exit occurs due to by an attempt to execute an instruction that causes VM exits unconditionally or that has been configured to cause a VM exit via the VM-execution controls, the value saved references that instruction.
  - If the VM exit is caused by an occurrence of an INIT signal, a start-up IPI (SIPI), or system-management interrupt (SMI), the value saved is that which was in RIP before the event occurred.
  - If the VM exit occurs due to the 1-setting of either the “interrupt-window exiting” VM-execution control or the “NMI-window exiting” VM-execution control, the value saved is that which would be in the register had the VM exit not occurred.
  - If the VM exit is due to an external interrupt, non-maskable interrupt (NMI), or hardware exception (as defined in Section 27.2.2), the value saved is the return pointer that would have been saved (either on the stack had the event been delivered through a trap or interrupt gate,<sup>1</sup> or into the old task-state segment had the event been delivered through a task gate).

---

1. The reference here is to the full value of RIP before any truncation that would occur had the stack width been only 32 bits or 16 bits.

- If the VM exit is due to a triple fault, the value saved is the return pointer that would have been saved (either on the stack had the event been delivered through a trap or interrupt gate, or into the old task-state segment had the event been delivered through a task gate) had delivery of the double fault not encountered the nested exception that caused the triple fault.
- If the VM exit is due to a software exception (due to an execution of INT3 or INTO), the value saved references the INT3 or INTO instruction that caused that exception.
- Suppose that the VM exit is due to a task switch that was caused by execution of CALL, IRET, or JMP or by execution of a software interrupt (INT *n*) or software exception (due to execution of INT3 or INTO) that encountered a task gate in the IDT. The value saved references the instruction that caused the task switch (CALL, IRET, JMP, INT *n*, INT3, or INTO).
- Suppose that the VM exit is due to a task switch that was caused by a task gate in the IDT that was encountered for any reason except the direct access by a software interrupt or software exception. The value saved is that which would have been saved in the old task-state segment had the task switch completed normally.
- If the VM exit is due to an execution of MOV to CR8 or WRMSR that reduced the value of bits 7:4 of VTPR (see Section 29.1.1) below that of TPR threshold VM-execution control field (see Section 29.1.2), the value saved references the instruction following the MOV to CR8 or WRMSR.
- If the VM exit was caused by APIC-write emulation (see Section 29.4.3.2) that results from an APIC access as part of instruction execution, the value saved references the instruction following the one whose execution caused the APIC-write emulation.
- The contents of the RSP register are saved into the RSP field.
- With the exception of the resume flag (RF; bit 16), the contents of the RFLAGS register is saved into the RFLAGS field. RFLAGS.RF is saved as follows:
  - If the VM exit is caused directly by an event that would normally be delivered through the IDT, the value saved is that which would appear in the saved RFLAGS image (either that which would be saved on the stack had the event been delivered through a trap or interrupt gate<sup>1</sup> or into the old task-state segment had the event been delivered through a task gate) had the event been delivered through the IDT. See below for VM exits due to task switches caused by task gates in the IDT.
  - If the VM exit is caused by a triple fault, the value saved is that which the logical processor would have in RF in the RFLAGS register had the triple fault taken the logical processor to the shutdown state.
  - If the VM exit is caused by a task switch (including one caused by a task gate in the IDT), the value saved is that which would have been saved in the RFLAGS image in the old task-state segment (TSS) had the task switch completed normally without exception.
  - If the VM exit is caused by an attempt to execute an instruction that unconditionally causes VM exits or one that was configured to do with a VM-execution control, the value saved is 0.<sup>2</sup>
  - For APIC-access VM exits and for VM exits caused by EPT violations and EPT misconfigurations, the value saved depends on whether the VM exit occurred during delivery of an event through the IDT:
    - If the VM exit stored 0 for bit 31 for IDT-vectoring information field (because the VM exit did not occur during delivery of an event through the IDT; see Section 27.2.3), the value saved is 1.
    - If the VM exit stored 1 for bit 31 for IDT-vectoring information field (because the VM exit did occur during delivery of an event through the IDT), the value saved is the value that would have appeared in the saved RFLAGS image had the event been delivered through the IDT (see above).
  - For all other VM exits, the value saved is the value RFLAGS.RF had before the VM exit occurred.

---

1. The reference here is to the full value of RFLAGS before any truncation that would occur had the stack width been only 32 bits or 16 bits.

2. This is true even if RFLAGS.RF was 1 before the instruction was executed. If, in response to such a VM exit, a VM monitor re-enters the guest to re-execute the instruction that caused the VM exit (for example, after clearing the VM-execution control that caused the VM exit), the instruction may encounter a code breakpoint that has already been processed. A VM monitor can avoid this by setting the guest value of RFLAGS.RF to 1 before resuming guest software.

## 27.3.4 Saving Non-Register State

Information corresponding to guest non-register state is saved as follows:

- The activity-state field is saved with the logical processor's activity state before the VM exit.<sup>1</sup> See Section 27.1 for details of how events leading to a VM exit may affect the activity state.
- The interruptibility-state field is saved to reflect the logical processor's interruptibility before the VM exit. See Section 27.1 for details of how events leading to a VM exit may affect this state. VM exits that end outside system-management mode (SMM) save bit 2 (blocking by SMI) as 0 regardless of the state of such blocking before the VM exit.

Bit 3 (blocking by NMI) is treated specially if the "virtual NMIs" VM-execution control is 1. In this case, the value saved for this field does not indicate the blocking of NMIs but rather the state of virtual-NMI blocking.

- The pending debug exceptions field is saved as clear for all VM exits except the following:
  - A VM exit caused by an INIT signal, a machine-check exception, or a system-management interrupt (SMI).
  - A VM exit with basic exit reason "TPR below threshold",<sup>2</sup> "virtualized EOI", "APIC write", or "monitor trap flag."
  - VM exits that are not caused by debug exceptions and that occur while there is MOV-SS blocking of debug exceptions.

For VM exits that do not clear the field, the value saved is determined as follows:

- Each of bits 3:0 may be set if it corresponds to a matched breakpoint. This may be true even if the corresponding breakpoint is not enabled in DR7.
- Suppose that a VM exit is due to an INIT signal, a machine-check exception, or an SMI; or that a VM exit has basic exit reason "TPR below threshold" or "monitor trap flag." In this case, the value saved sets bits corresponding to the causes of any debug exceptions that were pending at the time of the VM exit.

If the VM exit occurs immediately after VM entry, the value saved may match that which was loaded on VM entry (see Section 26.6.3). Otherwise, the following items apply:

- Bit 12 (enabled breakpoint) is set to 1 if there was at least one matched data or I/O breakpoint that was enabled in DR7. Bit 12 is also set if it had been set on VM entry, causing there to be valid pending debug exceptions (see Section 26.6.3) and the VM exit occurred before those exceptions were either delivered or lost. In other cases, bit 12 is cleared to 0.
- Bit 14 (BS) is set if RFLAGS.TF = 1 in either of the following cases:
  - IA32\_DEBUGCTL.BTF = 0 and the cause of a pending debug exception was the execution of a single instruction.
  - IA32\_DEBUGCTL.BTF = 1 and the cause of a pending debug exception was a taken branch.
- Suppose that a VM exit is due to another reason (but not a debug exception) and occurs while there is MOV-SS blocking of debug exceptions. In this case, the value saved sets bits corresponding to the causes of any debug exceptions that were pending at the time of the VM exit. If the VM exit occurs immediately after VM entry (no instructions were executed in VMX non-root operation), the value saved may match that which was loaded on VM entry (see Section 26.6.3). Otherwise, the following items apply:
  - Bit 12 (enabled breakpoint) is set to 1 if there was at least one matched data or I/O breakpoint that was enabled in DR7. Bit 12 is also set if it had been set on VM entry, causing there to be valid pending debug exceptions (see Section 26.6.3) and the VM exit occurred before those exceptions were either delivered or lost. In other cases, bit 12 is cleared to 0.
  - The setting of bit 14 (BS) is implementation-specific. However, it is not set if RFLAGS.TF = 0 or IA32\_DEBUGCTL.BTF = 1.
- The reserved bits in the field are cleared.

1. If this activity state was an inactive state resulting from execution of a specific instruction (HLT or MWAIT), the value saved for RIP by that VM exit will reference the following instruction.

2. This item includes VM exits that occur as a result of certain VM entries (Section 26.6.7).

- If the “save VMX-preemption timer value” VM-exit control is 1, the value of timer is saved into the VMX-preemption timer-value field. This is the value loaded from this field on VM entry as subsequently decremented (see Section 25.5.1). VM exits due to timer expiration save the value 0. Other VM exits may also save the value 0 if the timer expired during VM exit. (If the “save VMX-preemption timer value” VM-exit control is 0, VM exit does not modify the value of the VMX-preemption timer-value field.)
- If the logical processor supports the 1-setting of the “enable EPT” VM-execution control, values are saved into the four (4) PDPTE fields as follows:
  - If the “enable EPT” VM-execution control is 1 and the logical processor was using PAE paging at the time of the VM exit, the PDPTE values currently in use are saved:<sup>1</sup>
    - The values saved into bits 11:9 of each of the fields is undefined.
    - If the value saved into one of the fields has bit 0 (present) clear, the value saved into bits 63:1 of that field is undefined. That value need not correspond to the value that was loaded by VM entry or to any value that might have been loaded in VMX non-root operation.
    - If the value saved into one of the fields has bit 0 (present) set, the value saved into bits 63:12 of the field is a guest-physical address.
  - If the “enable EPT” VM-execution control is 0 or the logical processor was not using PAE paging at the time of the VM exit, the values saved are undefined.

## 27.4 SAVING MSRS

After processor state is saved to the guest-state area, values of MSRs may be stored into the VM-exit MSR-store area (see Section 24.7.2). Specifically each entry in that area (up to the number specified in the VM-exit MSR-store count) is processed in order by storing the value of the MSR indexed by bits 31:0 (as they would be read by RDMSR) into bits 127:64. Processing of an entry fails in either of the following cases:

- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be read only in system-management mode (SMM) and the VM exit will not end in SMM. (IA32\_SMBASE is an MSR that can be read only in SMM.)
- The value of bits 31:0 indicates an MSR that cannot be saved on VM exits for model-specific reasons. A processor may prevent certain MSRs (based on the value of bits 31:0) from being stored on VM exits, even if they can normally be read by RDMSR. Such model-specific behavior is documented in Chapter 35.
- Bits 63:32 of the entry are not all 0.
- An attempt to read the MSR indexed by bits 31:0 would cause a general-protection exception if executed via RDMSR with CPL = 0.

A VMX abort occurs if processing fails for any entry. See Section 27.7.

## 27.5 LOADING HOST STATE

Processor state is updated on VM exits in the following ways:

- Some state is loaded from or otherwise determined by the contents of the host-state area.
- Some state is determined by VM-exit controls.
- Some state is established in the same way on every VM exit.
- The page-directory pointers are loaded based on the values of certain control registers.

This loading may be performed in any order.

1. A logical processor uses PAE paging if CRO.PG = 1, CR4.PAE = 1 and IA32\_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM exit functions as if the “enable EPT” VM-execution control were 0. See Section 24.6.2.

On processors that support Intel 64 architecture, the full values of each 64-bit field loaded (for example, the base address for GDTR) is loaded regardless of the mode of the logical processor before and after the VM exit.

The loading of host state is detailed in Section 27.5.1 to Section 27.5.5. These sections reference VMCS fields that correspond to processor state. Unless otherwise stated, these references are to fields in the host-state area.

A logical processor is in IA-32e mode after a VM exit only if the “host address-space size” VM-exit control is 1. If the logical processor was in IA-32e mode before the VM exit and this control is 0, a VMX abort occurs. See Section 27.7.

In addition to loading host state, VM exits clear address-range monitoring (Section 27.5.6).

After the state loading described in this section, VM exits may load MSRs from the VM-exit MSR-load area (see Section 27.6). This loading occurs only after the state loading described in this section.

## 27.5.1 Loading Host Control Registers, Debug Registers, MSRs

VM exits load new values for controls registers, debug registers, and some MSRs:

- CRO, CR3, and CR4 are loaded from the CRO field, the CR3 field, and the CR4 field, respectively, with the following exceptions:
  - The following bits are not modified:
    - For CRO, ET, CD, NW; bits 63:32 (on processors that support Intel 64 architecture), 28:19, 17, and 15:6; and any bits that are fixed in VMX operation (see Section 23.8).<sup>1</sup>
    - For CR3, bits 63:52 and bits in the range 51:32 beyond the processor’s physical-address width (they are cleared to 0).<sup>2</sup> (This item applies only to processors that support Intel 64 architecture.)
    - For CR4, any bits that are fixed in VMX operation (see Section 23.8).
  - CR4.PAE is set to 1 if the “host address-space size” VM-exit control is 1.
  - CR4.PCIDE is set to 0 if the “host address-space size” VM-exit control is 0.
- DR7 is set to 400H.
- The following MSRs are established as follows:
  - The IA32\_DEBUGCTL MSR is cleared to 00000000\_00000000H.
  - The IA32\_SYSENTER\_CS MSR is loaded from the IA32\_SYSENTER\_CS field. Since that field has only 32 bits, bits 63:32 of the MSR are cleared to 0.
  - IA32\_SYSENTER\_ESP MSR and IA32\_SYSENTER\_EIP MSR are loaded from the IA32\_SYSENTER\_ESP field and the IA32\_SYSENTER\_EIP field, respectively.
 

If the processor does not support the Intel 64 architecture, these fields have only 32 bits; bits 63:32 of the MSRs are cleared to 0.

If the processor does support the Intel 64 architecture and the processor supports  $N < 64$  linear-address bits, each of bits 63:N is set to the value of bit  $N-1$ .<sup>3</sup>
  - The following steps are performed on processors that support Intel 64 architecture:
    - The MSRs FS.base and GS.base are loaded from the base-address fields for FS and GS, respectively (see Section 27.5.2).
    - The LMA and LME bits in the IA32\_EFER MSR are each loaded with the setting of the “host address-space size” VM-exit control.

1. Bits 28:19, 17, and 15:6 of CRO and CRO.ET are unchanged by executions of MOV to CRO. CRO.ET is always 1 and the other bits are always 0.

2. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

3. Software can determine the number N by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

- If the “load IA32\_PERF\_GLOBAL\_CTRL” VM-exit control is 1, the IA32\_PERF\_GLOBAL\_CTRL MSR is loaded from the IA32\_PERF\_GLOBAL\_CTRL field. Bits that are reserved in that MSR are maintained with their reserved values.
- If the “load IA32\_PAT” VM-exit control is 1, the IA32\_PAT MSR is loaded from the IA32\_PAT field. Bits that are reserved in that MSR are maintained with their reserved values.
- If the “load IA32\_EFER” VM-exit control is 1, the IA32\_EFER MSR is loaded from the IA32\_EFER field. Bits that are reserved in that MSR are maintained with their reserved values.

With the exception of FS.base and GS.base, any of these MSRs is subsequently overwritten if it appears in the VM-exit MSR-load area. See Section 27.6.

## 27.5.2 Loading Host Segment and Descriptor-Table Registers

Each of the registers CS, SS, DS, ES, FS, GS, and TR is loaded as follows (see below for the treatment of LDTR):

- The selector is loaded from the selector field. The segment is unusable if its selector is loaded with zero. The checks specified Section 26.3.1.2 limit the selector values that may be loaded. In particular, CS and TR are never loaded with zero and are thus never unusable. SS can be loaded with zero only on processors that support Intel 64 architecture and only if the VM exit is to 64-bit mode (64-bit mode allows use of segments marked unusable).
- The base address is set as follows:
  - CS. Cleared to zero.
  - SS, DS, and ES. Undefined if the segment is unusable; otherwise, cleared to zero.
  - FS and GS. Undefined (but, on processors that support Intel 64 architecture, canonical) if the segment is unusable and the VM exit is not to 64-bit mode; otherwise, loaded from the base-address field.
 

If the processor supports the Intel 64 architecture and the processor supports  $N < 64$  linear-address bits, each of bits 63:N is set to the value of bit  $N-1$ .<sup>1</sup> The values loaded for base addresses for FS and GS are also manifest in the FS.base and GS.base MSRs.
  - TR. Loaded from the host-state area. If the processor supports the Intel 64 architecture and the processor supports  $N < 64$  linear-address bits, each of bits 63:N is set to the value of bit  $N-1$ .
- The segment limit is set as follows:
  - CS. Set to FFFFFFFFH (corresponding to a descriptor limit of FFFFFH and a G-bit setting of 1).
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to FFFFFFFFH.
  - TR. Set to 00000067H.
- The type field and S bit are set as follows:
  - CS. Type set to 11 and S set to 1 (execute/read, accessed, non-conforming code segment).
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, type set to 3 and S set to 1 (read/write, accessed, expand-up data segment).
  - TR. Type set to 11 and S set to 0 (busy 32-bit task-state segment).
- The DPL is set as follows:
  - CS, SS, and TR. Set to 0. The current privilege level (CPL) will be 0 after the VM exit completes.
  - DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 0.
- The P bit is set as follows:
  - CS, TR. Set to 1.
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.

---

1. Software can determine the number  $N$  by executing CPUID with 80000008H in EAX. The number of linear-address bits supported is returned in bits 15:8 of EAX.

- On processors that support Intel 64 architecture, CS.L is loaded with the setting of the “host address-space size” VM-exit control. Because the value of this control is also loaded into IA32\_EFER.LMA (see Section 27.5.1), no VM exit is ever to compatibility mode (which requires IA32\_EFER.LMA = 1 and CS.L = 0).
- D/B.
  - CS. Loaded with the inverse of the setting of the “host address-space size” VM-exit control. For example, if that control is 0, indicating a 32-bit guest, CS.D/B is set to 1.
  - SS. Set to 1.
  - DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.
  - TR. Set to 0.
- G.
  - CS. Set to 1.
  - SS, DS, ES, FS, and GS. Undefined if the segment is unusable; otherwise, set to 1.
  - TR. Set to 0.

The host-state area does not contain a selector field for LDTR. LDTR is established as follows on all VM exits: the selector is cleared to 0000H, the segment is marked unusable and is otherwise undefined (although the base address is always canonical).

The base addresses for GDTR and IDTR are loaded from the GDTR base-address field and the IDTR base-address field, respectively. If the processor supports the Intel 64 architecture and the processor supports  $N < 64$  linear-address bits, each of bits 63:N of each base address is set to the value of bit N–1 of that base address. The GDTR and IDTR limits are each set to FFFFH.

### 27.5.3 Loading Host RIP, RSP, and RFLAGS

RIP and RSP are loaded from the RIP field and the RSP field, respectively. RFLAGS is cleared, except bit 1, which is always set.

### 27.5.4 Checking and Loading Host Page-Directory-Pointer-Table Entries

If CR0.PG = 1, CR4.PAE = 1, and IA32\_EFER.LMA = 0, the logical processor uses **PAE paging**. See Section 4.4 of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.<sup>1</sup> When in PAE paging is in use, the physical address in CR3 references a table of **page-directory-pointer-table entries** (PDPTEs). A MOV to CR3 when PAE paging is in use checks the validity of the PDPTEs and, if they are valid, loads them into the processor (into internal, non-architectural registers).

A VM exit is to a VMM that uses PAE paging if (1) bit 5 (corresponding to CR4.PAE) is set in the CR4 field in the host-state area of the VMCS; and (2) the “host address-space size” VM-exit control is 0. Such a VM exit may check the validity of the PDPTEs referenced by the CR3 field in the host-state area of the VMCS. Such a VM exit must check their validity if either (1) PAE paging was not in use before the VM exit; or (2) the value of CR3 is changing as a result of the VM exit. A VM exit to a VMM that does not use PAE paging must not check the validity of the PDPTEs.

A VM exit that checks the validity of the PDPTEs uses the same checks that are used when CR3 is loaded with MOV to CR3 when PAE paging is in use. If MOV to CR3 would cause a general-protection exception due to the PDPTEs that would be loaded (e.g., because a reserved bit is set), a VMX abort occurs (see Section 27.7). If a VM exit to a VMM that uses PAE does not cause a VMX abort, the PDPTEs are loaded into the processor as would MOV to CR3, using the value of CR3 being load by the VM exit.

---

1. On processors that support Intel 64 architecture, the physical-address extension may support more than 36 physical-address bits. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

## 27.5.5 Updating Non-Register State

VM exits affect the non-register state of a logical processor as follows:

- A logical processor is always in the active state after a VM exit.
- Event blocking is affected as follows:
  - There is no blocking by STI or by MOV SS after a VM exit.
  - VM exits caused directly by non-maskable interrupts (NMIs) cause blocking by NMI (see Table 24-3). Other VM exits do not affect blocking by NMI. (See Section 27.1 for the case in which an NMI causes a VM exit indirectly.)
- There are no pending debug exceptions after a VM exit.

Section 28.3 describes how the VMX architecture controls how a logical processor manages information in the TLBs and paging-structure caches. The following items detail how VM exits invalidate cached mappings:

- If the “enable VPID” VM-execution control is 0, the logical processor invalidates linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP).
- VM exits are not required to invalidate any guest-physical mappings, nor are they required to invalidate any linear mappings or combined mappings if the “enable VPID” VM-execution control is 1.

## 27.5.6 Clearing Address-Range Monitoring

The Intel 64 and IA-32 architectures allow software to monitor a specified address range using the MONITOR and MWAIT instructions. See Section 8.10.4 in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*. VM exits clear any address-range monitoring that may be in effect.

## 27.6 LOADING MSRS

VM exits may load MSRs from the VM-exit MSR-load area (see Section 24.7.2). Specifically each entry in that area (up to the number specified in the VM-exit MSR-load count) is processed in order by loading the MSR indexed by bits 31:0 with the contents of bits 127:64 as they would be written by WRMSR.

Processing of an entry fails in any of the following cases:

- The value of bits 31:0 is either C0000100H (the IA32\_FS\_BASE MSR) or C0000101H (the IA32\_GS\_BASE MSR).
- The value of bits 31:8 is 000008H, meaning that the indexed MSR is one that allows access to an APIC register when the local APIC is in x2APIC mode.
- The value of bits 31:0 indicates an MSR that can be written only in system-management mode (SMM) and the VM exit will not end in SMM. (IA32\_SMM\_MONITOR\_CTL is an MSR that can be written only in SMM.)
- The value of bits 31:0 indicates an MSR that cannot be loaded on VM exits for model-specific reasons. A processor may prevent loading of certain MSRs even if they can normally be written by WRMSR. Such model-specific behavior is documented in Chapter 35.
- Bits 63:32 are not all 0.
- An attempt to write bits 127:64 to the MSR indexed by bits 31:0 of the entry would cause a general-protection exception if executed via WRMSR with CPL = 0.<sup>1</sup>

If processing fails for any entry, a VMX abort occurs. See Section 27.7.

If any MSR is being loaded in such a way that would architecturally require a TLB flush, the TLBs are updated so that, after VM exit, the logical processor does not use any translations that were cached before the transition.

---

1. Note the following about processors that support Intel 64 architecture. If CR0.PG = 1, WRMSR to the IA32\_EFER MSR causes a general-protection exception if it would modify the LME bit. Since CR0.PG is always 1 in VMX operation, the IA32\_EFER MSR should not be included in the VM-exit MSR-load area for the purpose of modifying the LME bit.

## 27.7 VMX ABORTS

A problem encountered during a VM exit leads to a **VMX abort**. A VMX abort takes a logical processor into a shut-down state as described below.

A VMX abort does not modify the VMCS data in the VMCS region of any active VMCS. The contents of these data are thus suspect after the VMX abort.

On a VMX abort, a logical processor saves a nonzero 32-bit VMX-abort indicator field at byte offset 4 in the VMCS region of the VMCS whose misconfiguration caused the failure (see Section 24.2). The following values are used:

1. There was a failure in saving guest MSRs (see Section 27.4).
2. Host checking of the page-directory-pointer-table entries (PDPTes) failed (see Section 27.5.4).
3. The current VMCS has been corrupted (through writes to the corresponding VMCS region) in such a way that the logical processor cannot complete the VM exit properly.
4. There was a failure on loading host MSRs (see Section 27.6).
5. There was a machine-check event during VM exit (see Section 27.8).
6. The logical processor was in IA-32e mode before the VM exit and the “host address-space size” VM-entry control was 0 (see Section 27.5).

Some of these causes correspond to failures during the loading of state from the host-state area. Because the loading of such state may be done in any order (see Section 27.5) a VM exit that might lead to a VMX abort for multiple reasons (for example, the current VMCS may be corrupt and the host PDPTes might not be properly configured). In such cases, the VMX-abort indicator could correspond to any one of those reasons.

A logical processor never reads the VMX-abort indicator in a VMCS region and writes it only with one of the non-zero values mentioned above. The VMX-abort indicator allows software on one logical processor to diagnose the VMX-abort on another. For this reason, it is recommended that software running in VMX root operation zero the VMX-abort indicator in the VMCS region of any VMCS that it uses.

After saving the VMX-abort indicator, operation of a logical processor experiencing a VMX abort depends on whether the logical processor is in SMX operation:<sup>1</sup>

- If the logical processor is in SMX operation, an Intel® TXT shutdown condition occurs. The error code used is 000DH, indicating “VMX abort.” See *Intel® Trusted Execution Technology Measured Launched Environment Programming Guide*.
- If the logical processor is outside SMX operation, it issues a special bus cycle (to notify the chipset) and enters the **VMX-abort shutdown state**. RESET is the only event that wakes a logical processor from the VMX-abort shutdown state. The following events do not affect a logical processor in this state: machine-check events; INIT signals; external interrupts; non-maskable interrupts (NMIs); start-up IPIs (SIPIs); and system-management interrupts (SMIs).

## 27.8 MACHINE-CHECK EVENTS DURING VM EXIT

If a machine-check event occurs during VM exit, one of the following occurs:

- The machine-check event is handled as if it occurred before the VM exit:
  - If CR4.MCE = 0, operation of the logical processor depends on whether the logical processor is in SMX operation:<sup>2</sup>

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENDER]. A logical processor is outside SMX operation if GETSEC[SENDER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENDER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

2. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENDER]. A logical processor is outside SMX operation if GETSEC[SENDER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENDER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

## VM EXITS

- If the logical processor is in SMX operation, an Intel<sup>®</sup> TXT shutdown condition occurs. The error code used is 000CH, indicating “unrecoverable machine-check condition.”
- If the logical processor is outside SMX operation, it goes to the shutdown state.
- If CR4.MCE = 1, a machine-check exception (#MC) is generated:
  - If bit 18 (#MC) of the exception bitmap is 0, the exception is delivered through the guest IDT.
  - If bit 18 of the exception bitmap is 1, the exception causes a VM exit.
- The machine-check event is handled after VM exit completes:
  - If the VM exit ends with CR4.MCE = 0, operation of the logical processor depends on whether the logical processor is in SMX operation:
    - If the logical processor is in SMX operation, an Intel<sup>®</sup> TXT shutdown condition occurs with error code 000CH (unrecoverable machine-check condition).
    - If the logical processor is outside SMX operation, it goes to the shutdown state.
  - If the VM exit ends with CR4.MCE = 1, a machine-check exception (#MC) is delivered through the host IDT.
- A VMX abort is generated (see Section 27.7). The logical processor blocks events as done normally in VMX abort. The VMX abort indicator is 5, for “machine-check event during VM exit.”

The first option is not used if the machine-check event occurs after any host state has been loaded. The second option is used only if VM entry is able to load all host state.

The architecture for VMX operation includes two features that support address translation: virtual-processor identifiers (VPIDs) and the extended page-table mechanism (EPT). VPIDs are a mechanism for managing translations of linear addresses. EPT defines a layer of address translation that augments the translation of linear addresses.

Section 28.1 details the architecture of VPIDs. Section 28.2 provides the details of EPT. Section 28.3 explains how a logical processor may cache information from the paging structures, how it may use that cached information, and how software can managed the cached information.

## 28.1 VIRTUAL PROCESSOR IDENTIFIERS (VPIDS)

The original architecture for VMX operation required VMX transitions to flush the TLBs and paging-structure caches. This ensured that translations cached for the old linear-address space would not be used after the transition.

Virtual-processor identifiers (**VPIDs**) introduce to VMX operation a facility by which a logical processor may cache information for multiple linear-address spaces. When VPIDs are used, VMX transitions may retain cached information and the logical processor switches to a different linear-address space.

Section 28.3 details the mechanisms by which a logical processor manages information cached for multiple address spaces. A logical processor may tag some cached information with a 16-bit VPID. This section specifies how the current VPID is determined at any point in time:

- The current VPID is 0000H in the following situations:
  - Outside VMX operation. (This includes operation in system-management mode under the default treatment of SMIs and SMM with VMX operation; see Section 34.14.)
  - In VMX root operation.
  - In VMX non-root operation when the “enable VPID” VM-execution control is 0.
- If the logical processor is in VMX non-root operation and the “enable VPID” VM-execution control is 1, the current VPID is the value of the VPID VM-execution control field in the VMCS. (VM entry ensures that this value is never 0000H; see Section 26.2.1.1.)

VPIDs and PCIDs (see Section 4.10.1) can be used concurrently. When this is done, the processor associates cached information with both a VPID and a PCID. Such information is used only if the current VPID and PCID **both** match those associated with the cached information.

## 28.2 THE EXTENDED PAGE TABLE MECHANISM (EPT)

The extended page-table mechanism (**EPT**) is a feature that can be used to support the virtualization of physical memory. When EPT is in use, certain addresses that would normally be treated as physical addresses (and used to access memory) are instead treated as **guest-physical addresses**. Guest-physical addresses are translated by traversing a set of **EPT paging structures** to produce physical addresses that are used to access memory.

- Section 28.2.1 gives an overview of EPT.
- Section 28.2.2 describes operation of EPT-based address translation.
- Section 28.2.3 discusses VM exits that may be caused by EPT.
- Section 28.2.5 describes interactions between EPT and memory typing.

### 28.2.1 EPT Overview

EPT is used when the “enable EPT” VM-execution control is 1.<sup>1</sup> It translates the guest-physical addresses used in VMX non-root operation and those used by VM entry for event injection.

The translation from guest-physical addresses to physical addresses is determined by a set of **EPT paging structures**. The EPT paging structures are similar to those used to translate linear addresses while the processor is in IA-32e mode. Section 28.2.2 gives the details of the EPT paging structures.

If CR0.PG = 1, linear addresses are translated through paging structures referenced through control register CR3. While the “enable EPT” VM-execution control is 1, these are called **guest paging structures**. There are no guest paging structures if CR0.PG = 0.<sup>1</sup>

When the “enable EPT” VM-execution control is 1, the identity of **guest-physical addresses** depends on the value of CR0.PG:

- If CR0.PG = 0, each linear address is treated as a guest-physical address.
- If CR0.PG = 1, guest-physical addresses are those derived from the contents of control register CR3 and the guest paging structures. (This includes the values of the PDPTes, which logical processors store in internal, non-architectural registers.) The latter includes (in page-table entries and in other paging-structure entries for which bit 7—PS—is 1) the addresses to which linear addresses are translated by the guest paging structures.

If CR0.PG = 1, the translation of a linear address to a physical address requires multiple translations of guest-physical addresses using EPT. Assume, for example, that CR4.PAE = CR4.PSE = 0. The translation of a 32-bit linear address then operates as follows:

- Bits 31:22 of the linear address select an entry in the guest page directory located at the guest-physical address in CR3. The guest-physical address of the guest page-directory entry (PDE) is translated through EPT to determine the guest PDE’s physical address.
- Bits 21:12 of the linear address select an entry in the guest page table located at the guest-physical address in the guest PDE. The guest-physical address of the guest page-table entry (PTE) is translated through EPT to determine the guest PTE’s physical address.
- Bits 11:0 of the linear address is the offset in the page frame located at the guest-physical address in the guest PTE. The guest-physical address determined by this offset is translated through EPT to determine the physical address to which the original linear address translates.

In addition to translating a guest-physical address to a physical address, EPT specifies the privileges that software is allowed when accessing the address. Attempts at disallowed accesses are called **EPT violations** and cause VM exits. See Section 28.2.3.

A logical processor uses EPT to translate guest-physical addresses only when those addresses are used to access memory. This principle implies the following:

- The MOV to CR3 instruction loads CR3 with a guest-physical address. Whether that address is translated through EPT depends on whether PAE paging is being used.<sup>2</sup>
  - If PAE paging is not being used, the instruction does not use that address to access memory and does **not** cause it to be translated through EPT. (If CR0.PG = 1, the address will be translated through EPT on the next memory accessing using a linear address.)
  - If PAE paging is being used, the instruction loads the four (4) page-directory-pointer-table entries (PDPTes) from that address and it **does** cause the address to be translated through EPT.
- Section 4.4.1 identifies executions of MOV to CR0 and MOV to CR4 that load the PDPTes from the guest-physical address in CR3. Such executions cause that address to be translated through EPT.
- The PDPTes contain guest-physical addresses. The instructions that load the PDPTes (see above) do not use those addresses to access memory and do **not** cause them to be translated through EPT. The address in a PDPTE will be translated through EPT on the next memory accessing using a linear address that uses that PDPTE.

1. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, the logical processor operates as if the “enable EPT” VM-execution control were 0. See Section 24.6.2.

1. If the capability MSR IA32\_VMX\_CR0\_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG can be 0 in VMX non-root operation only if the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

2. A logical processor uses PAE paging if CR0.PG = 1, CR4.PAE = 1 and IA32\_EFER.LMA = 0. See Section 4.4 in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

## 28.2.2 EPT Translation Mechanism

The EPT translation mechanism uses only bits 47:0 of each guest-physical address.<sup>1</sup> It uses a page-walk length of 4, meaning that at most 4 EPT paging-structure entries are accessed to translate a guest-physical address.<sup>2</sup>

These 48 bits are partitioned by the logical processor to traverse the EPT paging structures:

- A 4-KByte naturally aligned EPT PML4 table is located at the physical address specified in bits 51:12 of the extended-page-table pointer (EPTP), a VM-execution control field (see Table 24-8 in Section 24.6.11). An EPT PML4 table comprises 512 64-bit entries (EPT PML4Es). An EPT PML4E is selected using the physical address defined as follows:
  - Bits 63:52 are all 0.
  - Bits 51:12 are from the EPTP.
  - Bits 11:3 are bits 47:39 of the guest-physical address.
  - Bits 2:0 are all 0.

Because an EPT PML4E is identified using bits 47:39 of the guest-physical address, it controls access to a 512-GByte region of the guest-physical-address space. The format of an EPT PML4E is given in Table 28-1.

**Table 28-1. Format of an EPT PML4 Entry (PML4E)**

Bit Position(s)	Contents
0	Read access; indicates whether reads are allowed from the 512-GByte region controlled by this entry
1	Write access; indicates whether writes are allowed to the 512-GByte region controlled by this entry
2	Execute access; indicates whether instruction fetches are allowed from the 512-GByte region controlled by this entry
7:3	Reserved (must be 0)
8	If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 512-GByte region controlled by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
11:9	Ignored
(N-1):12	Physical address of 4-KByte aligned EPT page-directory-pointer table referenced by this entry <sup>1</sup>
51:N	Reserved (must be 0)
63:52	Ignored

**NOTES:**

1. N is the physical-address width supported by the processor. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

- A 4-KByte naturally aligned EPT page-directory-pointer table is located at the physical address specified in bits 51:12 of the EPT PML4E. An EPT page-directory-pointer table comprises 512 64-bit entries (EPT PDPTes). An EPT PDPTe is selected using the physical address defined as follows:
  - Bits 63:52 are all 0.
  - Bits 51:12 are from the EPT PML4E.

---

1. No processors supporting the Intel 64 architecture support more than 48 physical-address bits. Thus, no such processor can produce a guest-physical address with more than 48 bits. An attempt to use such an address causes a page fault. An attempt to load CR3 with such an address causes a general-protection fault. If PAE paging is being used, an attempt to load CR3 that would load a PDPTe with such an address causes a general-protection fault.

2. Future processors may include support for other EPT page-walk lengths. Software should read the VMX capability MSR IA32\_VMX\_EPT\_VPID\_CAP (see Appendix A.10) to determine what EPT page-walk lengths are supported.

- Bits 11:3 are bits 38:30 of the guest-physical address.
- Bits 2:0 are all 0.

Because an EPT PDPTE is identified using bits 47:30 of the guest-physical address, it controls access to a 1-GByte region of the guest-physical-address space. Use of the EPT PDPTE depends on the value of bit 7 in that entry:<sup>1</sup>

- If bit 7 of the EPT PDPTE is 1, the EPT PDPTE maps a 1-GByte page. The final physical address is computed as follows:
  - Bits 63:52 are all 0.
  - Bits 51:30 are from the EPT PDPTE.
  - Bits 29:0 are from the original guest-physical address.

The format of an EPT PDPTE that maps a 1-GByte page is given in Table 28-2.

**Table 28-2. Format of an EPT Page-Directory-Pointer-Table Entry (PDPTE) that Maps a 1-GByte Page**

Bit Position(s)	Contents
0	Read access; indicates whether reads are allowed from the 1-GByte page referenced by this entry
1	Write access; indicates whether writes are allowed to the 1-GByte page referenced by this entry
2	Execute access; indicates whether instruction fetches are allowed from the 1-GByte page referenced by this entry
5:3	EPT memory type for this 1-GByte page (see Section 28.2.5)
6	Ignore PAT memory type for this 1-GByte page (see Section 28.2.5)
7	Must be 1 (otherwise, this entry references an EPT page directory)
8	If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 1-GByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
9	If bit 6 of EPTP is 1, dirty flag for EPT; indicates whether software has written to the 1-GByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
11:10	Ignored
29:12	Reserved (must be 0)
(N-1):30	Physical address of the 1-GByte page referenced by this entry <sup>1</sup>
51:N	Reserved (must be 0)
62:52	Ignored
63	Suppress #VE. If the “EPT-violation #VE” VM-execution control is 1, EPT violations caused by accesses to this page are convertible to virtualization exceptions only if this bit is 0 (see Section 25.5.6.1). If “EPT-violation #VE” VM-execution control is 0, this bit is ignored.

**NOTES:**

1. N is the physical-address width supported by the logical processor.

- If bit 7 of the EPT PDPTE is 0, a 4-KByte naturally aligned EPT page directory is located at the physical address specified in bits 51:12 of the EPT PDPTE. The format of an EPT PDPTE that references an EPT page directory is given in Table 28-3.

---

1. Not all processors allow bit 7 of an EPT PDPTE to be set to 1. Software should read the VMX capability MSR IA32\_VMX\_EPT\_VPID\_CAP (see Appendix A.10) to determine whether this is allowed.

**Table 28-3. Format of an EPT Page-Directory-Pointer-Table Entry (PDPTÉ) that References an EPT Page Directory**

Bit Position(s)	Contents
0	Read access; indicates whether reads are allowed from the 1-GByte region controlled by this entry
1	Write access; indicates whether writes are allowed to the 1-GByte region controlled by this entry
2	Execute access; indicates whether instruction fetches are allowed from the 1-GByte region controlled by this entry
7:3	Reserved (must be 0)
8	If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 1-GByte region controlled by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
11:9	Ignored
(N-1):12	Physical address of 4-KByte aligned EPT page directory referenced by this entry <sup>1</sup>
51:N	Reserved (must be 0)
63:52	Ignored

**NOTES:**

1. N is the physical-address width supported by the logical processor.

An EPT page-directory comprises 512 64-bit entries (PDEs). An EPT PDE is selected using the physical address defined as follows:

- Bits 63:52 are all 0.
- Bits 51:12 are from the EPT PDPTÉ.
- Bits 11:3 are bits 29:21 of the guest-physical address.
- Bits 2:0 are all 0.

Because an EPT PDE is identified using bits 47:21 of the guest-physical address, it controls access to a 2-MByte region of the guest-physical-address space. Use of the EPT PDE depends on the value of bit 7 in that entry:

- If bit 7 of the EPT PDE is 1, the EPT PDE maps a 2-MByte page. The final physical address is computed as follows:
  - Bits 63:52 are all 0.
  - Bits 51:21 are from the EPT PDE.
  - Bits 20:0 are from the original guest-physical address.

The format of an EPT PDE that maps a 2-MByte page is given in Table 28-4.

- If bit 7 of the EPT PDE is 0, a 4-KByte naturally aligned EPT page table is located at the physical address specified in bits 51:12 of the EPT PDE. The format of an EPT PDE that references an EPT page table is given in Table 28-5.

An EPT page table comprises 512 64-bit entries (PTEs). An EPT PTE is selected using a physical address defined as follows:

- Bits 63:52 are all 0.
- Bits 51:12 are from the EPT PDE.
- Bits 11:3 are bits 20:12 of the guest-physical address.
- Bits 2:0 are all 0.

- Because an EPT PTE is identified using bits 47:12 of the guest-physical address, every EPT PTE maps a 4-KByte page. The final physical address is computed as follows:
  - Bits 63:52 are all 0.

**Table 28-4. Format of an EPT Page-Directory Entry (PDE) that Maps a 2-MByte Page**

Bit Position(s)	Contents
0	Read access; indicates whether reads are allowed from the 2-MByte page referenced by this entry
1	Write access; indicates whether writes are allowed to the 2-MByte page referenced by this entry
2	Execute access; indicates whether instruction fetches are allowed from the 2-MByte page referenced by this entry
5:3	EPT memory type for this 2-MByte page (see Section 28.2.5)
6	Ignore PAT memory type for this 2-MByte page (see Section 28.2.5)
7	Must be 1 (otherwise, this entry references an EPT page table)
8	If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 2-MByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
9	If bit 6 of EPTP is 1, dirty flag for EPT; indicates whether software has written to the 2-MByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
11:10	Ignored
20:12	Reserved (must be 0)
(N-1):21	Physical address of the 2-MByte page referenced by this entry <sup>1</sup>
51:N	Reserved (must be 0)
62:52	Ignored
63	Suppress #VE. If the “EPT-violation #VE” VM-execution control is 1, EPT violations caused by accesses to this page are convertible to virtualization exceptions only if this bit is 0 (see Section 25.5.6.1). If “EPT-violation #VE” VM-execution control is 0, this bit is ignored.

**NOTES:**

1. N is the physical-address width supported by the logical processor.

- Bits 51:12 are from the EPT PTE.
- Bits 11:0 are from the original guest-physical address.

The format of an EPT PTE is given in Table 28-6.

If bits 2:0 of an EPT paging-structure entry are all 0, the entry is **not present**. The processor ignores bits 62:3 and uses the entry neither to reference another EPT paging-structure entry nor to produce a physical address. A reference using a guest-physical address whose translation encounters an EPT paging-structure that is not present causes an EPT violation (see Section 28.2.3.2). (If the “EPT-violation #VE” VM-execution control is 1, the EPT violation is convertible to a virtualization exception only if bit 63 is 0; see Section 25.5.6.1. If the “EPT-violation #VE” VM-execution control is 0, this bit is ignored.)

The discussion above describes how the EPT paging structures reference each other and how the logical processor traverses those structures when translating a guest-physical address. It does not cover all details of the translation process. Additional details are provided as follows:

- Situations in which the translation process may lead to VM exits (sometimes before the process completes) are described in Section 28.2.3.
- Interactions between the EPT translation mechanism and memory typing are described in Section 28.2.5.

Figure 28-1 gives a summary of the formats of the EPTP and the EPT paging-structure entries. For the EPT paging structure entries, it identifies separately the format of entries that map pages, those that reference other EPT paging structures, and those that do neither because they are “not present”; bits 2:0 and bit 7 are highlighted because they determine how a paging-structure entry is used.

**Table 28-5. Format of an EPT Page-Directory Entry (PDE) that References an EPT Page Table**

Bit Position(s)	Contents
0	Read access; indicates whether reads are allowed from the 2-MByte region controlled by this entry
1	Write access; indicates whether writes are allowed to the 2-MByte region controlled by this entry
2	Execute access; indicates whether instruction fetches are allowed from the 2-MByte region controlled by this entry
6:3	Reserved (must be 0)
7	Must be 0 (otherwise, this entry maps a 2-MByte page)
8	If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 2-MByte region controlled by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
11:9	Ignored
(N-1):12	Physical address of 4-KByte aligned EPT page table referenced by this entry <sup>1</sup>
51:N	Reserved (must be 0)
63:52	Ignored

**NOTES:**

1. N is the physical-address width supported by the logical processor.

### 28.2.3 EPT-Induced VM Exits

Accesses using guest-physical addresses may cause VM exits due to **EPT misconfigurations** and **EPT violations**. An EPT misconfiguration occurs when, in the course of translation a guest-physical address, the logical processor encounters an EPT paging-structure entry that contains an unsupported value. An EPT violation occurs when there is no EPT misconfiguration but the EPT paging-structure entries disallow an access using the guest-physical address.

EPT misconfigurations and EPT violations occur only due to an attempt to access memory with a guest-physical address. Loading CR3 with a guest-physical address with the MOV to CR3 instruction can cause neither an EPT configuration nor an EPT violation until that address is used to access a paging structure.<sup>1</sup>

If the “EPT-violation #VE” VM-execution control is 1, certain EPT violations may cause virtualization exceptions instead of VM exits. See Section 25.5.6.1.

#### 28.2.3.1 EPT Misconfigurations

AN EPT misconfiguration occurs if any of the following is identified while translating a guest-physical address:

- The value of bits 2:0 of an EPT paging-structure entry is either 010b (write-only) or 110b (write/execute).
- The value of bits 2:0 of an EPT paging-structure entry is 100b (execute-only) and this value is not supported by the logical processor. Software should read the VMX capability MSR IA32\_VMX\_EPT\_VPID\_CAP to determine whether this value is supported (see Appendix A.10).
- The value of bits 2:0 of an EPT paging-structure entry is not 000b (the entry is present) **and** one of the following holds:

1. If the logical processor is using PAE paging—because CR0.PG = CR4.PAE = 1 and IA32\_EFER.LMA = 0—the MOV to CR3 instruction loads the PDPTs from memory using the guest-physical address being loaded into CR3. In this case, therefore, the MOV to CR3 instruction may cause an EPT misconfiguration or an EPT violation.

**Table 28-6. Format of an EPT Page-Table Entry**

Bit Position(s)	Contents
0	Read access; indicates whether reads are allowed from the 4-KByte page referenced by this entry
1	Write access; indicates whether writes are allowed to the 4-KByte page referenced by this entry
2	Execute access; indicates whether instruction fetches are allowed from the 4-KByte page referenced by this entry
5:3	EPT memory type for this 4-KByte page (see Section 28.2.5)
6	Ignore PAT memory type for this 4-KByte page (see Section 28.2.5)
7	Ignored
8	If bit 6 of EPTP is 1, accessed flag for EPT; indicates whether software has accessed the 4-KByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
9	If bit 6 of EPTP is 1, dirty flag for EPT; indicates whether software has written to the 4-KByte page referenced by this entry (see Section 28.2.4). Ignored if bit 6 of EPTP is 0
11:10	Ignored
(N-1):12	Physical address of the 4-KByte page referenced by this entry <sup>1</sup>
51:N	Reserved (must be 0)
62:52	Ignored
63	Suppress #VE. If the “EPT-violation #VE” VM-execution control is 1, EPT violations caused by accesses to this page are convertible to virtualization exceptions only if this bit is 0 (see Section 25.5.6.1). If “EPT-violation #VE” VM-execution control is 0, this bit is ignored.

**NOTES:**

1. N is the physical-address width supported by the logical processor.

- A reserved bit is set. This includes the setting of a bit in the range 51: 12 that is beyond the logical processor’s physical-address width.<sup>1</sup> See Section 28.2.2 for details of which bits are reserved in which EPT paging-structure entries.
- The entry is the last one used to translate a guest physical address (either an EPT PDE with bit 7 set to 1 or an EPT PTE) and the value of bits 5: 3 (EPT memory type) is 2, 3, or 7 (these values are reserved).

EPT misconfigurations result when an EPT paging-structure entry is configured with settings reserved for future functionality. Software developers should be aware that such settings may be used in the future and that an EPT paging-structure entry that causes an EPT misconfiguration on one processor might not do so in the future.

**28.2.3.2 EPT Violations**

An EPT violation may occur during an access using a guest-physical address whose translation does not cause an EPT misconfiguration. An EPT violation occurs in any of the following situations:

- Translation of the guest-physical address encounters an EPT paging-structure entry that is not present (see Section 28.2.2).
- The access is a data read and bit 0 was clear in any of the EPT paging-structure entries used to translate the guest-physical address. Reads by the logical processor of guest paging structures to translate a linear address are considered to be data reads.

---

1. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.

### 28.2.3.3 Prioritization of EPT-Induced VM Exits

The translation of a linear address to a physical address requires one or more translations of guest-physical addresses using EPT (see Section 28.2.1). This section specifies the relative priority of EPT-induced VM exits with respect to each other and to other events that may be encountered when accessing memory using a linear address.

For an access to a guest-physical address, determination of whether an EPT misconfiguration or an EPT violation occurs is based on an iterative process:<sup>1</sup>

1. An EPT paging-structure entry is read (initially, this is an EPT PML4 entry):
  - a. If the entry is not present (bits 2:0 are all 0), an EPT violation occurs.
  - b. If the entry is present but its contents are not configured properly (see Section 28.2.3.1), an EPT misconfiguration occurs.
  - c. If the entry is present and its contents are configured properly, operation depends on whether the entry references another EPT paging structure (whether it is an EPT PDE with bit 7 set to 1 or an EPT PTE):
    - i) If the entry does reference another EPT paging structure, an entry from that structure is accessed; step 1 is executed for that other entry.
    - ii) Otherwise, the entry is used to produce the ultimate physical address (the translation of the original guest-physical address); step 2 is executed.
2. Once the ultimate physical address is determined, the privileges determined by the EPT paging-structure entries are evaluated:
  - a. If the access to the guest-physical address is not allowed by these privileges (see Section 28.2.3.2), an EPT violation occurs.
  - b. If the access to the guest-physical address is allowed by these privileges, memory is accessed using the ultimate physical address.

If  $CR0.PG = 1$ , the translation of a linear address is also an iterative process, with the processor first accessing an entry in the guest paging structure referenced by the guest-physical address in CR3 (or, if PAE paging is in use, the guest-physical address in the appropriate PDPTTE register), then accessing an entry in another guest paging structure referenced by the guest-physical address in the first guest paging-structure entry, etc. Each guest-physical address is itself translated using EPT and may cause an EPT-induced VM exit. The following items detail how page faults and EPT-induced VM exits are recognized during this iterative process:

1. An attempt is made to access a guest paging-structure entry with a guest-physical address (initially, the address in CR3 or PDPTTE register).
  - a. If the access fails because of an EPT misconfiguration or an EPT violation (see above), an EPT-induced VM exit occurs.
  - b. If the access does not cause an EPT-induced VM exit, bit 0 (the present flag) of the entry is consulted:
    - i) If the present flag is 0 or any reserved bit is set, a page fault occurs.
    - ii) If the present flag is 1, no reserved bit is set, operation depends on whether the entry references another guest paging structure (whether it is a guest PDE with  $PS = 1$  or a guest PTE):
      - If the entry does reference another guest paging structure, an entry from that structure is accessed; step 1 is executed for that other entry.
      - Otherwise, the entry is used to produce the ultimate guest-physical address (the translation of the original linear address); step 2 is executed.
2. Once the ultimate guest-physical address is determined, the privileges determined by the guest paging-structure entries are evaluated:
  - a. If the access to the linear address is not allowed by these privileges (e.g., it was a write to a read-only page), a page fault occurs.
  - b. If the access to the linear address is allowed by these privileges, an attempt is made to access memory at the ultimate guest-physical address:

---

1. This is a simplification of the more detailed description given in Section 28.2.2.

- i) If the access fails because of an EPT misconfiguration or an EPT violation (see above), an EPT-induced VM exit occurs.
- ii) If the access does not cause an EPT-induced VM exit, memory is accessed using the ultimate physical address (the translation, using EPT, of the ultimate guest-physical address).

If  $CR0.PG = 0$ , a linear address is treated as a guest-physical address and is translated using EPT (see above). This process, if it completes without an EPT violation or EPT misconfiguration, produces a physical address and determines the privileges allowed by the EPT paging-structure entries. If these privileges do not allow the access to the physical address (see Section 28.2.3.2), an EPT violation occurs. Otherwise, memory is accessed using the physical address.

## 28.2.4 Accessed and Dirty Flags for EPT

The Intel 64 architecture supports **accessed and dirty flags** in ordinary paging-structure entries (see Section 4.8). Some processors also support corresponding flags in EPT paging-structure entries. Software should read the VMX capability MSR `IA32_VMX_EPT_VPID_CAP` (see Appendix A.10) to determine whether the processor supports this feature.

Software can enable accessed and dirty flags for EPT using bit 6 of the extended-page-table pointer (EPTP), a VM-execution control field (see Table 24-8 in Section 24.6.11). If this bit is 1, the processor will set the accessed and dirty flags for EPT as described below. In addition, setting this flag causes processor accesses to guest paging-structure entries to be treated as writes (see below and Section 28.2.3.2).

For any EPT paging-structure entry that is used during guest-physical-address translation, bit 8 is the accessed flag. For a EPT paging-structure entry that maps a page (as opposed to referencing another EPT paging structure), bit 9 is the dirty flag.

Whenever the processor uses an EPT paging-structure entry as part of guest-physical-address translation, it sets the accessed flag in that entry (if it is not already set).

Whenever there is a write to a guest-physical address, the processor sets the dirty flag (if it is not already set) in the EPT paging-structure entry that identifies the final physical address for the guest-physical address (either an EPT PTE or an EPT paging-structure entry in which bit 7 is 1).

When accessed and dirty flags for EPT are enabled, processor accesses to guest paging-structure entries are treated as writes (see Section 28.2.3.2). Thus, such an access will cause the processor to set the dirty flag in the EPT paging-structure entry that identifies the final physical address of the guest paging-structure entry.

(This does not apply to loads of the PDPT registers for PAE paging by the MOV to CR instruction; see Section 4.4.1. Those loads of guest PDPTs are treated as reads and do not cause the processor to set the dirty flag in any EPT paging-structure entry.)

These flags are “sticky,” meaning that, once set, the processor does not clear them; only software can clear them.

A processor may cache information from the EPT paging-structure entries in TLBs and paging-structure caches (see Section 28.3). This fact implies that, if software changes an accessed flag or a dirty flag from 1 to 0, the processor might not set the corresponding bit in memory on a subsequent access using an affected guest-physical address.

## 28.2.5 EPT and Memory Typing

This section specifies how a logical processor determines the memory type use for a memory access while EPT is in use. (See Chapter 11, “Memory Cache Control” of *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* for details of memory typing in the Intel 64 architecture.) Section 28.2.5.1 explains how the memory type is determined for accesses to the EPT paging structures. Section 28.2.5.2 explains how the memory type is determined for an access using a guest-physical address that is translated using EPT.

### 28.2.5.1 Memory Type Used for Accessing EPT Paging Structures

This section explains how the memory type is determined for accesses to the EPT paging structures. The determination is based first on the value of bit 30 (cache disable—CD) in control register CR0:

- If CR0.CD = 0, the memory type used for any such reference is the EPT paging-structure memory type, which is specified in bits 2:0 of the extended-page-table pointer (EPTP), a VM-execution control field (see Section 24.6.11). A value of 0 indicates the uncacheable type (UC), while a value of 6 indicates the write-back type (WB). Other values are reserved.
- If CR0.CD = 1, the memory type used for any such reference is uncacheable (UC).

The MTRRs have no effect on the memory type used for an access to an EPT paging structure.

### 28.2.5.2 Memory Type Used for Translated Guest-Physical Addresses

The **effective memory type** of a memory access using a guest-physical address (an access that is translated using EPT) is the memory type that is used to access memory. The effective memory type is based on the value of bit 30 (cache disable—CD) in control register CR0; the **last** EPT paging-structure entry used to translate the guest-physical address (either an EPT PDE with bit 7 set to 1 or an EPT PTE); and the PAT memory type (see below):

- The **PAT memory type** depends on the value of CR0.PG:
  - If CR0.PG = 0, the PAT memory type is WB (writeback).<sup>1</sup>
  - If CR0.PG = 1, the PAT memory type is the memory type selected from the IA32\_PAT MSR as specified in Section 11.12.3, “Selecting a Memory Type from the PAT”.<sup>2</sup>
- The **EPT memory type** is specified in bits 5:3 of the last EPT paging-structure entry: 0 = UC; 1 = WC; 4 = WT; 5 = WP; and 6 = WB. Other values are reserved and cause EPT misconfigurations (see Section 28.2.3).
- If CR0.CD = 0, the effective memory type depends upon the value of bit 6 of the last EPT paging-structure entry:
  - If the value is 0, the effective memory type is the combination of the EPT memory type and the PAT memory type specified in Table 11-7 in Section 11.5.2.2, using the EPT memory type in place of the MTRR memory type.
  - If the value is 1, the memory type used for the access is the EPT memory type. The PAT memory type is ignored.
- If CR0.CD = 1, the effective memory type is UC.

The MTRRs have no effect on the memory type used for an access to a guest-physical address.

## 28.3 CACHING TRANSLATION INFORMATION

Processors supporting Intel® 64 and IA-32 architectures may accelerate the address-translation process by caching on the processor data from the structures in memory that control that process. Such caching is discussed in Section 4.10, “Caching Translation Information” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*. The current section describes how this caching interacts with the VMX architecture.

The VPID and EPT features of the architecture for VMX operation augment this caching architecture. EPT defines the guest-physical address space and defines translations to that address space (from the linear-address space) and from that address space (to the physical-address space). Both features control the ways in which a logical processor may create and use information cached from the paging structures.

Section 28.3.1 describes the different kinds of information that may be cached. Section 28.3.2 specifies when such information may be cached and how it may be used. Section 28.3.3 details how software can invalidate cached information.

1. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG can be 0 in VMX non-root operation only if the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.
2. Table 11-11 in Section 11.12.3, “Selecting a Memory Type from the PAT” illustrates how the PAT memory type is selected based on the values of the PAT, PCD, and PWT bits in a page-table entry (or page-directory entry with PS = 1). For accesses to a guest paging-structure entry X, the PAT memory type is selected from the table by using a value of 0 for the PAT bit with the values of PCD and PWT from the paging-structure entry Y that references X (or from CR3 if X is in the root paging structure). With PAE paging, the PAT memory type for accesses to the PDPTes is WB.

### 28.3.1 Information That May Be Cached

Section 4.10, “Caching Translation Information” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* identifies two kinds of translation-related information that may be cached by a logical processor: **translations**, which are mappings from linear page numbers to physical page frames, and **paging-structure caches**, which map the upper bits of a linear page number to information from the paging-structure entries used to translate linear addresses matching those upper bits.

The same kinds of information may be cached when VPIDs and EPT are in use. A logical processor may cache and use such information based on its function. Information with different functionality is identified as follows:

- **Linear mappings.**<sup>1</sup> There are two kinds:

- Linear translations. Each of these is a mapping from a linear page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
- Linear paging-structure-cache entries. Each of these is a mapping from the upper portion of a linear address to the physical address of the paging structure used to translate the corresponding region of the linear-address space, along with information about access privileges. For example, bits 47:39 of a linear address would map to the address of the relevant page-directory-pointer table.

Linear mappings do not contain information from any EPT paging structure.

- **Guest-physical mappings.**<sup>2</sup> There are two kinds:

- Guest-physical translations. Each of these is a mapping from a guest-physical page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
- Guest-physical paging-structure-cache entries. Each of these is a mapping from the upper portion of a guest-physical address to the physical address of the EPT paging structure used to translate the corresponding region of the guest-physical address space, along with information about access privileges.

The information in guest-physical mappings about access privileges and memory typing is derived from EPT paging structures.

- **Combined mappings.**<sup>3</sup> There are two kinds:

- Combined translations. Each of these is a mapping from a linear page number to the physical page frame to which it translates, along with information about access privileges and memory typing.
- Combined paging-structure-cache entries. Each of these is a mapping from the upper portion of a linear address to the physical address of the paging structure used to translate the corresponding region of the linear-address space, along with information about access privileges.

The information in combined mappings about access privileges and memory typing is derived from both guest paging structures and EPT paging structures.

### 28.3.2 Creating and Using Cached Translation Information

The following items detail the creation of the mappings described in the previous section:<sup>4</sup>

- The following items describe the creation of mappings while EPT is not in use (including execution outside VMX non-root operation):
  - Linear mappings may be created. They are derived from the paging structures referenced (directly or indirectly) by the current value of CR3 and are associated with the current VPID and the current PCID.

---

1. Earlier versions of this manual used the term “VPID-tagged” to identify linear mappings.  
 2. Earlier versions of this manual used the term “EPTP-tagged” to identify guest-physical mappings.  
 3. Earlier versions of this manual used the term “dual-tagged” to identify combined mappings.  
 4. This section associated cached information with the current VPID and PCID. If PCIDs are not supported or are not being used (e.g., because CR4.PCIDE = 0), all the information is implicitly associated with PCID 000H; see Section 4.10.1, “Process-Context Identifiers (PCIDs),” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

- No linear mappings are created with information derived from paging-structure entries that are not present (bit 0 is 0) or that set reserved bits. For example, if a PTE is not present, no linear mapping are created for any linear page number whose translation would use that PTE.
- No guest-physical or combined mappings are created while EPT is not in use.
- The following items describe the creation of mappings while EPT is in use:
  - Guest-physical mappings may be created. They are derived from the EPT paging structures referenced (directly or indirectly) by bits 51:12 of the current EPTP. These 40 bits contain the address of the EPT-PML4-table. (the notation **EP4TA** refers to those 40 bits). Newly created guest-physical mappings are associated with the current EP4TA.
  - Combined mappings may be created. They are derived from the EPT paging structures referenced (directly or indirectly) by the current EP4TA. If  $CR0.PG = 1$ , they are also derived from the paging structures referenced (directly or indirectly) by the current value of CR3. They are associated with the current VPID, the current PCID, and the current EP4TA.<sup>1</sup> No combined paging-structure-cache entries are created if  $CR0.PG = 0$ .<sup>2</sup>
  - No guest-physical mappings or combined mappings are created with information derived from EPT paging-structure entries that are not present (bits 2:0 are all 0) or that are misconfigured (see Section 28.2.3.1).
  - No combined mappings are created with information derived from guest paging-structure entries that are not present or that set reserved bits.
  - No linear mappings are created while EPT is in use.

The following items detail the use of the various mappings:

- If EPT is not in use (e.g., when outside VMX non-root operation), a logical processor may use cached mappings as follows:
  - For accesses using linear addresses, it may use linear mappings associated with the current VPID and the current PCID. It may also use global TLB entries (linear mappings) associated with the current VPID and any PCID.
  - No guest-physical or combined mappings are used while EPT is not in use.
- If EPT is in use, a logical processor may use cached mappings as follows:
  - For accesses using linear addresses, it may use combined mappings associated with the current VPID, the current PCID, and the current EP4TA. It may also use global TLB entries (combined mappings) associated with the current VPID, the current EP4TA, and any PCID.
  - For accesses using guest-physical addresses, it may use guest-physical mappings associated with the current EP4TA.
  - No linear mappings are used while EPT is in use.

### 28.3.3 Invalidating Cached Translation Information

Software modifications of paging structures (including EPT paging structures) may result in inconsistencies between those structures and the mappings cached by a logical processor. Certain operations invalidate information cached by a logical processor and can be used to eliminate such inconsistencies.

#### 28.3.3.1 Operations that Invalidate Cached Mappings

The following operations invalidate cached mappings as indicated:

- 
1. At any given time, a logical processor may be caching combined mappings for a VPID and a PCID that are associated with different EP4TAs. Similarly, it may be caching combined mappings for an EP4TA that are associated with different VPIDs and PCIDs.
  2. If the capability MSR IA32\_VMX\_CR0\_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG can be 0 in VMX non-root operation only if the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

- Operations that architecturally invalidate entries in the TLBs or paging-structure caches independent of VMX operation (e.g., the INVLPG and INVPCID instructions) invalidate linear mappings and combined mappings.<sup>1</sup> They are required to do so only for the current VPID (but, for combined mappings, all EP4TAs). Linear mappings for the current VPID are invalidated even if EPT is in use.<sup>2</sup> Combined mappings for the current VPID are invalidated even if EPT is not in use.<sup>3</sup>
  - An EPT violation invalidates any guest-physical mappings (associated with the current EP4TA) that would be used to translate the guest-physical address that caused the EPT violation. If that guest-physical address was the translation of a linear address, the EPT violation also invalidates any combined mappings for that linear address associated with the current PCID, the current VPID and the current EP4TA.
  - If the “enable VPID” VM-execution control is 0, VM entries and VM exits invalidate linear mappings and combined mappings associated with VPID 0000H (for all PCIDs). Combined mappings for VPID 0000H are invalidated for all EP4TAs.
  - Execution of the INVVPID instruction invalidates linear mappings and combined mappings. Invalidation is based on instruction operands, called the INVVPID type and the INVVPID descriptor. Four INVVPID types are currently defined:
    - **Individual-address.** If the INVVPID type is 0, the logical processor invalidates linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor and that would be used to translate the linear address specified in of the INVVPID descriptor. Linear mappings and combined mappings for that VPID and linear address are invalidated for all PCIDs and, for combined mappings, all EP4TAs. (The instruction may also invalidate mappings associated with other VPIDs and for other linear addresses.)
    - **Single-context.** If the INVVPID type is 1, the logical processor invalidates all linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor. Linear mappings and combined mappings for that VPID are invalidated for all PCIDs and, for combined mappings, all EP4TAs. (The instruction may also invalidate mappings associated with other VPIDs.)
    - **All-context.** If the INVVPID type is 2, the logical processor invalidates linear mappings and combined mappings associated with all VPIDs except VPID 0000H and with all PCIDs. (The instruction may also invalidate linear mappings with VPID 0000H.) Combined mappings are invalidated for all EP4TAs.
    - **Single-context-retaining-globals.** If the INVVPID type is 3, the logical processor invalidates linear mappings and combined mappings associated with the VPID specified in the INVVPID descriptor. Linear mappings and combined mappings for that VPID are invalidated for all PCIDs and, for combined mappings, all EP4TAs. The logical processor is **not** required to invalidate information that was used for **global** translations (although it may do so). See Section 4.10, “Caching Translation Information” for details regarding global translations. (The instruction may also invalidate mappings associated with other VPIDs.)
- See Chapter 30 for details of the INVVPID instruction. See Section 28.3.3.3 for guidelines regarding use of this instruction.
- Execution of the INVEPT instruction invalidates guest-physical mappings and combined mappings. Invalidation is based on instruction operands, called the INVEPT type and the INVEPT descriptor. Two INVEPT types are currently defined:
    - **Single-context.** If the INVEPT type is 1, the logical processor invalidates all guest-physical mappings and combined mappings associated with the EP4TA specified in the INVEPT descriptor. Combined mappings for that EP4TA are invalidated for all VPIDs and all PCIDs. (The instruction may invalidate mappings associated with other EP4TAs.)
    - **All-context.** If the INVEPT type is 2, the logical processor invalidates guest-physical mappings and combined mappings associated with all EP4TAs (and, for combined mappings, for all VPIDs and PCIDs).

---

1. See Section 4.10.4, “Invalidation of TLBs and Paging-Structure Caches,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* for an enumeration of operations that architecturally invalidate entries in the TLBs and paging-structure caches independent of VMX operation.

2. While no linear mappings are created while EPT is in use, a logical processor may retain, while EPT is in use, linear mappings (for the same VPID as the current one) there were created earlier, when EPT was not in use.

3. While no combined mappings are created while EPT is not in use, a logical processor may retain, while EPT is in not use, combined mappings (for the same VPID as the current one) there were created earlier, when EPT was in use.

See Chapter 30 for details of the INVEPT instruction. See Section 28.3.3.4 for guidelines regarding use of this instruction.

- A power-up or a reset invalidates all linear mappings, guest-physical mappings, and combined mappings.

### 28.3.3.2 Operations that Need Not Invalidate Cached Mappings

The following items detail cases of operations that are not required to invalidate certain cached mappings:

- Operations that architecturally invalidate entries in the TLBs or paging-structure caches independent of VMX operation are not required to invalidate any guest-physical mappings.
- The INVVPID instruction is not required to invalidate any guest-physical mappings.
- The INVEPT instruction is not required to invalidate any linear mappings.
- VMX transitions are not required to invalidate any guest-physical mappings. If the “enable VPID” VM-execution control is 1, VMX transitions are not required to invalidate any linear mappings or combined mappings.
- The VMXOFF and VMXON instructions are not required to invalidate any linear mappings, guest-physical mappings, or combined mappings.

A logical processor may invalidate any cached mappings at any time. For this reason, the operations identified above may invalidate the indicated mappings despite the fact that doing so is not required.

### 28.3.3.3 Guidelines for Use of the INVVPID Instruction

The need for VMM software to use the INVVPID instruction depends on how that software is virtualizing memory (e.g., see Section 32.3, “Memory Virtualization”).

If EPT is not in use, it is likely that the VMM is virtualizing the guest paging structures. Such a VMM may configure the VMCS so that all or some of the operations that invalidate entries in the TLBs and the paging-structure caches (e.g., the INVLPG instruction) cause VM exits. If VMM software is emulating these operations, it may be necessary to use the INVVPID instruction to ensure that the logical processor’s TLBs and the paging-structure caches are appropriately invalidated.

Requirements of when software should use the INVVPID instruction depend on the specific algorithm being used for page-table virtualization. The following items provide guidelines for software developers:

- Emulation of the INVLPG instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is individual-address (0).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.
  - The linear address in the INVVPID descriptor is that of the operand of the INVLPG instruction being emulated.
- Some instructions invalidate all entries in the TLBs and paging-structure caches—except for global translations. An example is the MOV to CR3 instruction. (See Section 4.10, “Caching Translation Information” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A* for details regarding global translations.) Emulation of such an instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is single-context-retaining-globals (3).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.
- Some instructions invalidate all entries in the TLBs and paging-structure caches—including for global translations. An example is the MOV to CR4 instruction if the value of value of bit 4 (page global enable—PGE) is changing. Emulation of such an instruction may require execution of the INVVPID instruction as follows:
  - The INVVPID type is single-context (1).
  - The VPID in the INVVPID descriptor is the one assigned to the virtual processor whose execution is being emulated.

If EPT is not in use, the logical processor associates all mappings it creates with the current VPID, and it will use such mappings to translate linear addresses. For that reason, a VMM should not use the same VPID for different

non-EPT guests that use different page tables. Doing so may result in one guest using translations that pertain to the other.

If EPT is in use, the instructions enumerated above might not be configured to cause VM exits and the VMM might not be emulating them. In that case, executions of the instructions by guest software properly invalidate the required entries in the TLBs and paging-structure caches (see Section 28.3.3.1); execution of the INVVPID instruction is not required.

If EPT is in use, the logical processor associates all mappings it creates with the value of bits 51:12 of current EPTP. If a VMM uses different EPTP values for different guests, it may use the same VPID for those guests. Doing so cannot result in one guest using translations that pertain to the other.

The following guidelines apply more generally and are appropriate even if EPT is in use:

- As detailed in Section 29.4.5, an access to the APIC-access page might not cause an APIC-access VM exit if software does not properly invalidate information that may be cached from the paging structures. If, at one time, the current VPID on a logical processor was a non-zero value X, it is recommended that software use the INVVPID instruction with the “single-context” INVVPID type and with VPID X in the INVVPID descriptor before a VM entry on the same logical processor that establishes VPID X and either (a) the “virtualize APIC accesses” VM-execution control was changed from 0 to 1; or (b) the value of the APIC-access address was changed.
- Software can use the INVVPID instruction with the “all-context” INVVPID type immediately after execution of the VMXON instruction or immediately prior to execution of the VMXOFF instruction. Either prevents potentially undesired retention of information cached from paging structures between separate uses of VMX operation.

#### 28.3.3.4 Guidelines for Use of the INVEPT Instruction

The following items provide guidelines for use of the INVEPT instruction to invalidate information cached from the EPT paging structures.

- Software should use the INVEPT instruction with the “single-context” INVEPT type after making any of the following changes to an EPT paging-structure entry (the INVEPT descriptor should contain an EPTP value that references — directly or indirectly — the modified EPT paging structure):
  - Changing any of the privilege bits 2:0 from 1 to 0.
  - Changing the physical address in bits 51:12.
  - Clearing bit 8 (the accessed flag) if accessed and dirty flags for EPT will be enabled.
  - For an EPT PDPTE or an EPT PDE, changing bit 7 (which determines whether the entry maps a page).
  - For the **last** EPT paging-structure entry used to translate a guest-physical address (an EPT PDPTE with bit 7 set to 1, an EPT PDE with bit 7 set to 1, or an EPT PTE), changing either bits 5:3 or bit 6. (These bits determine the effective memory type of accesses using that EPT paging-structure entry; see Section 28.2.5.)
  - For the **last** EPT paging-structure entry used to translate a guest-physical address (an EPT PDPTE with bit 7 set to 1, an EPT PDE with bit 7 set to 1, or an EPT PTE), clearing bit 9 (the dirty flag) if accessed and dirty flags for EPT will be enabled.
- Software should use the INVEPT instruction with the “single-context” INVEPT type before a VM entry with an EPTP value X such that  $X[6] = 1$  (accessed and dirty flags for EPT are enabled) if the logical processor had earlier been in VMX non-root operation with an EPTP value Y such that  $Y[6] = 0$  (accessed and dirty flags for EPT are not enabled) and  $Y[51:12] = X[51:12]$ .
- Software may use the INVEPT instruction after modifying a present EPT paging-structure entry to change any of the privilege bits 2:0 from 0 to 1. Failure to do so may cause an EPT violation that would not otherwise occur. Because an EPT violation invalidates any mappings that would be used by the access that caused the EPT violation (see Section 28.3.3.1), an EPT violation will not recur if the original access is performed again, even if the INVEPT instruction is not executed.
- Because a logical processor does not cache any information derived from EPT paging-structure entries that are not present or misconfigured (see Section 28.2.3.1), it is not necessary to execute INVEPT following modification of an EPT paging-structure entry that had been not present or misconfigured.
- As detailed in Section 29.4.5, an access to the APIC-access page might not cause an APIC-access VM exit if software does not properly invalidate information that may be cached from the EPT paging structures. If EPT

was in use on a logical processor at one time with EPTP X, it is recommended that software use the INVEPT instruction with the “single-context” INVEPT type and with EPTP X in the INVEPT descriptor before a VM entry on the same logical processor that enables EPT with EPTP X and either (a) the “virtualize APIC accesses” VM-execution control was changed from 0 to 1; or (b) the value of the APIC-access address was changed.

- Software can use the INVEPT instruction with the “all-context” INVEPT type immediately after execution of the VMXON instruction or immediately prior to execution of the VMXOFF instruction. Either prevents potentially undesired retention of information cached from EPT paging structures between separate uses of VMX operation.

In a system containing more than one logical processor, software must account for the fact that information from an EPT paging-structure entry may be cached on logical processors other than the one that modifies that entry. The process of propagating the changes to a paging-structure entry is commonly referred to as “TLB shutdown.” A discussion of TLB shutdown appears in Section 4.10.5, “Propagation of Paging-Structure Changes to Multiple Processors,” in the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

# CHAPTER 29

## APIC VIRTUALIZATION AND VIRTUAL INTERRUPTS

---

The VMCS includes controls that enable the virtualization of interrupts and the Advanced Programmable Interrupt Controller (APIC).

When these controls are used, the processor will emulate many accesses to the APIC, track the state of the virtual APIC, and deliver virtual interrupts — all in VMX non-root operation with out a VM exit.<sup>1</sup>

The processor tracks the state of the virtual APIC using a virtual-APIC page identified by the virtual-machine monitor (VMM). Section 29.1 discusses the virtual-APIC page and how the processor uses it to track the state of the virtual APIC.

The following are the VM-execution controls relevant to APIC virtualization and virtual interrupts (see Section 24.6 for information about the locations of these controls):

- **Virtual-interrupt delivery.** This control enables the evaluation and delivery of pending virtual interrupts (Section 29.2). It also enables the emulation of writes (memory-mapped or MSR-based, as enabled) to the APIC registers that control interrupt prioritization.
- **Use TPR shadow.** This control enables emulation of accesses to the APIC's task-priority register (TPR) via CR8 (Section 29.3) and, if enabled, via the memory-mapped or MSR-based interfaces.
- **Virtualize APIC accesses.** This control enables virtualization of memory-mapped accesses to the APIC (Section 29.4) by causing VM exits on accesses to a VMM-specified APIC-access page. Some of the other controls, if set, may cause some of these accesses to be emulated rather than causing VM exits.
- **Virtualize x2APIC mode.** This control enables virtualization of MSR-based accesses to the APIC (Section 29.5).
- **APIC-register virtualization.** This control allows memory-mapped and MSR-based reads of most APIC registers (as enabled) by satisfying them from the virtual-APIC page. It directs memory-mapped writes to the APIC-access page to the virtual-APIC page, following them by VM exits for VMM emulation.
- **Process posted interrupts.** This control allows software to post virtual interrupts in a data structure and send a notification to another logical processor; upon receipt of the notification, the target processor will process the posted interrupts by copying them into the virtual-APIC page (Section 29.6).

“Virtualize APIC accesses”, “virtualize x2APIC mode”, “virtual-interrupt delivery”, and “APIC-register virtualization” are all secondary processor-based VM-execution controls. If bit 31 of the primary processor-based VM-execution controls is 0, the processor operates as if these controls were all 0. See Section 24.6.2.

## 29.1 VIRTUAL APIC STATE

The **virtual-APIC page** is a 4-KByte region of memory that the processor uses the virtual-APIC page to virtualize certain accesses to APIC registers and to manage virtual interrupts. The physical address of the virtual-APIC page is the **virtual-APIC address**, a 64-bit VM-execution control field in the VMCS (see Section 24.6.8).

Depending on the settings of certain VM-execution controls, the processor may virtualize certain fields on the virtual-APIC page with functionality analogous to that performed by the local APIC. Section 29.1.1 identifies and defines these fields. Section 29.1.2, Section 29.1.3, Section 29.1.4, and Section 29.1.5 detail the actions taken to virtualize updates to some of these fields.

### 29.1.1 Virtualized APIC Registers

Depending on the setting of certain VM-execution controls, a logical processor may virtualize certain accesses to APIC registers using the following fields on the virtual-APIC page:

- **Virtual task-priority register (VTPR):** the 32-bit field located at offset 080H on the virtual-APIC page.

---

1. In most cases, it is not necessary for a virtual-machine monitor (VMM) to inject virtual interrupts as part of VM entry.

- **Virtual processor-priority register (VPPR)**: the 32-bit field located at offset 0A0H on the virtual-APIC page.
- **Virtual end-of-interrupt register (VEOI)**: the 32-bit field located at offset 0B0H on the virtual-APIC page.
- **Virtual interrupt-service register (VISR)**: the 256-bit value comprising eight non-contiguous 32-bit fields at offsets 100H, 110H, 120H, 130H, 140H, 150H, 160H, and 170H on the virtual-APIC page. Bit  $x$  of the VISR is at bit position  $(x \& 1FH)$  at offset  $(100H \mid ((x \& E0H) \gg 1))$ . The processor uses only the low 4 bytes of each of the 16-byte fields at offsets 100H, 110H, 120H, 130H, 140H, 150H, 160H, and 170H.
- **Virtual interrupt-request register (VIRR)**: the 256-bit value comprising eight non-contiguous 32-bit fields at offsets 200H, 210H, 220H, 230H, 240H, 250H, 260H, and 270H on the virtual-APIC page. Bit  $x$  of the VIRR is at bit position  $(x \& 1FH)$  at offset  $(200H \mid ((x \& E0H) \gg 1))$ . The processor uses only the low 4 bytes of each of the 16-Byte fields at offsets 200H, 210H, 220H, 230H, 240H, 250H, 260H, and 270H.
- **Virtual interrupt-command register (VICR\_LO)**: the 32-bit field located at offset 300H on the virtual-APIC page
- **Virtual interrupt-command register (VICR\_HI)**: the 32-bit field located at offset 310H on the virtual-APIC page.

### 29.1.2 TPR Virtualization

The processor performs **TPR virtualization** in response to the following operations: (1) virtualization of the MOV to CR8 instruction; (2) virtualization of a write to offset 080H on the APIC-access page; and (3) virtualization of the WRMSR instruction with ECX = 808H. See Section 29.3, Section 29.4.3, and Section 29.5 for details of when TPR virtualization is performed.

The following pseudocode details the behavior of TPR virtualization:

```

IF "virtual-interrupt delivery" is 0
    THEN
        IF VTPR[7:4] < TPR threshold (see Section 24.6.8)
            THEN cause VM exit due to TPR below threshold;
        FI;
    ELSE
        perform PPR virtualization (see Section 29.1.3);
        evaluate pending virtual interrupts (see Section 29.2.1);
    FI;

```

Any VM exit caused by TPR virtualization is trap-like: the instruction causing TPR virtualization completes before the VM exit occurs (for example, the value of CS:RIP saved in the guest-state area of the VMCS references the next instruction).

### 29.1.3 PPR Virtualization

The processor performs **PPR virtualization** in response to the following operations: (1) VM entry; (2) TPR virtualization; and (3) EOI virtualization. See Section 26.3.2.5, Section 29.1.2, and Section 29.1.4 for details of when PPR virtualization is performed.

PPR virtualization uses the guest interrupt status (specifically, SVI; see Section 24.4.2) and VTPR. The following pseudocode details the behavior of PPR virtualization:

```

IF VTPR[7:4] ≥ SVI[7:4]
    THEN VPPR ← VTPR & FFH;
    ELSE VPPR ← SVI & FOH;
FI;

```

PPR virtualization always clears bytes 3:1 of VPPR.

PPR virtualization is caused only by TPR virtualization, EOI virtualization, and VM entry. Delivery of a virtual interrupt also modifies VPPR, but in a different way (see Section 29.2.2). No other operations modify VPPR, even if they modify SVI, VISR, or VTPR.

## 29.1.4 EOI Virtualization

The processor performs **EOI virtualization** in response to the following operations: (1) virtualization of a write to offset 0B0H on the APIC-access page; and (2) virtualization of the WRMSR instruction with ECX = 80BH. See Section 29.4.3 and Section 29.5 for details of when EOI virtualization is performed. EOI virtualization occurs only if the “virtual-interrupt delivery” VM-execution control is 1.

EOI virtualization uses and updates the guest interrupt status (specifically, SVI; see Section 24.4.2). The following pseudocode details the behavior of EOI virtualization:

```

Vector ← SVI;
VISR[Vector] ← 0; (see Section 29.1.1 for definition of VISR)
IF any bits set in VISR
    THEN SVI ← highest index of bit set in VISR
    ELSE SVI ← 0;
FI;
perform PPR virtualiation (see Section 29.1.3);
IF EOI_exit_bitmap[Vector] = 1 (see Section 24.6.8 for definition of EOI_exit_bitmap)
    THEN cause EOI-induced VM exit with Vector as exit qualification;
    ELSE evaluate pending virtual interrupts; (see Section 29.2.1)
FI;
```

Any VM exit caused by EOI virtualization is trap-like: the instruction causing EOI virtualization completes before the VM exit occurs (for example, the value of CS:RIP saved in the guest-state area of the VMCS references the next instruction).

## 29.1.5 Self-IPI Virtualization

The processor performs **self-IPI virtualization** in response to the following operations: (1) virtualization of a write to offset 300H on the APIC-access page; and (2) virtualization of the WRMSR instruction with ECX = 83FH. See Section 29.4.3 and Section 29.5 for details of when self-IPI virtualization is performed. Self-IPI virtualization occurs only if the “virtual-interrupt delivery” VM-execution control is 1.

Each operation that leads to self-IPI virtualization provides an 8-bit vector (see Section 29.4.3 and Section 29.5). Self-IPI virtualization updates the guest interrupt status (specifically, RVI; see Section 24.4.2). The following pseudocode details the behavior of self-IPI virtualization:

```

VIRR[Vector] ← 1; (see Section 29.1.1 for definition of VIRR)
RVI ← max[RVI,Vector];
evaluate pending virtual interrupts; (see Section 29.2.1)
```

## 29.2 EVALUATION AND DELIVERY OF VIRTUAL INTERRUPTS

If the “virtual-interrupt delivery” VM-execution control is 1, certain actions in VMX non-root operation or during VM entry cause the processor to evaluate and deliver virtual interrupts.

Evaluation of virtual interrupts is triggered by certain actions change the state of the virtual-APIC page and is described in Section 29.2.1. This evaluation may result in recognition of a virtual interrupt. Once a virtual interrupt is recognized, the processor may deliver it within VMX non-root operation without a VM exit. Virtual-interrupt delivery is described in Section 29.2.2.

### 29.2.1 Evaluation of Pending Virtual Interrupts

If the “virtual-interrupt delivery” VM-execution control is 1, certain actions cause a logical processor to **evaluate pending virtual interrupts**.

The following actions cause the evaluation of pending virtual interrupts: VM entry; TPR virtualization; EOI virtualization; self-IPI virtualization; and posted-interrupt processing. See Section 26.3.2.5, Section 29.1.2, Section

29.1.4, Section 29.1.5, and Section 29.6 for details of when evaluation of pending virtual interrupts is performed. No other operations cause the evaluation of pending virtual interrupts, even if they modify RVI or VPPR.

Evaluation of pending virtual interrupts uses the guest interrupt status (specifically, RVI; see Section 24.4.2). The following pseudocode details the evaluation of pending virtual interrupts:

```

IF "interrupt-window exiting" is 0 AND
RVI[7:4] > VPPR[7:4] (see Section 29.1.1 for definition of VPPR)
    THEN recognize a pending virtual interrupt;
ELSE
    do not recognize a pending virtual interrupt;
FI;
    
```

Once recognized, a virtual interrupt may be delivered in VMX non-root operation; see Section 29.2.2.

Evaluation of pending virtual interrupts is caused only by VM entry, TPR virtualization, EOI virtualization, self-IPI virtualization, and posted-interrupt processing. No other operations do so, even if they modify RVI or VPPR. The logical processor ceases recognition of a pending virtual interrupt following the delivery of a virtual interrupt.

## 29.2.2 Virtual-Interrupt Delivery

If a virtual interrupt has been recognized (see Section 29.2.1), it will be delivered at an instruction boundary when the following conditions all hold: (1) RFLAGS.IF = 1; (2) there is no blocking by STI; (3) there is no blocking by MOV SS or by POP SS; and (4) the "interrupt-window exiting" VM-execution control is 0.

Virtual-interrupt delivery has the same priority as that of VM exits due to the 1-setting of the "interrupt-window exiting" VM-execution control.<sup>1</sup> Thus, non-maskable interrupts (NMIs) and higher priority events take priority over delivery of a virtual interrupt; delivery of a virtual interrupt takes priority over external interrupts and lower priority events.

Virtual-interrupt delivery wakes a logical processor from the same inactive activity states as would an external interrupt. Specifically, it wakes a logical processor from the states entered using the HLT and MWAIT instructions. It does not wake a logical processor in the shutdown state or in the wait-for-SIPI state.

Virtual-interrupt delivery updates the guest interrupt status (both RVI and SVI; see Section 24.4.2) and delivers an event within VMX non-root operation without a VM exit. The following pseudocode details the behavior of virtual-interrupt delivery (see Section 29.1.1 for definition of VISR, VIRR, and VPPR):

```

Vector ← RVI;
VISR[Vector] ← 1;
SVI ← Vector;
VPPR ← Vector & FOH;
VIRR[Vector] ← 0;
IF any bits set in VIRR
    THEN RVI ← highest index of bit set in VIRR
    ELSE RVI ← 0;
FI;
deliver interrupt with Vector through IDT;
cease recognition of any pending virtual interrupt;
    
```

## 29.3 VIRTUALIZING CR8-BASED TPR ACCESSES

In 64-bit mode, software can access the local APIC's task-priority register (TPR) through CR8. Specifically, software uses the MOV from CR8 and MOV to CR8 instructions (see Section 10.8.6, "Task Priority in IA-32e Mode"). This section describes how these accesses can be virtualized.

---

1. A logical processor never recognizes or delivers a virtual interrupt if the "interrupt-window exiting" VM-execution control is 1. Because of this, the relative priority of virtual-interrupt delivery and VM exits due to the 1-setting of that control is not defined.

A virtual-machine monitor can virtualize these CR8-based APIC accesses by setting the “CR8-load exiting” and “CR8-store exiting” VM-execution controls, ensuring that the accesses cause VM exits (see Section 25.1.3). Alternatively, there are methods for virtualizing some CR8-based APIC accesses without VM exits.

Normally, an execution of MOV from CR8 or MOV to CR8 that does not fault or cause a VM exit accesses the APIC’s TPR. However, such an execution are treated specially if the “use TPR shadow” VM-execution control is 1. The following items provide details:

- **MOV from CR8.** The instruction loads bits 3:0 of its destination operand with bits 7:4 of VTPR (see Section 29.1.1). Bits 63:4 of the destination operand are cleared.
- **MOV to CR8.** The instruction stores bits 3:0 of its source operand into bits 7:4 of VTPR; the remainder of VTPR (bits 3:0 and bits 31:8) are cleared. Following this, the processor performs TPR virtualization (see Section 29.1.2).

## 29.4 VIRTUALIZING MEMORY-MAPPED APIC ACCESSES

When the local APIC is in xAPIC mode, software accesses the local APIC’s control registers using a memory-mapped interface. Specifically, software uses linear addresses that translate to physical addresses on page frame indicated by the base address in the IA32\_APIC\_BASE MSR (see Section 10.4.4, “Local APIC Status and Location”). This section describes how these accesses can be virtualized.

A virtual-machine monitor (VMM) can virtualize these memory-mapped APIC accesses by ensuring that any access to a linear address that would access the local APIC instead causes a VM exit. This could be done using paging or the extended page-table mechanism (EPT). Another way is by using the 1-setting of the “virtualize APIC accesses” VM-execution control.

If the “virtualize APIC accesses” VM-execution control is 1, the logical processor treats specially memory accesses using linear addresses that translate to physical addresses in the 4-KByte **APIC-access page**.<sup>1</sup> (The APIC-access page is identified by the **APIC-access address**, a field in the VMCS; see Section 24.6.8.)

In general, an access to the APIC-access page causes an **APIC-access VM exit**. APIC-access VM exits provide a VMM with information about the access causing the VM exit. Section 29.4.1 discusses the priority of APIC-access VM exits.

Certain VM-execution controls enable the processor to virtualize certain accesses to the APIC-access page without a VM exit. In general, this virtualization causes these accesses to be made to the virtual-APIC page instead of the APIC-access page.

### NOTES

Unless stated otherwise, this section characterizes only linear accesses to the APIC-access page; an access to the APIC-access page is a linear access if (1) it results from a memory access using a linear address; and (2) the access’s physical address is the translation of that linear address. Section 29.4.6 discusses accesses to the APIC-access page that are not linear accesses.

The distinction between the APIC-access page and the virtual-APIC page allows a VMM to share paging structures or EPT paging structures among the virtual processors of a virtual machine (the shared paging structures referencing the same APIC-access address, which appears in the VMCS of all the virtual processors) while giving each virtual processor its own virtual APIC (the VMCS of each virtual processor will have a unique virtual-APIC address).

Section 29.4.2 discusses when and how the processor may virtualize read accesses from the APIC-access page. Section 29.4.3 does the same for write accesses. When virtualizing a write to the APIC-access page, the processor typically takes actions in addition to passing the write through to the virtual-APIC page.

---

1. Even when addresses are translated using EPT (see Section 28.2), the determination of whether an APIC-access VM exit occurs depends on an access’s physical address, not its guest-physical address. Even when CR0.PG = 0, ordinary memory accesses by software use linear addresses; the fact that CR0.PG = 0 means only that the identity translation is used to convert linear addresses to physical (or guest-physical) addresses.

The discussion in those sections uses the concept of an **operation** within which these memory accesses may occur. For those discussions, an “operation” can be an iteration of a REP-prefixed string instruction, an execution of any other instruction, or delivery of an event through the IDT.

The 1-setting of the “virtualize APIC accesses” VM-execution control may also affect accesses to the APIC-access page that do not result directly from linear addresses. This is discussed in Section 29.4.6.

### 29.4.1 Priority of APIC-Access VM Exits

The following items specify the priority of APIC-access VM exits relative to other events.

- The priority of an APIC-access VM exit due to a memory access is below that of any page fault or EPT violation that that access may incur. That is, an access does not cause an APIC-access VM exit if it would cause a page fault or an EPT violation.
- A memory access does not cause an APIC-access VM exit until after the accessed flags are set in the paging structures (including EPT paging structures, if enabled).
- A write access does not cause an APIC-access VM exit until after the dirty flags are set in the appropriate paging structure and EPT paging structure (if enabled).
- With respect to all other events, any APIC-access VM exit due to a memory access has the same priority as any page fault or EPT violation that the access could cause. (This item applies to other events that the access may generate as well as events that may be generated by other accesses by the same operation.)

These principles imply, among other things, that an APIC-access VM exit may occur during the execution of a repeated string instruction (including INS and OUTS). Suppose, for example, that the first  $n$  iterations ( $n$  may be 0) of such an instruction do not access the APIC-access page and that the next iteration does access that page. As a result, the first  $n$  iterations may complete and be followed by an APIC-access VM exit. The instruction pointer saved in the VMCS references the repeated string instruction and the values of the general-purpose registers reflect the completion of  $n$  iterations.

### 29.4.2 Virtualizing Reads from the APIC-Access Page

A read access from the APIC-access page causes an APIC-access VM exit if any of the following are true:

- The “use TPR shadow” VM-execution control is 0.
- The access is for an instruction fetch.
- The access is more than 32 bits in size.
- The access is part of an operation for which the processor has already virtualized a write to the APIC-access page.
- The access is not entirely contained within the low 4 bytes of a naturally aligned 16-byte region. That is, bits 3:2 of the access’s address are 0, and the same is true of the address of the highest byte accessed.

If none of the above are true, whether a read access is virtualized depends on the setting of the “APIC-register virtualization” VM-execution control:

- If “APIC-register virtualization” is 0, a read access is virtualized if its page offset is 080H (task priority); otherwise, the access causes an APIC-access VM exit.
- If “APIC-register virtualization” is 1, a read access is virtualized if it is entirely within one of the following ranges of offsets:
  - 020H–023H (local APIC ID);
  - 030H–033H (local APIC version);
  - 080H–083H (task priority);
  - 0B0H–0B3H (end of interrupt);
  - 0D0H–0D3H (logical destination);
  - 0E0H–0E3H (destination format);

- 0F0H–0F3H (spurious-interrupt vector);
- 100H–103H, 110H–113H, 120H–123H, 130H–133H, 140H–143H, 150H–153H, 160H–163H, or 170H–173H (in-service);
- 180H–183H, 190H–193H, 1A0H–1A3H, 1B0H–1B3H, 1C0H–1C3H, 1D0H–1D3H, 1E0H–1E3H, or 1F0H–1F3H (trigger mode);
- 200H–203H, 210H–213H, 220H–223H, 230H–233H, 240H–243H, 250H–253H, 260H–263H, or 270H–273H (interrupt request);
- 280H–283H (error status);
- 300H–303H or 310H–313H (interrupt command);
- 320H–323H, 330H–333H, 340H–343H, 350H–353H, 360H–363H, or 370H–373H (LVT entries);
- 380H–383H (initial count); or
- 3E0H–3E3H (divide configuration).

In all other cases, the access causes an APIC-access VM exit.

A read access from the APIC-access page that is virtualized returns data from the corresponding page offset on the virtual-APIC page.<sup>1</sup>

### 29.4.3 Virtualizing Writes to the APIC-Access Page

Whether a write access to the APIC-access page is virtualized depends on the settings of the VM-execution controls and the page offset of the access. Section 29.4.3.1 details when APIC-write virtualization occurs.

Unlike reads, writes to the local APIC have side effects; because of this, virtualization of writes to the APIC-access page may require emulation specific to the access's page offset (which identifies the APIC register being accessed). Section 29.4.3.2 describes this **APIC-write emulation**.

For some page offsets, it is necessary for software to complete the virtualization after a write completes. In these cases, the processor causes an **APIC-write VM exit** to invoke VMM software. Section 29.4.3.3 discusses APIC-write VM exits.

#### 29.4.3.1 Determining Whether a Write Access is Virtualized

A write access to the APIC-access page causes an APIC-access VM exit if any of the following are true:

- The “use TPR shadow” VM-execution control is 0.
- The access is more than 32 bits in size.
- The access is part of an operation for which the processor has already virtualized a write (with a different page offset or a different size) to the APIC-access page.
- The access is not entirely contained within the low 4 bytes of a naturally aligned 16-byte region. That is, bits 3:2 of the access's address are 0, and the same is true of the address of the highest byte accessed.

If none of the above are true, whether a write access is virtualized depends on the settings of the “APIC-register virtualization” and “virtual-interrupt delivery” VM-execution controls:

- If the “APIC-register virtualization” and “virtual-interrupt delivery” VM-execution controls are both 0, a write access is virtualized if its page offset is 080H; otherwise, the access causes an APIC-access VM exit.
- If the “APIC-register virtualization” VM-execution control is 0 and the “virtual-interrupt delivery” VM-execution control is 1, a write access is virtualized if its page offset is 080H (task priority), 0B0H (end of interrupt), and 300H (interrupt command — low); otherwise, the access causes an APIC-access VM exit.
- If “APIC-register virtualization is 1, a write access is virtualized if it is entirely within one the following ranges of offsets:

---

1. The memory type used for accesses that read from the virtual-APIC page is reported in bits 53:50 of the IA32\_VMX\_BASIC MSR (see Appendix A.1).

- 020H–023H (local APIC ID);
- 080H–083H (task priority);
- 0B0H–0B3H (end of interrupt);
- 0D0H–0D3H (logical destination);
- 0E0H–0E3H (destination format);
- 0F0H–0F3H (spurious-interrupt vector);
- 280H–283H (error status);
- 300H–303H or 310H–313H (interrupt command);
- 320H–323H, 330H–333H, 340H–343H, 350H–353H, 360H–363H, or 370H–373H (LVT entries);
- 380H–383H (initial count); or
- 3E0H–3E3H (divide configuration).

In all other cases, the access causes an APIC-access VM exit.

The processor virtualizes a write access to the APIC-access page by writing data to the corresponding page offset on the virtual-APIC page.<sup>1</sup> Following this, the processor performs certain actions after completion of the operation of which the access was a part.<sup>2</sup> APIC-write emulation is described in Section 29.4.3.2.

### 29.4.3.2 APIC-Write Emulation

If the processor virtualizes a write access to the APIC-access page, it performs additional actions after completion of an operation of which the access was a part. These actions are called **APIC-write emulation**.

The details of APIC-write emulation depend upon the page offset of the virtualized write access:<sup>3</sup>

- 080H (task priority). The processor clears bytes 3:1 of VTPR and then causes TPR virtualization (Section 29.1.2).
- 0B0H (end of interrupt). If the “virtual-interrupt delivery” VM-execution control is 1, the processor clears VEOI and then causes EOI virtualization (Section 29.1.4); otherwise, the processor causes an APIC-write VM exit (Section 29.4.3.3).
- 300H (interrupt command — low). If the “virtual-interrupt delivery” VM-execution control is 1, the processor checks the value of VICR\_LO to determine whether the following are all true:
  - Reserved bits (31:20, 17:16, 13) and bit 12 (delivery status) are all 0.
  - Bits 19:18 (destination shorthand) are 01B (self).
  - Bit 15 (trigger mode) is 0 (edge).
  - Bits 10:8 (delivery mode) are 000B (fixed).
  - Bits 7:4 (the upper half of the vector) are **not** 0000B.

If all of the items above are true, the processor performs self-IPI virtualization using the 8-bit vector in byte 0 of VICR\_LO (Section 29.1.5).

If the “virtual-interrupt delivery” VM-execution control is 0, or if any of the items above are false, the processor causes an APIC-write VM exit (Section 29.4.3.3).

- 310H–313H (interrupt command — high). The processor clears bytes 2:0 of VICR\_HI. No other virtualization or VM exit occurs.
- Any other page offset. The processor causes an APIC-write VM exit (Section 29.4.3.3).

1. The memory type used for accesses that write to the virtual-APIC page is reported in bits 53:50 of the IA32\_VMX\_BASIC MSR (see Appendix A.1).

2. Recall that, for the purposes of this discussion, an operation is an iteration of a REP-prefixed string instruction, an execution of any other instruction, or delivery of an event through the IDT.

3. For any operation, there can be only one page offset for which a write access was virtualized. This is because a write access is not virtualized if the processor has already virtualized a write access for the same operation with a different page offset.

APIC-write emulation takes priority over system-management interrupts (SMIs), INIT signals, and lower priority events. APIC-write emulation is not blocked if RFLAGS.IF = 0 or by the MOV SS, POP SS, or STI instructions.

If an operation causes a fault after a write access to the APIC-access page and before APIC-write emulation. In this case, APIC-write emulation occurs after the fault is delivered and before the fault handler can execute. However, if the operation causes a VM exit (perhaps due to a fault), the APIC-write emulation does not occur.

### 29.4.3.3 APIC-Write VM Exits

In certain cases, VMM software must be invoked to complete the virtualization of a write access to the APIC-access page. In this case, APIC-write emulation causes an **APIC-write VM exit**. (Section 29.4.3.2 details the cases that causes APIC-write VM exits.)

APIC-write VM exits are invoked by APIC-write emulation, and APIC-write emulation occurs after an operation that performs a write access to the APIC-access page. Because of this, every APIC-write VM exit is trap-like: it occurs after completion of the operation containing the write access that caused the VM exit (for example, the value of CS:RIP saved in the guest-state area of the VMCS references the next instruction).

The basic exit reason for an APIC-write VM exit is “APIC write.” The exit qualification is the page offset of the write access that led to the VM exit.

As noted in Section 29.5, execution of WRMSR with ECX = 83FH (self-IPI MSR) can lead to an APIC-write VM exit if the “virtual-interrupt delivery” VM-execution control is 1. The exit qualification for such an APIC-write VM exit is 3FOH.

## 29.4.4 Instruction-Specific Considerations

Certain instructions that use linear address may cause page faults even though they do not use those addresses to access memory. The APIC-virtualization features may affect these instructions as well:

- **CLFLUSH.** With regard to faulting, the processor operates as if CLFLUSH reads from the linear address in its source operand. If that address translates to one on the APIC-access page, the instruction may cause an APIC-access VM exit. If it does not, it will flush the corresponding cache line on the virtual-APIC page instead of the APIC-access page.
- **ENTER.** With regard to faulting, the processor operates if ENTER writes to the byte referenced by the final value of the stack pointer (even though it does not if its size operand is non-zero). If that value translates to an address on the APIC-access page, the instruction may cause an APIC-access VM exit. If it does not, it will cause the APIC-write emulation appropriate to the address's page offset.
- **MASKMOVQ and MAKSMOVDQU.** Even if the instruction's mask is zero, the processor may operate with regard to faulting as if MASKMOVQ or MASKMOVDQU writes to memory (the behavior is implementation-specific). In such a situation, an APIC-access VM exit may occur.
- **MONITOR.** With regard to faulting, the processor operates as if MONITOR reads from the effective address in RAX. If the resulting linear address translates to one on the APIC-access page, the instruction may cause an APIC-access VM exit.<sup>1</sup> If it does not, it will monitor the corresponding address on the virtual-APIC page instead of the APIC-access page.
- **PREFETCH.** An execution of the PREFETCH instruction that would result in an access to the APIC-access page does not cause an APIC-access VM exit. Such an access may prefetch data; if so, it is from the corresponding address on the virtual-APIC page.

Virtualization of accesses to the APIC-access page is principally intended for basic instructions such as AND, MOV, OR, TEST, XCHG, and XOR. Use of instructions that normally operate on floating-point, SSE, or AVX registers may cause APIC-access VM exit unconditionally regardless of the page offset they access on the APIC-access page.

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For IA-32 processors, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to lower 32 bits of the indicated register.

## 29.4.5 Issues Pertaining to Page Size and TLB Management

The 1-setting of the “virtualize APIC accesses” VM-execution is guaranteed to apply only if translations to the APIC-access address use a 4-KByte page. The following items provide details:

- If EPT is not in use, any linear address that translates to an address on the APIC-access page should use a 4-KByte page. Any access to a linear address that translates to the APIC-access page using a larger page may operate as if the “virtualize APIC accesses” VM-execution control were 0.
- If EPT is in use, any guest-physical address that translates to an address on the APIC-access page should use a 4-KByte page. Any access to a linear address that translates to a guest-physical address that in turn translates to the APIC-access page using a larger page may operate as if the “virtualize APIC accesses” VM-execution control were 0. (This is true also for guest-physical accesses to the APIC-access page; see Section 29.4.6.1.)

In addition, software should perform appropriate TLB invalidation when making changes that may affect APIC-virtualization. The specifics depend on whether VPIDs or EPT is being used:

- **VPIDs being used but EPT not being used.** Suppose that there is a VPID that has been used before and that software has since made either of the following changes: (1) set the “virtualize APIC accesses” VM-execution control when it had previously been 0; or (2) changed the paging structures so that some linear address translates to the APIC-access address when it previously did not. In that case, software should execute INVVPID (see “INVVPID— Invalidate Translations Based on VPID” in Section 30.3) before performing on the same logical processor and with the same VPID.<sup>1</sup>
- **EPT being used.** Suppose that there is an EPTP value that has been used before and that software has since made either of the following changes: (1) set the “virtualize APIC accesses” VM-execution control when it had previously been 0; or (2) changed the EPT paging structures so that some guest-physical address translates to the APIC-access address when it previously did not. In that case, software should execute INVEPT (see “INVEPT— Invalidate Translations Derived from EPT” in Section 30.3) before performing on the same logical processor and with the same EPTP value.<sup>2</sup>
- **Neither VPIDs nor EPT being used.** No invalidation is required.

Failure to perform the appropriate TLB invalidation may result in the logical processor operating as if the “virtualize APIC accesses” VM-execution control were 0 in responses to accesses to the affected address. (No invalidation is necessary if neither VPIDs nor EPT is being used.)

## 29.4.6 APIC Accesses Not Directly Resulting From Linear Addresses

Section 29.4 has described the treatment of accesses that use linear addresses that translate to addresses on the APIC-access page. This section considers memory accesses that do not result directly from linear addresses.

- An access is called a **guest-physical access** if (1) CR0.PG = 1;<sup>3</sup> (2) the “enable EPT” VM-execution control is 1;<sup>4</sup> (3) the access’s physical address is the result of an EPT translation; and (4) either (a) the access was not generated by a linear address; or (b) the access’s guest-physical address is not the translation of the access’s linear address. Section 29.4.6.1 discusses the treatment of guest-physical accesses to the APIC-access page.
- An access is called a **physical access** if (1) either (a) the “enable EPT” VM-execution control is 0; or (b) the access’s physical address is not the result of a translation through the EPT paging structures; and (2) either (a) the access is not generated by a linear address; or (b) the access’s physical address is not the translation of its linear address. Section 29.4.6.2 discusses the treatment of physical accesses to the APIC-access page.

---

1. INVVPID should use either (1) the all-contexts INVVPID type; (2) the single-context INVVPID type with the VPID in the INVVPID descriptor; or (3) the individual-address INVVPID type with the linear address and the VPID in the INVVPID descriptor.

2. INVEPT should use either (1) the global INVEPT type; or (2) the single-context INVEPT type with the EPTP value in the INVEPT descriptor.

3. If the capability MSR IA32\_VMX\_CRO\_FIXED0 reports that CR0.PG must be 1 in VMX operation, CR0.PG must be 1 unless the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls are both 1.

4. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VMX non-root operation functions as if the “enable EPT” VM-execution control were 0. See Section 24.6.2.

### 29.4.6.1 Guest-Physical Accesses to the APIC-Access Page

Guest-physical accesses include the following when guest-physical addresses are being translated using EPT:

- Reads from the guest paging structures when translating a linear address (such an access uses a guest-physical address that is not the translation of that linear address).
- Loads of the page-directory-pointer-table entries by MOV to CR when the logical processor is using (or that causes the logical processor to use) PAE paging (see Section 4.4).
- Updates to the accessed and dirty flags in the guest paging structures when using a linear address (such an access uses a guest-physical address that is not the translation of that linear address).

Every guest-physical access to an address on the APIC-access page causes an APIC-access VM exit. Such accesses are never virtualized regardless of the page offset.

The following items specify the priority relative to other events of APIC-access VM exits caused by guest-physical accesses to the APIC-access page.

- The priority of an APIC-access VM exit caused by a guest-physical access to memory is below that of any EPT violation that that access may incur. That is, a guest-physical access does not cause an APIC-access VM exit if it would cause an EPT violation.
- With respect to all other events, any APIC-access VM exit caused by a guest-physical access has the same priority as any EPT violation that the guest-physical access could cause.

### 29.4.6.2 Physical Accesses to the APIC-Access Page

Physical accesses include the following:

- If the “enable EPT” VM-execution control is 0:
  - Reads from the paging structures when translating a linear address.
  - Loads of the page-directory-pointer-table entries by MOV to CR when the logical processor is using (or that causes the logical processor to use) PAE paging (see Section 4.4).
  - Updates to the accessed and dirty flags in the paging structures.
- If the “enable EPT” VM-execution control is 1, accesses to the EPT paging structures (including updates to the accessed and dirty flags for EPT).
- Any of the following accesses made by the processor to support VMX non-root operation:
  - Accesses to the VMCS region.
  - Accesses to data structures referenced (directly or indirectly) by physical addresses in VM-execution control fields in the VMCS. These include the I/O bitmaps, the MSR bitmaps, and the virtual-APIC page.
- Accesses that effect transitions into and out of SMM.<sup>1</sup> These include the following:
  - Accesses to SMRAM during SMI delivery and during execution of RSM.
  - Accesses during SMM VM exits (including accesses to MSEG) and during VM entries that return from SMM.

A physical access to the APIC-access page may or may not cause an APIC-access VM exit. If it does not cause an APIC-access VM exit, it may access the APIC-access page or the virtual-APIC page. Physical write accesses to the APIC-access page may or may not cause APIC-write emulation or APIC-write VM exits.

The priority of an APIC-access VM exit caused by physical access is not defined relative to other events that the access may cause.

It is recommended that software not set the APIC-access address to any of the addresses used by physical memory accesses (identified above). For example, it should not set the APIC-access address to the physical address of any of the active paging structures if the “enable EPT” VM-execution control is 0.

---

1. Technically, these accesses do not occur in VMX non-root operation. They are included here for clarity.

## 29.5 VIRTUALIZING MSR-BASED APIC ACCESSES

When the local APIC is in x2APIC mode, software accesses the local APIC's control registers using the MSR interface. Specifically, software uses the RDMSR and WRMSR instructions, setting ECX (identifying the MSR being accessed) to values in the range 800H–8FFH (see Section 10.12, “Extended XAPIC (x2APIC)”). This section describes how these accesses can be virtualized.

A virtual-machine monitor can virtualize these MSR-based APIC accesses by configuring the MSR bitmaps (see Section 24.6.9) to ensure that the accesses cause VM exits (see Section 25.1.3). Alternatively, there are methods for virtualizing some MSR-based APIC accesses without VM exits.

Normally, an execution of RDMSR or WRMSR that does not fault or cause a VM exit accesses the MSR indicated in ECX. However, such an execution treats some values of ECX in the range 800H–8FFH specially if the “virtualize x2APIC mode” VM-execution control is 1. The following items provide details:

- **RDMSR.** The instruction's behavior depends on the setting of the “APIC-register virtualization” VM-execution control.
  - If the “APIC-register virtualization” VM-execution control is 0, behavior depends upon the value of ECX.
    - If ECX contains 808H (indicating the TPR MSR), the instruction reads the 8 bytes from offset 080H on the virtual-APIC page (VTPR and the 4 bytes above it) into EDX:EAX. This occurs even if the local APIC is not in x2APIC mode (no general-protection fault occurs because the local APIC is not x2APIC mode).
    - If ECX contains any other value in the range 800H–8FFH, the instruction operates normally. If the local APIC is in x2APIC mode and ECX indicates a readable APIC register, EDX and EAX are loaded with the value of that register. If the local APIC is not in x2APIC mode or ECX does not indicate a readable APIC register, a general-protection fault occurs.
  - If “APIC-register virtualization” is 1 and ECX contains a value in the range 800H–8FFH, the instruction reads the 8 bytes from offset X on the virtual-APIC page into EDX:EAX, where  $X = (ECX \& FFH) \ll 4$ . This occurs even if the local APIC is not in x2APIC mode (no general-protection fault occurs because the local APIC is not in x2APIC mode).
- **WRMSR.** The instruction's behavior depends on the value of ECX and the setting of the “virtual-interrupt delivery” VM-execution control.

Special processing applies in the following cases: (1) ECX contains 808H (indicating the TPR MSR); (2) ECX contains 80BH (indicating the EOI MSR) and the “virtual-interrupt delivery” VM-execution control is 1; and (3) ECX contains 83FH (indicating the self-IPI MSR) and the “virtual-interrupt delivery” VM-execution control is 1.

If special processing applies, no general-protection exception is produced due to the fact that the local APIC is in xAPIC mode. However, WRMSR does perform the normal reserved-bit checking:

- If ECX contains 808H or 83FH, a general-protection fault occurs if either EDX or EAX[31:8] is non-zero.
- If ECX contains 80BH, a general-protection fault occurs if either EDX or EAX is non-zero.

If there is no fault, WRMSR stores EDX:EAX at offset X on the virtual-APIC page, where  $X = (ECX \& FFH) \ll 4$ . Following this, the processor performs an operation depending on the value of ECX:

- If ECX contains 808H, the processor performs TPR virtualization (see Section 29.1.2).
- If ECX contains 80BH, the processor performs EOI virtualization (see Section 29.1.4).
- If ECX contains 83FH, the processor It then checks the value of EAX[7:4] and proceeds as follows:
  - If the value is non-zero, the logical processor performs self-IPI virtualization with the 8-bit vector in EAX[7:0] (see Section 29.1.5).
  - If the value is zero, the logical processor causes an APIC-write VM exit as if there had been a write access to page offset 3F0H on the APIC-access page (see Section 29.4.3.3).

If special processing does not apply, the instruction operates normally. If the local APIC is in x2APIC mode and ECX indicates a writeable APIC register, the value in EDX:EAX is written to that register. If the local APIC is not in x2APIC mode or ECX does not indicate a writeable APIC register, a general-protection fault occurs.

## 29.6 POSTED-INTERRUPT PROCESSING

Posted-interrupt processing is a feature by which a processor processes the virtual interrupts by recording them as pending on the virtual-APIC page.

Posted-interrupt processing is enabled by setting the “process posted interrupts” VM-execution control. The processing is performed in response to the arrival of an interrupt with the **posted-interrupt notification vector**. In response to such an interrupt, the processor processes virtual interrupts recorded in a data structure called a **posted-interrupt descriptor**. The posted-interrupt notification vector and the address of the posted-interrupt descriptor are fields in the VMCS; see Section 24.6.8.

If the “process posted interrupts” VM-execution control is 1, a logical processor uses a 64-byte posted-interrupt descriptor located at the posted-interrupt descriptor address. The posted-interrupt descriptor has the following format:

**Table 29-1. Format of Posted-Interrupt Descriptor**

Bit Position(s)	Name	Description
255:0	Posted-interrupt requests	One bit for each interrupt vector. There is a posted-interrupt request for a vector if the corresponding bit is 1
256	Outstanding notification	If this bit is set, there is a notification outstanding for one or more posted interrupts in bits 255:0
511:257	Reserved for software and other agents	These bits may be used by software and by other agents in the system (e.g., chipset). The processor does not modify these bits.

The notation **PIR** (posted-interrupt requests) refers to the 256 posted-interrupt bits in the posted-interrupt descriptor.

Use of the posted-interrupt descriptor differs from that of other data structures that are referenced by pointers in a VMCS. There is a general requirement that software ensure that each such data structure is modified only when no logical processor with a current VMCS that references it is in VMX non-root operation. That requirement does not apply to the posted-interrupt descriptor. There is a requirement, however, that such modifications be done using locked read-modify-write instructions.

If the “external-interrupt exiting” VM-execution control is 1, any unmasked external interrupt causes a VM exit (see Section 25.2). If the “process posted interrupts” VM-execution control is also 1, this behavior is changed and the processor handles an external interrupt as follows:<sup>1</sup>

1. The local APIC is acknowledged; this provides the processor core with an interrupt vector, called here the **physical vector**.
2. If the physical vector equals the posted-interrupt notification vector, the logical processor continues to the next step. Otherwise, a VM exit occurs as it would normally due to an external interrupt; the vector is saved in the VM-exit interruption-information field.
3. The processor clears the outstanding-notification bit in the posted-interrupt descriptor. This is done atomically so as to leave the remainder of the descriptor unmodified (e.g., with a locked AND operation).
4. The processor writes zero to the EOI register in the local APIC; this dismisses the interrupt with the posted-interrupt notification vector from the local APIC.
5. The logical processor performs a logical-OR of PIR into VIRR and clears PIR. No other agent can read or write a PIR bit (or group of bits) between the time it is read (to determine what to OR into VIRR) and when it is cleared.
6. The logical processor sets RVI to be the maximum of the old value of RVI and the highest index of all bits that were set in PIR; if no bit was set in PIR, RVI is left unmodified.
7. The logical processor evaluates pending virtual interrupts as described in Section 29.2.1.

The logical processor performs the steps above in an uninterruptible manner. If step #7 leads to recognition of a virtual interrupt, the processor may deliver that interrupt immediately.

1. VM entry ensures that the “process posted interrupts” VM-execution control is 1 only if the “external-interrupt exiting” VM-execution control is also 1. See Section 26.2.1.1.

## APIC VIRTUALIZATION AND VIRTUAL INTERRUPTS

Steps #1 to #7 above occur when the interrupt controller delivers an unmasked external interrupt to the CPU core. This delivery can occur when the logical processor is in the active, HLT, or MWAIT states. If the logical processor had been in the active or MWAIT state before the arrival of the interrupt, it is in the active state following completion of step #7; if it had been in the HLT state, it returns to the HLT state after step #7 (if a pending virtual interrupt was recognized, the logical processor may immediately wake from the HLT state).

### NOTE

This chapter was previously located in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2B* as chapter 5.

## 30.1 OVERVIEW

This chapter describes the virtual-machine extensions (VMX) for the Intel 64 and IA-32 architectures. VMX is intended to support virtualization of processor hardware and a system software layer acting as a host to multiple guest software environments. The virtual-machine extensions (VMX) includes five instructions that manage the virtual-machine control structure (VMCS), four instructions that manage VMX operation, two TLB-management instructions, and two instructions for use by guest software. Additional details of VMX are described in Chapter 23 through Chapter 29.

The behavior of the VMCS-maintenance instructions is summarized below:

- **VMPTRLD** — This instruction takes a single 64-bit source operand that is in memory. It makes the referenced VMCS active and current, loading the current-VMCS pointer with this operand and establishes the current VMCS based on the contents of VMCS-data area in the referenced VMCS region. Because this makes the referenced VMCS active, a logical processor may start maintaining on the processor some of the VMCS data for the VMCS.
- **VMPTRST** — This instruction takes a single 64-bit destination operand that is in memory. The current-VMCS pointer is stored into the destination operand.
- **VMCLEAR** — This instruction takes a single 64-bit operand that is in memory. The instruction sets the launch state of the VMCS referenced by the operand to “clear”, renders that VMCS inactive, and ensures that data for the VMCS have been written to the VMCS-data area in the referenced VMCS region. If the operand is the same as the current-VMCS pointer, that pointer is made invalid.
- **VMREAD** — This instruction reads a component from a VMCS (the encoding of that field is given in a register operand) and stores it into a destination operand that may be a register or in memory.
- **VMWRITE** — This instruction writes a component to a VMCS (the encoding of that field is given in a register operand) from a source operand that may be a register or in memory.

The behavior of the VMX management instructions is summarized below:

- **VMLAUNCH** — This instruction launches a virtual machine managed by the VMCS. A VM entry occurs, transferring control to the VM.
- **VMRESUME** — This instruction resumes a virtual machine managed by the VMCS. A VM entry occurs, transferring control to the VM.
- **VMXOFF** — This instruction causes the processor to leave VMX operation.
- **VMXON** — This instruction takes a single 64-bit source operand that is in memory. It causes a logical processor to enter VMX root operation and to use the memory referenced by the operand to support VMX operation.

The behavior of the VMX-specific TLB-management instructions is summarized below:

- **INVEPT** — This instruction invalidates entries in the TLBs and paging-structure caches that were derived from extended page tables (EPT).
- **INVVPID** — This instruction invalidates entries in the TLBs and paging-structure caches based on a Virtual-Processor Identifier (VPID).

None of the instructions above can be executed in compatibility mode; they generate invalid-opcode exceptions if executed in compatibility mode.

The behavior of the guest-available instructions is summarized below:

- **VMCALL** — This instruction allows software in VMX non-root operation to call the VMM for service. A VM exit occurs, transferring control to the VMM.

- **VMFUNC** — This instruction allows software in VMX non-root operation to invoke a VM function (processor functionality enabled and configured by software in VMX root operation) without a VM exit.

## 30.2 CONVENTIONS

The operation sections for the VMX instructions in Section 30.3 use the pseudo-function VMexit, which indicates that the logical processor performs a VM exit.

The operation sections also use the pseudo-functions VMsucceed, VMfail, VMfailInvalid, and VMfailValid. These pseudo-functions signal instruction success or failure by setting or clearing bits in RFLAGS and, in some cases, by writing the VM-instruction error field. The following pseudocode fragments detail these functions:

VMsucceed:

```
CF ← 0;
PF ← 0;
AF ← 0;
ZF ← 0;
SF ← 0;
OF ← 0;
```

VMfail(ErrorNumber):

```
IF VMCS pointer is valid
  THEN VMfailValid(ErrorNumber);
  ELSE VMfailInvalid;
FI;
```

VMfailInvalid:

```
CF ← 1;
PF ← 0;
AF ← 0;
ZF ← 0;
SF ← 0;
OF ← 0;
```

VMfailValid(ErrorNumber)// executed only if there is a current VMCS

```
CF ← 0;
PF ← 0;
AF ← 0;
ZF ← 1;
SF ← 0;
OF ← 0;
```

Set the VM-instruction error field to ErrorNumber;

The different VM-instruction error numbers are enumerated in Section 30.4, “VM Instruction Error Numbers”.

## 30.3 VMX INSTRUCTIONS

This section provides detailed descriptions of the VMX instructions.

## INVEPT— Invalidate Translations Derived from EPT

Opcode	Instruction	Description
66 0F 38 80	INVEPT r64, m128	Invalidates EPT-derived entries in the TLBs and paging-structure caches (in 64-bit mode)
66 0F 38 80	INVEPT r32, m128	Invalidates EPT-derived entries in the TLBs and paging-structure caches (outside 64-bit mode)

### Description

Invalidates mappings in the translation lookaside buffers (TLBs) and paging-structure caches that were derived from extended page tables (EPT). (See Chapter 28, “VMX Support for Address Translation”.) Invalidation is based on the **INVEPT type** specified in the register operand and the **INVEPT descriptor** specified in the memory operand.

Outside IA-32e mode, the register operand is always 32 bits, regardless of the value of CS.D; in 64-bit mode, the register operand has 64 bits (the instruction cannot be executed in compatibility mode).

The INVEPT types supported by a logical processors are reported in the IA32\_VMX\_EPT\_VPID\_CAP MSR (see Appendix A, “VMX Capability Reporting Facility”). There are two INVEPT types currently defined:

- Single-context invalidation. If the INVEPT type is 1, the logical processor invalidates all mappings associated with bits 51:12 of the EPT pointer (EPTP) specified in the INVEPT descriptor. It may invalidate other mappings as well.
- Global invalidation: If the INVEPT type is 2, the logical processor invalidates mappings associated with all EPTPs.

If an unsupported INVEPT type is specified, the instruction fails.

INVEPT invalidates all the specified mappings for the indicated EPTP(s) regardless of the VPID and PCID values with which those mappings may be associated.

The INVEPT descriptor comprises 128 bits and contains a 64-bit EPTP value in bits 63:0 (see Figure 30-1).

Figure 30-1. INVEPT Descriptor

## Operation

```

IF (not in VMX operation) or (CRO.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VM exit;
ELSIF CPL > 0
    THEN #GP(0);
ELSE
    INVEPT_TYPE ← value of register operand;
    IF IA32_VMX_EPT_VPID_CAP MSR indicates that processor does not support INVEPT_TYPE
        THEN VMfail(Invalid operand to INVEPT/INVVPID);
    ELSE // INVEPT_TYPE must be 1 or 2
        INVEPT_DESC ← value of memory operand;
        EPTP ← INVEPT_DESC[63:0];
        CASE INVEPT_TYPE OF
            1: // single-context invalidation
                IF VM entry with the "enable EPT" VM execution control set to 1
                    would fail due to the EPTP value
                    THEN VMfail(Invalid operand to INVEPT/INVVPID);
                ELSE
                    Invalidate mappings associated with EPTP[51:12];
                    VMSucceed;
                FI;
            BREAK;
            2: // global invalidation
                Invalidate mappings associated with all EPTPs;
                VMSucceed;
                BREAK;
        ESAC;
    FI;
FI;

```

## Flags Affected

See the operation section and Section 30.2.

## Protected Mode Exceptions

#GP(0)	<p>If the current privilege level is not 0.</p> <p>If the memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.</p> <p>If the DS, ES, FS, or GS register contains an unusable segment.</p> <p>If the source operand is located in an execute-only code segment.</p>
#PF(fault-code)	If a page fault occurs in accessing the memory operand.
#SS(0)	<p>If the memory operand effective address is outside the SS segment limit.</p> <p>If the SS register contains an unusable segment.</p>
#UD	<p>If not in VMX operation.</p> <p>If the logical processor does not support EPT (IA32_VMX_PROCBASED_CTLSS2[33]=0).</p> <p>If the logical processor supports EPT (IA32_VMX_PROCBASED_CTLSS2[33]=1) but does not support the INVEPT instruction (IA32_VMX_EPT_VPID_CAP[20]=0).</p>

## Real-Address Mode Exceptions

#UD	A logical processor cannot be in real-address mode while in VMX operation and the INVEPT instruction is not recognized outside VMX operation.
-----	---

### Virtual-8086 Mode Exceptions

#UD The INVEPT instruction is not recognized in virtual-8086 mode.

### Compatibility Mode Exceptions

#UD The INVEPT instruction is not recognized in compatibility mode.

### 64-Bit Mode Exceptions

#GP(0) If the current privilege level is not 0.  
If the memory operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form.

#PF(fault-code) If a page fault occurs in accessing the memory operand.

#SS(0) If the memory operand is in the SS segment and the memory address is in a non-canonical form.

#UD If not in VMX operation.  
If the logical processor does not support EPT (IA32\_VMX\_PROCBASED\_CTL2[33]=0).  
If the logical processor supports EPT (IA32\_VMX\_PROCBASED\_CTL2[33]=1) but does not support the INVEPT instruction (IA32\_VMX\_EPT\_VPID\_CAP[20]=0).

## INVVPID— Invalidate Translations Based on VPID

Opcode	Instruction	Description
66 0F 38 81	INVVPID r64, m128	Invalidates entries in the TLBs and paging-structure caches based on VPID (in 64-bit mode)
66 0F 38 81	INVVPID r32, m128	Invalidates entries in the TLBs and paging-structure caches based on VPID (outside 64-bit mode)

### Description

Invalidates mappings in the translation lookaside buffers (TLBs) and paging-structure caches based on **virtual-processor identifier** (VPID). (See Chapter 28, “VMX Support for Address Translation”.) Invalidation is based on the **INVVPID type** specified in the register operand and the **INVVPID descriptor** specified in the memory operand.

Outside IA-32e mode, the register operand is always 32 bits, regardless of the value of CS.D; in 64-bit mode, the register operand has 64 bits (the instruction cannot be executed in compatibility mode).

The INVVPID types supported by a logical processors are reported in the IA32\_VMX\_EPT\_VPID\_CAP MSR (see Appendix A, “VMX Capability Reporting Facility”). There are four INVVPID types currently defined:

- Individual-address invalidation: If the INVVPID type is 0, the logical processor invalidates mappings for the linear address and VPID specified in the INVVPID descriptor. In some cases, it may invalidate mappings for other linear addresses (or other VPIDs) as well.
- Single-context invalidation: If the INVVPID type is 1, the logical processor invalidates all mappings tagged with the VPID specified in the INVVPID descriptor. In some cases, it may invalidate mappings for other VPIDs as well.
- All-contexts invalidation: If the INVVPID type is 2, the logical processor invalidates all mappings tagged with all VPIDs except VPID 0000H. In some cases, it may invalidate translations with VPID 0000H as well.
- Single-context invalidation, retaining global translations: If the INVVPID type is 3, the logical processor invalidates all mappings tagged with the VPID specified in the INVVPID descriptor except global translations. In some cases, it may invalidate global translations (and mappings with other VPIDs) as well. See the “Caching Translation Information” section in Chapter 4 of the *IA-32 Intel Architecture Software Developer’s Manual, Volumes 3A* for information about global translations.

If an unsupported INVVPID type is specified, the instruction fails.

INVVPID invalidates all the specified mappings for the indicated VPID(s) regardless of the EPTP and PCID values with which those mappings may be associated.

The INVVPID descriptor comprises 128 bits and consists of a VPID and a linear address as shown in Figure 30-2.

Figure 30-2. INVVPID Descriptor

## Operation

```

IF (not in VMX operation) or (CRO.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VM exit;
ELSIF CPL > 0
    THEN #GP(0);
ELSE
    INVVPID_TYPE ← value of register operand;
    IF IA32_VMX_EPT_VPID_CAP MSR indicates that processor does not support
    INVVPID_TYPE
        THEN VMfail(Invalid operand to INVEPT/INVVPID);
    ELSE // INVVPID_TYPE must be in the range 0–3
        INVVPID_DESC ← value of memory operand;
        IF INVVPID_DESC[63:16] ≠ 0
            THEN VMfail(Invalid operand to INVEPT/INVVPID);
        ELSE
            CASE INVVPID_TYPE OF
            0: // individual-address invalidation
                VPID ← INVVPID_DESC[15:0];
                IF VPID = 0
                    THEN VMfail(Invalid operand to INVEPT/INVVPID);
                ELSE
                    GL_ADDR ← INVVPID_DESC[127:64];
                    IF (GL_ADDR is not in a canonical form)
                        THEN
                            VMfail(Invalid operand to INVEPT/INVVPID);
                        ELSE
                            Invalidate mappings for GL_ADDR tagged with VPID;
                            VMsucceed;
                    FI;
                FI;
                BREAK;
            1: // single-context invalidation
                VPID ← INVVPID_DESC[15:0];

**Flags Affected**

See the operation section and Section 30.2.

**Protected Mode Exceptions**

- #GP(0) If the current privilege level is not 0.  
If the memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.  
If the DS, ES, FS, or GS register contains an unusable segment.  
If the source operand is located in an execute-only code segment.
- #PF(fault-code) If a page fault occurs in accessing the memory operand.
- #SS(0) If the memory operand effective address is outside the SS segment limit.  
If the SS register contains an unusable segment.
- #UD If not in VMX operation.  
If the logical processor does not support VPIDs (IA32\_VMX\_PROCBASED\_CTLSS2[37]=0).  
If the logical processor supports VPIDs (IA32\_VMX\_PROCBASED\_CTLSS2[37]=1) but does not support the INVVPID instruction (IA32\_VMX\_EPT\_VPID\_CAP[32]=0).

**Real-Address Mode Exceptions**

- #UD A logical processor cannot be in real-address mode while in VMX operation and the INVVPID instruction is not recognized outside VMX operation.

**Virtual-8086 Mode Exceptions**

- #UD The INVVPID instruction is not recognized in virtual-8086 mode.

**Compatibility Mode Exceptions**

- #UD The INVVPID instruction is not recognized in compatibility mode.

**64-Bit Mode Exceptions**

- #GP(0) If the current privilege level is not 0.  
If the memory operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form.
- #PF(fault-code) If a page fault occurs in accessing the memory operand.
- #SS(0) If the memory destination operand is in the SS segment and the memory address is in a non-canonical form.
- #UD If not in VMX operation.  
If the logical processor does not support VPIDs (IA32\_VMX\_PROCBASED\_CTLSS2[37]=0).  
If the logical processor supports VPIDs (IA32\_VMX\_PROCBASED\_CTLSS2[37]=1) but does not support the INVVPID instruction (IA32\_VMX\_EPT\_VPID\_CAP[32]=0).

## VMCALL—Call to VM Monitor

Opcode	Instruction	Description
OF 01 C1	VMCALL	Call to VM monitor by causing VM exit.

### Description

This instruction allows guest software can make a call for service into an underlying VM monitor. The details of the programming interface for such calls are VMM-specific; this instruction does nothing more than cause a VM exit, registering the appropriate exit reason.

Use of this instruction in VMX root operation invokes an SMM monitor (see Section 34.15.2). This invocation will activate the dual-monitor treatment of system-management interrupts (SMIs) and system-management mode (SMM) if it is not already active (see Section 34.15.6).

### Operation

```

IF not in VMX operation
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VM exit;
ELSIF (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF CPL > 0
    THEN #GP(0);
ELSIF in SMM or the logical processor does not support the dual-monitor treatment of SMIs and SMM or the valid bit in the
IA32_SMM_MONITOR_CTL MSR is clear
    THEN VMfail (VMCALL executed in VMX root operation);
ELSIF dual-monitor treatment of SMIs and SMM is active
    THEN perform an SMM VM exit (see Section 34.15.2);
ELSIF current-VMCS pointer is not valid
    THEN VMfailInvalid;
ELSIF launch state of current VMCS is not clear
    THEN VMfailValid(VMCALL with non-clear VMCS);
ELSIF VM-exit control fields are not valid (see Section 34.15.6.1)
    THEN VMfailValid (VMCALL with invalid VM-exit control fields);
ELSE
    enter SMM;
    read revision identifier in MSEG;
    IF revision identifier does not match that supported by processor
        THEN
            leave SMM;
            VMfailValid(VMCALL with incorrect MSEG revision identifier);
        ELSE
            read SMM-monitor features field in MSEG (see Section 34.15.6.2);
            IF features field is invalid
                THEN
                    leave SMM;
                    VMfailValid(VMCALL with invalid SMM-monitor features);
                ELSE activate dual-monitor treatment of SMIs and SMM (see Section 34.15.6);
            FI;
        FI;
    FI;

```

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

- #GP(0) If the current privilege level is not 0 and the logical processor is in VMX root operation.
- #UD If executed outside VMX operation.

### Real-Address Mode Exceptions

- #UD If executed outside VMX operation.

### Virtual-8086 Mode Exceptions

- #UD If executed outside VMX non-root operation.

### Compatibility Mode Exceptions

- #UD If executed outside VMX non-root operation.

### 64-Bit Mode Exceptions

- #UD If executed outside VMX non-root operation.

## VMCLEAR—Clear Virtual-Machine Control Structure

Opcode	Instruction	Description
66 0F C7 /6	VMCLEAR m64	Copy VMCS data to VMCS region in memory.

### Description

This instruction applies to the VMCS whose VMCS region resides at the physical address contained in the instruction operand. The instruction ensures that VMCS data for that VMCS (some of these data may be currently maintained on the processor) are copied to the VMCS region in memory. It also initializes parts of the VMCS region (for example, it sets the launch state of that VMCS to clear). See Chapter 24, “Virtual-Machine Control Structures”.

The operand of this instruction is always 64 bits and is always in memory. If the operand is the current-VMCS pointer, then that pointer is made invalid (set to FFFFFFFF\_FFFFFFFFH).

Note that the VMCLEAR instruction might not explicitly write any VMCS data to memory; the data may be already resident in memory before the VMCLEAR is executed.

### Operation

```

IF (register operand) or (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
  THEN #UD;
ELSIF in VMX non-root operation
  THEN VM exit;
ELSIF CPL > 0
  THEN #GP(0);
ELSE
  addr ← contents of 64-bit in-memory operand;
  IF addr is not 4KB-aligned OR
  addr sets any bits beyond the physical-address width1
    THEN VMfail(VMCLEAR with invalid physical address);
  ELSIF addr = VMXON pointer
    THEN VMfail(VMCLEAR with VMXON pointer);
  ELSE
    ensure that data for VMCS referenced by the operand is in memory;
    initialize implementation-specific data in VMCS region;
    launch state of VMCS referenced by the operand ← “clear”
    IF operand addr = current-VMCS pointer
      THEN current-VMCS pointer ← FFFFFFFF_FFFFFFFFH;
    FI;
    VMSucceed;
  FI;
FI;

```

### Flags Affected

See the operation section and Section 30.2.

1. If IA32\_VMX\_BASIC[48] is read as 1, VMfail occurs if addr sets any bits in the range 63:32; see Appendix A.1.

### Protected Mode Exceptions

#GP(0)	<p>If the current privilege level is not 0.</p> <p>If the memory operand effective address is outside the CS, DS, ES, FS, or GS segment limit.</p> <p>If the DS, ES, FS, or GS register contains an unusable segment.</p> <p>If the operand is located in an execute-only code segment.</p>
#PF(fault-code)	If a page fault occurs in accessing the memory operand.
#SS(0)	<p>If the memory operand effective address is outside the SS segment limit.</p> <p>If the SS register contains an unusable segment.</p>
#UD	<p>If operand is a register.</p> <p>If not in VMX operation.</p>

### Real-Address Mode Exceptions

#UD	A logical processor cannot be in real-address mode while in VMX operation and the VMCLEAR instruction is not recognized outside VMX operation.
-----	--

### Virtual-8086 Mode Exceptions

#UD	The VMCLEAR instruction is not recognized in virtual-8086 mode.
-----	---

### Compatibility Mode Exceptions

#UD	The VMCLEAR instruction is not recognized in compatibility mode.
-----	--

### 64-Bit Mode Exceptions

#GP(0)	<p>If the current privilege level is not 0.</p> <p>If the source operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form.</p>
#PF(fault-code)	If a page fault occurs in accessing the memory operand.
#SS(0)	If the source operand is in the SS segment and the memory address is in a non-canonical form.
#UD	<p>If operand is a register.</p> <p>If not in VMX operation.</p>

## VMFUNC—Invoke VM function

Opcode	Instruction	Description
0F 01 D4	VMFUNC	Invoke VM function specified in EAX.

### Description

This instruction allows software in VMX non-root operation to invoke a VM function, which is processor functionality enabled and configured by software in VMX root operation. The value of EAX selects the specific VM function being invoked.

The behavior of each VM function (including any additional fault checking) is specified in Section 25.5.5, “VM Functions”.

### Operation

Perform functionality of the VM function specified in EAX;

### Flags Affected

Depends on the VM function specified in EAX. See Section 25.5.5, “VM Functions”.

### Protected Mode Exceptions (not including those defined by specific VM functions)

#UD If executed outside VMX non-root operation.  
 If “enable VM functions” VM-execution control is 0.  
 If  $EAX \geq 64$ .

### Real-Address Mode Exceptions

Same exceptions as in protected mode.

### Virtual-8086 Exceptions

Same exceptions as in protected mode.

### Compatibility Mode Exceptions

Same exceptions as in protected mode.

### 64-Bit Mode Exceptions

Same exceptions as in protected mode.

## VMLAUNCH/VMRESUME—Launch/Resume Virtual Machine

Opcode	Instruction	Description
OF 01 C2	VMLAUNCH	Launch virtual machine managed by current VMCS.
OF 01 C3	VMRESUME	Resume virtual machine managed by current VMCS.

### Description

Effects a VM entry managed by the current VMCS.

- VMLAUNCH fails if the launch state of current VMCS is not “clear”. If the instruction is successful, it sets the launch state to “launched.”
- VMRESUME fails if the launch state of the current VMCS is not “launched.”

If VM entry is attempted, the logical processor performs a series of consistency checks as detailed in Chapter 26, “VM Entries”. Failure to pass checks on the VMX controls or on the host-state area passes control to the instruction following the VMLAUNCH or VMRESUME instruction. If these pass but checks on the guest-state area fail, the logical processor loads state from the host-state area of the VMCS, passing control to the instruction referenced by the RIP field in the host-state area.

VM entry is not allowed when events are blocked by MOV SS or POP SS. Neither VMLAUNCH nor VMRESUME should be used immediately after either MOV to SS or POP to SS.

### Operation

```

IF (not in VMX operation) or (CRO.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
  THEN #UD;
ELSIF in VMX non-root operation
  THEN VMexit;
ELSIF CPL > 0
  THEN #GP(0);
ELSIF current-VMCS pointer is not valid
  THEN VMfailInvalid;
ELSIF events are being blocked by MOV SS
  THEN VMfailValid(VM entry with events blocked by MOV SS);
ELSIF (VMLAUNCH and launch state of current VMCS is not “clear”)
  THEN VMfailValid(VMLAUNCH with non-clear VMCS);
ELSIF (VMRESUME and launch state of current VMCS is not “launched”)
  THEN VMfailValid(VMRESUME with non-launched VMCS);
ELSE
  Check settings of VMX controls and host-state area;
  IF invalid settings
    THEN VMfailValid(VM entry with invalid VMX-control field(s)) or
      VMfailValid(VM entry with invalid host-state field(s)) or
      VMfailValid(VM entry with invalid executive-VMCS pointer)) or
      VMfailValid(VM entry with non-launched executive VMCS) or
      VMfailValid(VM entry with executive-VMCS pointer not VMXON pointer) or
      VMfailValid(VM entry with invalid VM-execution control fields in executive
      VMCS)
    as appropriate;
  ELSE
    Attempt to load guest state and PDPTRs as appropriate;
    clear address-range monitoring;
    IF failure in checking guest state or PDPTRs
      THEN VM entry fails (see Section 26.7);

```

```

ELSE
  Attempt to load MSRs from VM-entry MSR-load area;
  IF failure
    THEN VM entry fails
    (see Section 26.7);
    ELSE
      IF VMLAUNCH
        THEN launch state of VMCS ← "launched";
        FI;
      IF in SMM and "entry to SMM" VM-entry control is 0
        THEN
          IF "deactivate dual-monitor treatment" VM-entry
            control is 0
            THEN SMM-transfer VMCS pointer ←
              current-VMCS pointer;
            FI;
          IF executive-VMCS pointer is VMX pointer
            THEN current-VMCS pointer ←
              VMCS-link pointer;
            ELSE current-VMCS pointer ←
              executive-VMCS pointer;
            FI;
          leave SMM;
        FI;
      VM entry succeeds;
    FI;
  FI;
FI;

```

Further details of the operation of the VM-entry appear in Chapter 26.

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

#GP(0) If the current privilege level is not 0.  
 #UD If executed outside VMX operation.

### Real-Address Mode Exceptions

#UD A logical processor cannot be in real-address mode while in VMX operation and the VMLAUNCH and VMRESUME instructions are not recognized outside VMX operation.

### Virtual-8086 Mode Exceptions

#UD The VMLAUNCH and VMRESUME instructions are not recognized in virtual-8086 mode.

### Compatibility Mode Exceptions

#UD The VMLAUNCH and VMRESUME instructions are not recognized in compatibility mode.

### 64-Bit Mode Exceptions

#GP(0) If the current privilege level is not 0.  
 #UD If executed outside VMX operation.

## VMPTRLD—Load Pointer to Virtual-Machine Control Structure

Opcode	Instruction	Description
OF C7 /6	VMPTRLD m64	Loads the current VMCS pointer from memory.

### Description

Marks the current-VMCS pointer valid and loads it with the physical address in the instruction operand. The instruction fails if its operand is not properly aligned, sets unsupported physical-address bits, or is equal to the VMXON pointer. In addition, the instruction fails if the 32 bits in memory referenced by the operand do not match the VMCS revision identifier supported by this processor.<sup>2</sup>

The operand of this instruction is always 64 bits and is always in memory.

### Operation

```

IF (register operand) or (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
  THEN #UD;
ELSIF in VMX non-root operation
  THEN VMexit;
ELSIF CPL > 0
  THEN #GP(0);
ELSE
  addr ← contents of 64-bit in-memory source operand;
  IF addr is not 4KB-aligned OR
  addr sets any bits beyond the physical-address width3
    THEN VMfail(VMPTRLD with invalid physical address);
  ELSIF addr = VMXON pointer
    THEN VMfail(VMPTRLD with VMXON pointer);
  ELSE
    rev ← 32 bits located at physical address addr;
    IF rev[30:0] ≠ VMCS revision identifier supported by processor OR
    rev[31] = 1 AND processor does not support 1-setting of “VMCS shadowing”
      THEN VMfail(VMPTRLD with incorrect VMCS revision identifier);
    ELSE
      current-VMCS pointer ← addr;
      VMsucceed;
    FI;
  FI;
FI;

```

### Flags Affected

See the operation section and Section 30.2.

2. Software should consult the VMX capability MSR VMX\_BASIC to discover the VMCS revision identifier supported by this processor (see Appendix A, “VMX Capability Reporting Facility”).

3. If IA32\_VMX\_BASIC[48] is read as 1, VMfail occurs if addr sets any bits in the range 63:32; see Appendix A.1.

### Protected Mode Exceptions

#GP(0)	<p>If the current privilege level is not 0.</p> <p>If the memory source operand effective address is outside the CS, DS, ES, FS, or GS segment limit.</p> <p>If the DS, ES, FS, or GS register contains an unusable segment.</p> <p>If the source operand is located in an execute-only code segment.</p>
#PF(fault-code)	If a page fault occurs in accessing the memory source operand.
#SS(0)	<p>If the memory source operand effective address is outside the SS segment limit.</p> <p>If the SS register contains an unusable segment.</p>

## VMPTRST—Store Pointer to Virtual-Machine Control Structure

Opcode	Instruction	Description
0F C7 77	VMPTRST m64	Stores the current VMCS pointer into memory.

### Description

Stores the current-VMCS pointer into a specified memory address. The operand of this instruction is always 64 bits and is always in memory.

### Operation

```
IF (register operand) or (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
  THEN #UD;
ELSIF in VMX non-root operation
  THEN VMexit;
ELSIF CPL > 0
  THEN #GP(0);
ELSE
  64-bit in-memory destination operand ← current-VMCS pointer;
  VMSucceed;
FI;
```

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

#GP(0)	<p>If the current privilege level is not 0.</p> <p>If the memory destination operand effective address is outside the CS, DS, ES, FS, or GS segment limit.</p> <p>If the DS, ES, FS, or GS register contains an unusable segment.</p> <p>If the destination operand is located in a read-only data segment or any code segment.</p>

#SS(0)	<p>If the memory destination operand effective address is outside the SS segment limit.</p> <p>If the SS register contains an unusable segment.</p>
#UD	<p>If operand is a register.</p> <p>If not in VMX operation.</p>

### Real-Address Mode Exceptions

#UD	A logical processor cannot be in real-address mode while in VMX operation and the VMPTRST instruction is not recognized outside VMX operation.
-----	--

### Virtual-8086 Mode Exceptions

#UD	The VMPTRST instruction is not recognized in virtual-8086 mode.
-----	---

### Compatibility Mode Exceptions

#UD	The VMPTRST instruction is not recognized in compatibility mode.
-----	--

### 64-Bit Mode Exceptions

- #GP(0)                    If the current privilege level is not 0.  
                          If the destination operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form.
- #PF(fault-code)        If a page fault occurs in accessing the memory destination operand.
- #SS(0)                    If the destination operand is in the SS segment and the memory address is in a non-canonical form.
- #UD                        If operand is a register.  
                          If not in VMX operation.

## VMREAD—Read Field from Virtual-Machine Control Structure

Opcode	Instruction	Description
OF 78	VMREAD r/m64, r64	Reads a specified VMCS field (in 64-bit mode).
OF 78	VMREAD r/m32, r32	Reads a specified VMCS field (outside 64-bit mode).

### Description

Reads a specified field from a VMCS and stores it into a specified destination operand (register or memory). In VMX root operation, the instruction reads from the current VMCS. If executed in VMX non-root operation, the instruction reads from the VMCS referenced by the VMCS link pointer field in the current VMCS.

The VMCS field is specified by the VMCS-field encoding contained in the register source operand. Outside IA-32e mode, the source operand has 32 bits, regardless of the value of CS.D. In 64-bit mode, the source operand has 64 bits; however, if bits 63:32 of the source operand are not zero, VMREAD will fail due to an attempt to access an unsupported VMCS component (see operation section).

The effective size of the destination operand, which may be a register or in memory, is always 32 bits outside IA-32e mode (the setting of CS.D is ignored with respect to operand size) and 64 bits in 64-bit mode. If the VMCS field specified by the source operand is shorter than this effective operand size, the high bits of the destination operand are cleared to 0. If the VMCS field is longer, then the high bits of the field are not read.

Note that any faults resulting from accessing a memory destination operand can occur only after determining, in the operation section below, that the relevant VMCS pointer is valid and that the specified VMCS field is supported.

### Operation

```

IF (not in VMX operation) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
  THEN #UD;
ELSIF in VMX non-root operation AND ("VMCS shadowing" is 0 OR source operand sets bits in range 63:15 OR
VMREAD bit corresponding to bits 14:0 of source operand is 1)4
  THEN VMexit;
ELSIF CPL > 0
  THEN #GP(0);
ELSIF (in VMX root operation AND current-VMCS pointer is not valid) OR
(in VMX non-root operation AND VMCS link pointer is not valid)
  THEN VMfailInvalid;
ELSIF source operand does not correspond to any VMCS field
  THEN VMfailValid(VMREAD/VMWRITE from/to unsupported VMCS component);
ELSE
  IF in VMX root operation
    THEN destination operand ← contents of field indexed by source operand in current VMCS;
    ELSE destination operand ← contents of field indexed by source operand in VMCS referenced by VMCS link pointer;
  FI;
  VMsucceed;
FI;

```

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

#GP(0) If the current privilege level is not 0.

4. The VMREAD bit for a source operand is defined as follows. Let *x* be the value of bits 14:0 of the source operand and let *addr* be the VMREAD-bitmap address. The corresponding VMREAD bit is in bit position *x* & 7 of the byte at physical address *addr* | (*x* >> 3).

	If a memory destination operand effective address is outside the CS, DS, ES, FS, or GS segment limit.
	If the DS, ES, FS, or GS register contains an unusable segment.
	If the destination operand is located in a read-only data segment or any code segment.
#PF(fault-code)	If a page fault occurs in accessing a memory destination operand.
#SS(0)	If a memory destination operand effective address is outside the SS segment limit.
	If the SS register contains an unusable segment.
#UD	If not in VMX operation.

### Real-Address Mode Exceptions

#UD	A logical processor cannot be in real-address mode while in VMX operation and the VMREAD instruction is not recognized outside VMX operation.
-----	---

### Virtual-8086 Mode Exceptions

#UD	The VMREAD instruction is not recognized in virtual-8086 mode.
-----	--

### Compatibility Mode Exceptions

#UD	The VMREAD instruction is not recognized in compatibility mode.
-----	---

### 64-Bit Mode Exceptions

#GP(0)	If the current privilege level is not 0.
	If the memory destination operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form.
#PF(fault-code)	If a page fault occurs in accessing a memory destination operand.
#SS(0)	If the memory destination operand is in the SS segment and the memory address is in a non-canonical form.
#UD	If not in VMX operation.

## **VMRESUME—Resume Virtual Machine**

See VMLAUNCH/VMRESUME—Launch/Resume Virtual Machine.

## VMWRITE—Write Field to Virtual-Machine Control Structure

Opcode	Instruction	Description
0F 79	VMWRITE r64, r/m64	Writes a specified VMCS field (in 64-bit mode)
0F 79	VMWRITE r32, r/m32	Writes a specified VMCS field (outside 64-bit mode)

### Description

Writes the contents of a primary source operand (register or memory) to a specified field in a VMCS. In VMX root operation, the instruction writes to the current VMCS. If executed in VMX non-root operation, the instruction writes to the VMCS referenced by the VMCS link pointer field in the current VMCS.

The VMCS field is specified by the VMCS-field encoding contained in the register secondary source operand. Outside IA-32e mode, the secondary source operand is always 32 bits, regardless of the value of CS.D. In 64-bit mode, the secondary source operand has 64 bits; however, if bits 63:32 of the secondary source operand are not zero, VMWRITE will fail due to an attempt to access an unsupported VMCS component (see operation section).

The effective size of the primary source operand, which may be a register or in memory, is always 32 bits outside IA-32e mode (the setting of CS.D is ignored with respect to operand size) and 64 bits in 64-bit mode. If the VMCS field specified by the secondary source operand is shorter than this effective operand size, the high bits of the primary source operand are ignored. If the VMCS field is longer, then the high bits of the field are cleared to 0.

Note that any faults resulting from accessing a memory source operand occur after determining, in the operation section below, that the relevant VMCS pointer is valid but before determining if the destination VMCS field is supported.

### Operation

```

IF (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation AND ("VMCS shadowing" is 0 OR secondary source operand sets bits in range 63:15 OR
VMWRITE bit corresponding to bits 14:0 of secondary source operand is 1)5
    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
ELSIF (in VMX root operation AND current-VMCS pointer is not valid) OR
(in VMX non-root operation AND VMCS-link pointer is not valid)
    THEN VMfailInvalid;
ELSIF secondary source operand does not correspond to any VMCS field
    THEN VMfailValid(VMREAD/VMWRITE from/to unsupported VMCS component);
ELSIF VMCS field indexed by secondary source operand is a VM-exit information field AND
processor does not support writing to such fields6
    THEN VMfailValid(VMWRITE to read-only VMCS component);
ELSE
    IF in VMX root operation
        THEN field indexed by secondary source operand in current VMCS ← primary source operand;
        THEN field indexed by secondary source operand in VMCS referenced by VMCS link pointer ← primary source operand;
    FI;
    VMsucceed;
FI;

```

5. The VMWRITE bit for a secondary source operand is defined as follows. Let  $x$  be the value of bits 14:0 of the secondary source operand and let  $addr$  be the VMWRITE-bitmap address. The corresponding VMWRITE bit is in bit position  $x \& 7$  of the byte at physical address  $addr | (x \gg 3)$ .

6. Software can discover whether these fields can be written by reading the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6).

**Flags Affected**

See the operation section and Section 30.2.

### Protected Mode Exceptions

#GP(0)	<p>If the current privilege level is not 0.</p> <p>If a memory source operand effective address is outside the CS, DS, ES, FS, or GS segment limit.</p> <p>If the DS, ES, FS, or GS register contains an unusable segment.</p> <p>If the source operand is located in an execute-only code segment.</p>
#PF(fault-code)	If a page fault occurs in accessing a memory source operand.
#SS(0)	<p>If a memory source operand effective address is outside the SS segment limit.</p> <p>If the SS register contains an unusable segment.</p>
#UD	If not in VMX operation.

### Real-Address Mode Exceptions

#UD	A logical processor cannot be in real-address mode while in VMX operation and the VMWRITE instruction is not recognized outside VMX operation.
-----	--

### Virtual-8086 Mode Exceptions

#UD	The VMWRITE instruction is not recognized in virtual-8086 mode.
-----	---

### Compatibility Mode Exceptions

#UD	The VMWRITE instruction is not recognized in compatibility mode.
-----	--

### 64-Bit Mode Exceptions

#GP(0)	<p>If the current privilege level is not 0.</p> <p>If the memory source operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form.</p>
#PF(fault-code)	If a page fault occurs in accessing a memory source operand.
#SS(0)	If the memory source operand is in the SS segment and the memory address is in a non-canonical form.
#UD	If not in VMX operation.

## VMXOFF—Leave VMX Operation

Opcode	Instruction	Description
OF 01 C4	VMXOFF	Leaves VMX operation.

### Description

Takes the logical processor out of VMX operation, unblocks INIT signals, conditionally re-enables A2OM, and clears any address-range monitoring.<sup>7</sup>

### Operation

```

IF (not in VMX operation) or (CR0.PE = 0) or (RFLAGS.VM = 1) or (IA32_EFER.LMA = 1 and CS.L = 0)
    THEN #UD;
ELSIF in VMX non-root operation
    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
ELSIF dual-monitor treatment of SMIs and SMM is active
    THEN VMfail(VMXOFF under dual-monitor treatment of SMIs and SMM);
ELSE
    leave VMX operation;
    unblock INIT;
    IF IA32_SMM_MONITOR_CTL[2] = 08
        THEN unblock SMIs;
    IF outside SMX operation9
        THEN unblock and enable A2OM;
    FI;
    clear address-range monitoring;
    VMsucceed;
FI;

```

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

#GP(0) If executed in VMX root operation with CPL > 0.  
 #UD If executed outside VMX operation.

### Real-Address Mode Exceptions

#UD A logical processor cannot be in real-address mode while in VMX operation and the VMXOFF instruction is not recognized outside VMX operation.

- 
7. See the information on MONITOR/MWAIT in Chapter 8, “Multiple-Processor Management,” of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.
  8. Setting IA32\_SMM\_MONITOR\_CTL[bit 2] to 1 prevents VMXOFF from unblocking SMIs regardless of the value of the register’s value bit (bit 0). Not all processors allow this bit to be set to 1. Software should consult the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6) to determine whether this is allowed.
  9. A logical processor is outside SMX operation if GETSEC[SENDER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENDER]. See Chapter 6, “Safer Mode Extensions Reference.”

### Virtual-8086 Mode Exceptions

#UD                      The VMXOFF instruction is not recognized in virtual-8086 mode.

### Compatibility Mode Exceptions

#UD                      The VMXOFF instruction is not recognized in compatibility mode.

### 64-Bit Mode Exceptions

#GP(0)                  If executed in VMX root operation with CPL > 0.

#UD                      If executed outside VMX operation.

## VMXON—Enter VMX Operation

Opcode	Instruction	Description
F3 0F C7 /6	VMXON m64	Enter VMX root operation.

### Description

Puts the logical processor in VMX operation with no current VMCS, blocks INIT signals, disables A20M, and clears any address-range monitoring established by the MONITOR instruction.<sup>10</sup>

The operand of this instruction is a 4KB-aligned physical address (the VMXON pointer) that references the VMXON region, which the logical processor may use to support VMX operation. This operand is always 64 bits and is always in memory.

### Operation

IF (register operand) or (CR0.PE = 0) or (CR4.VMXE = 0) or (RFLAGS.VM = 1) or (IA32\_EFER.LMA = 1 and CS.L = 0)  
THEN #UD;

ELSIF not in VMX operation

THEN

IF (CPL > 0) or (in A20M mode) or  
(the values of CR0 and CR4 are not supported in VMX operation<sup>11</sup>) or  
(bit 0 (lock bit) of IA32\_FEATURE\_CONTROL MSR is clear) or  
(in SMX operation<sup>12</sup> and bit 1 of IA32\_FEATURE\_CONTROL MSR is clear) or  
(outside SMX operation and bit 2 of IA32\_FEATURE\_CONTROL MSR is clear)

THEN #GP(0);

ELSE

addr ← contents of 64-bit in-memory source operand;

IF addr is not 4KB-aligned or

addr sets any bits beyond the physical-address width<sup>13</sup>

THEN VMfailInvalid;

ELSE

rev ← 32 bits located at physical address addr;

IF rev[30:0] ≠ VMCS revision identifier supported by processor OR rev[31] = 1

THEN VMfailInvalid;

ELSE

current-VMCS pointer ← FFFFFFFF\_FFFFFFFFH;

enter VMX operation;

block INIT signals;

block and disable A20M;

clear address-range monitoring;

VMsucceed;

FI;

FI;

FI;

ELSIF in VMX non-root operation

10. See the information on MONITOR/MWAIT in Chapter 8, “Multiple-Processor Management,” of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*.

11. See Section 19.8 of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B*.

12. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENDER]. A logical processor is outside SMX operation if GETSEC[SENDER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENDER]. See Chapter 6, “Safer Mode Extensions Reference.”

13. If IA32\_VMX\_BASIC[48] is read as 1, VMfailInvalid occurs if addr sets any bits in the range 63:32; see Appendix A.1.

```

    THEN VMexit;
ELSIF CPL > 0
    THEN #GP(0);
    ELSE VMfail("VMXON executed in VMX root operation");
FI;

```

### Flags Affected

See the operation section and Section 30.2.

### Protected Mode Exceptions

#GP(0)	<p>If executed outside VMX operation with CPL&gt;0 or with invalid CR0 or CR4 fixed bits.</p> <p>If executed in A20M mode.</p> <p>If the memory source operand effective address is outside the CS, DS, ES, FS, or GS segment limit.</p> <p>If the DS, ES, FS, or GS register contains an unusable segment.</p> <p>If the source operand is located in an execute-only code segment.</p>
#PF(fault-code)	If a page fault occurs in accessing the memory source operand.
#SS(0)	<p>If the memory source operand effective address is outside the SS segment limit.</p> <p>If the SS register contains an unusable segment.</p>
#UD	<p>If operand is a register.</p> <p>If executed with CR4.VMXE = 0.</p>

### Real-Address Mode Exceptions

#UD	The VMXON instruction is not recognized in real-address mode.
-----	---

### Virtual-8086 Mode Exceptions

#UD	The VMXON instruction is not recognized in virtual-8086 mode.
-----	---

### Compatibility Mode Exceptions

#UD	The VMXON instruction is not recognized in compatibility mode.
-----	--

### 64-Bit Mode Exceptions

#GP(0)	<p>If executed outside VMX operation with CPL &gt; 0 or with invalid CR0 or CR4 fixed bits.</p> <p>If executed in A20M mode.</p> <p>If the source operand is in the CS, DS, ES, FS, or GS segments and the memory address is in a non-canonical form.</p>
#PF(fault-code)	If a page fault occurs in accessing the memory source operand.
#SS(0)	If the source operand is in the SS segment and the memory address is in a non-canonical form.
#UD	<p>If operand is a register.</p> <p>If executed with CR4.VMXE = 0.</p>

## 30.4 VM INSTRUCTION ERROR NUMBERS

For certain error conditions, the VM-instruction error field is loaded with an error number to indicate the source of the error. Table 30-1 lists VM-instruction error numbers.

**Table 30-1. VM-Instruction Error Numbers**

Error Number	Description
1	VMCALL executed in VMX root operation
2	VMCLEAR with invalid physical address
3	VMCLEAR with VMXON pointer
4	VMLAUNCH with non-clear VMCS
5	VMRESUME with non-launched VMCS
6	VMRESUME after VMXOFF (VMXOFF and VMXON between VMLAUNCH and VMRESUME) <sup>1</sup>
7	VM entry with invalid control field(s) <sup>2,3</sup>
8	VM entry with invalid host-state field(s) <sup>2</sup>
9	VMPTRLD with invalid physical address
10	VMPTRLD with VMXON pointer
11	VMPTRLD with incorrect VMCS revision identifier
12	VMREAD/VMWRITE from/to unsupported VMCS component
13	VMWRITE to read-only VMCS component
15	VMXON executed in VMX root operation
16	VM entry with invalid executive-VMCS pointer <sup>2</sup>
17	VM entry with non-launched executive VMCS <sup>2</sup>
18	VM entry with executive-VMCS pointer not VMXON pointer (when attempting to deactivate the dual-monitor treatment of SMIs and SMM) <sup>2</sup>
19	VMCALL with non-clear VMCS (when attempting to activate the dual-monitor treatment of SMIs and SMM)
20	VMCALL with invalid VM-exit control fields
22	VMCALL with incorrect MSEG revision identifier (when attempting to activate the dual-monitor treatment of SMIs and SMM)
23	VMXOFF under dual-monitor treatment of SMIs and SMM
24	VMCALL with invalid SMM-monitor features (when attempting to activate the dual-monitor treatment of SMIs and SMM)
25	VM entry with invalid VM-execution control fields in executive VMCS (when attempting to return from SMM) <sup>2,3</sup>
26	VM entry with events blocked by MOV SS.
28	Invalid operand to INVEPT/INVVPID.

### NOTES:

1. Earlier versions of this manual described this error as “VMRESUME with a corrupted VMCS”.
2. VM-entry checks on control fields and host-state fields may be performed in any order. Thus, an indication by error number of one cause does not imply that there are not also other errors. Different processors may give different error numbers for the same VMCS.
3. Error number 7 is not used for VM entries that return from SMM that fail due to invalid VM-execution control fields in the executive VMCS. Error number 25 is used for these cases.

# CHAPTER 31

## VIRTUAL-MACHINE MONITOR PROGRAMMING CONSIDERATIONS

---

### 31.1 VMX SYSTEM PROGRAMMING OVERVIEW

The Virtual Machine Monitor (VMM) is a software class used to manage virtual machines (VM). This chapter describes programming considerations for VMMs.

Each VM behaves like a complete physical machine and can run operating system (OS) and applications. The VMM software layer runs at the most privileged level and has complete ownership of the underlying system hardware. The VMM controls creation of a VM, transfers control to a VM, and manages situations that can cause transitions between the guest VMs and host VMM. The VMM allows the VMs to share the underlying hardware and yet provides isolation between the VMs. The guest software executing in a VM is unaware of any transitions that might have occurred between the VM and its host.

### 31.2 SUPPORTING PROCESSOR OPERATING MODES IN GUEST ENVIRONMENTS

Typically, VMMs transfer control to a VM using VMX transitions referred to as VM entries. The boundary conditions that define what a VM is allowed to execute in isolation are specified in a virtual-machine control structure (VMCS).

As noted in Section 23.8, processors may fix certain bits in CR0 and CR4 to specific values and not support other values. The first processors to support VMX operation require that CR0.PE and CR0.PG be 1 in VMX operation. Thus, a VM entry is allowed only to guests with paging enabled that are in protected mode or in virtual-8086 mode. Guest execution in other processor operating modes need to be specially handled by the VMM.

One example of such a condition is guest execution in real-mode. A VMM could support guest real-mode execution using at least two approaches:

- By using a fast instruction set emulator in the VMM.
- By using the similarity between real-mode and virtual-8086 mode to support real-mode guest execution in a virtual-8086 container. The virtual-8086 container may be implemented as a virtual-8086 container task within a monitor that emulates real-mode guest state and instructions, or by running the guest VM as the virtual-8086 container (by entering the guest with RFLAGS.VM<sup>1</sup> set). Attempts by real-mode code to access privileged state outside the virtual-8086 container would trap to the VMM and would also need to be emulated.

Another example of such a condition is guest execution in protected mode with paging disabled. A VMM could support such guest execution by using "identity" page tables to emulate unpagged protected mode.

#### 31.2.1 Using Unrestricted Guest Mode

Processors which support the "unrestricted guest" VM-execution control allow VM software to run in real-address mode and unpagged protected mode. Since these modes do not use paging, VMM software must virtualize guest memory using EPT.

Special notes for 64-bit VMM software using the 1-setting of the "unrestricted guest" VM-execution control:

- It is recommended that 64-bit VMM software use the 1-settings of the "load IA32\_EFER" VM entry control and the "save IA32\_EFER" VM-exit control. If VM entry is establishing CR0.PG=0 and if the "IA-32e mode guest" and "load IA32\_EFER" VM entry controls are both 0, VM entry leaves IA32\_EFER.LME unmodified (i.e., the host value will persist in the guest).
- It is not necessary for VMM software to track guest transitions into and out of IA-32e mode for the purpose of maintaining the correct setting of the "IA-32e mode guest" VM entry control. This is because VM exits on

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

processors supporting the 1-setting of the "unrestricted guest" VM-execution control save the (guest) value of IA32\_EFER.LMA into the "IA-32e mode guest" VM entry control.

### 31.3 MANAGING VMCS REGIONS AND POINTERS

A VMM must observe necessary procedures when working with a VMCS, the associated VMCS pointer, and the VMCS region. It must also not assume the state of persistency for VMCS regions in memory or cache.

Before entering VMX operation, the host VMM allocates a VMXON region. A VMM can host several virtual machines and have many VMCSs active under its management. A unique VMCS region is required for each virtual machine; a VMXON region is required for the VMM itself.

A VMM determines the VMCS region size by reading IA32\_VMX\_BASIC MSR; it creates VMCS regions of this size using a 4-KByte-aligned area of physical memory. Each VMCS region needs to be initialized with a VMCS revision identifier (at byte offset 0) identical to the revision reported by the processor in the VMX capability MSR.

#### NOTE

Software must not read or write directly to the VMCS data region as the format is not architecturally defined. Consequently, Intel recommends that the VMM remove any linear-address mappings to VMCS regions before loading.

System software does not need to do special preparation to the VMXON region before entering into VMX operation. The address of the VMXON region for the VMM is provided as an operand to VMXON instruction. Once in VMX root operation, the VMM needs to prepare data fields in the VMCS that control the execution of a VM upon a VM entry. The VMM can make a VMCS the current VMCS by using the VMPTRLD instruction. VMCS data fields must be read or written only through VMREAD and VMWRITE commands respectively.

Every component of the VMCS is identified by a 32-bit encoding that is provided as an operand to VMREAD and VMWRITE. Appendix B provides the encodings. A VMM must properly initialize all fields in a VMCS before using the current VMCS for VM entry.

A VMCS is referred to as a controlling VMCS if it is the current VMCS on a logical processor in VMX non-root operation. A current VMCS for controlling a logical processor in VMX non-root operation may be referred to as a working VMCS if the logical processor is not in VMX non-root operation. The relationship of active, current (i.e. working) and controlling VMCS during VMX operation is shown in Figure 31-1.

#### NOTE

As noted in Section 24.1, the processor may optimize VMX operation by maintaining the state of an active VMCS (one for which VMPTRLD has been executed) on the processor. Before relinquishing control to other system software that may, without informing the VMM, remove power from the processor (e.g., for transitions to S3 or S4) or leave VMX operation, a VMM must VMCLEAR all active VMCSs. This ensures that all VMCS data cached by the processor are flushed to memory and that no other software can corrupt the current VMM's VMCS data. It is also recommended that the VMM execute VMXOFF after such executions of VMCLEAR.

The VMX capability MSR IA32\_VMX\_BASIC reports the memory type used by the processor for accessing a VMCS or any data structures referenced through pointers in the VMCS. Software must maintain the VMCS structures in cache-coherent memory. Software must always map the regions hosting the I/O bitmaps, MSR bitmaps, VM-exit MSR-store area, VM-exit MSR-load area, and VM-entry MSR-load area to the write-back (WB) memory type. Mapping these regions to uncacheable (UC) memory type is supported, but strongly discouraged due to negative impact on performance.

### 31.4 USING VMX INSTRUCTIONS

VMX instructions are allowed only in VMX root operation. An attempt to execute a VMX instruction in VMX non-root operation causes a VM exit.

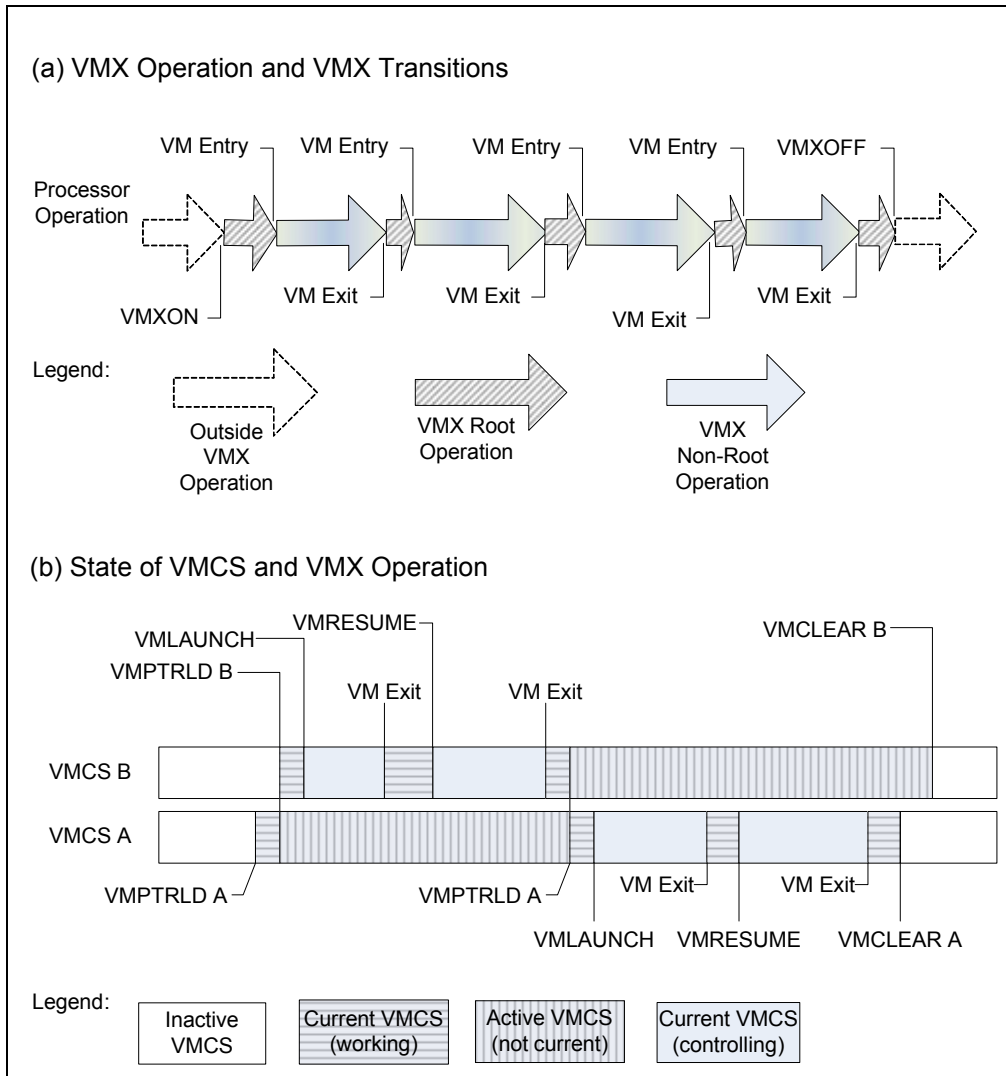

Figure 31-1. VMX Transitions and States of VMCS in a Logical Processor

Processors perform various checks while executing any VMX instruction. They follow well-defined error handling on failures. VMX instruction execution failures detected before loading of a guest state are handled by the processor as follows:

- If the working-VMCS pointer is not valid, the instruction fails by setting RFLAGS.CF to 1.
- If the working-VMCS pointer is valid, RFLAGS.ZF is set to 1 and the proper error-code is saved in the VM-instruction error field of the working-VMCS.

Software is required to check RFLAGS.CF and RFLAGS.ZF to determine the success or failure of VMX instruction executions.

The following items provide details regarding use of the VM-entry instructions (VMLAUNCH and VMRESUME):

- If the working-VMCS pointer is valid, the state of the working VMCS may cause the VM-entry instruction to fail. RFLAGS.ZF is set to 1 and one of the following values is saved in the VM-instruction error field:
  - 4: VMLAUNCH with non-clear VMCS.  
If this error occurs, software can avoid the error by executing VMRESUME.
  - 5: VMRESUME with non-launched VMCS.  
If this error occurs, software can avoid the error by executing VMLAUNCH.

- 6: VMRESUME after VMXOFF.<sup>1</sup>

If this error occurs, software can avoid the error by executing the following sequence of instructions:

```
VMPTRST <working-VMCS pointer>
VMCLEAR <working-VMCS pointer>
VMPTRLD <working-VMCS pointer>
VMLAUNCH
```

(VMPTRST may not be necessary if software already knows the working-VMCS pointer.)

- If none of the above errors occur, the processor checks on the VMX controls and host-state area. If any of these checks fail, the VM-entry instruction fails. RFLAGS.ZF is set to 1 and either 7 (VM entry with invalid control field(s)) or 8 (VM entry with invalid host-state field(s)) is saved in the VM-instruction error field.
- After a VM-entry instruction (VMRESUME or VMLAUNCH) successfully completes the general checks and checks on VMX controls and the host-state area (see Section 26.2), any errors encountered while loading of guest-state (due to bad guest-state or bad MSR loading) causes the processor to load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 31.7).

This failure behavior differs from that of VM exits in that no guest-state is saved to the guest-state area. A VMM can detect its VM-exit handler was invoked by such a failure by checking bit 31 (for 1) in the exit reason field of the working VMCS and further identify the failure by using the exit qualification field.

See Chapter 26 for more details about the VM-entry instructions.

## 31.5 VMM SETUP & TEAR DOWN

VMMs need to ensure that the processor is running in protected mode with paging before entering VMX operation. The following list describes the minimal steps required to enter VMX root operation with a VMM running at CPL = 0.

- Check VMX support in processor using CPUID.
- Determine the VMX capabilities supported by the processor through the VMX capability MSRs. See Section 31.5.1 and Appendix A.
- Create a VMXON region in non-pageable memory of a size specified by IA32\_VMX\_BASIC MSR and aligned to a 4-KByte boundary. Software should read the capability MSRs to determine width of the physical addresses that may be used for the VMXON region and ensure the entire VMXON region can be addressed by addresses with that width. Also, software must ensure that the VMXON region is hosted in cache-coherent memory.
- Initialize the version identifier in the VMXON region (the first 31 bits) with the VMCS revision identifier reported by capability MSRs. Clear bit 31 of the first 4 bytes of the VMXON region.
- Ensure the current processor operating mode meets the required CR0 fixed bits (CR0.PE = 1, CR0.PG = 1). Other required CR0 fixed bits can be detected through the IA32\_VMX\_CR0\_FIXED0 and IA32\_VMX\_CR0\_FIXED1 MSRs.
- Enable VMX operation by setting CR4.VMXE = 1. Ensure the resultant CR4 value supports all the CR4 fixed bits reported in the IA32\_VMX\_CR4\_FIXED0 and IA32\_VMX\_CR4\_FIXED1 MSRs.
- Ensure that the IA32\_FEATURE\_CONTROL MSR (MSR index 3AH) has been properly programmed and that its lock bit is set (Bit 0 = 1). This MSR is generally configured by the BIOS using WRMSR.
- Execute VMXON with the physical address of the VMXON region as the operand. Check successful execution of VMXON by checking if RFLAGS.CF = 0.

Upon successful execution of the steps above, the processor is in VMX root operation.

A VMM executing in VMX root operation and CPL = 0 leaves VMX operation by executing VMXOFF and verifies successful execution by checking if RFLAGS.CF = 0 and RFLAGS.ZF = 0.

If an SMM monitor has been configured to service SMIs while in VMX operation (see Section 34.15), the SMM monitor needs to be torn down before the executive monitor can leave VMX operation (see Section 34.15.7). VMXOFF fails for the executive monitor (a VMM that entered VMX operation by way of issuing VMXON) if SMM monitor is configured.

---

1. Earlier versions of this manual described this error as “VMRESUME with a corrupted VMCS”.

### 31.5.1 Algorithms for Determining VMX Capabilities

As noted earlier, a VMM should determine the VMX capabilities supported by the processor by reading the VMX capability MSR. The architecture for these MSRs is detailed in Appendix A.

As noted in Chapter 26, “VM Entries”, certain VMX controls are reserved and must be set to a specific value (0 or 1) determined by the processor. The specific value to which a reserved control must be set is its **default setting**. Most controls have a default setting of 0; Appendix A.2 identifies those controls that have a default setting of 1. The term **default1** describes the class of controls whose default setting is 1. These are controls in this class from the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. There are no secondary processor-based VM-execution controls in the default1 class.

Future processors may define new functionality for one or more reserved controls. Such processors would allow each newly defined control to be set either to 0 or to 1. Software that does not desire a control’s new functionality should set the control to its default setting.

The capability MSRs IA32\_VMX\_PINBASED\_CTLX, IA32\_VMX\_PROCBASED\_CTLX, IA32\_VMX\_EXIT\_CTLX, and IA32\_VMX\_ENTRY\_CTLX report, respectively, on the allowed settings of most of the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. However, they will always report that any control in the default1 class must be 1. If a logical processor allows any control in the default1 class to be 0, it indicates this fact by returning 1 for the value of bit 55 of the IA32\_VMX\_BASIC MSR. If this bit is 1, the logical processor supports the capability MSRs IA32\_VMX\_TRUE\_PINBASED\_CTLX, IA32\_VMX\_TRUE\_PROCBASED\_CTLX, IA32\_VMX\_TRUE\_EXIT\_CTLX, and IA32\_VMX\_TRUE\_ENTRY\_CTLX. These capability MSRs report, respectively, on the allowed settings of all of the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls.

Software may use one of the following high-level algorithms to determine the correct default control settings:<sup>1</sup>

1. The following algorithm does not use the details given in Appendix A.2:
  - a. Ignore bit 55 of the IA32\_VMX\_BASIC MSR.
  - b. Using RDMSR, read the VMX capability MSRs IA32\_VMX\_PINBASED\_CTLX, IA32\_VMX\_PROCBASED\_CTLX, IA32\_VMX\_EXIT\_CTLX, and IA32\_VMX\_ENTRY\_CTLX.
  - c. Set the VMX controls as follows:
    - i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.
    - ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control’s meaning is known to the VMM; then set the control based on functionality desired.
    - iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control’s meaning is not known to the VMM; then set the control to 0.

A VMM using this algorithm will set to 1 all controls in the default1 class (in step (c)(i)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. However, such a VMM will not be able to use the new features enabled by the 0-setting of such controls. For that reason, this algorithm is not recommended.
2. The following algorithm uses the details given in Appendix A.2. This algorithm requires software to know the identity of the controls in the default1 class:
  - a. Using RDMSR, read the IA32\_VMX\_BASIC MSR.
  - b. Use bit 55 of that MSR as follows:
    - i) If bit 55 is 0, use RDMSR to read the VMX capability MSRs IA32\_VMX\_PINBASED\_CTLX, IA32\_VMX\_PROCBASED\_CTLX, IA32\_VMX\_EXIT\_CTLX, and IA32\_VMX\_ENTRY\_CTLX.
    - ii) If bit 55 is 1, use RDMSR to read the VMX capability MSRs IA32\_VMX\_TRUE\_PINBASED\_CTLX, IA32\_VMX\_TRUE\_PROCBASED\_CTLX, IA32\_VMX\_TRUE\_EXIT\_CTLX, and IA32\_VMX\_TRUE\_ENTRY\_CTLX.

---

1. These algorithms apply only to the pin-based VM-execution controls, the primary processor-based VM-execution controls, the VM-exit controls, and the VM-entry controls. Because there are no secondary processor-based VM-execution controls in the default1 class, a VMM can always set to 0 any such control whose meaning is unknown to it.

- c. Set the VMX controls as follows:
  - i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.
  - ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.
  - iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the control is not in the default1 class; then set the control to 0.
  - iv) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the control is in the default1 class; then set the control to 1.

A VMM using this algorithm will set to 1 all controls in default1 class whose meaning it does not know (either in step (c)(i) or step (c)(iv)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. Unlike a VMM using Algorithm 1, a VMM using Algorithm 2 will be able to use the new features enabled by the 0-setting of such controls.

- 3. The following algorithm uses the details given in Appendix A.2. This algorithm does not require software to know the identity of the controls in the default1 class:
  - a. Using RDMSR, read the VMX capability MSRs IA32\_VMX\_BASIC, IA32\_VMX\_PINBASED\_CTLs, IA32\_VMX\_PROCBASED\_CTLs, IA32\_VMX\_EXIT\_CTLs, and IA32\_VMX\_ENTRY\_CTLs.
  - b. If bit 55 of the IA32\_VMX\_BASIC MSR is 0, set the VMX controls as follows:
    - i) If the relevant VMX capability MSR reports that a control has a single setting, use that setting.
    - ii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.
    - iii) If (1) the relevant VMX capability MSR reports that a control can be set to 0 or 1; and (2) the control's meaning is not known to the VMM; then set the control to 0.
  - c. If bit 55 of the IA32\_VMX\_BASIC MSR is 1, use RDMSR to read the VMX capability MSRs IA32\_VMX\_TRUE\_PINBASED\_CTLs, IA32\_VMX\_TRUE\_PROCBASED\_CTLs, IA32\_VMX\_TRUE\_EXIT\_CTLs, and IA32\_VMX\_TRUE\_ENTRY\_CTLs. Set the VMX controls as follows:
    - i) If the relevant VMX capability MSR just read reports that a control has a single setting, use that setting.
    - ii) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; and (2) the control's meaning is known to the VMM; then set the control based on functionality desired.
    - iii) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the relevant VMX capability MSR as read in step (a) reports that a control can be set to 0; then set the control to 0.
    - iv) If (1) the relevant VMX capability MSR just read reports that a control can be set to 0 or 1; (2) the control's meaning is not known to the VMM; and (3) the relevant VMX capability MSR as read in step (a) reports that a control must be 1; then set the control to 1.

A VMM using this algorithm will set to 1 all controls in the default1 class whose meaning it does not know (in step (b)(i), step (c)(i), or step (c)(iv)). It will operate correctly even on processors that allow some controls in the default1 class to be 0. Unlike a VMM using Algorithm 1, a VMM using Algorithm 3 will be able to use the new features enabled by the 0-setting of such controls. Unlike a VMM using Algorithm 2, a VMM using Algorithm 3 need not know the identities of the controls in the default1 class.

## 31.6 PREPARATION AND LAUNCHING A VIRTUAL MACHINE

The following list describes the minimal steps required by the VMM to set up and launch a guest VM.

- Create a VMCS region in non-pageable memory of size specified by the VMX capability MSR IA32\_VMX\_BASIC and aligned to 4-KBytes. Software should read the capability MSRs to determine width of the physical addresses that may be used for a VMCS region and ensure the entire VMCS region can be addressed by

addresses with that width. The term “guest-VMCS address” refers to the physical address of the new VMCS region for the following steps.

- Initialize the version identifier in the VMCS (first 31 bits) with the VMCS revision identifier reported by the VMX capability MSR IA32\_VMX\_BASIC. Clear bit 31 of the first 4 bytes of the VMCS region.
- Execute the VMCLEAR instruction by supplying the guest-VMCS address. This will initialize the new VMCS region in memory and set the launch state of the VMCS to “clear”. This action also invalidates the working-VMCS pointer register to FFFFFFFF\_FFFFFFFFH. Software should verify successful execution of VMCLEAR by checking if RFLAGS.CF = 0 and RFLAGS.ZF = 0.
- Execute the VMPTRLD instruction by supplying the guest-VMCS address. This initializes the working-VMCS pointer with the new VMCS region’s physical address.
- Issue a sequence of VMWRITES to initialize various host-state area fields in the working VMCS. The initialization sets up the context and entry-points to the VMM upon subsequent VM exits from the guest. Host-state fields include control registers (CR0, CR3 and CR4), selector fields for the segment registers (CS, SS, DS, ES, FS, GS and TR), and base-address fields (for FS, GS, TR, GDTR and IDTR; RSP, RIP and the MSRs that control fast system calls).

Chapter 27 describes the host-state consistency checking done by the processor for VM entries. The VMM is required to set up host-state that comply with these consistency checks. For example, VMX requires the host-area to have a task register (TR) selector with TI and RPL fields set to 0 and pointing to a valid TSS.

- Use VMWRITES to set up the various VM-exit control fields, VM-entry control fields, and VM-execution control fields in the VMCS. Care should be taken to make sure the settings of individual fields match the allowed 0 and 1 settings for the respective controls as reported by the VMX capability MSRs (see Appendix A). Any settings inconsistent with the settings reported by the capability MSRs will cause VM entries to fail.
- Use VMWRITE to initialize various guest-state area fields in the working VMCS. This sets up the context and entry-point for guest execution upon VM entry. Chapter 27 describes the guest-state loading and checking done by the processor for VM entries to protected and virtual-8086 guest execution.
- The VMM is required to set up guest-state that complies with these consistency checks:
  - If the VMM design requires the initial VM launch to cause guest software (typically the guest virtual BIOS) execution from the guest’s reset vector, it may need to initialize the guest execution state to reflect the state of a physical processor at power-on reset (described in Chapter 9, *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*).
  - The VMM may need to initialize additional guest execution state that is not captured in the VMCS guest-state area by loading them directly on the respective processor registers. Examples include general purpose registers, the CR2 control register, debug registers, floating point registers and so forth. VMM may support lazy loading of FPU, MMX, SSE, and SSE2 states with CR0.TS = 1 (described in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A*).
- Execute VMLAUNCH to launch the guest VM. If VMLAUNCH fails due to any consistency checks before guest-state loading, RFLAGS.CF or RFLAGS.ZF will be set and the VM-instruction error field (see Section 24.9.5) will contain the error-code. If guest-state consistency checks fail upon guest-state loading, the processor loads state from the host-state area as if a VM exit had occurred (see Section 31.6).

VMLAUNCH updates the controlling-VMCS pointer with the working-VMCS pointer and saves the old value of controlling-VMCS as the parent pointer. In addition, the launch state of the guest VMCS is changed to “launched” from “clear”. Any programmed exit conditions will cause the guest to VM exit to the VMM. The VMM should execute VMRESUME instruction for subsequent VM entries to guests in a “launched” state.

## 31.7 HANDLING OF VM EXITS

This section provides examples of software steps involved in a VMM’s handling of VM-exit conditions:

- Determine the exit reason through a VMREAD of the exit-reason field in the working-VMCS. Appendix C describes exit reasons and their encodings.
- VMREAD the exit-qualification from the VMCS if the exit-reason field provides a valid qualification. The exit-qualification field provides additional details on the VM-exit condition. For example, in case of page faults, the exit-qualification field provides the guest linear address that caused the page fault.

- Depending on the exit reason, fetch other relevant fields from the VMCS. Appendix C lists the various exit reasons.
- Handle the VM-exit condition appropriately in the VMM. This may involve the VMM emulating one or more guest instructions, programming the underlying host hardware resources, and then re-entering the VM to continue execution.

### 31.7.1 Handling VM Exits Due to Exceptions

As noted in Section 25.2, an exception causes a VM exit if the bit corresponding to the exception's vector is set in the exception bitmap. (For page faults, the error code also determines whether a VM exit occurs.) This section provides some guidelines of how a VMM might handle such exceptions.

Exceptions result when a logical processor encounters an unusual condition that software may not have expected. When guest software encounters an exception, it may be the case that the condition was caused by the guest software. For example, a guest application may attempt to access a page that is restricted to supervisor access. Alternatively, the condition causing the exception may have been established by the VMM. For example, a guest OS may attempt to access a page that the VMM has chosen to make not present.

When the condition causing an exception was established by guest software, the VMM may choose to **reflect** the exception to guest software. When the condition was established by the VMM itself, the VMM may choose to **resume** guest software after removing the condition.

#### 31.7.1.1 Reflecting Exceptions to Guest Software

If the VMM determines that a VM exit was caused by an exception due to a condition established by guest software, it may reflect that exception to guest software. The VMM would cause the exception to be delivered to guest software, where it can be handled as it would be if the guest were running on a physical machine. This section describes how that may be done.

In general, the VMM can deliver the exception to guest software using VM-entry event injection as described in Section 26.5. The VMM can copy (using VMREAD and VMWRITE) the contents of the VM-exit interruption-information field (which is valid, since the VM exit was caused by an exception) to the VM-entry interruption-information field (which, if valid, will cause the exception to be delivered as part of the next VM entry). The VMM would also copy the contents of the VM-exit interruption error-code field to the VM-entry exception error-code field; this need not be done if bit 11 (error code valid) is clear in the VM-exit interruption-information field. After this, the VMM can execute VMRESUME.

The following items provide details that may qualify the general approach:

- Care should be taken to ensure that reserved bits 30:12 in the VM-entry interruption-information field are 0. In particular, some VM exits may set bit 12 in the VM-exit interruption-information field to indicate NMI unblocking due to IRET. If this bit is copied as 1 into the VM-entry interruption-information field, the next VM entry will fail because that bit should be 0.
- Bit 31 (valid) of the IDT-vectoring information field indicates, if set, that the exception causing the VM exit occurred while another event was being delivered to guest software. If this is the case, it may not be appropriate simply to reflect that exception to guest software. To provide proper virtualization of the exception architecture, a VMM should handle nested events as a physical processor would. Processor handling is described in Chapter 6, "Interrupt 8—Double Fault Exception (#DF)" in *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*.
  - The VMM should reflect the exception causing the VM exit to guest software in any of the following cases:
    - The value of bits 10:8 (interruption type) of the IDT-vectoring information field is anything other than 3 (hardware exception).
    - The value of bits 7:0 (vector) of the IDT-vectoring information field indicates a benign exception (1, 2, 3, 4, 5, 6, 7, 9, 16, 17, 18, or 19).
    - The value of bits 7:0 (vector) of the VM-exit interruption-information field indicates a benign exception.

- The value of bits 7:0 of the IDT-vectoring information field indicates a contributory exception (0, 10, 11, 12, or 13) and the value of bits 7:0 of the VM-exit interruption-information field indicates a page fault (14).
  - If the value of bits 10:8 of the IDT-vectoring information field is 3 (hardware exception), the VMM should reflect a double-fault exception to guest software in any of the following cases:
    - The value of bits 7:0 of the IDT-vectoring information field and the value of bits 7:0 of the VM-exit interruption-information field each indicates a contributory exception.
    - The value of bits 7:0 of the IDT-vectoring information field indicates a page fault and the value of bits 7:0 of the VM-exit interruption-information field indicates either a contributory exception or a page fault.
- A VMM can reflect a double-fault exception to guest software by setting the VM-entry interruption-information and VM-entry exception error-code fields as follows:
- Set bits 7:0 (vector) of the VM-entry interruption-information field to 8 (#DF).
  - Set bits 10:8 (interruption type) of the VM-entry interruption-information field to 3 (hardware exception).
  - Set bit 11 (deliver error code) of the VM-entry interruption-information field to 1.
  - Clear bits 30:12 (reserved) of VM-entry interruption-information field.
  - Set bit 31 (valid) of VM-entry interruption-information field.
  - Set the VM-entry exception error-code field to zero.
- If the value of bits 10:8 of the IDT-vectoring information field is 3 (hardware exception) and the value of bits 7:0 is 8 (#DF), guest software would have encountered a triple fault. Event injection should not be used in this case. The VMM may choose to terminate the guest, or it might choose to enter the guest in the shutdown activity state.

### 31.7.1.2 Resuming Guest Software after Handling an Exception

If the VMM determines that a VM exit was caused by an exception due to a condition established by the VMM itself, it may choose to resume guest software after removing the condition. The approach for removing the condition may be specific to the VMM's software architecture, and algorithms. This section describes how guest software may be resumed after removing the condition.

In general, the VMM can resume guest software simply by executing VMRESUME. The following items provide details of cases that may require special handling:

- If the "NMI exiting" VM-execution control is 0, bit 12 of the VM-exit interruption-information field indicates that the VM exit was due to a fault encountered during an execution of the IRET instruction that unblocked non-maskable interrupts (NMIs). In particular, it provides this indication if the following are both true:
    - Bit 31 (valid) in the IDT-vectoring information field is 0.
    - The value of bits 7:0 (vector) of the VM-exit interruption-information field is not 8 (the VM exit is not due to a double-fault exception).
- If both are true and bit 12 of the VM-exit interruption-information field is 1, NMIs were blocked before guest software executed the IRET instruction that caused the fault that caused the VM exit. The VMM should set bit 3 (blocking by NMI) in the interruptibility-state field (using VMREAD and VMWRITE) before resuming guest software.
- If the "virtual NMIs" VM-execution control is 1, bit 12 of the VM-exit interruption-information field indicates that the VM exit was due to a fault encountered during an execution of the IRET instruction that removed virtual-NMI blocking. In particular, it provides this indication if the following are both true:
    - Bit 31 (valid) in the IDT-vectoring information field is 0.
    - The value of bits 7:0 (vector) of the VM-exit interruption-information field is not 8 (the VM exit is not due to a double-fault exception).

If both are true and bit 12 of the VM-exit interruption-information field is 1, there was virtual-NMI blocking before guest software executed the IRET instruction that caused the fault that caused the VM exit. The VMM

should set bit 3 (blocking by NMI) in the interruptibility-state field (using VMREAD and VMWRITE) before resuming guest software.

- Bit 31 (valid) of the IDT-vectoring information field indicates, if set, that the exception causing the VM exit occurred while another event was being delivered to guest software. The VMM should ensure that the other event is delivered when guest software is resumed. It can do so using the VM-entry event injection described in Section 26.5 and detailed in the following paragraphs:
  - The VMM can copy (using VMREAD and VMWRITE) the contents of the IDT-vectoring information field (which is presumed valid) to the VM-entry interruption-information field (which, if valid, will cause the exception to be delivered as part of the next VM entry).
    - The VMM should ensure that reserved bits 30:12 in the VM-entry interruption-information field are 0. In particular, the value of bit 12 in the IDT-vectoring information field is undefined after all VM exits. If this bit is copied as 1 into the VM-entry interruption-information field, the next VM entry will fail because the bit should be 0.
    - If the “virtual NMIs” VM-execution control is 1 and the value of bits 10:8 (interruption type) in the IDT-vectoring information field is 2 (indicating NMI), the VM exit occurred during delivery of an NMI that had been injected as part of the previous VM entry. In this case, bit 3 (blocking by NMI) will be 1 in the interruptibility-state field in the VMCS. The VMM should clear this bit; otherwise, the next VM entry will fail (see Section 26.3.1.5).
  - The VMM can also copy the contents of the IDT-vectoring error-code field to the VM-entry exception error-code field. This need not be done if bit 11 (error code valid) is clear in the IDT-vectoring information field.
  - The VMM can also copy the contents of the VM-exit instruction-length field to the VM-entry instruction-length field. This need be done only if bits 10:8 (interruption type) in the IDT-vectoring information field indicate either software interrupt, privileged software exception, or software exception.

## 31.8 MULTI-PROCESSOR CONSIDERATIONS

The most common VMM design will be the symmetric VMM. This type of VMM runs the same VMM binary on all logical processors. Like a symmetric operating system, the symmetric VMM is written to ensure all critical data is updated by only one processor at a time, IO devices are accessed sequentially, and so forth. Asymmetric VMM designs are possible. For example, an asymmetric VMM may run its scheduler on one processor and run just enough of the VMM on other processors to allow the correct execution of guest VMs. The remainder of this section focuses on the multi-processor considerations for a symmetric VMM.

A symmetric VMM design does not preclude asymmetry in its operations. For example, a symmetric VMM can support asymmetric allocation of logical processor resources to guests. Multiple logical processors can be brought into a single guest environment to support an MP-aware guest OS. Because an active VMCS can not control more than one logical processor simultaneously, a symmetric VMM must make copies of its VMCS to control the VM allocated to support an MP-aware guest OS. Care must be taken when accessing data structures shared between these VMCSs. See Section 31.8.4.

Although it may be easier to develop a VMM that assumes a fully-symmetric view of hardware capabilities (with all processors supporting the same processor feature sets, including the same revision of VMX), there are advantages in developing a VMM that comprehends different levels of VMX capability (reported by VMX capability MSRs). One possible advantage of such an approach could be that an existing software installation (VMM and guest software stack) could continue to run without requiring software upgrades to the VMM, when the software installation is upgraded to run on hardware with enhancements in the processor’s VMX capabilities. Another advantage could be that a single software installation image, consisting of a VMM and guests, could be deployed to multiple hardware platforms with varying VMX capabilities. In such cases, the VMM could fall back to a common subset of VMX features supported by all VMX revisions, or choose to understand the asymmetry of the VMX capabilities and assign VMs accordingly.

This section outlines some of the considerations to keep in mind when developing an MP-aware VMM.

### 31.8.1 Initialization

Before enabling VMX, an MP-aware VMM must check to make sure that all processors in the system are compatible and support features required. This can be done by:

- Checking the CPUID on each logical processor to ensure VMX is supported and that the overall feature set of each logical processor is compatible.
- Checking VMCS revision identifiers on each logical processor.
- Checking each of the “allowed-1” or “allowed-0” fields of the VMX capability MSR’s on each processor.

### 31.8.2 Moving a VMCS Between Processors

An MP-aware VMM is free to assign any logical processor to a VM. But for performance considerations, moving a guest VMCS to another logical processor is slower than resuming that guest VMCS on the same logical processor. Certain VMX performance features (such as caching of portions of the VMCS in the processor) are optimized for a guest VMCS that runs on the same logical processor.

The reasons are:

- To restart a guest on the same logical processor, a VMM can use VMRESUME. VMRESUME is expected to be faster than VMLAUNCH in general.
- To migrate a VMCS to another logical processor, a VMM must use the sequence of VMCLEAR, VMPTRLD and VMLAUNCH.
- Operations involving VMCLEAR can impact performance negatively. See Section 24.11.3.

A VMM scheduler should make an effort to schedule a guest VMCS to run on the logical processor where it last ran. Such a scheduler might also benefit from doing lazy VMCLEARs (that is: performing a VMCLEAR on a VMCS only when the scheduler knows the VMCS is being moved to a new logical processor). The remainder of this section describes the steps a VMM must take to move a VMCS from one processor to another.

A VMM must check the VMCS revision identifier in the VMX capability MSR IA32\_VMX\_BASIC to determine if the VMCS regions are identical between all logical processors. If the VMCS regions are identical (same revision ID) the following sequence can be used to move or copy the VMCS from one logical processor to another:

- Perform a VMCLEAR operation on the source logical processor. This ensures that all VMCS data that may be cached by the processor are flushed to memory.
- Copy the VMCS region from one memory location to another location. This is an optional step assuming the VMM wishes to relocate the VMCS or move the VMCS to another system.
- Perform a VMPTRLD of the physical address of VMCS region on the destination processor to establish its current VMCS pointer.

If the revision identifiers are different, each field must be copied to an intermediate structure using individual reads (VMREAD) from the source fields and writes (VMWRITE) to destination fields. Care must be taken on fields that are hard-wired to certain values on some processor implementations.

### 31.8.3 Paired Index-Data Registers

A VMM may need to virtualize hardware that is visible to software using paired index-data registers. Paired index-data register interfaces, such as those used in PCI (CF8, CFC), require special treatment in cases where a VM performing writes to these pairs can be moved during execution. In this case, the index (e.g. CF8) should be part of the virtualized state. If the VM is moved during execution, writes to the index should be redone so subsequent data reads/writes go to the right location.

### 31.8.4 External Data Structures

Certain fields in the VMCS point to external data structures (for example: the MSR bitmap, the I/O bitmaps). If a logical processor is in VMX non-root operation, none of the external structures referenced by that logical

processor's current VMCS should be modified by any logical processor or DMA. Before updating one of these structures, the VMM must ensure that no logical processor whose current VMCS references the structure is in VMX non-root operation.

If a VMM uses multiple VMCS with each VMCS using separate external structures, and these structures must be kept synchronized, the VMM must apply the same care to updating these structures.

### 31.8.5 CPUID Emulation

CPUID reports information that is used by OS and applications to detect hardware features. It also provides multi-threading/multi-core configuration information. For example, MP-aware OSs rely on data reported by CPUID to discover the topology of logical processors in a platform (see Section 8.9, "Programming Considerations for Hardware Multi-Threading Capable Processors," in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*).

If a VMM is to support asymmetric allocation of logical processor resources to guest OSs that are MP aware, then the VMM must emulate CPUID for its guests. The emulation of CPUID by the VMM must ensure the guest's view of CPUID leaves are consistent with the logical processor allocation committed by the VMM to each guest OS.

## 31.9 32-BIT AND 64-BIT GUEST ENVIRONMENTS

For the most part, extensions provided by VMX to support virtualization are orthogonal to the extensions provided by Intel 64 architecture. There are considerations that impact VMM designs. These are described in the following subsections.

### 31.9.1 Operating Modes of Guest Environments

For Intel 64 processors, VMX operation supports host and guest environments that run in IA-32e mode or without IA-32e mode. VMX operation also supports host and guest environments on IA-32 processors.

A VMM entering VMX operation while IA-32e mode is active is considered to be an IA-32e mode host. A VMM entering VMX operation while IA-32e mode is not activated or not available is referred to as a 32-bit VMM. The type of guest operations such VMMs support are summarized in Table 31-1.

**Table 31-1. Operating Modes for Host and Guest Environments**

Capability	Guest Operation in IA-32e mode	Guest Operation Not Requiring IA-32e Mode
IA-32e mode VMM	Yes	Yes
32-bit VMM	Not supported	Yes

A VM exit may occur to an IA-32e mode guest in either 64-bit sub-mode or compatibility sub-mode of IA-32e mode. VMMs may resume guests in either mode. The sub-mode in which an IA-32e mode guest resumes VMX non-root operation is determined by the attributes of the code segment which experienced the VM exit. If CS.L = 1, the guest is executing in 64-bit mode; if CS.L = 0, the guest is executing in compatibility mode (see Section 31.9.5).

Not all of an IA-32e mode VMM must run in 64-bit mode. While some parts of an IA-32e mode VMM must run in 64-bit mode, there are only a few restrictions preventing a VMM from executing in compatibility mode. The most notable restriction is that most VMX instructions cause exceptions when executed in compatibility mode.

### 31.9.2 Handling Widths of VMCS Fields

Individual VMCS control fields must be accessed using VMREAD or VMWRITE instructions. Outside of 64-Bit mode, VMREAD and VMWRITE operate on 32 bits of data. The widths of VMCS control fields may vary depending on whether a processor supports Intel 64 architecture.

Many VMCS fields are architected to extend transparently on processors supporting Intel 64 architecture (64 bits on processors that support Intel 64 architecture, 32 bits on processors that do not). Some VMCS fields are 64-bits wide regardless of whether the processor supports Intel 64 architecture or is in IA-32e mode.

### 31.9.2.1 Natural-Width VMCS Fields

Many VMCS fields operate using natural width. Such fields return (on reads) and set (on writes) 32-bits when operating in 32-bit mode and 64-bits when operating in 64-bit mode. For the most part, these fields return the naturally expected data widths. The “Guest RIP” field in the VMCS guest-state area is an example of this type of field.

### 31.9.2.2 64-Bit VMCS Fields

Unlike natural width fields, these fields are fixed to 64-bit width on all processors. When in 64-bit mode, reads of these fields return 64-bit wide data and writes to these fields write 64-bits. When outside of 64-bit mode, reads of these fields return the low 32-bits and writes to these fields write the low 32-bits and zero the upper 32-bits. Should a non-IA-32e mode host require access to the upper 32-bits of these fields, a separate VMCS encoding is used when issuing VMREAD/VMWRITE instructions.

The VMCS control field “MSR bitmap address” (which contains the physical address of a region of memory which specifies which MSR accesses should generate VM-exits) is an example of this type of field. Specifying encoding 00002004H to VMREAD returns the lower 32-bits to non-IA-32e mode hosts and returns 64-bits to 64-bit hosts. The separate encoding 00002005H returns only the upper 32-bits.

## 31.9.3 IA-32e Mode Hosts

An IA-32e mode host is required to support 64-bit guest environments. Because activating IA-32e mode currently requires that paging be disabled temporarily and VMX entry requires paging to be enabled, IA-32e mode must be enabled before entering VMX operation. For this reason, it is not possible to toggle in and out of IA-32e mode in a VMM.

Section 31.5 describes the steps required to launch a VMM. An IA-32e mode host is also required to set the “host address-space size” VMCS VM-exit control to 1. The value of this control is then loaded in the IA32\_EFER.LME/LMA and CS.L bits on each VM exit. This establishes a 64-bit host environment as execution transfers to the VMM entry point. At a minimum, the entry point is required to be in a 64-bit code segment. Subsequently, the VMM can, if it chooses, switch to 32-bit compatibility mode on a code-segment basis (see Section 31.9.1). Note, however, that VMX instructions other than VMCALL and VMFUNC are not supported in compatibility mode; they generate an invalid opcode exception if used.

The following VMCS controls determine the value of IA32\_EFER when a VM exit occurs: the “host address-space size” control (described above), the “load IA32\_EFER” VM-exit control, the “VM-exit MSR-load count,” and the “VM-exit MSR-load address” (see Section 27.3).

If the “load IA32\_EFER” VM-exit control is 1, the value of the LME and LMA bits in the IA32\_EFER field in the host-state area must be the value of the “host address-space size” VM-exit control.

The loading of IA32\_EFER.LME/LMA and CS.L bits established by the “host address-space size” control precede any loading of the IA32\_EFER MSR due from the VM-exit MSR-load area. If IA32\_EFER is specified in the VM-exit MSR-load area, the value of the LME bit in the load image of IA32\_EFER should match the setting of the “host address-space size” control. Otherwise the attempt to modify the LME bit (while paging is enabled) will lead to a VMX-abort. However, IA32\_EFER.LMA is always set by the processor to equal IA32\_EFER.LME & CR0.PG; the value specified for LMA in the load image of the IA32\_EFER MSR is ignored. For these and performance reasons, VMM writers may choose to not use the VM-exit/entry MSR-load/save areas for IA32\_EFER.

On a VMM teardown, VMX operation should be exited before deactivating IA-32e mode if the latter is required.

## 31.9.4 IA-32e Mode Guests

A 32-bit guest can be launched by either IA-32e-mode hosts or non-IA-32e-mode hosts. A 64-bit guests can only be launched by a IA-32e-mode host.

In addition to the steps outlined in Section 31.6, VMM writers need to:

- Set the “IA-32e-mode guest” VM-entry control to 1 in the VMCS to assure VM-entry (VMLAUNCH or VMRESUME) will establish a 64-bit (or 32-bit compatible) guest operating environment.
- Enable paging (CR0.PG) and PAE mode (CR4.PAE) to assure VM-entry to a 64-bit guest will succeed.
- Ensure that the host to be in IA-32e mode (the IA32\_EFER.LMA must be set to 1) and the setting of the VM-exit “host address-space size” control bit in the VMCS must also be set to 1.

If each of the above conditions holds true, then VM-entry will copy the value of the VM-entry “IA-32e-mode guest” control bit into the guests IA32\_EFER.LME bit, which will result in subsequent activation of IA-32e mode. If any of the above conditions is false, the VM-entry will fail and load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 26.7).

The following VMCS controls determine the value of IA32\_EFER on a VM entry: the “IA-32e-mode guest” VM-entry control (described above), the “load IA32\_EFER” VM-entry control, the “VM-entry MSR-load count,” and the “VM-entry MSR-load address” (see Section 26.4).

If the “load IA32\_EFER” VM-entry control is 1, the value of the LME and LMA bits in the IA32\_EFER field in the guest-state area must be the value of the “IA-32e-mode guest” VM-entry control. Otherwise, the VM entry fails.

The loading of IA32\_EFER.LME bit (described above) precedes any loading of the IA32\_EFER MSR from the VM-entry MSR-load area of the VMCS. If loading of IA32\_EFER is specified in the VM-entry MSR-load area, the value of the LME bit in the load image should be match the setting of the “IA-32e-mode guest” VM-entry control. Otherwise, the attempt to modify the LME bit (while paging is enabled) results in a failed VM entry. However, IA32\_EFER.LMA is always set by the processor to equal IA32\_EFER.LME & CR0.PG; the value specified for LMA in the load image of the IA32\_EFER MSR is ignored. For these and performance reasons, VMM writers may choose to not use the VM-exit/entry MSR-load/save areas for IA32\_EFER MSR.

Note that the VMM can control the processor’s architectural state when transferring control to a VM. VMM writers may choose to launch guests in protected mode and subsequently allow the guest to activate IA-32e mode or they may allow guests to toggle in and out of IA-32e mode. In this case, the VMM should require VM exit on accesses to the IA32\_EFER MSR to detect changes in the operating mode and modify the VM-entry “IA-32e-mode guest” control accordingly.

A VMM should save/restore the extended (full 64-bit) contents of the guest general-purpose registers, the new general-purpose registers (R8-R15) and the SIMD registers introduced in 64-bit mode should it need to modify these upon VM exit.

### 31.9.5 32-Bit Guests

To launch or resume a 32-bit guest, VMM writers can follow the steps outlined in Section 31.6, making sure that the “IA-32e-mode guest” VM-entry control bit is set to 0. Then the “IA-32e-mode guest” control bit is copied into the guest IA32\_EFER.LME bit, establishing IA32\_EFER.LMA as 0.

## 31.10 HANDLING MODEL SPECIFIC REGISTERS

Model specific registers (MSR) provide a wide range of functionality. They affect processor features, control the programming interfaces, or are used in conjunction with specific instructions. As part of processor virtualization, a VMM may wish to protect some or all MSR resources from direct guest access.

VMX operation provides the following features to virtualize processor MSRs.

### 31.10.1 Using VM-Execution Controls

Processor-based VM-execution controls provide two levels of support for handling guest access to processor MSRs using RDMSR and WRMSR:

- **MSR bitmaps:** In VMX implementations that support a 1-setting (see Appendix A) of the user-MSR-bitmaps execution control bit, MSR bitmaps can be used to provide flexibility in managing guest MSR accesses. The

MSR-bitmap-address in the guest VMCS can be programmed by VMM to point to a bitmap region which specifies VM-exit behavior when reading and writing individual MSRs.

MSR bitmaps form a 4-KByte region in physical memory and are required to be aligned to a 4-KByte boundary. The first 1-KByte region manages read control of MSRs in the range 00000000H-00001FFFH; the second 1-KByte region covers read control of MSR addresses in the range C0000000H-C0001FFFH. The bitmaps for write control of these MSRs are located in the 2-KByte region immediately following the read control bitmaps. While the MSR bitmap address is part of VMCS, the MSR bitmaps themselves are not. This implies MSR bitmaps are not accessible through VMREAD and VMWRITE instructions but rather by using ordinary memory writes. Also, they are not specially cached by the processor and may be placed in normal cache-coherent memory by the VMM.

When MSR bitmap addresses are properly programmed and the use-MSR-bitmap control (see Section 24.6.2) is set, the processor consults the associated bit in the appropriate bitmap on guest MSR accesses to the corresponding MSR and causes a VM exit if the bit in the bitmap is set. Otherwise, the access is permitted to proceed. This level of protection may be utilized by VMMs to selectively allow guest access to some MSRs while virtualizing others.

- **Default MSR protection:** If the use-MSR-bitmap control is not set, an attempt by a guest to access any MSR causes a VM exit. This also occurs for any attempt to access an MSR outside the ranges identified above (even if the use-MSR-bitmap control is set).

VM exits due to guest MSR accesses may be identified by the VMM through VM-exit reason codes. The MSR-read exit reason implies guest software attempted to read an MSR protected either by default or through MSR bitmaps. The MSR-write exit reason implies guest software attempting to write a MSR protected through the VM-execution controls. Upon VM exits caused by MSR accesses, the VMM may virtualize the guest MSR access through emulation of RDMSR/WRMSR.

### 31.10.2 Using VM-Exit Controls for MSRs

If a VMM allows its guest to access MSRs directly, the VMM may need to store guest MSR values and load host MSR values for these MSRs on VM exits. This is especially true if the VMM uses the same MSRs while in VMX root operation.

A VMM can use the VM-exit MSR-store-address and the VM-exit MSR-store-count exit control fields (see Section 24.7.2) to manage how MSRs are stored on VM exits. The VM-exit MSR-store-address field contains the physical address (16-byte aligned) of the VM-exit MSR-store area (a table of entries with 16 bytes per entry). Each table entry specifies an MSR whose value needs to be stored on VM exits. The VM-exit MSR-store-count contains the number of entries in the table.

Similarly the VM-exit MSR-load-address and VM-exit MSR-load-count fields point to the location and size of the VM-exit MSR load area. The entries in the VM-exit MSR-load area contain the host expected values of specific MSRs when a VM exit occurs.

Upon VM-exit, bits 127:64 of each entry in the VM-exit MSR-store area is updated with the contents of the MSR indexed by bits 31:0. Also, bits 127:64 of each entry in the VM-exit MSR-load area is updated by loading with values from bits 127:64 the contents of the MSR indexed by bits 31:0.

### 31.10.3 Using VM-Entry Controls for MSRs

A VMM may require specific MSRs to be loaded explicitly on VM entries while launching or resuming guest execution. The VM-entry MSR-load-address and VM-entry MSR-load-count entry control fields determine how MSRs are loaded on VM-entries. The VM-entry MSR-load-address and count fields are similar in structure and function to the VM-exit MSR-load address and count fields, except the MSR loading is done on VM-entries.

### 31.10.4 Handling Special-Case MSRs and Instructions

A number of instructions make use of designated MSRs in their operation. The VMM may need to consider saving the states of those MSRs. Instructions that merit such consideration include SYSENTER/SYSEXIT, SYSCALL/SYSRET, SWAPGS.

### 31.10.4.1 Handling IA32\_EFER MSR

The IA32\_EFER MSR includes bit fields that allow system software to enable processor features. For example: the SCE bit enables SYSCALL/SYSRET and the NXE bit enables the execute-disable bits in the paging-structure entries.

VMX provides hardware support to load the IA32\_EFER MSR on VMX transitions and to save it on VM exits. Because of this, VMM software need not use the RDMSR and WRMSR instruction to give the register different values during host and guest execution.

### 31.10.4.2 Handling the SYSENTER and SYSEXIT Instructions

The SYSENTER and SYSEXIT instructions use three dedicated MSRs (IA32\_SYSENTER\_CS, IA32\_SYSENTER\_ESP and IA32\_SYSENTER\_EIP) to manage fast system calls. These MSRs may be utilized by both the VMM and the guest OS to manage system calls in VMX root operation and VMX non-root operation respectively.

VM entries load these MSRs from fields in the guest-state area of the VMCS. VM exits save the values of these MSRs into those fields and loads the MSRs from fields in the host-state area.

### 31.10.4.3 Handling the SYSCALL and SYSRET Instructions

The SYSCALL/SYSRET instructions are similar to SYSENTER/SYSEXIT but are designed to operate within the context of a 64-bit flat code segment. They are available only in 64-bit mode and only when the SCE bit of the IA32\_EFER MSR is set. SYSCALL/SYSRET invocations can occur from either 32-bit compatibility mode application code or from 64-bit application code. Three related MSR registers (IA32\_STAR, IA32\_LSTAR, IA32\_FMASK) are used in conjunction with fast system calls/returns that use these instructions.

64-Bit hosts which make use of these instructions in the VMM environment will need to save the guest state of the above registers on VM exit, load the host state, and restore the guest state on VM entry. One possible approach is to use the VM-exit MSR-save and MSR-load areas and the VM-entry MSR-load area defined by controls in the VMCS. A disadvantage to this approach, however, is that the approach results in the unconditional saving, loading, and restoring of MSR registers on each VM exit or VM entry.

Depending on the design of the VMM, it is likely that many VM-exits will require no fast system call support but the VMM will be burdened with the additional overhead of saving and restoring MSRs if the VMM chooses to support fast system call uniformly. Further, even if the host intends to support fast system calls during a VM-exit, some of the MSR values (such as the setting of the SCE bit in IA32\_EFER) may not require modification as they may already be set to the appropriate value in the guest.

For performance reasons, a VMM may perform lazy save, load, and restore of these MSR values on certain VM exits when it is determined that this is acceptable. The lazy-save-load-restore operation can be carried out “manually” using RDMSR and WRMSR.

### 31.10.4.4 Handling the SWAPGS Instruction

The SWAPGS instruction is available only in 64-bit mode. It swaps the contents of two specific MSRs (IA32\_GSBASE and IA32\_KERNEL\_GSBASE). The IA32\_GSBASE MSR shadows the base address portion of the GS descriptor register; the IA32\_KERNEL\_GSBASE MSR holds the base address of the GS segment used by the kernel (typically it houses kernel structures). SWAPGS is intended for use with fast system calls when in 64-bit mode to allow immediate access to kernel structures on transition to kernel mode.

Similar to SYSCALL/SYSRET, IA-32e mode hosts which use fast system calls may need to save, load, and restore these MSR registers on VM exit and VM entry using the guidelines discussed in previous paragraphs.

### 31.10.4.5 Implementation Specific Behavior on Writing to Certain MSRs

As noted in Section 26.4 and Section 27.4, a processor may prevent writing to certain MSRs when loading guest states on VM entries or storing guest states on VM exits. This is done to ensure consistent operation. The subset and number of MSRs subject to restrictions are implementation specific. For initial VMX implementations, there are two MSRs: IA32\_BIOS\_UPDT\_TRIG and IA32\_BIOS\_SIGN\_ID (see Chapter 35).

### 31.10.5 Handling Accesses to Reserved MSR Addresses

Privileged software (either a VMM or a guest OS) can access a model specific register by specifying addresses in MSR address space. VMMs, however, must prevent a guest from accessing reserved MSR addresses in MSR address space.

Consult Chapter 35 for lists of supported MSRs and their usage. Use the MSR bitmap control to cause a VM exit when a guest attempts to access a reserved MSR address. The response to such a VM exit should be to reflect #GP(0) back to the guest.

## 31.11 HANDLING ACCESSES TO CONTROL REGISTERS

Bit fields in control registers (CR0, CR4) control various aspects of processor operation. The VMM must prevent guests from modifying bits in CR0 or CR4 that are reserved at the time the VMM is written.

Guest/host masks should be used by the VMM to cause VM exits when a guest attempts to modify reserved bits. Read shadows should be used to ensure that the guest always reads the reserved value (usually 0) for such bits. The VMM response to VM exits due to attempts from a guest to modify reserved bits should be to emulate the response which the processor would have normally produced (usually a #GP(0)).

## 31.12 PERFORMANCE CONSIDERATIONS

VMX provides hardware features that may be used for improving processor virtualization performance. VMMs must be designed to use this support properly. The basic idea behind most of these performance optimizations of the VMM is to reduce the number of VM exits while executing a guest VM.

This section lists ways that VMMs can take advantage of the performance enhancing features in VMX.

- **Read Access to Control Registers.** Analysis of common client workloads with common PC operating systems in a virtual machine shows a large number of VM-exits are caused by control register read accesses (particularly CR0). Reads of CR0 and CR4 does not cause VM exits. Instead, they return values from the CR0/CR4 read-shadows configured by the VMM in the guest controlling-VMCS with the guest-expected values.
- **Write Access to Control Registers.** Most VMM designs require only certain bits of the control registers to be protected from direct guest access. Write access to CR0/CR4 registers can be reduced by defining the host-owned and guest-owned bits in them through the CR0/CR4 host/guest masks in the VMCS. CR0/CR4 write values by the guest are qualified with the mask bits. If they change only guest-owned bits, they are allowed without causing VM exits. Any write that cause changes to host-owned bits cause VM exits and need to be handled by the VMM.
- **Access Rights based Page Table protection.** For VMM that implement access-rights-based page table protection, the VMCS provides a CR3 target value list that can be consulted by the processor to determine if a VM exit is required. Loading of CR3 with a value matching an entry in the CR3 target-list are allowed to proceed without VM exits. The VMM can utilize the CR3 target-list to save page-table hierarchies whose state is previously verified by the VMM.
- **Page-fault handling.** Another common cause for a VM exit is due to page-faults induced by guest address remapping done through virtual memory virtualization. VMX provides page-fault error-code mask and match fields in the VMCS to filter VM exits due to page-faults based on their cause (reflected in the error-code).

## 31.13 USE OF THE VMX-PREEMPTION TIMER

The VMX-preemption timer allows VMM software to preempt guest VM execution after a specified amount of time. Typical VMX-preemption timer usage is to program the initial VM quantum into the timer, save the timer value on each successive VM-exit (using the VM-exit control “save preemption timer value”) and run the VM until the timer expires.

In an alternative scenario, the VMM may use another timer (e.g. the TSC) to track the amount of time the VM has run while still using the VMX-preemption timer for VM preemption. In this scenario the VMM would not save the

VMX-preemption timer on each VM-exit but instead would reload the VMX-preemption timer with initial VM quantum less the time the VM has already run. This scenario includes all the VM-entry and VM-exit latencies in the VM run time.

In both scenarios, on each successive VM-entry the VMX-preemption timer contains a smaller value until the VM quantum ends. If the VMX-preemption timer is loaded with a value smaller than the VM-entry latency then the VM will not execute any instructions before the timer expires. The VMM must ensure the initial VM quantum is greater than the VM-entry latency; otherwise the VM will make no forward progress.

### 32.1 OVERVIEW

When a VMM is hosting multiple guest environments (VMs), it must monitor potential interactions between software components using the same system resources. These interactions can require the virtualization of resources. This chapter describes the virtualization of system resources. These include: debugging facilities, address translation, physical memory, and microcode update facilities.

### 32.2 VIRTUALIZATION SUPPORT FOR DEBUGGING FACILITIES

The Intel 64 and IA-32 debugging facilities (see Chapter 17) provide breakpoint instructions, exception conditions, register flags, debug registers, control registers and storage buffers for functions related to debugging system and application software. In VMX operation, a VMM can support debugging system and application software from within virtual machines if the VMM properly virtualizes debugging facilities. The following list describes features relevant to virtualizing these facilities.

- The VMM can program the exception-bitmap (see Section 24.6.3) to ensure it gets control on debug functions (like breakpoint exceptions occurring while executing guest code such as INT3 instructions). Normally, debug exceptions modify debug registers (such as DR6, DR7, IA32\_DEBUGCTL). However, if debug exceptions cause VM exits, exiting occurs before register modification.
- The VMM may utilize the VM-entry event injection facilities described in Section 26.5 to inject debug or breakpoint exceptions to the guest. See Section 32.2.1 for a more detailed discussion.
- The MOV-DR exiting control bit in the processor-based VM-execution control field (see Section 24.6.2) can be enabled by the VMM to cause VM exits on explicit guest access of various processor debug registers (for example, MOV to/from DR0-DR7). These exits would always occur on guest access of DR0-DR7 registers regardless of the values in CPL, DR4.DE or DR7.GD. Since all guest task switches cause VM exits, a VMM can control any indirect guest access or modification of debug registers during guest task switches.
- Guest software access to debug-related model-specific registers (such as IA32\_DEBUGCTL MSR) can be trapped by the VMM through MSR access control features (such as the MSR-bitmaps that are part of processor-based VM-execution controls). See Section 31.10 for details on MSR virtualization.
- Debug registers such as DR7 and the IA32\_DEBUGCTL MSR may be explicitly modified by the guest (through MOV-DR or WRMSR instructions) or modified implicitly by the processor as part of generating debug exceptions. The current values of DR7 and the IA32\_DEBUGCTL MSR are saved to guest-state area of VMCS on every VM exit. Pending debug exceptions are debug exceptions that are recognized by the processor but not yet delivered. See Section 26.6.3 for details on pending debug exceptions.
- DR7 and the IA32-DEBUGCTL MSR are loaded from values in the guest-state area of the VMCS on every VM entry. This allows the VMM to properly virtualize debug registers when injecting debug exceptions to guest. Similarly, the RFLAGS<sup>1</sup> register is loaded on every VM entry (or pushed to stack if injecting a virtual event) from guest-state area of the VMCS. Pending debug exceptions are also loaded from guest-state area of VMCS so that they may be delivered after VM entry is completed.

#### 32.2.1 Debug Exceptions

If a VMM emulates a guest instruction that would encounter a debug trap (single step or data or I/O breakpoint), it should cause that trap to be delivered. The VMM should not inject the debug exception using VM-entry event injection, but should set the appropriate bits in the pending debug exceptions field. This method will give the trap the

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

right priority with respect to other events. (If the exception bitmap was programmed to cause VM exits on debug exceptions, the debug trap will cause a VM exit. At this point, the trap can be injected during VM entry with the proper priority.)

There is a valid pending debug exception if the BS bit (see Table 24-4) is set, regardless of the values of RFLAGS.TF or IA32\_DEBUGCTL.BTF. The values of these bits do not impact the delivery of pending debug exceptions.

VMMs should exercise care when emulating a guest write (attempted using WRMSR) to IA32\_DEBUGCTL to modify BTF if this is occurring with RFLAGS.TF = 1 and after a MOV SS or POP SS instruction (for example: while debug exceptions are blocked). Note the following:

- Normally, if WRMSR clears BTF while RFLAGS.TF = 1 and with debug exceptions blocked, a single-step trap will occur after WRMSR. A VMM emulating such an instruction should set the BS bit (see Table 24-4) in the pending debug exceptions field before VM entry.
- Normally, if WRMSR sets BTF while RFLAGS.TF = 1 and with debug exceptions blocked, neither a single-step trap nor a taken-branch trap can occur after WRMSR. A VMM emulating such an instruction should clear the BS bit (see Table 24-4) in the pending debug exceptions field before VM entry.

## 32.3 MEMORY VIRTUALIZATION

VMMs must control physical memory to ensure VM isolation and to remap guest physical addresses in host physical address space for virtualization. Memory virtualization allows the VMM to enforce control of physical memory and yet support guest OSs' expectation to manage memory address translation.

### 32.3.1 Processor Operating Modes & Memory Virtualization

Memory virtualization is required to support guest execution in various processor operating modes. This includes: protected mode with paging, protected mode with no paging, real-mode and any other transient execution modes. VMX allows guest operation in protected-mode with paging enabled and in virtual-8086 mode (with paging enabled) to support guest real-mode execution. Guest execution in transient operating modes (such as in real mode with one or more segment limits greater than 64-KByte) must be emulated by the VMM.

Since VMX operation requires processor execution in protected mode with paging (through CR0 and CR4 fixed bits), the VMM may utilize paging structures to support memory virtualization. To support guest real-mode execution, the VMM may establish a simple flat page table for guest linear to host physical address mapping. Memory virtualization algorithms may also need to capture other guest operating conditions (such as guest performing A20M# address masking) to map the resulting 20-bit effective guest physical addresses.

### 32.3.2 Guest & Host Physical Address Spaces

Memory virtualization provides guest software with contiguous guest physical address space starting zero and extending to the maximum address supported by the guest virtual processor's physical address width. The VMM utilizes guest physical to host physical address mapping to locate all or portions of the guest physical address space in host memory. The VMM is responsible for the policies and algorithms for this mapping which may take into account the host system physical memory map and the virtualized physical memory map exposed to a guest by the VMM. The memory virtualization algorithm needs to accommodate various guest memory uses (such as: accessing DRAM, accessing memory-mapped registers of virtual devices or core logic functions and so forth). For example:

- To support guest DRAM access, the VMM needs to map DRAM-backed guest physical addresses to host-DRAM regions. The VMM also requires the guest to host memory mapping to be at page granularity.
- Virtual devices (I/O devices or platform core logic) emulated by the VMM may claim specific regions in the guest physical address space to locate memory-mapped registers. Guest access to these virtual registers may be configured to cause page-fault induced VM-exits by marking these regions as always not present. The VMM may handle these VM exits by invoking appropriate virtual device emulation code.

### 32.3.3 Virtualizing Virtual Memory by Brute Force

VMX provides the hardware features required to fully virtualize guest virtual memory accesses. VMX allows the VMM to trap guest accesses to the PAT (Page Attribute Table) MSR and the MTRR (Memory Type Range Registers). This control allows the VMM to virtualize the specific memory type of a guest memory. The VMM may control caching by controlling the guest CR0.CRD and CR0.NW bits, as well as by trapping guest execution of the INVD instruction. The VMM can trap guest CR3 loads and stores, and it may trap guest execution of INVLPG.

Because a VMM must retain control of physical memory, it must also retain control over the processor's address-translation mechanisms. Specifically, this means that only the VMM can access CR3 (which contains the base of the page directory) and can execute INVLPG (the only other instruction that directly manipulates the TLB).

At the same time that the VMM controls address translation, a guest operating system will also expect to perform normal memory management functions. It will access CR3, execute INVLPG, and modify (what it believes to be) page directories and page tables. Virtualization of address translation must tolerate and support guest attempts to control address translation.

A simple-minded way to do this would be to ensure that all guest attempts to access address-translation hardware trap to the VMM where such operations can be properly emulated. It must ensure that accesses to page directories and page tables also get trapped. This may be done by protecting these in-memory structures with conventional page-based protection. The VMM can do this because it can locate the page directory because its base address is in CR3 and the VMM receives control on any change to CR3; it can locate the page tables because their base addresses are in the page directory.

Such a straightforward approach is not necessarily desirable. Protection of the in-memory translation structures may be cumbersome. The VMM may maintain these structures with different values (e.g., different page base addresses) than guest software. This means that there must be traps on guest attempt to read these structures and that the VMM must maintain, in auxiliary data structures, the values to return to these reads. There must also be traps on modifications to these structures even if the translations they effect are never used. All this implies considerable overhead that should be avoided.

### 32.3.4 Alternate Approach to Memory Virtualization

Guest software is allowed to freely modify the guest page-table hierarchy without causing traps to the VMM. Because of this, the active page-table hierarchy might not always be consistent with the guest hierarchy. Any potential problems arising from inconsistencies can be solved using techniques analogous to those used by the processor and its TLB.

This section describes an alternative approach that allows guest software to freely access page directories and page tables. Traps occur on CR3 accesses and executions of INVLPG. They also occur when necessary to ensure that guest modifications to the translation structures actually take effect. The software mechanisms to support this approach are collectively called virtual TLB. This is because they emulate the functionality of the processor's physical translation look-aside buffer (TLB).

The basic idea behind the virtual TLB is similar to that behind the processor TLB. While the page-table hierarchy defines the relationship between physical to linear address, it does not directly control the address translation of each memory access. Instead, translation is controlled by the TLB, which is occasionally filled by the processor with translations derived from the page-table hierarchy. With a virtual TLB, the page-table hierarchy established by guest software (specifically, the guest operating system) does not control translation, either directly or indirectly. Instead, translation is controlled by the processor (through its TLB) and by the VMM (through a page-table hierarchy that it maintains).

Specifically, the VMM maintains an alternative page-table hierarchy that effectively caches translations derived from the hierarchy maintained by guest software. The remainder of this document refers to the former as the active page-table hierarchy (because it is referenced by CR3 and may be used by the processor to load its TLB) and the latter as the guest page-table hierarchy (because it is maintained by guest software). The entries in the active hierarchy may resemble the corresponding entries in the guest hierarchy in some ways and may differ in others.

Guest software is allowed to freely modify the guest page-table hierarchy without causing VM exits to the VMM. Because of this, the active page-table hierarchy might not always be consistent with the guest hierarchy. Any potential problems arising from any inconsistencies can be solved using techniques analogous to those used by the processor and its TLB. Note the following:

- Suppose the guest page-table hierarchy allows more access than active hierarchy (for example: there is a translation for a linear address in the guest hierarchy but not in the active hierarchy); this is analogous to a situation in which the TLB allows less access than the page-table hierarchy. If an access occurs that would be allowed by the guest hierarchy but not the active one, a page fault occurs; this is analogous to a TLB miss. The VMM gains control (as it handles all page faults) and can update the active page-table hierarchy appropriately; this corresponds to a TLB fill.
- Suppose the guest page-table hierarchy allows less access than the active hierarchy; this is analogous to a situation in which the TLB allows more access than the page-table hierarchy. This situation can occur only if the guest operating system has modified a page-table entry to reduce access (for example: by marking it not-present). Because the older, more permissive translation may have been cached in the TLB, the processor is architecturally permitted to use the older translation and allow more access. Thus, the VMM may (through the active page-table hierarchy) also allow greater access. For the new, less permissive translation to take effect, guest software should flush any older translations from the TLB either by executing INVLPG or by loading CR3. Because both these operations will cause a trap to the VMM, the VMM will gain control and can remove from the active page-table hierarchy the translations indicated by guest software (the translation of a specific linear address for INVLPG or all translations for a load of CR3).

As noted previously, the processor reads the page-table hierarchy to cache translations in the TLB. It also writes to the hierarchy to main the accessed (A) and dirty (D) bits in the PDEs and PTEs. The virtual TLB emulates this behavior as follows:

- When a page is accessed by guest software, the A bit in the corresponding PTE (or PDE for a 4-MByte page) in the active page-table hierarchy will be set by the processor (the same is true for PDEs when active page tables are accessed by the processor). For guest software to operate properly, the VMM should update the A bit in the guest entry at this time. It can do this reliably if it keeps the active PTE (or PDE) marked not-present until it has set the A bit in the guest entry.
- When a page is written by guest software, the D bit in the corresponding PTE (or PDE for a 4-MByte page) in the active page-table hierarchy will be set by the processor. For guest software to operate properly, the VMM should update the D bit in the guest entry at this time. It can do this reliably if it keeps the active PTE (or PDE) marked read-only until it has set the D bit in the guest entry. This solution is valid for guest software running at privilege level 3; support for more privileged guest software is described in Section 32.3.5.

### 32.3.5 Details of Virtual TLB Operation

This section describes in more detail how a VMM could support a virtual TLB. It explains how an active page-table hierarchy is initialized and how it is maintained in response to page faults, uses of INVLPG, and accesses to CR3. The mechanisms described here are the minimum necessary. They may not result in the best performance.

Figure 32-1. Virtual TLB Scheme

As noted above, the VMM maintains an active page-table hierarchy for each virtual machine that it supports. It also maintains, for each machine, values that the machine expects for control registers CR0, CR2, CR3, and CR4 (they control address translation). These values are called the guest control registers.

In general, the VMM selects the physical-address space that is allocated to guest software. The term guest address refers to an address installed by guest software in the guest CR3, in a guest PDE (as a page table base address or a page base address), or in a guest PTE (as a page base address). While guest software considers these to be specific physical addresses, the VMM may map them differently.

### 32.3.5.1 Initialization of Virtual TLB

To enable the Virtual TLB scheme, the VMCS must be set up to trigger VM exits on:

- All writes to CR3 (the CR3-target count should be 0) or the paging-mode bits in CR0 and CR4 (using the CR0 and CR4 guest/host masks)
- Page-fault (#PF) exceptions
- Execution of INVLPG

When guest software first enables paging, the VMM creates an aligned 4-KByte active page directory that is invalid (all entries marked not-present). This invalid directory is analogous to an empty TLB.

### 32.3.5.2 Response to Page Faults

Page faults can occur for a variety of reasons. In some cases, the page fault alerts the VMM to an inconsistency between the active and guest page-table hierarchy. In such cases, the VMM can update the former and re-execute the faulting instruction. In other cases, the hierarchies are already consistent and the fault should be handled by the guest operating system. The VMM can detect this and use an established mechanism for raising a page fault to guest software.

The VMM can handle a page fault by following these steps (The steps below assume the guest is operating in a paging mode without PAE. Analogous steps to handle address translation using PAE or four-level paging mecha-

nisms can be derived by VMM developers according to the paging behavior defined in Chapter 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 3A*:

1. First consult the active PDE, which can be located using the upper 10 bits of the faulting address and the current value of CR3. The active PDE is the source of the fault if it is marked not present or if its R/W bit and U/S bits are inconsistent with the attempted guest access (the guest privilege level and the values of CR0.WP and CR4.SMEP should also be taken into account).
2. If the active PDE is the source of the fault, consult the corresponding guest PDE using the same 10 bits from the faulting address and the physical address that corresponds to the guest address in the guest CR3. If the guest PDE would cause a page fault (for example: it is marked not present), then raise a page fault to the guest operating system.

The following steps assume that the guest PDE would not have caused a page fault.

3. If the active PDE is the source of the fault and the guest PDE contains, as page-table base address (if PS = 0) or page base address (PS = 1), a guest address that the VMM has chosen not to support; then raise a machine check (or some other abort) to the guest operating system.

The following steps assume that the guest address in the guest PDE is supported for the virtual machine.

4. If the active PDE is marked not-present, then set the active PDE to correspond to guest PDE as follows:
  - a. If the active PDE contains a page-table base address (if PS = 0), then allocate an aligned 4-KByte active page table marked completely invalid and set the page-table base address in the active PDE to be the physical address of the newly allocated page table.
  - b. If the active PDE contains a page base address (if PS = 1), then set the page base address in the active PDE to be the physical page base address that corresponds to the guest address in the guest PDE.
  - c. Set the P, U/S, and PS bits in the active PDE to be identical to those in the guest PDE.
  - d. Set the PWT, PCD, and G bits according to the policy of the VMM.
  - e. Set A = 1 in the guest PDE.
  - f. If D = 1 in the guest PDE or PS = 0 (meaning that this PDE refers to a page table), then set the R/W bit in the active PDE as in the guest PDE.
  - g. If D = 0 in the guest PDE, PS = 1 (this is a 4-MByte page), and the attempted access is a write; then set R/W in the active PDE as in the guest PDE and set D = 1 in the guest PDE.
  - h. If D = 0 in the guest PDE, PS = 1, and the attempted access is not a write; then set R/W = 0 in the active PDE.
  - i. After modifying the active PDE, re-execute the faulting instruction.

The remaining steps assume that the active PDE is already marked present.

5. If the active PDE is the source of the fault, the active PDE refers to a 4-MByte page (PS = 1), the attempted access is a write; D = 0 in the guest PDE, and the active PDE has caused a fault solely because it has R/W = 0; then set R/W in the active PDE as in the guest PDE; set D = 1 in the guest PDE, and re-execute the faulting instruction.
6. If the active PDE is the source of the fault and none of the above cases apply, then raise a page fault of the guest operating system.

The remaining steps assume that the source of the original page fault is not the active PDE.

## NOTE

It is possible that the active PDE might be causing a fault even though the guest PDE would not. However, this can happen only if the guest operating system increased access in the guest PDE and did not take action to ensure that older translations were flushed from the TLB. Such translations might have caused a page fault if the guest software were running on bare hardware.

7. If the active PDE refers to a 4-MByte page (PS = 1) but is not the source of the fault, then the fault resulted from an inconsistency between the active page-table hierarchy and the processor's TLB. Since the transition to

the VMM caused an address-space change and flushed the processor's TLB, the VMM can simply re-execute the faulting instruction.

The remaining steps assume that  $PS = 0$  in the active and guest PDEs.

8. Consult the active PTE, which can be located using the next 10 bits of the faulting address (bits 21–12) and the physical page-table base address in the active PDE. The active PTE is the source of the fault if it is marked not-present or if its R/W bit and U/S bits are inconsistent with the attempted guest access (the guest privilege level and the values of CR0.WP and CR4.SMEP should also be taken into account).
9. If the active PTE is not the source of the fault, then the fault has resulted from an inconsistency between the active page-table hierarchy and the processor's TLB. Since the transition to the VMM caused an address-space change and flushed the processor's TLB, the VMM simply re-executes the faulting instruction.

The remaining steps assume that the active PTE is the source of the fault.

10. Consult the corresponding guest PTE using the same 10 bits from the faulting address and the physical address that correspond to the guest page-table base address in the guest PDE. If the guest PTE would cause a page fault (it is marked not-present), then raise a page fault to the guest operating system.

The following steps assume that the guest PTE would not have caused a page fault.

11. If the guest PTE contains, as page base address, a physical address that is not valid for the virtual machine being supported; then raise a machine check (or some other abort) to the guest operating system.

The following steps assume that the address in the guest PTE is valid for the virtual machine.

12. If the active PTE is marked not-present, then set the active PTE to correspond to guest PTE:
  - a. Set the page base address in the active PTE to be the physical address that corresponds to the guest page base address in the guest PTE.
  - b. Set the P, U/S, and PS bits in the active PTE to be identical to those in the guest PTE.
  - c. Set the PWT, PCD, and G bits according to the policy of the VMM.
  - d. Set  $A = 1$  in the guest PTE.
  - e. If  $D = 1$  in the guest PTE, then set the R/W bit in the active PTE as in the guest PTE.
  - f. If  $D = 0$  in the guest PTE and the attempted access is a write, then set R/W in the active PTE as in the guest PTE and set  $D = 1$  in the guest PTE.
  - g. If  $D = 0$  in the guest PTE and the attempted access is not a write, then set  $R/W = 0$  in the active PTE.
  - h. After modifying the active PTE, re-execute the faulting instruction.

The remaining steps assume that the active PTE is already marked present.

13. If the attempted access is a write,  $D = 0$  (not dirty) in the guest PTE and the active PTE has caused a fault solely because it has  $R/W = 0$  (read-only); then set R/W in the active PTE as in the guest PTE, set  $D = 1$  in the guest PTE and re-execute the faulting instruction.
14. If none of the above cases apply, then raise a page fault of the guest operating system.

### 32.3.5.3 Response to Uses of INVLPG

Operating-systems can use INVLPG to flush entries from the TLB. This instruction takes a linear address as an operand and software expects any cached translations for the address to be flushed. A VMM should set the processor-based VM-execution control "INVLPG exiting" to 1 so that any attempts by a privileged guest to execute INVLPG will trap to the VMM. The VMM can then modify the active page-table hierarchy to emulate the desired effect of the INVLPG.

The following steps are performed. Note that these steps are performed only if the guest invocation of INVLPG would not fault and only if the guest software is running at privilege level 0:

1. Locate the relevant active PDE using the upper 10 bits of the operand address and the current value of CR3. If the PDE refers to a 4-MByte page ( $PS = 1$ ), then set  $P = 0$  in the PDE.
2. If the PDE is marked present and refers to a page table ( $PS = 0$ ), locate the relevant active PTE using the next 10 bits of the operand address (bits 21–12) and the page-table base address in the PDE. Set  $P = 0$  in the PTE.

Examine all PTEs in the page table; if they are now all marked not-present, de-allocate the page table and set  $P = 0$  in the PDE (this step may be optional).

#### 32.3.5.4 Response to CR3 Writes

A guest operating system may attempt to write to CR3. Any write to CR3 implies a TLB flush and a possible page table change. The following steps are performed:

1. The VMM notes the new CR3 value (used later to walk guest page tables) and emulates the write.
2. The VMM allocates a new PD page, with all invalid entries.
3. The VMM sets actual processor CR3 register to point to the new PD page.

The VMM may, at this point, speculatively fill in VTLB mappings for performance reasons.

## 32.4 MICROCODE UPDATE FACILITY

The microcode code update facility may be invoked at various points during the operation of a platform. Typically, the BIOS invokes the facility on all processors during the BIOS boot process. This is sufficient to boot the BIOS and operating system. As a microcode update more current than the system BIOS may be available, system software should provide another mechanism for invoking the microcode update facility. The implications of the microcode update mechanism on the design of the VMM are described in this section.

### NOTE

Microcode updates must not be performed during VMX non-root operation. Updates performed in VMX non-root operation may result in unpredictable system behavior.

### 32.4.1 Early Load of Microcode Updates

The microcode update facility may be invoked early in the VMM or guest OS boot process. Loading the microcode update early provides the opportunity to correct errata affecting the boot process but the technique generally requires a reboot of the software.

A microcode update may be loaded from the OS or VMM image loader. Typically, such image loaders do not run on every logical processor, so this method effects only one logical processor. Later in the VMM or OS boot process, after bringing all application processors on-line, the VMM or OS needs to invoke the microcode update facility for all application processors.

Depending on the order of the VMM and the guest OS boot, the microcode update facility may be invoked by the VMM or the guest OS. For example, if the guest OS boots first and then loads the VMM, the guest OS may invoke the microcode update facility on all the logical processors. If a VMM boots before its guests, then the VMM may invoke the microcode update facility during its boot process. In both cases, the VMM or OS should invoke the microcode update facilities soon after performing the multiprocessor startup.

In the early load scenario, microcode updates may be contained in the VMM or OS image or, the VMM or OS may manage a separate database or file of microcode updates. Maintaining a separate microcode update image database has the advantage of reducing the number of required VMM or OS releases as a result of microcode update releases.

### 32.4.2 Late Load of Microcode Updates

A microcode update may be loaded during normal system operation. This allows system software to activate the microcode update at anytime without requiring a system reboot. This scenario does not allow the microcode update to correct errata which affect the processor's boot process but does allow high-availability systems to activate microcode updates without interrupting the availability of the system. In this late load scenario, either the VMM or a designated guest may load the microcode update. If the guest is loading the microcode update, the VMM must

make sure that the entire guest memory buffer (which contains the microcode update image) will not cause a page fault when accessed.

If the VMM loads the microcode update, then the VMM must have access to the current set of microcode updates. These updates could be part of the VMM image or could be contained in a separate microcode update image database (for example: a database file on disk or in memory). Again, maintaining a separate microcode update image database has the advantage of reducing the number of required VMM or OS releases as a result of microcode update releases.

The VMM may wish to prevent a guest from loading a microcode update or may wish to support the microcode update requested by a guest using emulation (without actually loading the microcode update). To prevent microcode update loading, the VMM may return a microcode update signature value greater than the value of IA32\_BIOS\_SIGN\_ID MSR. A well behaved guest will not attempt to load an older microcode update. The VMM may also drop the guest attempts to write to IA32\_BIOS\_UPDT\_TRIG MSR, preventing the guest from loading any microcode updates. Later, when the guest queries IA32\_BIOS\_SIGN\_ID MSR, the VMM could emulate the microcode update signature that the guest expects.

In general, loading a microcode update later will limit guest software's visibility of features that may be enhanced by a microcode update.

# CHAPTER 33

## HANDLING BOUNDARY CONDITIONS IN A VIRTUAL MACHINE MONITOR

---

### 33.1 OVERVIEW

This chapter describes what a VMM must consider when handling exceptions, interrupts, error conditions, and transitions between activity states.

### 33.2 INTERRUPT HANDLING IN VMX OPERATION

The following bullets summarize VMX support for handling interrupts:

- **Control of processor exceptions.** The VMM can get control on specific guest exceptions through the exception-bitmap in the guest controlling VMCS. The exception bitmap is a 32-bit field that allows the VMM to specify processor behavior on specific exceptions (including traps, faults, and aborts). Setting a specific bit in the exception bitmap implies VM exits will be generated when the corresponding exception occurs. Any exceptions that are programmed not to cause VM exits are delivered directly to the guest through the guest IDT. The exception bitmap also controls execution of relevant instructions such as BOUND, INTO and INT3. VM exits on page-faults are treated in such a way the page-fault error code is qualified through the page-fault-error-code mask and match fields in the VMCS.
- **Control over triple faults.** If a fault occurs while attempting to call a double-fault handler in the guest and that fault is not configured to cause a VM exit in the exception bitmap, the resulting triple fault causes a VM exit.
- **Control of external interrupts.** VMX allows both host and guest control of external interrupts through the “external-interrupt exiting” VM execution control. If the control is 0, external-interrupts do not cause VM exits and the interrupt delivery is masked by the guest programmed RFLAGS.IF value.<sup>1</sup> If the control is 1, external-interrupts causes VM exits and are not masked by RFLAGS.IF. The VMM can identify VM exits due to external interrupts by checking the exit reason for an “external interrupt” (value = 1).
- **Control of other events.** There is a pin-based VM-execution control that controls system behavior (exit or no-exit) for NMI events. Most VMM usages will need handling of NMI external events in the VMM and hence will specify host control of these events.

Some processors also support a pin-based VM-execution control called “virtual NMIs.” When this control is set, NMIs cause VM exits, but the processor tracks guest readiness for virtual NMIs. This control interacts with the “NMI-window exiting” VM-execution control (see below).

INIT and SIPI events always cause VM exits.

- **Acknowledge interrupt on exit.** The “acknowledge interrupt on exit” VM-exit control in the controlling VMCS controls processor behavior for external interrupt acknowledgement. If the control is 1, the processor acknowledges the interrupt controller to acquire the interrupt vector upon VM exit, and stores the vector in the VM-exit interruption-information field. If the control is 0, the external interrupt is not acknowledged during VM exit. Since RFLAGS.IF is automatically cleared on VM exits due to external interrupts, VMM re-enabling of interrupts (setting RFLAGS.IF = 1) initiates the external interrupt acknowledgement and vectoring of the external interrupt through the monitor/host IDT.
- **Event-masking Support.** VMX captures the masking conditions of specific events while in VMX non-root operation through the interruptibility-state field in the guest-state area of the VMCS.

This feature allows proper virtualization of various interrupt blocking states, such as: (a) blocking of external interrupts for the instruction following STI; (b) blocking of interrupts for the instruction following a MOV-SS or POP-SS instruction; (c) SMI blocking of subsequent SMIs until the next execution of RSM; and (d) NMI/SMI blocking of NMIs until the next execution of IRET or RSM.

---

1. This chapter uses the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of those registers (EAX, EIP, ESP, EFLAGS, etc.).

INIT and SIPI events are treated specially. INIT assertions are always blocked in VMX root operation and while in SMM, and unblocked otherwise. SIPI events are always blocked in VMX root operation.

The interruptibility state is loaded from the VMCS guest-state area on every VM entry and saved into the VMCS on every VM exit.

- **Event injection.** VMX operation allows injecting interruptions to a guest virtual machine through the use of VM-entry interrupt-information field in VMCS. Injectable interruptions include external interrupts, NMI, processor exceptions, software generated interrupts, and software traps. If the interrupt-information field indicates a valid interrupt, exception or trap event upon the next VM entry; the processor will use the information in the field to vector a virtual interruption through the guest IDT after all guest state and MSRs are loaded. Delivery through the guest IDT emulates vectoring in non-VMX operation by doing the normal privilege checks and pushing appropriate entries to the guest stack (entries may include RFLAGS, EIP and exception error code). A VMM with host control of NMI and external interrupts can use the event-injection facility to forward virtual interruptions to various guest virtual machines.
- **Interrupt-window exiting.** When set to 1, the “interrupt-window exiting” VM-execution control (Section 24.6.2) causes VM exits when guest RFLAGS.IF is 1 and no other conditions block external interrupts. A VM exit occurs at the beginning of any instruction at which RFLAGS.IF = 1 and on which the interruptibility state of the guest would allow delivery of an interrupt. For example: when the guest executes an STI instruction, RFLAGS = 1, and if at the completion of next instruction the interruptibility state masking due to STI is removed; a VM exit occurs if the “interrupt-window exiting” VM-execution control is 1. This feature allows a VMM to queue a virtual interrupt to the guest when the guest is not in an interruptible state. The VMM can set the “interrupt-window exiting” VM-execution control for the guest and depend on a VM exit to know when the guest becomes interruptible (and, therefore, when it can inject a virtual interrupt). The VMM can detect such VM exits by checking for the basic exit reason “interrupt-window” (value = 7). If this feature is not used, the VMM will need to poll and check the interruptibility state of the guest to deliver virtual interrupts.
- **NMI-window exiting.** If the “virtual NMIs” VM-execution is set, the processor tracks virtual-NMI blocking. The “NMI-window exiting” VM-execution control (Section 24.6.2) causes VM exits when there is no virtual-NMI blocking. For example, after execution of the IRET instruction, a VM exit occurs if the “NMI-window exiting” VM-execution control is 1. This feature allows a VMM to queue a virtual NMI to a guest when the guest is not ready to receive NMIs. The VMM can set the “NMI-window exiting” VM-execution control for the guest and depend on a VM exit to know when the guest becomes ready for NMIs (and, therefore, when it can inject a virtual NMI). The VMM can detect such VM exits by checking for the basic exit reason “NMI window” (value = 8). If this feature is not used, the VMM will need to poll and check the interruptibility state of the guest to deliver virtual NMIs.
- **VM-exit information.** The VM-exit information fields provide details on VM exits due to exceptions and interrupts. This information is provided through the exit-qualification, VM-exit-interruption-information, instruction-length and interruption-error-code fields. Also, for VM exits that occur in the course of vectoring through the guest IDT, information about the event that was being vectored through the guest IDT is provided in the IDT-vectoring-information and IDT-vectoring-error-code fields. These information fields allow the VMM to identify the exception cause and to handle it properly.

### 33.3 EXTERNAL INTERRUPT VIRTUALIZATION

VMX operation allows both host and guest control of external interrupts. While guest control of external interrupts might be suitable for partitioned usages (different CPU cores/threads and I/O devices partitioned to independent virtual machines), most VMMs built upon VMX are expected to utilize host control of external interrupts. The rest of this section describes a general host-controlled interrupt virtualization architecture for standard PC platforms through the use of VMX supported features.

With host control of external interrupts, the VMM (or the host OS in a hosted VMM model) manages the physical interrupt controllers in the platform and the interrupts generated through them. The VMM exposes software-emulated virtual interrupt controller devices (such as PIC and APIC) to each guest virtual machine instance.

### 33.3.1 Virtualization of Interrupt Vector Space

The Intel 64 and IA-32 architectures use 8-bit vectors of which 224 (20H – FFH) are available for external interrupts. Vectors are used to select the appropriate entry in the interrupt descriptor table (IDT). VMX operation allows each guest to control its own IDT. Host vectors refer to vectors delivered by the platform to the processor during the interrupt acknowledgement cycle. Guest vectors refer to vectors programmed by a guest to select an entry in its guest IDT. Depending on the I/O resource management models supported by the VMM design, the guest vector space may or may not overlap with the underlying host vector space.

- Interrupts from virtual devices: Guest vector numbers for virtual interrupts delivered to guests on behalf of emulated virtual devices have no direct relation to the host vector numbers of interrupts from physical devices on which they are emulated. A guest-vector assigned for a virtual device by the guest operating environment is saved by the VMM and utilized when injecting virtual interrupts on behalf of the virtual device.
- Interrupts from assigned physical devices: Hardware support for I/O device assignment allows physical I/O devices in the host platform to be assigned (direct-mapped) to VMs. Guest vectors for interrupts from direct-mapped physical devices take up equivalent space from the host vector space, and require the VMM to perform host-vector to guest-vector mapping for interrupts.

Figure 33-1 illustrates the functional relationship between host external interrupts and guest virtual external interrupts. Device A is owned by the host and generates external interrupts with host vector X. The host IDT is set up such that the interrupt service routine (ISR) for device driver A is hooked to host vector X as normal. VMM emulates (over device A) virtual device C in software which generates virtual interrupts to the VM with guest expected vector P. Device B is assigned to a VM and generates external interrupts with host vector Y. The host IDT is programmed to hook the VMM interrupt service routine (ISR) for assigned devices for vector Y, and the VMM handler injects virtual interrupt with guest vector Q to the VM. The guest operating system programs the guest to hook appropriate guest driver's ISR to vectors P and Q.

Figure 33-1. Host External Interrupts and Guest Virtual Interrupts

### 33.3.2 Control of Platform Interrupts

To meet the interrupt virtualization requirements, the VMM needs to take ownership of the physical interrupts and the various interrupt controllers in the platform. VMM control of physical interrupts may be enabled through the host-control settings of the “external-interrupt exiting” VM-execution control. To take ownership of the platform interrupt controllers, the VMM needs to expose the virtual interrupt controller devices to the virtual machines and restrict guest access to the platform interrupt controllers.

Intel 64 and IA-32 platforms can support three types of external interrupt control mechanisms: Programmable Interrupt Controllers (PIC), Advanced Programmable Interrupt Controllers (APIC), and Message Signaled Interrupts (MSI). The following sections provide information on the virtualization of each of these mechanisms.

#### 33.3.2.1 PIC Virtualization

Typical PIC-enabled platform implementations support dual 8259 interrupt controllers cascaded as master and slave controllers. They supporting up to 15 possible interrupt inputs. The 8259 controllers are programmed through initialization command words (ICWx) and operation command words (OCWx) accessed through specific I/O ports. The various interrupt line states are captured in the PIC through interrupt requests, interrupt service routines and interrupt mask registers.

Guest access to the PIC I/O ports can be restricted by activating I/O bitmaps in the guest controlling-VMCS (activate-I/O-bitmap bit in VM-execution control field set to 1) and pointing the I/O-bitmap physical addresses to valid

bitmap regions. Bits corresponding to the PIC I/O ports can be cleared to cause a VM exit on guest access to these ports.

If the VMM is not supporting direct access to any I/O ports from a guest, it can set the unconditional-I/O-exiting in the VM-execution control field instead of activating I/O bitmaps. The exit-reason field in VM-exit information allows identification of VM exits due to I/O access and can provide an exit-qualification to identify details about the guest I/O operation that caused the VM exit.

The VMM PIC virtualization needs to emulate the platform PIC functionality including interrupt priority, mask, request and service states, and specific guest programmed modes of PIC operation.

### 33.3.2.2 xAPIC Virtualization

Most modern Intel 64 and IA-32 platforms include support for an APIC. While the standard PIC is intended for use on uniprocessor systems, APIC can be used in either uniprocessor or multi-processor systems.

APIC based interrupt control consists of two physical components: the interrupt acceptance unit (Local APIC) which is integrated with the processor, and the interrupt delivery unit (I/O APIC) which is part of the I/O subsystem. APIC virtualization involves protecting the platform's local and I/O APICs and emulating them for the guest.

### 33.3.2.3 Local APIC Virtualization

The local APIC is responsible for the local interrupt sources, interrupt acceptance, dispensing interrupts to the logical processor, and generating inter-processor interrupts. Software interacts with the local APIC by reading and writing its memory-mapped registers residing within a 4-KByte uncached memory region with base address stored in the IA32\_APIC\_BASE MSR. Since the local APIC registers are memory-mapped, the VMM can utilize memory virtualization techniques (such as page-table virtualization) to trap guest accesses to the page frame hosting the virtual local APIC registers.

Local APIC virtualization in the VMM needs to emulate the various local APIC operations and registers, such as: APIC identification/format registers, the local vector table (LVT), the interrupt command register (ICR), interrupt capture registers (TMR, IRR and ISR), task and processor priority registers (TPR, PPR), the EOI register and the APIC-timer register. Since local APICs are designed to operate with non-specific EOI, local APIC emulation also needs to emulate broadcast of EOI to the guest's virtual I/O APICs for level triggered virtual interrupts.

A local APIC allows interrupt masking at two levels: (1) mask bit in the local vector table entry for local interrupts and (2) raising processor priority through the TPR registers for masking lower priority external interrupts. The VMM needs to comprehend these virtual local APIC mask settings as programmed by the guest in addition to the guest virtual processor interruptibility state (when injecting APIC routed external virtual interrupts to a guest VM).

VMX provides several features which help the VMM to virtualize the local APIC. These features allow many of guest TPR accesses (using CR8 only) to occur without VM exits to the VMM:

- The VMCS contains a "virtual-APIC address" field. This 64-bit field is the physical address of the 4-KByte virtual APIC page (4-KByte aligned). The virtual-APIC page contains a TPR shadow, which is accessed by the MOV CR8 instruction. The TPR shadow comprises bits 7:4 in byte 80H of the virtual-APIC page.
- The TPR threshold: bits 3:0 of this 32-bit field determine the threshold below which the TPR shadow cannot fall. A VM exit will occur after an execution of MOV CR8 that reduces the TPR shadow below this value.
- The processor-based VM-execution controls field contains a "use TPR shadow" bit and a "CR8-store exiting" bit. If the "use TPR shadow" VM-execution control is 1 and the "CR8-store exiting" VM-execution control is 0, then a MOV from CR8 reads from the TPR shadow. If the "CR8-store exiting" VM-execution control is 1, then MOV from CR8 causes a VM exit; the "use TPR shadow" VM-execution control is ignored in this case.
- The processor-based VM-execution controls field contains a "CR8-load exiting" bit. If the "use TPR shadow" VM-execution control is set and the "CR8-load exiting" VM-execution control is clear, then MOV to CR8 writes to the "TPR shadow". A VM exit will occur after this write if the value written is below the TPR threshold. If the "CR8-load exiting" VM-execution control is set, then MOV to CR8 causes a VM exit; the "use TPR shadow" VM-execution control is ignored in this case.

### 33.3.2.4 I/O APIC Virtualization

The I/O APIC registers are typically mapped to a 1 MByte region where each I/O APIC is allocated a 4K address window within this range. The VMM may utilize physical memory virtualization to trap guest accesses to the virtual I/O APIC memory-mapped registers. The I/O APIC virtualization needs to emulate the various I/O APIC operations and registers such as identification/version registers, indirect-I/O-access registers, EOI register, and the I/O redirection table. I/O APIC virtualization also need to emulate various redirection table entry settings such as delivery mode, destination mode, delivery status, polarity, masking, and trigger mode programmed by the guest and track remote-IRR state on guest EOI writes to various virtual local APICs.

### 33.3.2.5 Virtualization of Message Signaled Interrupts

The *PCI Local Bus Specification* (Rev. 2.2) introduces the concept of message signaled interrupts (MSI). MSI enable PCI devices to request service by writing a system-specified message to a system specified address. The transaction address specifies the message destination while the transaction data specifies the interrupt vector, trigger mode and delivery mode. System software is expected to configure the message data and address during MSI device configuration, allocating one or more no-shared messages to MSI capable devices. Chapter 10, “Advanced Programmable Interrupt Controller (APIC),” specifies the MSI message address and data register formats to be followed on Intel 64 and IA-32 platforms. While MSI is optional for conventional PCI devices, it is the preferred interrupt mechanism for PCI-Express devices.

Since the MSI address and data are configured through PCI configuration space, to control these physical interrupts the VMM needs to assume ownership of PCI configuration space. This allows the VMM to capture the guest configuration of message address and data for MSI-capable virtual and assigned guest devices. PCI configuration transactions on PC-compatible systems are generated by software through two different methods:

1. The standard CONFIG\_ADDRESS/CONFIG\_DATA register mechanism (CFCH/CF8H ports) as defined in the *PCI Local Bus Specification*.
2. The enhanced flat memory-mapped (MEMCFG) configuration mechanism as defined in the *PCI-Express Base Specification* (Rev. 1.0a.).

The CFCH/CF8H configuration access from guests can be trapped by the VMM through use of I/O-bitmap VM-execution controls. The memory-mapped PCI-Express MEMCFG guest configuration accesses can be trapped by VMM through physical memory virtualization.

## 33.3.3 Examples of Handling of External Interrupts

The following sections illustrate interrupt processing in a VMM (when used to support the external interrupt virtualization requirements).

### 33.3.3.1 Guest Setup

The VMM sets up the guest to cause a VM exit to the VMM on external interrupts. This is done by setting the “external-interrupt exiting” VM-execution control in the guest controlling-VMCS.

### 33.3.3.2 Processor Treatment of External Interrupt

Interrupts are automatically masked by hardware in the processor on VM exit by clearing RFLAGS.IF. The exit-reason field in VMCS is set to 1 to indicate an external interrupt as the exit reason.

If the VMM is utilizing the acknowledge-on-exit feature (by setting the “acknowledge interrupt on exit” VM-execution control), the processor acknowledges the interrupt, retrieves the host vector, and saves the interrupt in the VM-exit-interrupt-information field (in the VM-exit information region of the VMCS) before transitioning control to the VMM.

### 33.3.3.3 Processing of External Interrupts by VMM

Upon VM exit, the VMM can determine the exit cause of an external interrupt by checking the exit-reason field (value = 1) in VMCS. If the acknowledge-interrupt-on-exit control (see Section 24.7.1) is enabled, the VMM can use the saved host vector (in the exit-interruption-information field) to switch to the appropriate interrupt handler. If the “acknowledge interrupt on exit” VM-exit control is 0, the VMM may re-enable interrupts (by setting RFLAGS.IF) to allow vectoring of external interrupts through the monitor/host IDT.

The following steps may need to be performed by the VMM to process an external interrupt:

- **Host Owned I/O Devices:** For host-owned I/O devices, the interrupting device is owned by the VMM (or hosting OS in a hosted VMM). In this model, the interrupt service routine in the VMM/host driver is invoked and, upon ISR completion, the appropriate write sequences (TPR updates, EOI etc.) to respective interrupt controllers are performed as normal. If the work completion indicated by the driver implies virtual device activity, the VMM runs the virtual device emulation. Depending on the device class, physical device activity could imply activity by multiple virtual devices mapped over the device. For each affected virtual device, the VMM injects a virtual external interrupt event to respective guest virtual machines. The guest driver interacts with the emulated virtual device to process the virtual interrupt. The interrupt controller emulation in the VMM supports various guest accesses to the VMM’s virtual interrupt controller.
- **Guest Assigned I/O Devices:** For assigned I/O devices, either the VMM uses a software proxy or it can directly map the physical device to the assigned VM. In both cases, servicing of the interrupt condition on the physical device is initiated by the driver running inside the guest VM. With host control of external interrupts, interrupts from assigned physical devices cause VM exits to the VMM and vectoring through the host IDT to the registered VMM interrupt handler. To unblock delivery of other low priority platform interrupts, the VMM interrupt handler must mask the interrupt source (for level triggered interrupts) and issue the appropriate EOI write sequences.

Once the physical interrupt source is masked and the platform EOI generated, the VMM can map the host vector to its corresponding guest vector to inject the virtual interrupt into the assigned VM. The guest software does EOI write sequences to its virtual interrupt controller after completing interrupt processing. For level triggered interrupts, these EOI writes to the virtual interrupt controller may be trapped by the VMM which may in turn unmask the previously masked interrupt source.

### 33.3.3.4 Generation of Virtual Interrupt Events by VMM

The following provides some of the general steps that need to be taken by VMM designs when generating virtual interrupts:

1. Check virtual processor interruptibility state. The virtual processor interruptibility state is reflected in the guest RFLAGS.IF flag and the processor interruptibility-state saved in the guest state area of the controlling-VMCS. If RFLAGS.IF is set and the interruptibility state indicates readiness to take external interrupts (STI-masking and MOV-SS/POP-SS-masking bits are clear), the guest virtual processor is ready to take external interrupts. If the VMM design supports non-active guest sleep states, the VMM needs to make sure the current guest sleep state allows injection of external interrupt events.
2. If the guest virtual processor state is currently not interruptible, a VMM may utilize the “interrupt-window exiting” VM-execution to notify the VM (through a VM exit) when the virtual processor state changes to interruptible state.
3. Check the virtual interrupt controller state. If the guest VM exposes a virtual local APIC, the current value of its processor priority register specifies if guest software allows dispensing an external virtual interrupt with a specific priority to the virtual processor. If the virtual interrupt is routed through the local vector table (LVT) entry of the local APIC, the mask bits in the corresponding LVT entry specifies if the interrupt is currently masked. Similarly, the virtual interrupt controller’s current mask (IO-APIC or PIC) and priority settings reflect guest state to accept specific external interrupts. The VMM needs to check both the virtual processor and interrupt controller states to verify its guest interruptibility state. If the guest is currently interruptible, the VMM can inject the virtual interrupt. If the current guest state does not allow injecting a virtual interrupt, the interrupt needs to be queued by the VMM until it can be delivered.
4. Prioritize the use of VM-entry event injection. A VMM may use VM-entry event injection to deliver various virtual events (such as external interrupts, exceptions, traps, and so forth). VMM designs may prioritize use of virtual-interrupt injection between these event types. Since each VM entry allows injection of one event,

depending on the VMM event priority policies, the VMM may need to queue the external virtual interrupt if a higher priority event is to be delivered on the next VM entry. Since the VMM has masked this particular interrupt source (if it was level triggered) and done EOI to the platform interrupt controller, other platform interrupts can be serviced while this virtual interrupt event is queued for later delivery to the VM.

5. Update the virtual interrupt controller state. When the above checks have passed, before generating the virtual interrupt to the guest, the VMM updates the virtual interrupt controller state (Local-APIC, IO-APIC and/or PIC) to reflect assertion of the virtual interrupt. This involves updating the various interrupt capture registers, and priority registers as done by the respective hardware interrupt controllers. Updating the virtual interrupt controller state is required for proper interrupt event processing by guest software.
6. Inject the virtual interrupt on VM entry. To inject an external virtual interrupt to a guest VM, the VMM sets up the VM-entry interruption-information field in the guest controlling-VMCS before entry to guest using VMRESUME. Upon VM entry, the processor will use this vector to access the gate in guest's IDT and the value of RFLAGS and EIP in guest-state area of controlling-VMCS is pushed on the guest stack. If the guest RFLAGS.IF is clear, the STI-masking bit is set, or the MOV-SS/POP-SS-masking bit is set, the VM entry will fail and the processor will load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 26.7).

## 33.4 ERROR HANDLING BY VMM

Error conditions may occur during VM entries and VM exits and a few other situations. This section describes how VMM should handle these error conditions, including triple faults and machine-check exceptions.

### 33.4.1 VM-Exit Failures

All VM exits load processor state from the host-state area of the VMCS that was the controlling VMCS before the VM exit. This state is checked for consistency while being loaded. Because the host-state is checked on VM entry, these checks will generally succeed. Failure is possible only if host software is incorrect or if VMCS data in the VMCS region in memory has been written by guest software (or by I/O DMA) since the last VM entry. VM exits may fail for the following reasons:

- There was a failure on storing guest MSRs.
- There was failure in loading a PDPTTR.
- The controlling VMCS has been corrupted (through writes to the corresponding VMCS region) in such a way that the implementation cannot complete the VM exit.
- There was a failure on loading host MSRs.
- A machine-check event occurred.

If one of these problems occurs on a VM exit, a VMX abort results.

### 33.4.2 Machine-Check Considerations

The following sequence determine how machine-check events are handled during VMXON, VMXOFF, VM entries, and VM exits:

- VMXOFF and VMXON:
  - If a machine-check event occurs during VMXOFF or VMXON and CR4.MCE = 1, a machine-check exception (#MC) is generated. If CR4.MCE = 0, the processor goes to shutdown state.
- VM entry:
  - If a machine-check event occurs during VM entry, one of the following three treatments must occur:
    - a. Normal delivery before VM entry. If CR4.MCE = 1 before VM entry, delivery of a machine-check exception (#MC) through the host IDT occurs. If CR4.MCE = 0, the processor goes to shutdown state.

- b. Normal delivery after VM entry. If CR4.MCE = 1 after VM entry, delivery of a machine-check exception (#MC) through the guest IDT occurs (alternatively, this exception may cause a VM exit). If CR4.MCE = 0, the processor goes to shutdown state.
- c. Load state from the host-state area of the working VMCS as if a VM exit had occurred (see Section 26.7). The basic exit reason will be “VM-entry failure due to machine-check event.”

If the machine-check event occurs after any guest state has been loaded, option a above will not be used; it may be used if the machine-check event occurs while checking host state and VMX controls (or while reporting a failure due to such checks). An implementation may use option b only if all guest state has been loaded properly.

- VM exit:

If a machine-check event occurs during VM exit, one of the following three treatments must occur:

- a. Normal delivery before VM exit. If CR4.MCE = 1 before the VM exit, delivery of a machine-check exception (#MC) through the guest IDT (alternatively, this may cause a VM exit). If CR4.MCE = 0, the processor goes to shutdown state.
- b. Normal delivery after VM exit. If CR4.MCE = 1 after the VM exit, delivery of a machine-check exception (#MC) through the host IDT. If CR4.MCE = 0, the processor goes to shutdown state.
- c. Fail the VM exit. If the VM exit is to VMX root operation, a VMX abort will result; it will block events as done normally in VMX abort. The VMX abort indicator will show that a machine-check event induced the abort operation.

If a machine-check event is induced by an action in VMX non-root operation before any determination is made that the inducing action may cause a VM exit, that machine-check event should be considered as happening during guest execution in VMX non-root operation. This is the case even if the part of the action that caused the machine-check event was VMX-specific (for example, the processor’s consulting an I/O bitmap). If a machine-check exception occurs and if bit 12H of the exception bitmap is cleared to 0, the exception is delivered to the guest through gate 12H of its IDT; if the bit is set to 1, the machine-check exception causes a VM exit.

## NOTE

The state saved in the guest-state area on VM exits due to machine-check exceptions should be considered suspect. A VMM should consult the RIPV and EIPV bits in the IA32\_MCG\_STATUS MSR before resuming a guest that caused a VM exit due to a machine-check exception.

### 33.4.3 MCA Error Handling Guidelines for VMM

Section 33.4.2 covers general requirements for VMMs to handle machine-check exceptions, when normal operation of the guest machine and/or the VMM is no longer possible. enhancements of machine-check architecture in newer processors may support software recovery of uncorrected MC errors (UCR) signaled through either machine-check exceptions or corrected machine-check interrupt (CMCI). Section 15.5 and Section 15.6 describes details of these more recent enhancements of machine-check architecture.

In general, Virtual Machine Monitor (VMM) error handling should follow the recommendations for OS error handling described in Section 15.3, Section 15.6, Section 15.9, and Section 15.10. This section describes additional guidelines for hosted and native hypervisor-based VMM implementations to support corrected MC errors and recoverable uncorrected MC errors.

Because a hosted VMM provides virtualization services in the context of an existing standard host OS, the host OS controls platform hardware through the host OS services such as the standard OS device drivers. In hosted VMMs, MCA errors will be handled by the host OS error handling software.

In native VMMs, the hypervisor runs on the hardware directly, and may provide only a limited set of platform services for guest VMs. Most platform services may instead be provided by a “control OS”. In hypervisor-based VMMs, MCA errors will either be delivered directly to the VMM MCA handler (when the error is signaled while in the VMM context) or cause by a VM exit from a guest VM or be delivered to the MCA intercept handler. There are two general approaches the hypervisor can use to handle the MCA error: either within the hypervisor itself or by forwarding the error to the control OS.

### 33.4.3.1 VMM Error Handling Strategies

Broadly speaking, there are two strategies that VMMs may take for error handling:

- Basic error handling: in this approach the guest VM is treated as any other thread of execution. If the error recovery action does not support restarting the thread after handling the error, the guest VM should be terminated.
- MCA virtualization: in this approach, the VMM virtualizes the MCA events and hardware. This enables the VMM to intercept MCA events and inject an MCA into the guest VM. The guest VM then has the opportunity to attempt error recovery actions, rather than being terminated by the VMM.

Details of these approaches and implementation considerations for hosted and native VMMs are discussed below.

### 33.4.3.2 Basic VMM MCA error recovery handling

The simplest approach is for the VMM to treat the guest VM as any other thread of execution:

- MCE's that occur outside the stream of execution of a virtual machine guest will cause an MCE abort and may be handled by the MCA error handler following the recovery actions and guidelines described in Section 15.9, and Section 15.10. This includes logging the error and taking appropriate recovery actions when necessary. The VMM must not resume the interrupted thread of execution or another VM until it has taken the appropriate recovery action or, in the case of fatal MCAs, reset the system.
- MCE's that occur while executing in the context of a virtual machine will be intercepted by the VMM. The MCA intercept handler may follow the error handling guidelines listed in Section 15.9 and Section 15.10 for SRAO and SRAR errors. For SRAR errors, terminating the thread of execution will involve terminating the affected guest VM. For fatal errors the MCA handler should log the error and reset the system -- the VMM should not resume execution of the interrupted VM.

### 33.4.3.3 Implementation Considerations for the Basic Model

For hosted VMMs, the host OS MCA error handling code will perform error analysis and initiate the appropriate recovery actions. For the basic model this flow does not change when terminating a guest VM although the specific actions needed to terminate a guest VM may be different than terminating an application or user process.

For native, hypervisor-based VMMs, MCA errors will either be delivered directly to the VMM MCA handler (when the error is signaled while in the VMM context) or cause a VM exit from a guest VM or be delivered to the MCA intercept handler. There are two general approaches the hypervisor can use to handle the MCA error: either by forwarding the error to the control OS or within the hypervisor itself. These approaches are described in the following paragraphs.

The hypervisor may forward the error to the control OS for handling errors. This approach simplifies the hypervisor error handling since it relies on the control OS to implement the basic error handling model. The control OS error handling code will be similar to the error handling code in the hosted VMM. Errors can be forwarded to the control OS via an OS callback or by injecting an MCE event into the control OS. Injecting an MCE will cause the control OS MCA error handler to be invoked. The control OS is responsible for terminating the affected guest VM, if necessary, which may require cooperation from the hypervisor.

Alternatively, the error may be handled completely in the hypervisor. The hypervisor error handler is enhanced to implement the basic error handling model and the hypervisor error handler has the capability to fully analyze the error information and take recovery actions based on the guidelines. In this case error handling steps in the hypervisor are similar to those for the hosted VMM described above (where the hypervisor replaces the host OS actions). The hypervisor is responsible for terminating the affected guest VM, if necessary.

In all cases, if a fatal error is detected the VMM error handler should log the error and reset the system. The VMM error handler must ensure that guest VMs are not resumed after a fatal error is detected to ensure error containment is maintained.

### 33.4.3.4 MCA Virtualization

A more sophisticated approach for handling errors is to virtualize the MCA. This involves virtualizing the MCA hardware and intercepting the MCA event in the VMM when a guest VM is interrupted by an MCA. After analyzing the

error, the VMM error handler may then decide to inject an MCE abort into the guest VM for attempted guest VM error recovery. This would enable the guest OS the opportunity to take recovery actions specific to that guest.

For MCA virtualization, the VMM must provide the guest physical address for memory errors instead of the system physical address when reporting the errors to the guest VM. To compute the guest physical address, the VMM needs to maintain a reverse mapping of system physical page addresses to guest physical page addresses.

When the MCE is injected into the guest VM, the guest OS MCA handler would be invoked. The guest OS implements the MCA handling guidelines and it could potentially terminate the interrupted thread of execution within the guest instead of terminating the VM. The guest OS may also disable use of the affected page by the guest. When disabling the page the VMM error handler may handle the case where a page is shared by the VMM and a guest or by two guests. In these cases the page use must be disabled in both contexts to ensure no subsequent consumption errors are generated.

#### **33.4.3.5 Implementation Considerations for the MCA Virtualization Model**

MCA virtualization may be done in either hosted VMMs or hypervisor-based VMMs. The error handling flow is similar to the flow described in the basic handling case. The major difference is that the recovery action includes injecting the MCE abort into the guest VM to enable recovery by the guest OS when the MCA interrupts the execution of a guest VM.

## **33.5 HANDLING ACTIVITY STATES BY VMM**

A VMM might place a logic processor in the wait-for-SIPI activity state if supporting certain guest operating system using the multi-processor (MP) start-up algorithm. A guest with direct access to the physical local APIC and using the MP start-up algorithm sends an INIT-SIPI-SIPI IPI sequence to start the application processor. In order to trap the SIPIs, the VMM must start the logic processor which is the target of the SIPIs in wait-for-SIPI mode.

This chapter describes aspects of IA-64 and IA-32 architecture used in system management mode (SMM).

SMM provides an alternate operating environment that can be used to monitor and manage various system resources for more efficient energy usage, to control system hardware, and/or to run proprietary code. It was introduced into the IA-32 architecture in the Intel386 SL processor (a mobile specialized version of the Intel386 processor). It is also available in the Pentium M, Pentium 4, Intel Xeon, P6 family, and Pentium and Intel486 processors (beginning with the enhanced versions of the Intel486 SL and Intel486 processors).

### 34.1 SYSTEM MANAGEMENT MODE OVERVIEW

SMM is a special-purpose operating mode provided for handling system-wide functions like power management, system hardware control, or proprietary OEM-designed code. It is intended for use only by system firmware, not by applications software or general-purpose systems software. The main benefit of SMM is that it offers a distinct and easily isolated processor environment that operates transparently to the operating system or executive and software applications.

When SMM is invoked through a system management interrupt (SMI), the processor saves the current state of the processor (the processor's context), then switches to a separate operating environment defined by a new address space. The system management software executive (SMI handler) starts execution in that environment, and the critical code and data of the SMI handler reside in a physical memory region (SMRAM) within that address space. While in SMM, the processor executes SMI handler code to perform operations such as powering down unused disk drives or monitors, executing proprietary code, or placing the whole system in a suspended state. When the SMI handler has completed its operations, it executes a resume (RSM) instruction. This instruction causes the processor to reload the saved context of the processor, switch back to protected or real mode, and resume executing the interrupted application or operating-system program or task.

The following SMM mechanisms make it transparent to applications programs and operating systems:

- The only way to enter SMM is by means of an SMI.
- The processor executes SMM code in a separate address space that can be made inaccessible from the other operating modes.
- Upon entering SMM, the processor saves the context of the interrupted program or task.
- All interrupts normally handled by the operating system are disabled upon entry into SMM.
- The RSM instruction can be executed only in SMM.

Section 34.3 describes transitions into and out of SMM. The execution environment after entering SMM is in real-address mode with paging disabled ( $CR0.PE = CR0.PG = 0$ ). In this initial execution environment, the SMI handler can address up to 4 GBytes of memory and can execute all I/O and system instructions. Section 34.5 describes in detail the initial SMM execution environment for an SMI handler and operation within that environment. The SMI handler may subsequently switch to other operating modes while remaining in SMM.

#### NOTES

Software developers should be aware that, even if a logical processor was using the physical-address extension (PAE) mechanism (introduced in the P6 family processors) or was in IA-32e mode before an SMI, this will not be the case after the SMI is delivered. This is because delivery of an SMI disables paging (see Table 34-4). (This does not apply if the dual-monitor treatment of SMIs and SMM is active; see Section 34.15.)

#### 34.1.1 System Management Mode and VMX Operation

Traditionally, SMM services system management interrupts and then resumes program execution (back to the software stack consisting of executive and application software; see Section 34.2 through Section 34.13).

A virtual machine monitor (VMM) using VMX can act as a host to multiple virtual machines and each virtual machine can support its own software stack of executive and application software. On processors that support VMX, virtual-machine extensions may use system-management interrupts (SMIs) and system-management mode (SMM) in one of two ways:

- **Default treatment.** System firmware handles SMIs. The processor saves architectural states and critical states relevant to VMX operation upon entering SMM. When the firmware completes servicing SMIs, it uses RSM to resume VMX operation.
- **Dual-monitor treatment.** Two VM monitors collaborate to control the servicing of SMIs: one VMM operates outside of SMM to provide basic virtualization in support for guests; the other VMM operates inside SMM (while in VMX operation) to support system-management functions. The former is referred to as **executive monitor**, the latter **SMM-transfer monitor (STM)**.<sup>1</sup>

The default treatment is described in Section 34.14, “Default Treatment of SMIs and SMM with VMX Operation and SMX Operation”. Dual-monitor treatment of SMM is described in Section 34.15, “Dual-Monitor Treatment of SMIs and SMM”.

## 34.2 SYSTEM MANAGEMENT INTERRUPT (SMI)

The only way to enter SMM is by signaling an SMI through the SMI# pin on the processor or through an SMI message received through the APIC bus. The SMI is a nonmaskable external interrupt that operates independently from the processor’s interrupt- and exception-handling mechanism and the local APIC. The SMI takes precedence over an NMI and a maskable interrupt. SMM is non-reentrant; that is, the SMI is disabled while the processor is in SMM.

### NOTES

In the Pentium 4, Intel Xeon, and P6 family processors, when a processor that is designated as an application processor during an MP initialization sequence is waiting for a startup IPI (SIPI), it is in a mode where SMIs are masked. However if a SMI is received while an application processor is in the wait for SIPI mode, the SMI will be pended. The processor then responds on receipt of a SIPI by immediately servicing the pended SMI and going into SMM before handling the SIPI.

An SMI may be blocked for one instruction following execution of STI, MOV to SS, or POP into SS.

## 34.3 SWITCHING BETWEEN SMM AND THE OTHER PROCESSOR OPERATING MODES

Figure 2-3 shows how the processor moves between SMM and the other processor operating modes (protected, real-address, and virtual-8086). Signaling an SMI while the processor is in real-address, protected, or virtual-8086 modes always causes the processor to switch to SMM. Upon execution of the RSM instruction, the processor always returns to the mode it was in when the SMI occurred.

### 34.3.1 Entering SMM

The processor always handles an SMI on an architecturally defined “interruptible” point in program execution (which is commonly at an IA-32 architecture instruction boundary). When the processor receives an SMI, it waits for all instructions to retire and for all stores to complete. The processor then saves its current context in SMRAM (see Section 34.4), enters SMM, and begins to execute the SMI handler.

Upon entering SMM, the processor signals external hardware that SMI handling has begun. The signaling mechanism used is implementation dependent. For the P6 family processors, an SMI acknowledge transaction is gener-

1. The dual-monitor treatment may not be supported by all processors. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1) to determine whether it is supported.

ated on the system bus and the multiplexed status signal EXF4 is asserted each time a bus transaction is generated while the processor is in SMM. For the Pentium and Intel486 processors, the SMIACK# pin is asserted.

An SMI has a greater priority than debug exceptions and external interrupts. Thus, if an NMI, maskable hardware interrupt, or a debug exception occurs at an instruction boundary along with an SMI, only the SMI is handled. Subsequent SMI requests are not acknowledged while the processor is in SMM. The first SMI interrupt request that occurs while the processor is in SMM (that is, after SMM has been acknowledged to external hardware) is latched and serviced when the processor exits SMM with the RSM instruction. The processor will latch only one SMI while in SMM.

See Section 34.5 for a detailed description of the execution environment when in SMM.

### 34.3.2 Exiting From SMM

The only way to exit SMM is to execute the RSM instruction. The RSM instruction is only available to the SMI handler; if the processor is not in SMM, attempts to execute the RSM instruction result in an invalid-opcode exception (#UD) being generated.

The RSM instruction restores the processor's context by loading the state save image from SMRAM back into the processor's registers. The processor then returns an SMIACK transaction on the system bus and returns program control back to the interrupted program.

Upon successful completion of the RSM instruction, the processor signals external hardware that SMM has been exited. For the P6 family processors, an SMI acknowledge transaction is generated on the system bus and the multiplexed status signal EXF4 is no longer generated on bus cycles. For the Pentium and Intel486 processors, the SMIACK# pin is deserted.

If the processor detects invalid state information saved in the SMRAM, it enters the shutdown state and generates a special bus cycle to indicate it has entered shutdown state. Shutdown happens only in the following situations:

- A reserved bit in control register CR4 is set to 1 on a write to CR4. This error should not happen unless SMI handler code modifies reserved areas of the SMRAM saved state map (see Section 34.4.1). CR4 is saved in the state map in a reserved location and cannot be read or modified in its saved state.
- An illegal combination of bits is written to control register CR0, in particular PG set to 1 and PE set to 0, or NW set to 1 and CD set to 0.
- CR4.PCIDE would be set to 1 and IA32\_EFER.LMA to 0.
- (For the Pentium and Intel486 processors only.) If the address stored in the SMBASE register when an RSM instruction is executed is not aligned on a 32-KByte boundary. This restriction does not apply to the P6 family processors.

In the shutdown state, Intel processors stop executing instructions until a RESET#, INIT# or NMI# is asserted. While Pentium family processors recognize the SMI# signal in shutdown state, P6 family and Intel486 processors do not. Intel does not support using SMI# to recover from shutdown states for any processor family; the response of processors in this circumstance is not well defined. On Pentium 4 and later processors, shutdown will inhibit INTR and A20M but will not change any of the other inhibits. On these processors, NMIs will be inhibited if no action is taken in the SMI handler to uninhibit them (see Section 34.8).

If the processor is in the HALT state when the SMI is received, the processor handles the return from SMM slightly differently (see Section 34.10). Also, the SMBASE address can be changed on a return from SMM (see Section 34.11).

## 34.4 SMRAM

Upon entering SMM, the processor switches to a new address space. Because paging is disabled upon entering SMM, this initial address space maps all memory accesses to the low 4 GBytes of the processor's physical address space. The SMI handler's critical code and data reside in a memory region referred to as system-management RAM (SMRAM). The processor uses a pre-defined region within SMRAM to save the processor's pre-SMI context. SMRAM can also be used to store system management information (such as the system configuration and specific information about powered-down devices) and OEM-specific information.

The default SMRAM size is 64 KBytes beginning at a base physical address in physical memory called the SMBASE (see Figure 34-1). The SMBASE default value following a hardware reset is 30000H. The processor looks for the first instruction of the SMI handler at the address [SMBASE + 8000H]. It stores the processor's state in the area from [SMBASE + FE00H] to [SMBASE + FFFFH]. See Section 34.4.1 for a description of the mapping of the state save area.

The system logic is minimally required to decode the physical address range for the SMRAM from [SMBASE + 8000H] to [SMBASE + FFFFH]. A larger area can be decoded if needed. The size of this SMRAM can be between 32 KBytes and 4 GBytes.

The location of the SMRAM can be changed by changing the SMBASE value (see Section 34.11). It should be noted that all processors in a multiple-processor system are initialized with the same SMBASE value (30000H). Initialization software must sequentially place each processor in SMM and change its SMBASE so that it does not overlap those of other processors.

The actual physical location of the SMRAM can be in system memory or in a separate RAM memory. The processor generates an SMI acknowledge transaction (P6 family processors) or asserts the SMIACK# pin (Pentium and Intel486 processors) when the processor receives an SMI (see Section 34.3.1).

System logic can use the SMI acknowledge transaction or the assertion of the SMIACK# pin to decode accesses to the SMRAM and redirect them (if desired) to specific SMRAM memory. If a separate RAM memory is used for SMRAM, system logic should provide a programmable method of mapping the SMRAM into system memory space when the processor is not in SMM. This mechanism will enable start-up procedures to initialize the SMRAM space (that is, load the SMI handler) before executing the SMI handler during SMM.

### 34.4.1 SMRAM State Save Map

When an IA-32 processor that does not support Intel 64 architecture initially enters SMM, it writes its state to the state save area of the SMRAM. The state save area begins at [SMBASE + 8000H + 7FFFH] and extends down to [SMBASE + 8000H + 7E00H]. Table 34-1 shows the state save map. The offset in column 1 is relative to the SMBASE value plus 8000H. Reserved spaces should not be used by software.

Some of the registers in the SMRAM state save area (marked YES in column 3) may be read and changed by the SMI handler, with the changed values restored to the processor registers by the RSM instruction. Some register images are read-only, and must not be modified (modifying these registers will result in unpredictable behavior). An SMI handler should not rely on any values stored in an area that is marked as reserved.

Figure 34-1. SMRAM Usage

Table 34-1. SMRAM State Save Map

Offset (Added to SMBASE + 8000H)	Register	Writable?
7FFCH	CR0	No
7FF8H	CR3	No
7FF4H	EFLAGS	Yes
7FF0H	EIP	Yes
7FECH	EDI	Yes
7FE8H	ESI	Yes
7FE4H	EBP	Yes
7FE0H	ESP	Yes
7FDCH	EBX	Yes
7FD8H	EDX	Yes
7FD4H	ECX	Yes
7FD0H	EAX	Yes
7FCCH	DR6	No
7FC8H	DR7	No
7FC4H	TR <sup>1</sup>	No
7FC0H	Reserved	No
7FBCH	GS <sup>1</sup>	No
7FB8H	FS <sup>1</sup>	No
7FB4H	DS <sup>1</sup>	No
7FB0H	SS <sup>1</sup>	No
7FACH	CS <sup>1</sup>	No
7FA8H	ES <sup>1</sup>	No
7FA4H	I/O State Field, see Section 34.7	No
7FA0H	I/O Memory Address Field, see Section 34.7	No
7F9FH-7F03H	Reserved	No
7F02H	Auto HALT Restart Field (Word)	Yes
7F00H	I/O Instruction Restart Field (Word)	Yes
7EFCH	SMM Revision Identifier Field (Doubleword)	No
7EF8H	SMBASE Field (Doubleword)	Yes
7EF7H - 7E00H	Reserved	No

**NOTE:**

1. The two most significant bytes are reserved.

The following registers are saved (but not readable) and restored upon exiting SMM:

- Control register CR4. (This register is cleared to all 0s when entering SMM).
- The hidden segment descriptor information stored in segment registers CS, DS, ES, FS, GS, and SS.

If an SMI request is issued for the purpose of powering down the processor, the values of all reserved locations in the SMM state save must be saved to nonvolatile memory.

The following state is not automatically saved and restored following an SMI and the RSM instruction, respectively:

- Debug registers DR0 through DR3.
- The x87 FPU registers.
- The MTRRs.
- Control register CR2.
- The model-specific registers (for the P6 family and Pentium processors) or test registers TR3 through TR7 (for the Pentium and Intel486 processors).
- The state of the trap controller.
- The machine-check architecture registers.
- The APIC internal interrupt state (ISR, IRR, etc.).
- The microcode update state.

If an SMI is used to power down the processor, a power-on reset will be required before returning to SMM, which will reset much of this state back to its default values. So an SMI handler that is going to trigger power down should first read these registers listed above directly, and save them (along with the rest of RAM) to nonvolatile storage. After the power-on reset, the continuation of the SMI handler should restore these values, along with the rest of the system's state. Anytime the SMI handler changes these registers in the processor, it must also save and restore them.

### NOTES

A small subset of the MSRs (such as, the time-stamp counter and performance-monitoring counters) are not arbitrarily writable and therefore cannot be saved and restored. SMM-based power-down and restoration should only be performed with operating systems that do not use or rely on the values of these registers.

Operating system developers should be aware of this fact and insure that their operating-system assisted power-down and restoration software is immune to unexpected changes in these register values.

#### 34.4.1.1 SMRAM State Save Map and Intel 64 Architecture

When the processor initially enters SMM, it writes its state to the state save area of the SMRAM. The state save area on an Intel 64 processor at [SMBASE + 8000H + 7FFFH] and extends to [SMBASE + 8000H + 7C00H].

Support for Intel 64 architecture is reported by CPUID.80000001:EDX[29] = 1. The layout of the SMRAM state save map is shown in Table 34-3.

Additionally, the SMRAM state save map shown in Table 34-3 also applies to processors with the following CPUID signatures listed in Table 34-2, irrespective of the value in CPUID.80000001:EDX[29].

**Table 34-2. Processor Signatures and 64-bit SMRAM State Save Map Format**

DisplayFamily_DisplayModel	Processor Families/Processor Number Series
06_17H	Intel Xeon Processor 5200, 5400 series, Intel Core 2 Quad processor Q9xxx, Intel Core 2 Duo processors E8000, T9000,
06_0FH	Intel Xeon Processor 3000, 3200, 5100, 5300, 7300 series, Intel Core 2 Quad, Intel Core 2 Extreme, Intel Core 2 Duo processors, Intel Pentium dual-core processors
06_1CH	Intel® Atom™ processors

7DCFH - 7C00H	Reserved	No

**NOTE:**

1. The two most significant bytes are reserved.

### 34.4.2 SMRAM Caching

An IA-32 processor does not automatically write back and invalidate its caches before entering SMM or before exiting SMM. Because of this behavior, care must be taken in the placement of the SMRAM in system memory and in the caching of the SMRAM to prevent cache incoherence when switching back and forth between SMM and protected mode operation. Either of the following three methods of locating the SMRAM in system memory will guarantee cache coherency:

- Place the SRAM in a dedicated section of system memory that the operating system and applications are prevented from accessing. Here, the SRAM can be designated as cacheable (WB, WT, or WC) for optimum processor performance, without risking cache incoherence when entering or exiting SMM.
- Place the SRAM in a section of memory that overlaps an area used by the operating system (such as the video memory), but designate the SMRAM as uncacheable (UC). This method prevents cache access when in SMM to maintain cache coherency, but the use of uncacheable memory reduces the performance of SMM code.
- Place the SRAM in a section of system memory that overlaps an area used by the operating system and/or application code, but explicitly flush (write back and invalidate) the caches upon entering and exiting SMM mode. This method maintains cache coherency, but incurs the overhead of two complete cache flushes.

For Pentium 4, Intel Xeon, and P6 family processors, a combination of the first two methods of locating the SMRAM is recommended. Here the SMRAM is split between an overlapping and a dedicated region of memory. Upon entering SMM, the SMRAM space that is accessed overlaps video memory (typically located in low memory). This SMRAM section is designated as UC memory. The initial SMM code then jumps to a second SMRAM section that is located in a dedicated region of system memory (typically in high memory). This SMRAM section can be cached for optimum processor performance.

For systems that explicitly flush the caches upon entering SMM (the third method described above), the cache flush can be accomplished by asserting the FLUSH# pin at the same time as the request to enter SMM (generally initiated by asserting the SMI# pin). The priorities of the FLUSH# and SMI# pins are such that the FLUSH# is serviced first. To guarantee this behavior, the processor requires that the following constraints on the interaction of FLUSH# and SMI# be met. In a system where the FLUSH# and SMI# pins are synchronous and the set up and hold times are met, then the FLUSH# and SMI# pins may be asserted in the same clock. In asynchronous systems, the FLUSH# pin must be asserted at least one clock before the SMI# pin to guarantee that the FLUSH# pin is serviced first.

Upon leaving SMM (for systems that explicitly flush the caches), the WBINVD instruction should be executed prior to leaving SMM to flush the caches.

## NOTES

In systems based on the Pentium processor that use the FLUSH# pin to write back and invalidate cache contents before entering SMM, the processor will prefetch at least one cache line in between when the Flush Acknowledge cycle is run and the subsequent recognition of SMI# and the assertion of SMIACK#.

It is the obligation of the system to ensure that these lines are not cached by returning KEN# inactive to the Pentium processor.

### 34.4.2.1 System Management Range Registers (SMRR)

SMI handler code and data stored by SMM code resides in SMRAM. The SMRR interface is an enhancement in Intel 64 architecture to limit cacheable reference of addresses in SMRAM to code running in SMM. The SMRR interface can be configured only by code running in SMM. Details of SMRR is described in Section 11.11.2.4.

## 34.5 SMI HANDLER EXECUTION ENVIRONMENT

Section 34.5.1 describes the initial execution environment for an SMI handler. An SMI handler may re-configure its execution environment to other supported operating modes. Section 34.5.2 discusses modifications an SMI handler can make to its execution environment.

### 34.5.1 Initial SMM Execution Environment

After saving the current context of the processor, the processor initializes its core registers to the values shown in Table 34-4. Upon entering SMM, the PE and PG flags in control register CR0 are cleared, which places the processor in an environment similar to real-address mode. The differences between the SMM execution environment and the real-address mode execution environment are as follows:

- The addressable address space ranges from 0 to FFFFFFFFH (4 GBytes).
- The normal 64-KByte segment limit for real-address mode is increased to 4 GBytes.
- The default operand and address sizes are set to 16 bits, which restricts the addressable SMRAM address space to the 1-MByte real-address mode limit for native real-address-mode code. However, operand-size and address-size override prefixes can be used to access the address space beyond the 1-MByte.

**Table 34-4. Processor Register Initialization in SMM**

Register	Contents
General-purpose registers	Undefined
EFLAGS	00000002H
EIP	00008000H
CS selector	SMM Base shifted right 4 bits (default 3000H)
CS base	SMM Base (default 30000H)
DS, ES, FS, GS, SS Selectors	0000H

**Table 34-4. Processor Register Initialization in SMM**

DS, ES, FS, GS, SS Bases	000000000H
DS, ES, FS, GS, SS Limits	0FFFFFFFFH
CR0	PE, EM, TS, and PG flags set to 0; others unmodified
CR4	Cleared to zero
DR6	Undefined
DR7	00000400H

- Near jumps and calls can be made to anywhere in the 4-GByte address space if a 32-bit operand-size override prefix is used. Due to the real-address-mode style of base-address formation, a far call or jump cannot transfer control to a segment with a base address of more than 20 bits (1 MByte). However, since the segment limit in SMM is 4 GBytes, offsets into a segment that go beyond the 1-MByte limit are allowed when using 32-bit operand-size override prefixes. Any program control transfer that does not have a 32-bit operand-size override prefix truncates the EIP value to the 16 low-order bits.
- Data and the stack can be located anywhere in the 4-GByte address space, but can be accessed only with a 32-bit address-size override if they are located above 1 MByte. As with the code segment, the base address for a data or stack segment cannot be more than 20 bits.

The value in segment register CS is automatically set to the default of 30000H for the SMBASE shifted 4 bits to the right; that is, 3000H. The EIP register is set to 8000H. When the EIP value is added to shifted CS value (the SMBASE), the resulting linear address points to the first instruction of the SMI handler.

The other segment registers (DS, SS, ES, FS, and GS) are cleared to 0 and their segment limits are set to 4 GBytes. In this state, the SMRAM address space may be treated as a single flat 4-GByte linear address space. If a segment register is loaded with a 16-bit value, that value is then shifted left by 4 bits and loaded into the segment base (hidden part of the segment register). The limits and attributes are not modified.

Maskable hardware interrupts, exceptions, NMI interrupts, SMI interrupts, A20M interrupts, single-step traps, breakpoint traps, and INIT operations are inhibited when the processor enters SMM. Maskable hardware interrupts, exceptions, single-step traps, and breakpoint traps can be enabled in SMM if the SMM execution environment provides and initializes an interrupt table and the necessary interrupt and exception handlers (see Section 34.6).

### 34.5.2 SMI Handler Operating Mode Switching

Within SMM, an SMI handler may change the processor's operating mode (e.g., to enable PAE paging, enter 64-bit mode, etc.) after it has made proper preparation and initialization to do so. For example, if switching to 32-bit protected mode, the SMI handler should follow the guidelines provided in Chapter 9, "Processor Management and Initialization". If the SMI handler does wish to change operating mode, it is responsible for executing the appropriate mode-transition code after each SMI.

It is recommended that the SMI handler make use of all means available to protect the integrity of its critical code and data. In particular, it should use the system-management range register (SMRR) interface if it is available (see Section 11.11.2.4). The SMRR interface can protect only the first 4 GBytes of the physical address space. The SMI handler should take that fact into account if it uses operating modes that allow access to physical addresses beyond that 4-GByte limit (e.g. PAE paging or 64-bit mode).

Execution of the RSM instruction restores the pre-SMI processor state from the SMRAM state-state map (see Section 34.4.1) into which it was stored when the processor entered SMM. (The SMBASE field in the SMRAM state-state map does not determine the state following RSM but rather the initial environment following the next entry to SMM.) Any required change to operating mode is performed by the RSM instruction; there is no need for the SMI handler to change modes explicitly prior to executing RSM.

## 34.6 EXCEPTIONS AND INTERRUPTS WITHIN SMM

When the processor enters SMM, all hardware interrupts are disabled in the following manner:

- The IF flag in the EFLAGS register is cleared, which inhibits maskable hardware interrupts from being generated.
- The TF flag in the EFLAGS register is cleared, which disables single-step traps.
- Debug register DR7 is cleared, which disables breakpoint traps. (This action prevents a debugger from accidentally breaking into an SMI handler if a debug breakpoint is set in normal address space that overlays code or data in SMRAM.)
- NMI, SMI, and A20M interrupts are blocked by internal SMM logic. (See Section 34.8 for more information about how NMIs are handled in SMM.)

Software-invoked interrupts and exceptions can still occur, and maskable hardware interrupts can be enabled by setting the IF flag. Intel recommends that SMM code be written in so that it does not invoke software interrupts (with the INT *n*, INTO, INT 3, or BOUND instructions) or generate exceptions.

If the SMI handler requires interrupt and exception handling, an SMM interrupt table and the necessary exception and interrupt handlers must be created and initialized from within SMM. Until the interrupt table is correctly initialized (using the LIDT instruction), exceptions and software interrupts will result in unpredictable processor behavior.

The following restrictions apply when designing SMM interrupt and exception-handling facilities:

- The interrupt table should be located at linear address 0 and must contain real-address mode style interrupt vectors (4 bytes containing CS and IP).
- Due to the real-address mode style of base address formation, an interrupt or exception cannot transfer control to a segment with a base address of more than 20 bits.
- An interrupt or exception cannot transfer control to a segment offset of more than 16 bits (64 KBytes).
- When an exception or interrupt occurs, only the 16 least-significant bits of the return address (EIP) are pushed onto the stack. If the offset of the interrupted procedure is greater than 64 KBytes, it is not possible for the interrupt/exception handler to return control to that procedure. (One solution to this problem is for a handler to adjust the return address on the stack.)
- The SMBASE relocation feature affects the way the processor will return from an interrupt or exception generated while the SMI handler is executing. For example, if the SMBASE is relocated to above 1 MByte, but the exception handlers are below 1 MByte, a normal return to the SMI handler is not possible. One solution is to provide the exception handler with a mechanism for calculating a return address above 1 MByte from the 16-bit return address on the stack, then use a 32-bit far call to return to the interrupted procedure.
- If an SMI handler needs access to the debug trap facilities, it must insure that an SMM accessible debug handler is available and save the current contents of debug registers DR0 through DR3 (for later restoration). Debug registers DR0 through DR3 and DR7 must then be initialized with the appropriate values.
- If an SMI handler needs access to the single-step mechanism, it must insure that an SMM accessible single-step handler is available, and then set the TF flag in the EFLAGS register.
- If the SMI design requires the processor to respond to maskable hardware interrupts or software-generated interrupts while in SMM, it must ensure that SMM accessible interrupt handlers are available and then set the IF flag in the EFLAGS register (using the STI instruction). Software interrupts are not blocked upon entry to SMM, so they do not need to be enabled.

## 34.7 MANAGING SYNCHRONOUS AND ASYNCHRONOUS SYSTEM MANAGEMENT INTERRUPTS

When coding for a multiprocessor system or a system with Intel HT Technology, it was not always possible for an SMI handler to distinguish between a synchronous SMI (triggered during an I/O instruction) and an asynchronous SMI. To facilitate the discrimination of these two events, incremental state information has been added to the SMM state save map.

Processors that have an SMM revision ID of 30004H or higher have the incremental state information described below.

### 34.7.1 I/O State Implementation

Within the extended SMM state save map, a bit (IO\_SMI) is provided that is set only when an SMI is either taken immediately after a *successful* I/O instruction or is taken after a *successful* iteration of a REP I/O instruction (the *successful* notion pertains to the processor point of view; not necessarily to the corresponding platform function). When set, the IO\_SMI bit provides a strong indication that the corresponding SMI was synchronous. In this case, the SMM State Save Map also supplies the port address of the I/O operation. The IO\_SMI bit and the I/O Port Address may be used in conjunction with the information logged by the platform to confirm that the SMI was indeed synchronous.

The IO\_SMI bit by itself is a strong indication, not a guarantee, that the SMI is synchronous. This is because an asynchronous SMI might coincidentally be taken after an I/O instruction. In such a case, the IO\_SMI bit would still be set in the SMM state save map.

Information characterizing the I/O instruction is saved in two locations in the SMM State Save Map (Table 34-5). The IO\_SMI bit also serves as a valid bit for the rest of the I/O information fields. The contents of these I/O information fields are not defined when the IO\_SMI bit is not set.

**Table 34-5. I/O Instruction Information in the SMM State Save Map**

State (SMM Rev. ID: 30004H or higher)	Format								
	31	16	15	8	7	4	3	1	0
I/O State Field SMRAM offset 7FA4		I/O Port		Reserved		I/O Type		I/O Length	IO_SMI
	31								0
I/O Memory Address Field SMRAM offset 7FA0	I/O Memory Address								

When IO\_SMI is set, the other fields may be interpreted as follows:

- I/O length:
  - 001 – Byte
  - 010 – Word
  - 100 – Dword
- I/O instruction type (Table 34-6)

**Table 34-6. I/O Instruction Type Encodings**

Instruction	Encoding
IN Immediate	1001
IN DX	0001
OUT Immediate	1000
OUT DX	0000
INS	0011
OUTS	0010
REP INS	0111
REP OUTS	0110

## 34.8 NMI HANDLING WHILE IN SMM

NMI interrupts are blocked upon entry to the SMI handler. If an NMI request occurs during the SMI handler, it is latched and serviced after the processor exits SMM. Only one NMI request will be latched during the SMI handler. If an NMI request is pending when the processor executes the RSM instruction, the NMI is serviced before the next instruction of the interrupted code sequence. This assumes that NMIs were not blocked before the SMI occurred. If NMIs were blocked before the SMI occurred, they are blocked after execution of RSM.

Although NMI requests are blocked when the processor enters SMM, they may be enabled through software by executing an IRET instruction. If the SMI handler requires the use of NMI interrupts, it should invoke a dummy interrupt service routine for the purpose of executing an IRET instruction. Once an IRET instruction is executed, NMI interrupt requests are serviced in the same “real mode” manner in which they are handled outside of SMM.

A special case can occur if an SMI handler nests inside an NMI handler and then another NMI occurs. During NMI interrupt handling, NMI interrupts are disabled, so normally NMI interrupts are serviced and completed with an IRET instruction one at a time. When the processor enters SMM while executing an NMI handler, the processor saves the SMRAM state save map but does not save the attribute to keep NMI interrupts disabled. Potentially, an NMI could be latched (while in SMM or upon exit) and serviced upon exit of SMM even though the previous NMI handler has still not completed. One or more NMIs could thus be nested inside the first NMI handler. The NMI interrupt handler should take this possibility into consideration.

Also, for the Pentium processor, exceptions that invoke a trap or fault handler will enable NMI interrupts from inside of SMM. This behavior is implementation specific for the Pentium processor and is not part of the IA-32 architecture.

## 34.9 SMM REVISION IDENTIFIER

The SMM revision identifier field is used to indicate the version of SMM and the SMM extensions that are supported by the processor (see Figure 34-2). The SMM revision identifier is written during SMM entry and can be examined in SMRAM space at offset 7EFCH. The lower word of the SMM revision identifier refers to the version of the base SMM architecture.

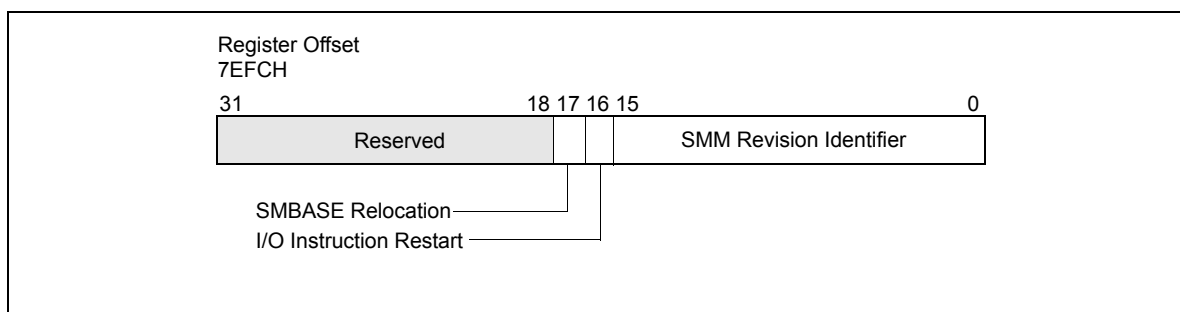

Figure 34-2. SMM Revision Identifier

The upper word of the SMM revision identifier refers to the extensions available. If the I/O instruction restart flag (bit 16) is set, the processor supports the I/O instruction restart (see Section 34.12); if the SMBASE relocation flag (bit 17) is set, SMRAM base address relocation is supported (see Section 34.11).

## 34.10 AUTO HALT RESTART

If the processor is in a HALT state (due to the prior execution of a HLT instruction) when it receives an SMI, the processor records the fact in the auto HALT restart flag in the saved processor state (see Figure 34-3). (This flag is located at offset 7F02H and bit 0 in the state save area of the SMRAM.)

If the processor sets the auto HALT restart flag upon entering SMM (indicating that the SMI occurred when the processor was in the HALT state), the SMI handler has two options:

- It can leave the auto HALT restart flag set, which instructs the RSM instruction to return program control to the HLT instruction. This option in effect causes the processor to re-enter the HALT state after handling the SMI. (This is the default operation.)
- It can clear the auto HALT restart flag, which instructs the RSM instruction to return program control to the instruction following the HLT instruction.

Figure 34-3. Auto HALT Restart Field

These options are summarized in Table 34-7. If the processor was not in a HALT state when the SMI was received (the auto HALT restart flag is cleared), setting the flag to 1 will cause unpredictable behavior when the RSM instruction is executed.

Table 34-7. Auto HALT Restart Flag Values

Value of Flag After Entry to SMM	Value of Flag When Exiting SMM	Action of Processor When Exiting SMM
0	0	Returns to next instruction in interrupted program or task.
0	1	Unpredictable.
1	0	Returns to next instruction after HLT instruction.
1	1	Returns to HALT state.

If the HLT instruction is restarted, the processor will generate a memory access to fetch the HLT instruction (if it is not in the internal cache), and execute a HLT bus transaction. This behavior results in multiple HLT bus transactions for the same HLT instruction.

### 34.10.1 Executing the HLT Instruction in SMM

The HLT instruction should not be executed during SMM, unless interrupts have been enabled by setting the IF flag in the EFLAGS register. If the processor is halted in SMM, the only event that can remove the processor from this state is a maskable hardware interrupt or a hardware reset.

## 34.11 SMBASE RELOCATION

The default base address for the SMRAM is 30000H. This value is contained in an internal processor register called the SMBASE register. The operating system or executive can relocate the SMRAM by setting the SMBASE field in the saved state map (at offset 7EF8H) to a new value (see Figure 34-4). The RSM instruction reloads the internal SMBASE register with the value in the SMBASE field each time it exits SMM. All subsequent SMI requests will use the new SMBASE value to find the starting address for the SMI handler (at SMBASE + 8000H) and the SMRAM state save area (from SMBASE + FE00H to SMBASE + FFFFH). (The processor resets the value in its internal SMBASE register to 30000H on a RESET, but does not change it on an INIT.)

**Figure 34-4. SMBASE Relocation Field**

In multiple-processor systems, initialization software must adjust the SMBASE value for each processor so that the SMRAM state save areas for each processor do not overlap. (For Pentium and Intel486 processors, the SMBASE values must be aligned on a 32-KByte boundary or the processor will enter shutdown state during the execution of a RSM instruction.)

If the SMBASE relocation flag in the SMM revision identifier field is set, it indicates the ability to relocate the SMBASE (see Section 34.9).

## 34.12 I/O INSTRUCTION RESTART

If the I/O instruction restart flag in the SMM revision identifier field is set (see Section 34.9), the I/O instruction restart mechanism is present on the processor. This mechanism allows an interrupted I/O instruction to be re-executed upon returning from SMM mode. For example, if an I/O instruction is used to access a powered-down I/O device, a chip set supporting this device can intercept the access and respond by asserting SMI#. This action invokes the SMI handler to power-up the device. Upon returning from the SMI handler, the I/O instruction restart mechanism can be used to re-execute the I/O instruction that caused the SMI.

The I/O instruction restart field (at offset 7F00H in the SMM state-save area, see Figure 34-5) controls I/O instruction restart. When an RSM instruction is executed, if this field contains the value FFH, then the EIP register is modified to point to the I/O instruction that received the SMI request. The processor will then automatically re-execute the I/O instruction that the SMI trapped. (The processor saves the necessary machine state to insure that re-execution of the instruction is handled coherently.)

**Figure 34-5. I/O Instruction Restart Field**

If the I/O instruction restart field contains the value 00H when the RSM instruction is executed, then the processor begins program execution with the instruction following the I/O instruction. (When a repeat prefix is being used, the next instruction may be the next I/O instruction in the repeat loop.) Not re-executing the interrupted I/O instruction is the default behavior; the processor automatically initializes the I/O instruction restart field to 00H upon entering SMM. Table 34-8 summarizes the states of the I/O instruction restart field.

**Table 34-8. I/O Instruction Restart Field Values**

Value of Flag After Entry to SMM	Value of Flag When Exiting SMM	Action of Processor When Exiting SMM
00H	00H	Does not re-execute trapped I/O instruction.
00H	FFH	Re-executes trapped I/O instruction.

The I/O instruction restart mechanism does not indicate the cause of the SMI. It is the responsibility of the SMI handler to examine the state of the processor to determine the cause of the SMI and to determine if an I/O instruction was interrupted and should be restarted upon exiting SMM. If an SMI interrupt is signaled on a non-I/O instruction boundary, setting the I/O instruction restart field to FFH prior to executing the RSM instruction will likely result in a program error.

### 34.12.1 Back-to-Back SMI Interrupts When I/O Instruction Restart Is Being Used

If an SMI interrupt is signaled while the processor is servicing an SMI interrupt that occurred on an I/O instruction boundary, the processor will service the new SMI request before restarting the originally interrupted I/O instruction. If the I/O instruction restart field is set to FFH prior to returning from the second SMI handler, the EIP will point to an address different from the originally interrupted I/O instruction, which will likely lead to a program error. To avoid this situation, the SMI handler must be able to recognize the occurrence of back-to-back SMI interrupts when I/O instruction restart is being used and insure that the handler sets the I/O instruction restart field to 00H prior to returning from the second invocation of the SMI handler.

## 34.13 SMM MULTIPLE-PROCESSOR CONSIDERATIONS

The following should be noted when designing multiple-processor systems:

- Any processor in a multiprocessor system can respond to an SMM.
- Each processor needs its own SMRAM space. This space can be in system memory or in a separate RAM.
- The SMRAMs for different processors can be overlapped in the same memory space. The only stipulation is that each processor needs its own state save area and its own dynamic data storage area. (Also, for the Pentium and Intel486 processors, the SMBASE address must be located on a 32-KByte boundary.) Code and static data can be shared among processors. Overlapping SMRAM spaces can be done more efficiently with the P6 family processors because they do not require that the SMBASE address be on a 32-KByte boundary.
- The SMI handler will need to initialize the SMBASE for each processor.
- Processors can respond to local SMIs through their SMI# pins or to SMIs received through the APIC interface. The APIC interface can distribute SMIs to different processors.
- Two or more processors can be executing in SMM at the same time.
- When operating Pentium processors in dual processing (DP) mode, the SMIACT# pin is driven only by the MRM processor and should be sampled with ADS#. For additional details, see Chapter 14 of the *Pentium Processor Family User's Manual, Volume 1*.

SMM is not re-entrant, because the SMRAM State Save Map is fixed relative to the SMBASE. If there is a need to support two or more processors in SMM mode at the same time then each processor should have dedicated SMRAM spaces. This can be done by using the SMBASE Relocation feature (see Section 34.11).

## 34.14 DEFAULT TREATMENT OF SMIS AND SMM WITH VMX OPERATION AND SMX OPERATION

Under the default treatment, the interactions of SMIs and SMM with VMX operation are few. This section details those interactions. It also explains how this treatment affects SMX operation.

### 34.14.1 Default Treatment of SMI Delivery

Ordinary SMI delivery saves processor state into SMRAM and then loads state based on architectural definitions. Under the default treatment, processors that support VMX operation perform SMI delivery as follows:

```

enter SMM;
save the following internal to the processor:
    CR4.VMXE
    an indication of whether the logical processor was in VMX operation (root or non-root)
IF the logical processor is in VMX operation
    THEN
        save current VMCS pointer internal to the processor;
        leave VMX operation;
        save VMX-critical state defined below;

```

```

Fi;
IF the logical processor supports SMX operation
  THEN
    save internal to the logical processor an indication of whether the Intel® TXT private space is locked;
    IF the TXT private space is unlocked
      THEN lock the TXT private space;
    Fi;
Fi;
CR4.VMXE ← 0;
perform ordinary SMI delivery:
  save processor state in SMRAM;
  set processor state to standard SMM values;1
  invalidate linear mappings and combined mappings associated with VPID 0000H (for all PCIDs); combined mappings for VPID 0000H
  are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 28.3);

```

The pseudocode above makes reference to the saving of **VMX-critical state**. This state consists of the following: (1) SS.DPL (the current privilege level); (2) RFLAGS.VM<sup>2</sup>; (3) the state of blocking by STI and by MOV SS (see Table 24-3 in Section 24.4.2); (4) the state of virtual-NMI blocking (only if the processor is in VMX non-root operation and the “virtual NMIs” VM-execution control is 1); and (5) an indication of whether an MTF VM exit is pending (see Section 25.5.2). These data may be saved internal to the processor or in the VMCS region of the current VMCS. Processors that do not support SMI recognition while there is blocking by STI or by MOV SS need not save the state of such blocking.

If the logical processor supports the 1-setting of the “enable EPT” VM-execution control and the logical processor was in VMX non-root operation at the time of an SMI, it saves the value of that control into bit 0 of the 32-bit field at offset SMBASE + 8000H + 7EE0H (SMBASE + FEE0H; see Table 34-3).<sup>3</sup> If the logical processor was not in VMX non-root operation at the time of the SMI, it saves 0 into that bit. If the logical processor saves 1 into that bit (it was in VMX non-root operation and the “enable EPT” VM-execution control was 1), it saves the value of the EPT pointer (EPTP) into the 64-bit field at offset SMBASE + 8000H + 7ED8H (SMBASE + FED8H).

Because SMI delivery causes a logical processor to leave VMX operation, all the controls associated with VMX non-root operation are disabled in SMM and thus cannot cause VM exits while the logical processor in SMM.

### 34.14.2 Default Treatment of RSM

Ordinary execution of RSM restores processor state from SMRAM. Under the default treatment, processors that support VMX operation perform RSM as follows:

```

IF VMXE = 1 in CR4 image in SMRAM
  THEN fail and enter shutdown state;
  ELSE
    restore state normally from SMRAM;
    invalidate linear mappings and combined mappings associated with all VPIDs and all PCIDs; combined mappings are invalidated
    for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 28.3);
    IF the logical processor supports SMX operation and the Intel® TXT private space was unlocked at the time of the last SMI (as
    saved)
      THEN unlock the TXT private space;
    Fi;
    CR4.VMXE ← value stored internally;

```

1. This causes the logical processor to block INIT signals, NMIs, and SMIs.
2. Section 34.14 and Section 34.15 use the notation RAX, RIP, RSP, RFLAGS, etc. for processor registers because most processors that support VMX operation also support Intel 64 architecture. For processors that do not support Intel 64 architecture, this notation refers to the 32-bit forms of these registers (EAX, EIP, ESP, EFLAGS, etc.). In a few places, notation such as EAX is used to refer specifically to the lower 32 bits of the register.
3. “Enable EPT” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, SMI functions as the “enable EPT” VM-execution control were 0. See Section 24.6.2.

IF internal storage indicates that the logical processor  
had been in VMX operation (root or non-root)

THEN

enter VMX operation (root or non-root);

restore VMX-critical state as defined in Section 34.14.1;

set to their fixed values any bits in CR0 and CR4 whose values must be fixed in VMX operation (see Section 23.8);<sup>1</sup>

IF RFLAGS.VM = 0 AND (in VMX root operation OR the “unrestricted guest” VM-execution control is 0)<sup>2</sup>

THEN

CS.RPL ← SS.DPL;

SS.RPL ← SS.DPL;

FI;

restore current VMCS pointer;

FI;

leave SMM;

IF logical processor will be in VMX operation or in SMX operation after RSM

THEN block A20M and leave A20M mode;

FI;

FI;

RSM unblocks SMIs. It restores the state of blocking by NMI (see Table 24-3 in Section 24.4.2) as follows:

- If the RSM is not to VMX non-root operation or if the “virtual NMIs” VM-execution control will be 0, the state of NMI blocking is restored normally.
- If the RSM is to VMX non-root operation and the “virtual NMIs” VM-execution control will be 1, NMIs are not blocked after RSM. The state of virtual-NMI blocking is restored as part of VMX-critical state.

INIT signals are blocked after RSM if and only if the logical processor will be in VMX root operation.

If RSM returns a logical processor to VMX non-root operation, it re-establishes the controls associated with the current VMCS. If the “interrupt-window exiting” VM-execution control is 1, a VM exit occurs immediately after RSM if the enabling conditions apply. The same is true for the “NMI-window exiting” VM-execution control. Such VM exits occur with their normal priority. See Section 25.2.

If an MTF VM exit was pending at the time of the previous SMI, an MTF VM exit is pending on the instruction boundary following execution of RSM. The following items detail the treatment of MTF VM exits that may be pending following RSM:

- System-management interrupts (SMIs), INIT signals, and higher priority events take priority over these MTF VM exits. These MTF VM exits take priority over debug-trap exceptions and lower priority events.
- These MTF VM exits wake the logical processor if RSM caused the logical processor to enter the HLT state (see Section 34.10). They do not occur if the logical processor just entered the shutdown state.

### 34.14.3 Protection of CR4.VMXE in SMM

Under the default treatment, CR4.VMXE is treated as a reserved bit while a logical processor is in SMM. Any attempt by software running in SMM to set this bit causes a general-protection exception. In addition, software cannot use VMX instructions or enter VMX operation while in SMM.

### 34.14.4 VMXOFF and SMI Unblocking

The VMXOFF instruction can be executed only with the default treatment (see Section 34.15.1) and only outside SMM. If SMIs are blocked when VMXOFF is executed, VMXOFF unblocks them unless

1. If the RSM is to VMX non-root operation and both the “unrestricted guest” VM-execution control and bit 31 of the primary processor-based VM-execution controls will be 1, CR0.PE and CR0.PG retain the values that were loaded from SMRAM regardless of what is reported in the capability MSR IA32\_VMX\_CRO\_FIXED0.
2. “Unrestricted guest” is a secondary processor-based VM-execution control. If bit 31 of the primary processor-based VM-execution controls is 0, VM entry functions as if the “unrestricted guest” VM-execution control were 0. See Section 24.6.2.

IA32\_SMM\_MONITOR\_CTL[bit 2] is 1 (see Section 34.15.5 for details regarding this MSR).<sup>1</sup> Section 34.15.7 identifies a case in which SMIs may be blocked when VMXOFF is executed.

Not all processors allow this bit to be set to 1. Software should consult the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6) to determine whether this is allowed.

## 34.15 DUAL-MONITOR TREATMENT OF SMIs AND SMM

Dual-monitor treatment is activated through the cooperation of the **executive monitor** (the VMM that operates outside of SMM to provide basic virtualization) and the **SMM-transfer monitor (STM)** (the VMM that operates inside SMM—while in VMX operation—to support system-management functions). Control is transferred to the STM through VM exits; VM entries are used to return from SMM.

The dual-monitor treatment may not be supported by all processors. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1) to determine whether it is supported.

### 34.15.1 Dual-Monitor Treatment Overview

The dual-monitor treatment uses an executive monitor and an SMM-transfer monitor (STM). Transitions from the executive monitor or its guests to the STM are called **SMM VM exits** and are discussed in Section 34.15.2. SMM VM exits are caused by SMIs as well as executions of VMCALL in VMX root operation. The latter allow the executive monitor to call the STM for service.

The STM runs in VMX root operation and uses VMX instructions to establish a VMCS and perform VM entries to its own guests. This is done all inside SMM (see Section 34.15.3). The STM returns from SMM, not by using the RSM instruction, but by using a VM entry that returns from SMM. Such VM entries are described in Section 34.15.4.

Initially, there is no STM and the default treatment (Section 34.14) is used. The dual-monitor treatment is not used until it is enabled and activated. The steps to do this are described in Section 34.15.5 and Section 34.15.6.

It is not possible to leave VMX operation under the dual-monitor treatment; VMXOFF will fail if executed. The dual-monitor treatment must be deactivated first. The STM deactivates dual-monitor treatment using a VM entry that returns from SMM with the “deactivate dual-monitor treatment” VM-entry control set to 1 (see Section 34.15.7).

The executive monitor configures any VMCS that it uses for VM exits to the executive monitor. SMM VM exits, which transfer control to the STM, use a different VMCS. Under the dual-monitor treatment, each logical processor uses a separate VMCS called the **SMM-transfer VMCS**. When the dual-monitor treatment is active, the logical processor maintains another VMCS pointer called the **SMM-transfer VMCS pointer**. The SMM-transfer VMCS pointer is established when the dual-monitor treatment is activated.

### 34.15.2 SMM VM Exits

An SMM VM exit is a VM exit that begins outside SMM and that ends in SMM.

Unlike other VM exits, SMM VM exits can begin in VMX root operation. SMM VM exits result from the arrival of an SMI outside SMM or from execution of VMCALL in VMX root operation outside SMM. Execution of VMCALL in VMX root operation causes an SMM VM exit only if the valid bit is set in the IA32\_SMM\_MONITOR\_CTL MSR (see Section 34.15.5).

Execution of VMCALL in VMX root operation causes an SMM VM exit even under the default treatment. This SMM VM exit activates the dual-monitor treatment (see Section 34.15.6).

Differences between SMM VM exits and other VM exits are detailed in Sections 34.15.2.1 through 34.15.2.5. Differences between SMM VM exits that activate the dual-monitor treatment and other SMM VM exits are described in Section 34.15.6.

---

1. Setting IA32\_SMM\_MONITOR\_CTL[bit 2] to 1 prevents VMXOFF from unblocking SMIs regardless of the value of the register’s valid bit (bit 0).

### 34.15.2.1 Architectural State Before a VM Exit

System-management interrupts (SMIs) that cause SMM VM exits always do so directly. They do not save state to SMRAM as they do under the default treatment.

### 34.15.2.2 Updating the Current-VMCS and Executive-VMCS Pointers

SMM VM exits begin by performing the following steps:

1. The executive-VMCS pointer field in the SMM-transfer VMCS is loaded as follows:
  - If the SMM VM exit commenced in VMX non-root operation, it receives the current-VMCS pointer.
  - If the SMM VM exit commenced in VMX root operation, it receives the VMXON pointer.
2. The current-VMCS pointer is loaded with the value of the SMM-transfer VMCS pointer.

The last step ensures that the current VMCS is the SMM-transfer VMCS. VM-exit information is recorded in that VMCS, and VM-entry control fields in that VMCS are updated. State is saved into the guest-state area of that VMCS. The VM-exit controls and host-state area of that VMCS determine how the VM exit operates.

### 34.15.2.3 Recording VM-Exit Information

SMM VM exits differ from other VM exit with regard to the way they record VM-exit information. The differences follow.

- **Exit reason.**
  - Bits 15:0 of this field contain the basic exit reason. The field is loaded with the reason for the SMM VM exit: I/O SMI (an SMI arrived immediately after retirement of an I/O instruction), other SMI, or VMCALL. See Appendix C, “VMX Basic Exit Reasons”.
  - SMM VM exits are the only VM exits that may occur in VMX root operation. Because the SMM-transfer monitor may need to know whether it was invoked from VMX root or VMX non-root operation, this information is stored in bit 29 of the exit-reason field (see Table 24-14 in Section 24.9.1). The bit is set by SMM VM exits from VMX root operation.
  - If the SMM VM exit occurred in VMX non-root operation and an MTF VM exit was pending, bit 28 of the exit-reason field is set; otherwise, it is cleared.
  - Bits 27:16 and bits 31:30 are cleared.
- **Exit qualification.** For an SMM VM exit due an SMI that arrives immediately after the retirement of an I/O instruction, the exit qualification contains information about the I/O instruction that retired immediately before the SMI. It has the format given in Table 34-9.

**Table 34-9. Exit Qualification for SMIs That Arrive Immediately After the Retirement of an I/O Instruction**

Bit Position(s)	Contents
2:0	Size of access: 0 = 1-byte 1 = 2-byte 3 = 4-byte  Other values not used.
3	Direction of the attempted access (0 = OUT, 1 = IN)
4	String instruction (0 = not string; 1 = string)
5	REP prefixed (0 = not REP; 1 = REP)
6	Operand encoding (0 = DX, 1 = immediate)

**Table 34-9. Exit Qualification for SMIs That Arrive Immediately After the Retirement of an I/O Instruction (Contd.)**

Bit Position(s)	Contents
15:7	Reserved (cleared to 0)
31:16	Port number (as specified in the I/O instruction)
63:32	Reserved (cleared to 0). These bits exist only on processors that support Intel 64 architecture.

- **Guest linear address.** This field is used for VM exits due to SMIs that arrive immediately after the retirement of an INS or OUTS instruction for which the relevant segment (ES for INS; DS for OUTS unless overridden by an instruction prefix) is usable. The field receives the value of the linear address generated by ES:(E)DI (for INS) or segment:(E)SI (for OUTS; the default segment is DS but can be overridden by a segment override prefix) at the time the instruction started. If the relevant segment is not usable, the value is undefined. On processors that support Intel 64 architecture, bits 63:32 are clear if the logical processor was not in 64-bit mode before the VM exit.
- **I/O RCX, I/O RSI, I/O RDI, and I/O RIP.** For an SMM VM exit due an SMI that arrives immediately after the retirement of an I/O instruction, these fields receive the values that were in RCX, RSI, RDI, and RIP, respectively, before the I/O instruction executed. Thus, the value saved for I/O RIP addresses the I/O instruction.

#### 34.15.2.4 Saving Guest State

SMM VM exits save the contents of the SMBASE register into the corresponding field in the guest-state area.

The value of the VMX-preemption timer is saved into the corresponding field in the guest-state area if the “save VMX-preemption timer value” VM-exit control is 1. That field becomes undefined if, in addition, either the SMM VM exit is from VMX root operation or the SMM VM exit is from VMX non-root operation and the “activate VMX-preemption timer” VM-execution control is 0.

#### 34.15.2.5 Updating Non-Register State

SMM VM exits affect the non-register state of a logical processor as follows:

- SMM VM exits cause non-maskable interrupts (NMIs) to be blocked; they may be unblocked through execution of IRET or through a VM entry (depending on the value loaded for the interruptibility state and the setting of the “virtual NMIs” VM-execution control).
- SMM VM exits cause SMIs to be blocked; they may be unblocked by a VM entry that returns from SMM (see Section 34.15.4).

SMM VM exits invalidate linear mappings and combined mappings associated with VPID 0000H for all PCIDs. Combined mappings for VPID 0000H are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 28.3). (Ordinary VM exits are not required to perform such invalidation if the “enable VPID” VM-execution control is 1; see Section 27.5.5.)

### 34.15.3 Operation of the SMM-Transfer Monitor

Once invoked, the SMM-transfer monitor (STM) is in VMX root operation and can use VMX instructions to configure VMCSs and to cause VM entries to virtual machines supported by those structures. As noted in Section 34.15.1, the VMXOFF instruction cannot be used under the dual-monitor treatment and thus cannot be used by the STM.

The RSM instruction also cannot be used under the dual-monitor treatment. As noted in Section 25.1.3, it causes a VM exit if executed in SMM in VMX non-root operation. If executed in VMX root operation, it causes an invalid-opcode exception. The STM uses VM entries to return from SMM (see Section 34.15.4).

### 34.15.4 VM Entries that Return from SMM

The SMM-transfer monitor (STM) returns from SMM using a VM entry with the “entry to SMM” VM-entry control clear. VM entries that return from SMM reverse the effects of an SMM VM exit (see Section 34.15.2).

VM entries that return from SMM may differ from other VM entries in that they do not necessarily enter VMX non-root operation. If the executive-VMCS pointer field in the current VMCS contains the VMXON pointer, the logical processor remains in VMX root operation after VM entry.

For differences between VM entries that return from SMM and other VM entries see Sections 34.15.4.1 through 34.15.4.10.

#### 34.15.4.1 Checks on the Executive-VMCS Pointer Field

VM entries that return from SMM perform the following checks on the executive-VMCS pointer field in the current VMCS:

- Bits 11:0 must be 0.
- The pointer must not set any bits beyond the processor’s physical-address width.<sup>1,2</sup>
- The 32 bits located in memory referenced by the physical address in the pointer must contain the processor’s VMCS revision identifier (see Section 24.2).

The checks above are performed before the checks described in Section 34.15.4.2 and before any of the following checks:

- If the “deactivate dual-monitor treatment” VM-entry control is 0 and the executive-VMCS pointer field does not contain the VMXON pointer, the launch state of the executive VMCS (the VMCS referenced by the executive-VMCS pointer field) must be launched (see Section 24.11.3).
- If the “deactivate dual-monitor treatment” VM-entry control is 1, the executive-VMCS pointer field must contain the VMXON pointer (see Section 34.15.7).<sup>3</sup>

#### 34.15.4.2 Checks on VM-Execution Control Fields

VM entries that return from SMM differ from other VM entries with regard to the checks performed on the VM-execution control fields specified in Section 26.2.1.1. They do not apply the checks to the current VMCS. Instead, VM-entry behavior depends on whether the executive-VMCS pointer field contains the VMXON pointer:

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the checks are not performed at all.
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), the checks are performed on the VM-execution control fields in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field in the current VMCS). These checks are performed after checking the executive-VMCS pointer field itself (for proper alignment).

Other VM entries ensure that, if “activate VMX-preemption timer” VM-execution control is 0, the “save VMX-preemption timer value” VM-exit control is also 0. This check is not performed by VM entries that return from SMM.

#### 34.15.4.3 Checks on VM-Entry Control Fields

VM entries that return from SMM differ from other VM entries with regard to the checks performed on the VM-entry control fields specified in Section 26.2.1.3.

Specifically, if the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the following must **not** all hold for the VM-entry interruption-information field:

- 
1. Software can determine a processor’s physical-address width by executing CPUID with 80000008H in EAX. The physical-address width is returned in bits 7:0 of EAX.
  2. If IA32\_VMX\_BASIC[48] is read as 1, this pointer must not set any bits in the range 63:32; see Appendix A.1.
  3. The STM can determine the VMXON pointer by reading the executive-VMCS pointer field in the current VMCS after the SMM VM exit that activates the dual-monitor treatment.

- the valid bit (bit 31) in the VM-entry interruption-information field is 1
- the interruption type (bits 10:8) is not 7 (other event); and
- the vector (bits 7:0) is not 0 (pending MTF VM exit).

#### 34.15.4.4 Checks on the Guest State Area

Section 26.3.1 specifies checks performed on fields in the guest-state area of the VMCS. Some of these checks are conditioned on the settings of certain VM-execution controls (e.g., “virtual NMIs” or “unrestricted guest”).

VM entries that return from SMM modify these checks based on whether the executive-VMCS pointer field contains the VMXON pointer:<sup>1</sup>

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the checks are performed as all relevant VM-execution controls were 0. (As a result, some checks may not be performed at all.)
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), this check is performed based on the settings of the VM-execution controls in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field in the current VMCS).

For VM entries that return from SMM, the activity-state field must not indicate the wait-for-SIPI state if the executive-VMCS pointer field contains the VMXON pointer (the VM entry is to VMX root operation).

#### 34.15.4.5 Loading Guest State

VM entries that return from SMM load the SMBASE register from the SMBASE field.

VM entries that return from SMM invalidate linear mappings and combined mappings associated with all VPIDs. Combined mappings are invalidated for all EP4TA values (EP4TA is the value of bits 51:12 of EPTP; see Section 28.3). (Ordinary VM entries are required to perform such invalidation only for VPID 0000H and are not required to do even that if the “enable VPID” VM-execution control is 1; see Section 26.3.2.5.)

#### 34.15.4.6 VMX-Preemption Timer

A VM entry that returns from SMM activates the VMX-preemption timer only if the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation) and the “activate VMX-preemption timer” VM-execution control is 1 in the executive VMCS (the VMCS referenced by the executive-VMCS pointer field). In this case, VM entry starts the VMX-preemption timer with the value in the VMX-preemption timer-value field in the current VMCS.

#### 34.15.4.7 Updating the Current-VMCS and SMM-Transfer VMCS Pointers

Successful VM entries (returning from SMM) load the SMM-transfer VMCS pointer with the current-VMCS pointer. Following this, they load the current-VMCS pointer from a field in the current VMCS:

- If the executive-VMCS pointer field contains the VMXON pointer (the VM entry remains in VMX root operation), the current-VMCS pointer is loaded from the VMCS-link pointer field.
- If the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation), the current-VMCS pointer is loaded with the value of the executive-VMCS pointer field.

If the VM entry successfully enters VMX non-root operation, the VM-execution controls in effect after the VM entry are those from the new current VMCS. This includes any structures external to the VMCS referenced by VM-execution control fields.

The updating of these VMCS pointers occurs before event injection. Event injection is determined, however, by the VM-entry control fields in the VMCS that was current when the VM entry commenced.

---

1. The STM can determine the VMXON pointer by reading the executive-VMCS pointer field in the current VMCS after the SMM VM exit that activates the dual-monitor treatment.

### 34.15.4.8 VM Exits Induced by VM Entry

Section 26.5.1.2 describes how the event-delivery process invoked by event injection may lead to a VM exit. Section 26.6.3 to Section 26.6.7 describe other situations that may cause a VM exit to occur immediately after a VM entry.

Whether these VM exits occur is determined by the VM-execution control fields in the current VMCS. For VM entries that return from SMM, they can occur only if the executive-VMCS pointer field does not contain the VMXON pointer (the VM entry enters VMX non-root operation).

In this case, determination is based on the VM-execution control fields in the VMCS that is current after the VM entry. This is the VMCS referenced by the value of the executive-VMCS pointer field at the time of the VM entry (see Section 34.15.4.7). This VMCS also controls the delivery of such VM exits. Thus, VM exits induced by a VM entry returning from SMM are to the executive monitor and not to the STM.

### 34.15.4.9 SMI Blocking

VM entries that return from SMM determine the blocking of system-management interrupts (SMIs) as follows:

- If the “deactivate dual-monitor treatment” VM-entry control is 0, SMIs are blocked after VM entry if and only if the bit 2 in the interruptibility-state field is 1.
- If the “deactivate dual-monitor treatment” VM-entry control is 1, the blocking of SMIs depends on whether the logical processor is in SMX operation:<sup>1</sup>
  - If the logical processor is in SMX operation, SMIs are blocked after VM entry.
  - If the logical processor is outside SMX operation, SMIs are unblocked after VM entry.

VM entries that return from SMM and that do not deactivate the dual-monitor treatment may leave SMIs blocked. This feature exists to allow the STM to invoke functionality outside of SMM without unblocking SMIs.

### 34.15.4.10 Failures of VM Entries That Return from SMM

Section 26.7 describes the treatment of VM entries that fail during or after loading guest state. Such failures record information in the VM-exit information fields and load processor state as would be done on a VM exit. The VMCS used is the one that was current before the VM entry commenced. Control is thus transferred to the STM and the logical processor remains in SMM.

## 34.15.5 Enabling the Dual-Monitor Treatment

Code and data for the SMM-transfer monitor (STM) reside in a region of SMRAM called the **monitor segment** (MSEG). Code running in SMM determines the location of MSEG and establishes its content. This code is also responsible for enabling the dual-monitor treatment.

SMM code enables the dual-monitor treatment and specifies the location of MSEG by writing to the IA32\_SMM\_MONITOR\_CTL MSR (index 9BH). The MSR has the following format:

- Bit 0 is the register’s valid bit. The STM may be invoked using VMCALL only if this bit is 1. Because VMCALL is used to activate the dual-monitor treatment (see Section 34.15.6), the dual-monitor treatment cannot be activated if the bit is 0. This bit is cleared when the logical processor is reset.
- Bit 1 is reserved.
- Bit 2 determines whether executions of VMXOFF unblock SMIs under the default treatment of SMIs and SMM. Executions of VMXOFF unblock SMIs unless bit 2 is 1 (the value of bit 0 is irrelevant). See Section 34.14.4.

Certain leaf functions of the GETSEC instruction clear this bit (see Chapter 5, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2C*)

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENDER]. A logical processor is outside SMX operation if GETSEC[SENDER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENDER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

- Bits 11:3 are reserved.
- Bits 31:12 contain a value that, when shifted right 12 bits, is the physical address of MSEG (the MSEG base address).
- Bits 63:32 are reserved.

The following items detail use of this MSR:

- The IA32\_SMM\_MONITOR\_CTL MSR is supported only on processors that support the dual-monitor treatment.<sup>1</sup> On other processors, accesses to the MSR using RDMSR or WRMSR generate a general-protection fault (#GP(0)).
- A write to the IA32\_SMM\_MONITOR\_CTL MSR using WRMSR generates a general-protection fault (#GP(0)) if executed outside of SMM or if an attempt is made to set any reserved bit. An attempt to write to the IA32\_SMM\_MONITOR\_CTL MSR fails if made as part of a VM exit that does not end in SMM or part of a VM entry that does not begin in SMM.
- Reads from the IA32\_SMM\_MONITOR\_CTL MSR using RDMSR are allowed any time RDMSR is allowed. The MSR may be read as part of any VM exit.
- The dual-monitor treatment can be activated only if the valid bit in the MSR is set to 1.

The 32 bytes located at the MSEG base address are called the **MSEG header**. The format of the MSEG header is given in Table 34-10 (each field is 32 bits).

**Table 34-10. Format of MSEG Header**

Byte Offset	Field
0	MSEG-header revision identifier
4	SMM-transfer monitor features
8	GDTR limit
12	GDTR base offset
16	CS selector
20	EIP offset
24	ESP offset
28	CR3 offset

To ensure proper behavior in VMX operation, software should maintain the MSEG header in writeback cacheable memory. Future implementations may allow or require a different memory type.<sup>2</sup> Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1).

SMM code should enable the dual-monitor treatment (by setting the valid bit in IA32\_SMM\_MONITOR\_CTL MSR) only after establishing the content of the MSEG header as follows:

- Bytes 3:0 contain the **MSEG revision identifier**. Different processors may use different MSEG revision identifiers. These identifiers enable software to avoid using an MSEG header formatted for one processor on a processor that uses a different format. Software can discover the MSEG revision identifier that a processor uses by reading the VMX capability MSR IA32\_VMX\_MISC (see Appendix A.6).

1. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1) to determine whether the dual-monitor treatment is supported.

2. Alternatively, software may map the MSEG header with the UC memory type; this may be necessary, depending on how memory is organized. Doing so is strongly discouraged unless necessary as it will cause the performance of transitions using those structures to suffer significantly. In addition, the processor will continue to use the memory type reported in the VMX capability MSR IA32\_VMX\_BASIC with exceptions noted in Appendix A.1.

- Bytes 7:4 contain the **SMM-transfer monitor features** field. Bits 31:1 of this field are reserved and must be zero. Bit 0 of the field is the **IA-32e mode SMM feature bit**. It indicates whether the logical processor will be in IA-32e mode after the STM is activated (see Section 34.15.6).
- Bytes 31:8 contain fields that determine how processor state is loaded when the STM is activated (see Section 34.15.6.6). SMM code should establish these fields so that activating of the STM invokes the STM's initialization code.

### 34.15.6 Activating the Dual-Monitor Treatment

The dual-monitor treatment may be enabled by SMM code as described in Section 34.15.5. The dual-monitor treatment is activated only if it is enabled and only by the executive monitor. The executive monitor activates the dual-monitor treatment by executing VMCALL in VMX root operation.

When VMCALL activates the dual-monitor treatment, it causes an SMM VM exit. Differences between this SMM VM exit and other SMM VM exits are discussed in Sections 34.15.6.1 through 34.15.6.7. See also “VMCALL—Call to VM Monitor” in Chapter 30.

#### 34.15.6.1 Initial Checks

An execution of VMCALL attempts to activate the dual-monitor treatment if (1) the processor supports the dual-monitor treatment;<sup>1</sup> (2) the logical processor is in VMX root operation; (3) the logical processor is outside SMM and the valid bit is set in the IA32\_SMM\_MONITOR\_CTL MSR; (4) the logical processor is not in virtual-8086 mode and not in compatibility mode; (5) CPL = 0; and (6) the dual-monitor treatment is not active.

The VMCS that manages SMM VM exit caused by this VMCALL is the current VMCS established by the executive monitor. The VMCALL performs the following checks on the current VMCS in the order indicated:

1. There must be a current VMCS pointer.
2. The launch state of the current VMCS must be clear.
3. Reserved bits in the VM-exit controls in the current VMCS must be set properly. Software may consult the VMX capability MSR IA32\_VMX\_EXIT\_CTLS to determine the proper settings (see Appendix A.4).

If any of these checks fail, subsequent checks are skipped and VMCALL fails. If all these checks succeed, the logical processor uses the IA32\_SMM\_MONITOR\_CTL MSR to determine the base address of MSEG. The following checks are performed in the order indicated:

1. The logical processor reads the 32 bits at the base of MSEG and compares them to the processor's MSEG revision identifier.
2. The logical processor reads the SMM-transfer monitor features field:
  - Bit 0 of the field is the IA-32e mode SMM feature bit, and it indicates whether the logical processor will be in IA-32e mode after the SMM-transfer monitor (STM) is activated.
    - If the VMCALL is executed on a processor that does not support Intel 64 architecture, the IA-32e mode SMM feature bit must be 0.
    - If the VMCALL is executed in 64-bit mode, the IA-32e mode SMM feature bit must be 1.
  - Bits 31:1 of this field are currently reserved and must be zero.

If any of these checks fail, subsequent checks are skipped and the VMCALL fails.

#### 34.15.6.2 MSEG Checking

SMM VM exits that activate the dual-monitor treatment check the following before updating the current-VMCS pointer and the executive-VMCS pointer field (see Section 34.15.2.2):

- 
1. Software should consult the VMX capability MSR IA32\_VMX\_BASIC (see Appendix A.1) to determine whether the dual-monitor treatment is supported.

- The 32 bits at the MSEG base address (used as a physical address) must contain the processor's MSEG revision identifier.
- Bits 31:1 of the SMM-transfer monitor features field in the MSEG header (see Table 34-10) must be 0. Bit 0 of the field (the IA-32e mode SMM feature bit) must be 0 if the processor does not support Intel 64 architecture.

If either of these checks fail, execution of VMCALL fails.

### 34.15.6.3 Updating the Current-VMCS and Executive-VMCS Pointers

Before performing the steps in Section 34.15.2.2, SMM VM exits that activate the dual-monitor treatment begin by loading the SMM-transfer VMCS pointer with the value of the current-VMCS pointer.

### 34.15.6.4 Saving Guest State

As noted in Section 34.15.2.4, SMM VM exits save the contents of the SMBASE register into the corresponding field in the guest-state area. While this is true also for SMM VM exits that activate the dual-monitor treatment, the VMCS used for those VM exits exists outside SMRAM.

The SMM-transfer monitor (STM) can also discover the current value of the SMBASE register by using the RDMSR instruction to read the IA32\_SMBASE MSR (MSR address 9EH). The following items detail use of this MSR:

- The MSR is supported only if IA32\_VMX\_MISC[15] = 1 (see Appendix A.6).
- A write to the IA32\_SMBASE MSR using WRMSR generates a general-protection fault (#GP(0)). An attempt to write to the IA32\_SMBASE MSR fails if made as part of a VM exit or part of a VM entry.
- A read from the IA32\_SMBASE MSR using RDMSR generates a general-protection fault (#GP(0)) if executed outside of SMM. An attempt to read from the IA32\_SMBASE MSR fails if made as part of a VM exit that does not end in SMM.

### 34.15.6.5 Saving MSRs

The VM-exit MSR-store area is not used by SMM VM exits that activate the dual-monitor treatment. No MSRs are saved into that area.

### 34.15.6.6 Loading Host State

The VMCS that is current during an SMM VM exit that activates the dual-monitor treatment was established by the executive monitor. It does not contain the VM-exit controls and host state required to initialize the STM. For this reason, such SMM VM exits do not load processor state as described in Section 27.5. Instead, state is set to fixed values or loaded based on the content of the MSEG header (see Table 34-10):

- CR0 is set to as follows:
  - PG, NE, ET, MP, and PE are all set to 1.
  - CD and NW are left unchanged.
  - All other bits are cleared to 0.
- CR3 is set as follows:
  - Bits 63:32 are cleared on processors that supports IA-32e mode.
  - Bits 31:12 are set to bits 31:12 of the sum of the MSEG base address and the CR3-offset field in the MSEG header.
  - Bits 11:5 and bits 2:0 are cleared (the corresponding bits in the CR3-offset field in the MSEG header are ignored).
  - Bits 4:3 are set to bits 4:3 of the CR3-offset field in the MSEG header.
- CR4 is set as follows:
  - MCE and PGE are cleared.
  - PAE is set to the value of the IA-32e mode SMM feature bit.

- If the IA-32e mode SMM feature bit is clear, PSE is set to 1 if supported by the processor; if the bit is set, PSE is cleared.
- All other bits are unchanged.
- DR7 is set to 400H.
- The IA32\_DEBUGCTL MSR is cleared to 00000000\_00000000H.
- The registers CS, SS, DS, ES, FS, and GS are loaded as follows:
  - All registers are usable.
  - CS.selector is loaded from the corresponding field in the MSEG header (the high 16 bits are ignored), with bits 2:0 cleared to 0. If the result is 0000H, CS.selector is set to 0008H.
  - The selectors for SS, DS, ES, FS, and GS are set to CS.selector+0008H. If the result is 0000H (if the CS selector was 0xFFF8), these selectors are instead set to 0008H.
  - The base addresses of all registers are cleared to zero.
  - The segment limits for all registers are set to FFFFFFFFH.
  - The AR bytes for the registers are set as follows:
    - CS.Type is set to 11 (execute/read, accessed, non-conforming code segment).
    - For SS, DS, FS, and GS, the Type is set to 3 (read/write, accessed, expand-up data segment).
    - The S bits for all registers are set to 1.
    - The DPL for each register is set to 0.
    - The P bits for all registers are set to 1.
    - On processors that support Intel 64 architecture, CS.L is loaded with the value of the IA-32e mode SMM feature bit.
    - CS.D is loaded with the inverse of the value of the IA-32e mode SMM feature bit.
    - For each of SS, DS, FS, and GS, the D/B bit is set to 1.
    - The G bits for all registers are set to 1.
- LDTR is unusable. The LDTR selector is cleared to 0000H, and the register is otherwise undefined (although the base address is always canonical)
- GDTR.base is set to the sum of the MSEG base address and the GDTR base-offset field in the MSEG header (bits 63:32 are always cleared on processors that supports IA-32e mode). GDTR.limit is set to the corresponding field in the MSEG header (the high 16 bits are ignored).
- IDTR.base is unchanged. IDTR.limit is cleared to 0000H.
- RIP is set to the sum of the MSEG base address and the value of the RIP-offset field in the MSEG header (bits 63:32 are always cleared on logical processors that support IA-32e mode).
- RSP is set to the sum of the MSEG base address and the value of the RSP-offset field in the MSEG header (bits 63:32 are always cleared on logical processor that supports IA-32e mode).
- RFLAGS is cleared, except bit 1, which is always set.
- The logical processor is left in the active state.
- Event blocking after the SMM VM exit is as follows:
  - There is no blocking by STI or by MOV SS.
  - There is blocking by non-maskable interrupts (NMIs) and by SMIs.
- There are no pending debug exceptions after the SMM VM exit.
- For processors that support IA-32e mode, the IA32\_EFER MSR is modified so that LME and LMA both contain the value of the IA-32e mode SMM feature bit.

If any of CR3[63:5], CR4.PAE, CR4.PSE, or IA32\_EFER.LMA is changing, the TLBs are updated so that, after VM exit, the logical processor does not use translations that were cached before the transition. This is not neces-

sary for changes that would not affect paging due to the settings of other bits (for example, changes to CR4.PSE if IA32\_EFER.LMA was 1 before and after the transition).

### 34.15.6.7 Loading MSRs

The VM-exit MSR-load area is not used by SMM VM exits that activate the dual-monitor treatment. No MSRs are loaded from that area.

## 34.15.7 Deactivating the Dual-Monitor Treatment

The SMM-transfer monitor may deactivate the dual-monitor treatment and return the processor to default treatment of SMIs and SMM (see Section 34.14). It does this by executing a VM entry with the “deactivate dual-monitor treatment” VM-entry control set to 1.

As noted in Section 26.2.1.3 and Section 34.15.4.1, an attempt to deactivate the dual-monitor treatment fails in the following situations: (1) the processor is not in SMM; (2) the “entry to SMM” VM-entry control is 1; or (3) the executive-VMCS pointer does not contain the VMXON pointer (the VM entry is to VMX non-root operation).

As noted in Section 34.15.4.9, VM entries that deactivate the dual-monitor treatment ignore the SMI bit in the interruptibility-state field of the guest-state area. Instead, the blocking of SMIs following such a VM entry depends on whether the logical processor is in SMX operation:<sup>1</sup>

- If the logical processor is in SMX operation, SMIs are blocked after VM entry. SMIs may later be unblocked by the VMXOFF instruction (see Section 34.14.4) or by certain leaf functions of the GETSEC instruction (see Chapter 5, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2C*).
- If the logical processor is outside SMX operation, SMIs are unblocked after VM entry.

## 34.16 SMI AND PROCESSOR EXTENDED STATE MANAGEMENT

On processors that support processor extended states using XSAVE/XRSTOR (see Chapter 13, “Managing State Using the XSAVE Feature Set” of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1*), the processor does not save any XSAVE/XRSTOR related state on an SMI. It is the responsibility of the SMI handler code to properly preserve the state information (including CR4.OSXSAVE, XCR0, and possibly processor extended states using XSAVE/XRSTOR). Therefore, the SMI handler must follow the rules described in Chapter 13, “Managing State Using the XSAVE Feature Set” of the *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1*.

## 34.17 MODEL-SPECIFIC SYSTEM MANAGEMENT ENHANCEMENT

This section describes enhancement of system management features that apply only to the 4th generation Intel Core processors. These features are model-specific. BIOS and SMM handler must use CPUID to enumerate DisplayFamily\_DisplayModel signature when programming with these interfaces.

### 34.17.1 SMM Handler Code Access Control

The BIOS may choose to restrict the address ranges of code that SMM handler executes. When SMM handler code execution check is enabled, an attempt by the SMM handler to execute outside the ranges specified by SMRR (see Section 34.4.2.1) will cause the assertion of an unrecoverable machine check exception (MCE).

---

1. A logical processor is in SMX operation if GETSEC[SEXIT] has not been executed since the last execution of GETSEC[SENDER]. A logical processor is outside SMX operation if GETSEC[SENDER] has not been executed or if GETSEC[SEXIT] was executed after the last execution of GETSEC[SENDER]. See Chapter 6, “Safer Mode Extensions Reference,” in *Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B*.

The interface to enable SMM handler code access check resides in a per-package scope model-specific register MSR\_SMM\_FEATURE\_CONTROL at address 4E0H. An attempt to access MSR\_SMM\_FEATURE\_CONTROL outside of SMM will cause a #GP. Writes to MSR\_SMM\_FEATURE\_CONTROL is further protected by configuration interface of MSR\_SMM\_MCA\_CAP at address 17DH.

Details of the interface of MSR\_SMM\_FEATURE\_CONTROL and MSR\_SMM\_MCA\_CAP are described in Table 35-18.

### 34.17.2 SMI Delivery Delay Reporting

Entry into the system management mode occurs at instruction boundary. In situations where a logical processor is executing an instruction involving a long flow of internal operations, servicing an SMI by that logical processor will be delayed. Delayed servicing of SMI of each logical processor due to executing long flows of internal operation in a physical processor can be queried via a package-scope register MSR\_SMM\_DELAYED at address 4E2H.

The interface to enable reporting of SMI delivery delay due to long internal flows resides in a per-package scope model-specific register MSR\_SMM\_DELAYED. An attempt to access MSR\_SMM\_DELAYED outside of SMM will cause a #GP. Availability to MSR\_SMM\_DELAYED is protected by configuration interface of MSR\_SMM\_MCA\_CAP at address 17DH.

Details of the interface of MSR\_SMM\_DELAYED and MSR\_SMM\_MCA\_CAP are described in Table 35-18.

### 34.17.3 Blocked SMI Reporting

A logical processor may have entered into a state and blocked from servicing other interrupts (including SMI). Logical processors in a physical processor that are blocked in serving SMI can be queried in a package-scope register MSR\_SMM\_BLOCKED at address 4E3H. An attempt to access MSR\_SMM\_BLOCKED outside of SMM will cause a #GP.

Details of the interface of MSR\_SMM\_BLOCKED is described in Table 35-18.

## CHAPTER 35 MODEL-SPECIFIC REGISTERS (MSRS)

This chapter lists MSRs across Intel processor families. All MSRs listed can be read with the RDMSR and written with the WRMSR instructions.

Register addresses are given in both hexadecimal and decimal. The register name is the mnemonic register name and the bit description describes individual bits in registers.

Model specific registers and its bit-fields may be supported for a finite range of processor families/models. To distinguish between different processor family and/or models, software must use CPUID.01H leaf function to query the combination of DisplayFamily and DisplayModel to determine model-specific availability of MSRs (see CPUID instruction in Chapter 3, "Instruction Set Reference, A-M" in the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*). Table 35-1 lists the signature values of DisplayFamily and DisplayModel for various processor families or processor number series.

**Table 35-1. CPUID Signature Values of DisplayFamily\_DisplayModel**

DisplayFamily_DisplayModel	Processor Families/Processor Number Series
06_3DH	Next Generation Intel Core Processor
06_3FH	Future Generation Intel Xeon Processor
06_3CH, 06_45H, 06_46H	4th Generation Intel Core Processor and Intel Xeon Processor E3-1200 v3 Product Family based on Intel® microarchitecture code name Haswell
06_3EH	Next Generation Intel Xeon Processor E7 Family based on Intel® microarchitecture code name Ivy Bridge-EP
06_3EH	Intel Xeon Processor E5-1600 v2/E5-2600 v2 Product Families based on Intel® microarchitecture code name Ivy Bridge-EP, Intel Core i7-49xx Processor Extreme Edition
06_3AH	3rd Generation Intel Core Processor and Intel Xeon Processor E3-1200 v2 Product Family based on Intel® microarchitecture code name Ivy Bridge
06_2DH	Intel Xeon Processor E5 Family based on Intel microarchitecture code name Sandy Bridge, Intel Core i7-39xx Processor Extreme Edition
06_2FH	Intel Xeon Processor E7 Family
06_2AH	Intel Xeon Processor E3-1200 Product Family; 2nd Generation Intel Core i7, i5, i3 Processors 2xxx Series
06_2EH	Intel Xeon processor 7500, 6500 series
06_25H, 06_2CH	Intel Xeon processors 3600, 5600 series, Intel Core i7, i5 and i3 Processors
06_1EH, 06_1FH	Intel Core i7 and i5 Processors
06_1AH	Intel Core i7 Processor, Intel Xeon Processor 3400, 3500, 5500 series
06_1DH	Intel Xeon Processor MP 7400 series
06_17H	Intel Xeon Processor 3100, 3300, 5200, 5400 series, Intel Core 2 Quad processors 8000, 9000 series
06_0FH	Intel Xeon Processor 3000, 3200, 5100, 5300, 7300 series, Intel Core 2 Quad processor 6000 series, Intel Core 2 Extreme 6000 series, Intel Core 2 Duo 4000, 5000, 6000, 7000 series processors, Intel Pentium dual-core processors
06_0EH	Intel Core Duo, Intel Core Solo processors
06_0DH	Intel Pentium M processor
06_37H, 06_4DH	Intel Atom Processor C2000, E3000 series
06_36H	Intel Atom Processor S1000 Series

**Table 35-1. CPUID Signature (Contd.)Values of DisplayFamily\_DisplayModel (Contd.)**

DisplayFamily_DisplayModel	Processor Families/Processor Number Series
06_1CH, 06_26H, 06_27H, 06_35H, 06_36H	Intel Atom Processor family, Intel Atom processor D2000, N2000, E2000, Z2000 series
0F_06H	Intel Xeon processor 7100, 5000 Series, Intel Xeon Processor MP, Intel Pentium 4, Pentium D processors
0F_03H, 0F_04H	Intel Xeon Processor, Intel Xeon Processor MP, Intel Pentium 4, Pentium D processors
06_09H	Intel Pentium M processor
0F_02H	Intel Xeon Processor, Intel Xeon Processor MP, Intel Pentium 4 processors

### 35.1 ARCHITECTURAL MSRS

Many MSRs have carried over from one generation of IA-32 processors to the next and to Intel 64 processors. A subset of MSRs and associated bit fields, which do not change on future processor generations, are now considered architectural MSRs. For historical reasons (beginning with the Pentium 4 processor), these “architectural MSRs” were given the prefix “IA32\_”. Table 35-2 lists the architectural MSRs, their addresses, their current names, their names in previous IA-32 processors, and bit fields that are considered architectural. MSR addresses outside Table 35-2 and certain bitfields in an MSR address that may overlap with architectural MSR addresses are model-specific. Code that accesses a machine specified MSR and that is executed on a processor that does not support that MSR will generate an exception.

Architectural MSR or individual bit fields in an architectural MSR may be introduced or transitioned at the granularity of certain processor family/model or the presence of certain CPUID feature flags. The right-most column of Table 35-2 provides information on the introduction of each architectural MSR or its individual fields. This information is expressed either as signature values of “DF\_DM” (see Table 35-1) or via CPUID flags.

Certain bit field position may be related to the maximum physical address width, the value of which is expressed as “MAXPHYWID” in Table 35-2. “MAXPHYWID” is reported by CPUID.8000\_0008H leaf.

MSR address range between 40000000H - 400000FFH is marked as a specially reserved range. All existing and future processors will not implement any features using any MSR in this range.

**Table 35-2. IA-32 Architectural MSRs**

Register Address		Architectural MSR Name and bit fields (Former MSR Name)	MSR/Bit Description	Introduced as Architectural MSR
Hex	Decimal			
0H	0	IA32_P5_MC_ADDR (P5_MC_ADDR)	See Section 35.16, “MSRs in Pentium Processors.”	<b>Pentium Processor (05_01H)</b>
1H	1	IA32_P5_MC_TYPE (P5_MC_TYPE)	See Section 35.16, “MSRs in Pentium Processors.”	DF_DM = 05_01H
6H	6	IA32_MONITOR_FILTER_SIZE	See Section 8.10.5, “Monitor/Mwait Address Range Determination.”	0F_03H
10H	16	IA32_TIME_STAMP_COUNTER (TSC)	See Section 17.13, “Time-Stamp Counter.”	05_01H

Table 35-2. IA-32 Architectural MSRs (Contd.)

Register Address		Architectural MSR Name and bit fields (Former MSR Name)	MSR/Bit Description	Introduced as Architectural MSR
Hex	Decimal			
17H	23	IA32_PLATFORM_ID (MSR_PLATFORM_ID)	<b>Platform ID (RO)</b> The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load.	06_01H
		49:0	Reserved.	
		52:50	<b>Platform Id (RO)</b> Contains information concerning the intended platform for the processor.  52 51 50 0 0 0 Processor Flag 0 0 0 1 Processor Flag 1 0 1 0 Processor Flag 2 0 1 1 Processor Flag 3 1 0 0 Processor Flag 4 1 0 1 Processor Flag 5 1 1 0 Processor Flag 6 1 1 1 Processor Flag 7	
		63:53	Reserved.	
1BH	27	IA32_APIC_BASE (APIC_BASE)		06_01H
		7:0	Reserved	
		8	BSP flag (R/W)	
		9	Reserved	
		10	Enable x2APIC mode	06_1AH
		11	APIC Global Enable (R/W)	
		(MAXPHYWID - 1):12	APIC Base (R/W)	
		63: MAXPHYWID	Reserved	
3AH	58	IA32_FEATURE_CONTROL	<b>Control Features in Intel 64 Processor (R/W)</b>	If CPUID.01H: ECX[bit 5 or bit 6] = 1
		0	Lock bit (R/WO): (1 = locked). When set, locks this MSR from being written, writes to this bit will result in GP(0).  Note: Once the Lock bit is set, the contents of this register cannot be modified. Therefore the lock bit must be set after configuring support	If CPUID.01H:ECX[bit 5 or bit 6] = 1
			for Intel Virtualization Technology and prior to transferring control to an option ROM or the OS. Hence, once the Lock bit is set, the entire  IA32_FEATURE_CONTROL_MSR contents are preserved across RESET when PWRGOOD is not deasserted.	

**Table 35-2. IA-32 Architectural MSRs (Contd.)**

Register Address		Architectural MSR Name and bit fields (Former MSR Name)	MSR/Bit Description	Introduced as Architectural MSR
Hex	Decimal			
		1	Enable VMX inside SMX operation (R/WL): This bit enables a system executive to use VMX in conjunction with SMX to support Intel® Trusted Execution Technology. BIOS must set this bit only when the CPUID function 1 returns VMX feature flag and SMX feature flag set (ECX bits 5 and 6 respectively).	If CPUID.01H:ECX[bit 5 and bit 6] are set to 1
		2	Enable VMX outside SMX operation (R/WL): This bit enables VMX for system executive that do not require SMX. BIOS must set this bit only when the CPUID function 1 returns VMX feature flag set (ECX bit 5).	If CPUID.01H:ECX[bit 5 or bit 6] = 1
		7:3	Reserved	
		14:8	SENTER Local Function Enables (R/WL): When set, each bit in the field represents an enable control for a corresponding SENTER function. This bit is supported only if CPUID.1:ECX.[bit 6] is set	If CPUID.01H:ECX[bit 6] = 1
		15	SENTER Global Enable (R/WL): This bit must be set to enable SENTER leaf functions. This bit is supported only if CPUID.1:ECX.[bit 6] is set	If CPUID.01H:ECX[bit 6] = 1
		63:16	Reserved	
3BH	59	IA32_TSC_ADJUST	Per Logical Processor TSC Adjust (R/Write to clear)	If CPUID.(EAX=07H, ECX=0H): EBX[1] = 1
		63:0	<b>THREAD_ADJUST:</b> Local offset value of the IA32_TSC for a logical processor. Reset value is Zero. A write to IA32_TSC will modify the local offset in IA32_TSC_ADJUST and the content of IA32_TSC, but does not affect the internal invariant TSC hardware.	
79H	121	IA32_BIOS_UPDT_TRIG (BIOS_UPDT_TRIG)	BIOS Update Trigger (W) Executing a WRMSR instruction to this MSR causes a microcode update to be loaded into the processor. See Section 9.11.6, "Microcode Update Loader."  A processor may prevent writing to this MSR when loading guest states on VM entries or saving guest states on VM exits.	06_01H

Table 35-2. IA-32 Architectural MSRs (Contd.)

Register Address		Architectural MSR Name and bit fields (Former MSR Name)	MSR/Bit Description	Introduced as Architectural MSR
Hex	Decimal			
8BH	139	IA32_BIOS_SIGN_ID (BIOS_SIGN/BBL_CR_D3)	BIOS Update Signature (RO) Returns the microcode update signature following the execution of CPUID.01H. A processor may prevent writing to this MSR when loading guest states on VM entries or saving guest states on VM exits.	06_01H
		31:0	Reserved	
		63:32	It is recommended that this field be pre-loaded with 0 prior to executing CPUID. If the field remains 0 following the execution of CPUID; this indicates that no microcode update is loaded. Any non-zero value is the microcode update signature.	
9BH	155	IA32_SMM_MONITOR_CTL	SMM Monitor Configuration (R/W)	If CPUID.01H: ECX[bit 5 or bit 6] = 1
		0	Valid (R/W)	
		1	Reserved	
		2	Controls SMI unblocking by VMXOFF (see Section 34.14.4)	If IA32_VMX_MISC[bit 28]
		11:3	Reserved	
		31:12	MSEG Base (R/W)	
		63:32	Reserved	
9EH	158	IA32_SMBASE	Base address of the logical processor's SMRAM image (RO, SMM only)	If IA32_VMX_MISC[bit 15]
C1H	193	IA32_PMC0 (PERFCTR0)	General Performance Counter 0 (R/W)	If CPUID.0AH: EAX[15:8] > 0
C2H	194	IA32_PMC1 (PERFCTR1)	General Performance Counter 1 (R/W)	If CPUID.0AH: EAX[15:8] > 1
C3H	195	IA32_PMC2	General Performance Counter 2 (R/W)	If CPUID.0AH: EAX[15:8] > 2
C4H	196	IA32_PMC3	General Performance Counter 3 (R/W)	If CPUID.0AH: EAX[15:8] > 3
C5H	197	IA32_PMC4	General Performance Counter 4 (R/W)	If CPUID.0AH: EAX[15:8] > 4
C6H	198	IA32_PMC5	General Performance Counter 5 (R/W)	If CPUID.0AH: EAX[15:8] > 5
C7H	199	IA32_PMC6	General Performance Counter 6 (R/W)	If CPUID.0AH: EAX[15:8] > 6
C8H	200	IA32_PMC7	General Performance Counter 7 (R/W)	If CPUID.0AH: EAX[15:8] > 7
E7H	231	IA32_MPERF	Maximum Qualified Performance Clock Counter (R/Write to clear)	If CPUID.06H: ECX[0] = 1

**Table 35-2. IA-32 Architectural MSRs (Contd.)**

Register Address		Architectural MSR Name and bit fields (Former MSR Name)	MSR/Bit Description	Introduced as Architectural MSR
Hex	Decimal			
		63:0	<b>CO_MCNT: C0 Maximum Frequency Clock Count</b> Increments at fixed interval (relative to TSC freq.) when the logical processor is in C0. Cleared upon overflow / wrap-around of IA32_APERF.	
E8H	232	IA32_APERF	Actual Performance Clock Counter (R/Write to clear)	If CPUID.06H: ECX[0] = 1
		63:0	<b>CO_ACNT: C0 Actual Frequency Clock Count</b> Accumulates core clock counts at the coordinated clock frequency, when the logical processor is in C0. Cleared upon overflow / wrap-around of IA32_MPERF.	
FEH	254	IA32_MTRRCAP (MTRRcap)	MTRR Capability (RO) Section 11.11.2.1, "IA32_MTRR_DEF_TYPE MSR."	06_01H
		7:0	VCNT: The number of variable memory type ranges in the processor.	
		8	Fixed range MTRRs are supported when set.	
		9	Reserved.	
		10	WC Supported when set.	
		11	SMRR Supported when set.	
		63:12	Reserved.	
174H	372	IA32_SYSENTER_CS	SYSENTER_CS_MSR (R/W)	06_01H
		15:0	CS Selector	
		63:16	Reserved.	
175H	373	IA32_SYSENTER_ESP	SYSENTER_ESP_MSR (R/W)	06_01H
176H	374	IA32_SYSENTER_EIP	SYSENTER_EIP_MSR (R/W)	06_01H
179H	377	IA32_MCG_CAP (MCG_CAP)	Global Machine Check Capability (RO)	06_01H
		7:0	Count: Number of reporting banks.	
		8	MCG_CTL_P: IA32_MCG_CTL is present if this bit is set	
		9	MCG_EXT_P: Extended machine check state registers are present if this bit is set	
		10	MCP_CMCI_P: Support for corrected MC error event is present.	06_1AH
		11	MCG_TES_P: Threshold-based error status register are present if this bit is set.	
		15:12	Reserved	

Table 35-2. IA-32 Architectural MSRs (Contd.)

Register Address		Architectural MSR Name and bit fields (Former MSR Name)	MSR/Bit Description	Introduced as Architectural MSR
Hex	Decimal			
		23:16	MCG_EXT_CNT: Number of extended machine check state registers present.	
		24	MCG_SER_P: The processor supports software error recovery if this bit is set.	
		25	Reserved.	
		26	MCG_ELOG_P: Indicates that the processor allows platform firmware to be invoked when an error is detected so that it may provide additional platform specific information in an ACPI format "Generic Error Data Entry" that augments the data included in machine check bank registers.	06_3EH
		63:27	Reserved.	
17AH	378	IA32_MCG_STATUS (MCG_STATUS)	Global Machine Check Status (R0)	06_01H
17BH	379	IA32_MCG_CTL (MCG_CTL)	Global Machine Check Control (R/W)	06_01H
180H-185H	384-389	Reserved		06_0EH <sup>1</sup>
186H	390	IA32_PERFVTSELO (PERFVTSELO)	Performance Event Select Register 0 (R/W)	If CPUID.0AH: EAX[15:8] > 0
		7:0	Event Select: Selects a performance event logic unit.	
		15:8	UMask: Qualifies the microarchitectural condition to detect on the selected event logic.	
		16	USR: Counts while in privilege level is not ring 0.	
		17	OS: Counts while in privilege level is ring 0.	
		18	Edge: Enables edge detection if set.	
		19	PC: enables pin control.	
		20	INT: enables interrupt on counter overflow.	
		21	AnyThread: When set to 1, it enables counting the associated event conditions occurring across all logical processors sharing a processor core. When set to 0, the counter only increments the associated event conditions occurring in the logical processor which programmed the MSR.	
		22	EN: enables the corresponding performance counter to commence counting when this bit is set.	
		23	INV: invert the CMASK.	

**Table 35-2. IA-32 Architectural MSRs (Contd.)**

Register Address		Architectural MSR Name and bit fields (Former MSR Name)	MSR/Bit Description	Introduced as Architectural MSR
Hex	Decimal			
		31:24	CMASK: When CMASK is not zero, the corresponding performance counter increments each cycle if the event count is greater than or equal to the CMASK.	
		63:32	Reserved.	
187H	391	IA32_PERFEVTSEL1 (PERFEVTSEL1)	Performance Event Select Register 1 (R/W)	If CPUID.0AH: EAX[15:8] > 1
188H	392	IA32_PERFEVTSEL2	Performance Event Select Register 2 (R/W)	If CPUID.0AH: EAX[15:8] > 2

		61:0	Resource Monitored Data	
		62	Unavailable: If 1, indicates data for this RMID is not available or not monitored for this resource or RMID.	
		63	Error: If 1, indicates and unsupported RMID or event type was written to IA32_PQR_QM_EVTSEL.	
C8FH	3215	IA32_PQR_ASSOC	QoS Resource Association Register (R/W)	If ( CPUID.(EAX=07H, ECX=0):EBX.[bit 12] = 1 )
		N-1:0	Resource Monitoring ID: ID for QoS monitoring hardware to track internal operation, e.g. memory access.	N = Log <sub>2</sub> ( CPUID.(EAX=0FH, ECX=0H).EBX[31:0] +1)
		63:N	Reserved.	

**Table 35-2. IA-32 Architectural MSRs (Contd.)**

Register Address		Architectural MSR Name and bit fields (Former MSR Name)	MSR/Bit Description	Introduced as Architectural MSR
Hex	Decimal			
4000_0000H - 4000_00FFH		Reserved MSR Address Space	<b>All existing and future processors will not implement MSR in this range.</b>	
C000_0080H		IA32_EFER	<b>Extended Feature Enables</b>	If (CPUID.80000001.EDX.[bit 20] or CPUID.80000001.EDX.[bit 29])
		0	<b>SYSCALL Enable (R/W)</b> Enables SYSCALL/SYSRET instructions in 64-bit mode.	
		7:1	Reserved.	
		8	<b>IA-32e Mode Enable (R/W)</b> Enables IA-32e mode operation.	
		9	Reserved.	
		10	<b>IA-32e Mode Active (R)</b> Indicates IA-32e mode is active when set.	
		11	<b>Execute Disable Bit Enable (R/W)</b>	
		63:12	Reserved.	
C000_0081H		IA32_STAR	<b>System Call Target Address (R/W)</b>	If CPUID.80000001.EDX.[bit 29] = 1
C000_0082H		IA32_LSTAR	<b>IA-32e Mode System Call Target Address (R/W)</b>	If CPUID.80000001.EDX.[bit 29] = 1
C000_0084H		IA32_FMASK	<b>System Call Flag Mask (R/W)</b>	If CPUID.80000001.EDX.[bit 29] = 1
C000_0100H		IA32_FS_BASE	<b>Map of BASE Address of FS (R/W)</b>	If CPUID.80000001.EDX.[bit 29] = 1
C000_0101H		IA32_GS_BASE	<b>Map of BASE Address of GS (R/W)</b>	If CPUID.80000001.EDX.[bit 29] = 1
C000_0102H		IA32_KERNEL_GS_BASE	<b>Swap Target of BASE Address of GS (R/W)</b>	If CPUID.80000001.EDX.[bit 29] = 1
C000_0103H		IA32_TSC_AUX	Auxiliary TSC (Rw)	If CPUID.80000001H: EDX[27] = 1
		31:0	AUX: Auxiliary signature of TSC	
		63:32	Reserved.	

**NOTES:**

1. In processors based on Intel NetBurst® microarchitecture, MSR addresses 180H-197H are supported, software must treat them as model-specific. Starting with Intel Core Duo processors, MSR addresses 180H-185H, 188H-197H are reserved.
2. The \*\_ADDR MSRs may or may not be present; this depends on flag settings in IA32\_MCI\_STATUS. See Section 15.3.2.3 and Section 15.3.2.4 for more information.

## 35.2 MSRS IN THE INTEL® CORE™ 2 PROCESSOR FAMILY

Table 35-3 lists model-specific registers (MSRs) for Intel Core 2 processor family and for Intel Xeon processors based on Intel Core microarchitecture, architectural MSR addresses are also included in Table 35-3. These processors have a CPUID signature with DisplayFamily\_DisplayModel of 06\_0FH, see Table 35-1.

MSRs listed in Table 35-2 and Table 35-3 are also supported by processors based on the Enhanced Intel Core microarchitecture. Processors based on the Enhanced Intel Core microarchitecture have the CPUID signature DisplayFamily\_DisplayModel of 06\_17H.

The column “Shared/Unique” applies to multi-core processors based on Intel Core microarchitecture. “Unique” means each processor core has a separate MSR, or a bit field in an MSR governs only a core independently. “Shared” means the MSR or the bit field in an MSR address governs the operation of both processor cores.

**Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
0H	0	IA32_P5_MC_ADDR	Unique	See Section 35.16, “MSRs in Pentium Processors.”
1H	1	IA32_P5_MC_TYPE	Unique	See Section 35.16, “MSRs in Pentium Processors.”
6H	6	IA32_MONITOR_FILTER_SIZE	Unique	See Section 8.10.5, “Monitor/Mwait Address Range Determination,” and Table 35-2.
10H	16	IA32_TIME_STAMP_COUNTER	Unique	See Section 17.13, “Time-Stamp Counter,” and see Table 35-2.
17H	23	IA32_PLATFORM_ID	Shared	<b>Platform ID (R)</b> See Table 35-2.
17H	23	MSR_PLATFORM_ID	Shared	<b>Model Specific Platform ID (R)</b>
		7:0		Reserved.
		12:8		<b>Maximum Qualified Ratio (R)</b> The maximum allowed bus ratio.

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		0		<b>RIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If cleared, the program cannot be reliably restarted.
		1		<b>EIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.
		2		<b>MCIP</b> When set, bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.
		63:3		Reserved.
186H	390	IA32_PERFEVTSELO	Unique	See Table 35-2.
187H	391	IA32_PERFEVTSEL1	Unique	See Table 35-2.
198H	408	IA32_PERF_STATUS	Shared	See Table 35-2.
198H	408	MSR_PERF_STATUS	Shared	
		15:0		Current Performance State Value.
		30:16		Reserved.
		31		XE Operation (R/O). If set, XE operation is enabled. Default is cleared.
		39:32		Reserved.
		44:40		Maximum Bus Ratio (R/O) Indicates maximum bus ratio configured for the processor.
		45		Reserved.
		46		Non-Integer Bus Ratio (R/O) Indicates non-integer bus ratio is enabled. Applies processors based on Enhanced Intel Core microarchitecture.
63:47		Reserved.		
199H	409	IA32_PERF_CTL	Unique	See Table 35-2.
19AH	410	IA32_CLOCK_MODULATION	Unique	<b>Clock Modulation (R/W)</b> See Table 35-2. IA32_CLOCK_MODULATION MSR was originally named IA32_THERM_CONTROL MSR.
19BH	411	IA32_THERM_INTERRUPT	Unique	<b>Thermal Interrupt Control (R/W)</b> See Table 35-2.
19CH	412	IA32_THERM_STATUS	Unique	<b>Thermal Monitor Status (R/W)</b> See Table 35-2.

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
19DH	413	MSR_THERM2_CTL	Unique	
		15:0		Reserved.
		16		<b>TM_SELECT (R/W)</b> Mode of automatic thermal monitor: 0 = Thermal Monitor 1 (thermally-initiated on-die modulation of the stop-clock duty cycle) 1 = Thermal Monitor 2 (thermally-initiated frequency transitions) If bit 3 of the IA32_MISC_ENABLE register is cleared, TM_SELECT has no effect. Neither TM1 nor TM2 are enabled.
		63:16		Reserved.
1A0	416	IA32_MISC_ENABLE		<b>Enable Misc. Processor Features (R/W)</b> Allows a variety of processor functions to be enabled and disabled.
		0		<b>Fast-Strings Enable</b> See Table 35-2.
		2:1		Reserved.
		3	Unique	<b>Automatic Thermal Control Circuit Enable (R/W)</b> See Table 35-2.
		6:4		Reserved.
		7	Shared	<b>Performance Monitoring Available (R)</b> See Table 35-2.
		8		Reserved.
		9		<b>Hardware Prefetcher Disable (R/W)</b> When set, disables the hardware prefetcher operation on streams of data. When clear (default), enables the prefetch queue. Disabling of the hardware prefetcher may impact processor performance.
		10	Shared	<b>FERR# Multiplexing Enable (R/W)</b> 1 = FERR# asserted by the processor to indicate a pending break event within the processor 0 = Indicates compatible FERR# signaling behavior This bit must be set to 1 to support XAPIC interrupt model usage.
		11	Shared	<b>Branch Trace Storage Unavailable (RO)</b> See Table 35-2.
12	Shared	<b>Precise Event Based Sampling Unavailable (RO)</b> See Table 35-2.		

**Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		13	Shared	<p><b>TM2 Enable (R/W)</b></p> <p>When this bit is set (1) and the thermal sensor indicates that the die temperature is at the pre-determined threshold, the Thermal Monitor 2 mechanism is engaged. TM2 will reduce the bus to core ratio and voltage according to the value last written to MSR_THERM2_CTL bits 15:0.</p>
				<p>When this bit is clear (0, default), the processor does not change the VID signals or the bus to core ratio when the processor enters a thermally managed state.</p> <p>The BIOS must enable this feature if the TM2 feature flag (CPUID.1:ECX[8]) is set; if the TM2 feature flag is not set, this feature is not supported and BIOS must not alter the contents of the TM2 bit location.</p> <p>The processor is operating out of specification if both this bit and the TM1 bit are set to 0.</p>
		15:14		Reserved.
		16	Shared	<p><b>Enhanced Intel SpeedStep Technology Enable (R/W)</b></p> <p>See Table 35-2.</p>
		18	Shared	<p><b>ENABLE MONITOR FSM (R/W)</b></p> <p>See Table 35-2.</p>
		19	Shared	<p><b>Adjacent Cache Line Prefetch Disable (R/W)</b></p> <p>When set to 1, the processor fetches the cache line that contains data currently required by the processor. When set to 0, the processor fetches cache lines that comprise a cache line pair (128 bytes).</p> <p>Single processor platforms should not set this bit. Server platforms should set or clear this bit based on platform performance observed in validation and testing.</p> <p>BIOS may contain a setup option that controls the setting of this bit.</p>
		20	Shared	<p><b>Enhanced Intel SpeedStep Technology Select Lock (R/W0)</b></p> <p>When set, this bit causes the following bits to become read-only:</p> <ul style="list-style-type: none"> <li>▪ Enhanced Intel SpeedStep Technology Select Lock (this bit),</li> <li>▪ Enhanced Intel SpeedStep Technology Enable bit.</li> </ul> <p>The bit must be set before an Enhanced Intel SpeedStep Technology transition is requested. This bit is cleared on reset.</p>
		21		Reserved.
		22	Shared	<p><b>Limit CPUID Maxval (R/W)</b></p> <p>See Table 35-2.</p>
		23	Shared	<p><b>xTPR Message Disable (R/W)</b></p> <p>See Table 35-2.</p>
		33:24		Reserved.

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		34	Unique	<b>XD Bit Disable (R/W)</b> See Table 35-2.
		36:35		Reserved.
		37	Unique	<b>DCU Prefetcher Disable (R/W)</b> When set to 1, The DCU L1 data cache prefetcher is disabled. The default value after reset is 0. BIOS may write '1' to disable this feature. The DCU prefetcher is an L1 data cache prefetcher. When the DCU prefetcher detects multiple loads from the same line done within a time limit, the DCU prefetcher assumes the next line will be required. The next line is prefetched in to the L1 data cache from memory or L2.
		38	Shared	<b>IDA Disable (R/W)</b> When set to 1 on processors that support IDA, the Intel Dynamic Acceleration feature (IDA) is disabled and the IDA_Enable feature flag will be clear (CPUID.06H: EAX[1]=0). When set to a 0 on processors that support IDA, CPUID.06H: EAX[1] reports the processor's support of IDA is enabled. <b>Note:</b> the power-on default value is used by BIOS to detect hardware support of IDA. If power-on default value is 1, IDA is available in the processor. If power-on default value is 0, IDA is not available.
		39	Unique	<b>IP Prefetcher Disable (R/W)</b> When set to 1, The IP prefetcher is disabled. The default value after reset is 0. BIOS may write '1' to disable this feature. The IP prefetcher is an L1 data cache prefetcher. The IP prefetcher looks for sequential load history to determine whether to prefetch the next expected data into the L1 cache from memory or L2.
		63:40		Reserved.
1C9H	457	MSR_LASTBRANCH_TOS	Unique	<b>Last Branch Record Stack TOS (R/W)</b> Contains an index (bits 0-3) that points to the MSR containing the most recent branch record. See MSR_LASTBRANCH_0_FROM_IP (at 40H).
1D9H	473	IA32_DEBUGCTL	Unique	<b>Debug Control (R/W)</b> See Table 35-2
1DDH	477	MSR_LER_FROM_LIP	Unique	<b>Last Exception Record From Linear IP (R)</b> Contains a pointer to the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.
1DEH	478	MSR_LER_TO_LIP	Unique	<b>Last Exception Record To Linear IP (R)</b> This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.

405H	1029	IA32_MC1_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
406H	1030	IA32_MC1_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC1_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
408H	1032	IA32_MC2_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
409H	1033	IA32_MC2_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40AH	1034	IA32_MC2_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	MSR_MC4_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
40DH	1037	MSR_MC4_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40EH	1038	MSR_MC4_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	MSR_MC3_CTL		See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
411H	1041	MSR_MC3_STATUS		See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
412H	1042	MSR_MC3_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC3_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
413H	1043	MSR_MC3_MISC	Unique	
414H	1044	MSR_MC5_CTL	Unique	
415H	1045	MSR_MC5_STATUS	Unique	
416H	1046	MSR_MC5_ADDR	Unique	
417H	1047	MSR_MC5_MISC	Unique	
419H	1045	MSR_MC6_STATUS	Unique	Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 15.3.2.2, "IA32_MCi_STATUS MSRS." and Chapter 23.

Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
480H	1152	IA32_VMX_BASIC	Unique	<b>Reporting Register of Basic VMX Capabilities (R/O)</b> See Table 35-2. See Appendix A.1, “Basic VMX Information.”
481H	1153	IA32_VMX_PINBASED_ CTLS	Unique	<b>Capability Reporting Register of Pin-based VM-execution Controls (R/O)</b> See Table 35-2. See Appendix A.3, “VM-Execution Controls.”
482H	1154	IA32_VMX_PROCBASED_ CTLS	Unique	<b>Capability Reporting Register of Primary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, “VM-Execution Controls.”
483H	1155	IA32_VMX_EXIT_ CTLS	Unique	<b>Capability Reporting Register of VM-exit Controls (R/O)</b> See Table 35-2. See Appendix A.4, “VM-Exit Controls.”
484H	1156	IA32_VMX_ENTRY_ CTLS	Unique	<b>Capability Reporting Register of VM-entry Controls (R/O)</b> See Table 35-2. See Appendix A.5, “VM-Entry Controls.”
485H	1157	IA32_VMX_MISC	Unique	<b>Reporting Register of Miscellaneous VMX Capabilities (R/O)</b> See Table 35-2. See Appendix A.6, “Miscellaneous Data.”
486H	1158	IA32_VMX_CRO_FIXED0	Unique	<b>Capability Reporting Register of CRO Bits Fixed to 0 (R/O)</b> See Table 35-2. See Appendix A.7, “VMX-Fixed Bits in CRO.”
487H	1159	IA32_VMX_CRO_FIXED1	Unique	<b>Capability Reporting Register of CRO Bits Fixed to 1 (R/O)</b> See Table 35-2. See Appendix A.7, “VMX-Fixed Bits in CRO.”
488H	1160	IA32_VMX_CR4_FIXED0	Unique	<b>Capability Reporting Register of CR4 Bits Fixed to 0 (R/O)</b> See Table 35-2. See Appendix A.8, “VMX-Fixed Bits in CR4.”
489H	1161	IA32_VMX_CR4_FIXED1	Unique	<b>Capability Reporting Register of CR4 Bits Fixed to 1 (R/O)</b> See Table 35-2. See Appendix A.8, “VMX-Fixed Bits in CR4.”
48AH	1162	IA32_VMX_VMCS_ENUM	Unique	<b>Capability Reporting Register of VMCS Field Enumeration (R/O)</b> See Table 35-2. See Appendix A.9, “VMCS Enumeration.”
48BH	1163	IA32_VMX_PROCBASED_ CTLS2	Unique	<b>Capability Reporting Register of Secondary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, “VM-Execution Controls.”

**Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
600H	1536	IA32_DS_AREA	Unique	<b>DS Save Area (R/W)</b> See Table 35-2. See Section 18.12.4, “Debug Store (DS) Mechanism.”
107CC H		MSR_EMON_L3_CTR_CTL0	Unique	<b>GBUSQ Event Control/Counter Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
107CD H		MSR_EMON_L3_CTR_CTL1	Unique	<b>GBUSQ Event Control/Counter Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
107CE H		MSR_EMON_L3_CTR_CTL2	Unique	<b>GSNPQ Event Control/Counter Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
107CF H		MSR_EMON_L3_CTR_CTL3	Unique	<b>GSNPQ Event Control/Counter Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
107D0 H		MSR_EMON_L3_CTR_CTL4	Unique	<b>FSB Event Control/Counter Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
107D1 H		MSR_EMON_L3_CTR_CTL5	Unique	<b>FSB Event Control/Counter Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
107D2 H		MSR_EMON_L3_CTR_CTL6	Unique	<b>FSB Event Control/Counter Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
107D3 H		MSR_EMON_L3_CTR_CTL7	Unique	<b>FSB Event Control/Counter Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
107D8 H		MSR_EMON_L3_GL_CTL	Unique	<b>L3/FSB Common Control Register (R/W)</b> Apply to Intel Xeon processor 7400 series (processor signature 06_1D) only. See Section 17.2.2
C000_0080H		IA32_EFER	Unique	<b>Extended Feature Enables</b> See Table 35-2.
C000_0081H		IA32_STAR	Unique	<b>System Call Target Address (R/W)</b> See Table 35-2.
C000_0082H		IA32_LSTAR	Unique	<b>IA-32e Mode System Call Target Address (R/W)</b> See Table 35-2.
C000_0084H		IA32_FMASK	Unique	<b>System Call Flag Mask (R/W)</b> See Table 35-2.
C000_0100H		IA32_FS_BASE	Unique	<b>Map of BASE Address of FS (R/W)</b> See Table 35-2.

**Table 35-3. MSRs in Processors Based on Intel® Core™ Microarchitecture (Contd.)**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
C000_0101H		IA32_GS_BASE	Unique	<b>Map of BASE Address of GS (R/W)</b> See Table 35-2.
C000_0102H		IA32_KERNEL_GSBASE	Unique	<b>Swap Target of BASE Address of GS (R/W)</b> See Table 35-2.

### 35.3 MSRS IN THE INTEL® ATOM™ PROCESSOR FAMILY

Table 35-4 lists model-specific registers (MSRs) for Intel Atom processor family, architectural MSR addresses are also included in Table 35-4. These processors have a CPUID signature with DisplayFamily\_DisplayModel of 06\_1CH, 06\_26H, 06\_27H, 06\_35H and 06\_36H, see Table 35-1.

The column “Shared/Unique” applies to logical processors sharing the same core in processors based on the Intel Atom microarchitecture. “Unique” means each logical processor has a separate MSR, or a bit field in an MSR governs only a logical processor. “Shared” means the MSR or the bit field in an MSR address governs the operation of both logical processors in the same core.

**Table 35-4. MSRs in Intel® Atom™ Processor Family**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
0H	0	IA32_P5_MC_ADDR	Shared	See Section 35.16, “MSRs in Pentium Processors.”
1H	1	IA32_P5_MC_TYPE	Shared	See Section 35.16, “MSRs in Pentium Processors.”
6H	6	IA32_MONITOR_FILTER_SIZE	Unique	See Section 8.10.5, “Monitor/Mwait Address Range Determination,” and Table 35-2
10H	16	IA32_TIME_STAMP_COUNTER	Unique	See Section 17.13, “Time-Stamp Counter,” and see Table 35-2.
17H	23	IA32_PLATFORM_ID	Shared	<b>Platform ID (R)</b> See Table 35-2.
17H	23	MSR_PLATFORM_ID	Shared	<b>Model Specific Platform ID (R)</b>
		7:0		Reserved.
		12:8		<b>Maximum Qualified Ratio (R)</b> The maximum allowed bus ratio.
		63:13		Reserved.
1BH	27	IA32_APIC_BASE	Unique	See Section 10.4.4, “Local APIC Status and Location,” and Table 35-2.
2AH	42	MSR_EBL_CR_POWERON	Shared	<b>Processor Hard Power-On Configuration (R/W)</b> Enables and disables processor features; <b>(R)</b> indicates current processor configuration.
		0		Reserved.

**Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		1		<b>Data Error Checking Enable (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		2		<b>Response Error Checking Enable (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		3		<b>AERR# Drive Enable (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		4		<b>BERR# Enable for initiator bus requests (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		5		Reserved.
		6		Reserved.
		7		<b>BINIT# Driver Enable (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		8		Reserved.
		9		<b>Execute BIST (R/O)</b> 1 = Enabled; 0 = Disabled
		10		<b>AERR# Observation Enabled (R/O)</b> 1 = Enabled; 0 = Disabled Always 0.
		11		Reserved.
		12		<b>BINIT# Observation Enabled (R/O)</b> 1 = Enabled; 0 = Disabled Always 0.
		13		<b>Reserved.</b>
		14		<b>1 MByte Power on Reset Vector (R/O)</b> 1 = 1 MByte; 0 = 4 GBytes
		15		Reserved
		17:16		<b>APIC Cluster ID (R/O)</b> Always 00B.
		19: 18		Reserved.
		21: 20		<b>Symmetric Arbitration ID (R/O)</b> Always 00B.
		26:22		<b>Integer Bus Frequency Ratio (R/O)</b>
3AH	58	IA32_FEATURE_CONTROL	Unique	<b>Control Features in Intel 64Processor (R/W)</b> See Table 35-2.

Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
40H	64	MSR_LASTBRANCH_0_FROM_IP	Unique	<b>Last Branch Record 0 From IP (R/W)</b> One of eight pairs of last branch record registers on the last branch record stack. This part of the stack contains pointers to the <b>source instruction</b> for one of the last eight branches, exceptions, or interrupts taken by the processor. See also: <ul style="list-style-type: none"> <li>Last Branch Record Stack TOS at 1C9H</li> <li>Section 17.11, “Last Branch, Interrupt, and Exception Recording (Pentium M Processors).”</li> </ul>
41H	65	MSR_LASTBRANCH_1_FROM_IP	Unique	<b>Last Branch Record 1 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
42H	66	MSR_LASTBRANCH_2_FROM_IP	Unique	<b>Last Branch Record 2 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
43H	67	MSR_LASTBRANCH_3_FROM_IP	Unique	<b>Last Branch Record 3 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
44H	68	MSR_LASTBRANCH_4_FROM_IP	Unique	<b>Last Branch Record 4 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
45H	69	MSR_LASTBRANCH_5_FROM_IP	Unique	<b>Last Branch Record 5 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
46H	70	MSR_LASTBRANCH_6_FROM_IP	Unique	<b>Last Branch Record 6 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
47H	71	MSR_LASTBRANCH_7_FROM_IP	Unique	<b>Last Branch Record 7 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
60H	96	MSR_LASTBRANCH_0_TO_IP	Unique	<b>Last Branch Record 0 To IP (R/W)</b> One of eight pairs of last branch record registers on the last branch record stack. This part of the stack contains pointers to the destination instruction for one of the last eight branches, exceptions, or interrupts taken by the processor.
61H	97	MSR_LASTBRANCH_1_TO_IP	Unique	<b>Last Branch Record 1 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
62H	98	MSR_LASTBRANCH_2_TO_IP	Unique	<b>Last Branch Record 2 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
63H	99	MSR_LASTBRANCH_3_TO_IP	Unique	<b>Last Branch Record 3 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
64H	100	MSR_LASTBRANCH_4_TO_IP	Unique	<b>Last Branch Record 4 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
65H	101	MSR_LASTBRANCH_5_TO_IP	Unique	<b>Last Branch Record 5 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
66H	102	MSR_LASTBRANCH_6_TO_IP	Unique	<b>Last Branch Record 6 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
67H	103	MSR_LASTBRANCH_7_TO_IP	Unique	<b>Last Branch Record 7 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.

**Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
79H	121	IA32_BIOS_UPDT_TRIG	Shared	<b>BIOS Update Trigger Register (W)</b> See Table 35-2.
8BH	139	IA32_BIOS_SIGN_ID	Unique	<b>BIOS Update Signature ID (RO)</b> See Table 35-2.
C1H	193	IA32_PMC0	Unique	<b>Performance counter register</b> See Table 35-2.
C2H	194	IA32_PMC1	Unique	<b>Performance Counter Register</b> See Table 35-2.
CDH	205	MSR_FSB_FREQ	Shared	<b>Scaleable Bus Speed(RO)</b> This field indicates the intended scaleable bus clock speed for processors based on Intel Atom microarchitecture:
		2:0		<ul style="list-style-type: none"> <li>▪ 111B: 083 MHz (FSB 333)</li> <li>▪ 101B: 100 MHz (FSB 400)</li> <li>▪ 001B: 133 MHz (FSB 533)</li> <li>▪ 011B: 167 MHz (FSB 667)</li> </ul> 133.33 MHz should be utilized if performing calculation with System Bus Speed when encoding is 001B. 166.67 MHz should be utilized if performing calculation with System Bus Speed when encoding is 011B.
		63:3		Reserved.
E7H	231	IA32_MPERF	Unique	<b>Maximum Performance Frequency Clock Count (RW)</b> See Table 35-2.
E8H	232	IA32_APERF	Unique	<b>Actual Performance Frequency Clock Count (RW)</b> See Table 35-2.
FEH	254	IA32_MTRRCAP	Shared	<b>Memory Type Range Register (R)</b> See Table 35-2.
11EH	281	MSR_BBL_CR_CTL3	Shared	
		0		<b>L2 Hardware Enabled (RO)</b> 1 = If the L2 is hardware-enabled 0 = Indicates if the L2 is hardware-disabled
		7:1		Reserved.
		8		<b>L2 Enabled. (R/W)</b> 1 = L2 cache has been initialized 0 = Disabled (default) Until this bit is set the processor will not respond to the WBINVD instruction or the assertion of the FLUSH# input.
		22:9		Reserved.
		23		<b>L2 Not Present (RO)</b> 0 = L2 Present 1 = L2 Not Present
		63:24		Reserved.

Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
174H	372	IA32_SYSENTER_CS	Unique	See Table 35-2.
175H	373	IA32_SYSENTER_ESP	Unique	See Table 35-2.
176H	374	IA32_SYSENTER_EIP	Unique	See Table 35-2.
179H	377	IA32_MCG_CAP	Unique	See Table 35-2.
17AH	378	IA32_MCG_STATUS	Unique	
		0		<b>RIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If cleared, the program cannot be reliably restarted
		1		<b>EIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.
		2		<b>MCIP</b> When set, bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.
		63:3		Reserved.
186H	390	IA32_PERFEVTSELO	Unique	See Table 35-2.
187H	391	IA32_PERFEVTSEL1	Unique	See Table 35-2.
198H	408	IA32_PERF_STATUS	Shared	See Table 35-2.
198H	408	MSR_PERF_STATUS	Shared	
		15:0		Current Performance State Value.
		39:16		Reserved.
		44:40		Maximum Bus Ratio (R/O) Indicates maximum bus ratio configured for the processor.
		63:45		Reserved.
199H	409	IA32_PERF_CTL	Unique	See Table 35-2.
19AH	410	IA32_CLOCK_MODULATION	Unique	<b>Clock Modulation (R/W)</b> See Table 35-2. IA32_CLOCK_MODULATION MSR was originally named IA32_THERM_CONTROL MSR.
19BH	411	IA32_THERM_INTERRUPT	Unique	<b>Thermal Interrupt Control (R/W)</b> See Table 35-2.
19CH	412	IA32_THERM_STATUS	Unique	<b>Thermal Monitor Status (R/W)</b> See Table 35-2.
19DH	413	MSR_THERM2_CTL	Shared	
		15:0		Reserved.

**Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		16		<b>TM_SELECT (R/W)</b> Mode of automatic thermal monitor: 0 = Thermal Monitor 1 (thermally-initiated on-die modulation of the stop-clock duty cycle) 1 = Thermal Monitor 2 (thermally-initiated frequency transitions) If bit 3 of the IA32_MISC_ENABLE register is cleared, TM_SELECT has no effect. Neither TM1 nor TM2 are enabled.
		63:17		Reserved.
1A0	416	IA32_MISC_ENABLE	Unique	<b>Enable Misc. Processor Features (R/W)</b> Allows a variety of processor functions to be enabled and disabled.
		0		<b>Fast-Strings Enable</b> See Table 35-2.
		2:1		Reserved.
		3	Unique	<b>Automatic Thermal Control Circuit Enable (R/W)</b> See Table 35-2.
		6:4		Reserved.
		7	Shared	<b>Performance Monitoring Available (R)</b> See Table 35-2.
		8		Reserved.
		9		Reserved.
		10	Shared	<b>FERR# Multiplexing Enable (R/W)</b> 1 = FERR# asserted by the processor to indicate a pending break event within the processor 0 = Indicates compatible FERR# signaling behavior This bit must be set to 1 to support XAPIC interrupt model usage.
		11	Shared	<b>Branch Trace Storage Unavailable (RO)</b> See Table 35-2.
		12	Shared	<b>Precise Event Based Sampling Unavailable (RO)</b> See Table 35-2.
		13	Shared	<b>TM2 Enable (R/W)</b> When this bit is set (1) and the thermal sensor indicates that the die temperature is at the pre-determined threshold, the Thermal Monitor 2 mechanism is engaged. TM2 will reduce the bus to core ratio and voltage according to the value last written to MSR_THERM2_CTL bits 15:0.

Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
				<p>When this bit is clear (0, default), the processor does not change the VID signals or the bus to core ratio when the processor enters a thermally managed state.</p> <p>The BIOS must enable this feature if the TM2 feature flag (CPUID.1:ECX[8]) is set; if the TM2 feature flag is not set, this feature is not supported and BIOS must not alter the contents of the TM2 bit location.</p> <p>The processor is operating out of specification if both this bit and the TM1 bit are set to 0.</p>
		15:14		Reserved.
		16	Shared	<b>Enhanced Intel SpeedStep Technology Enable (R/W)</b> See Table 35-2.
		18	Shared	<b>ENABLE MONITOR FSM (R/W)</b> See Table 35-2.
		19		Reserved.
		20	Shared	<p><b>Enhanced Intel SpeedStep Technology Select Lock (R/WO)</b></p> <p>When set, this bit causes the following bits to become read-only:</p> <ul style="list-style-type: none"> <li>▪ Enhanced Intel SpeedStep Technology Select Lock (this bit),</li> <li>▪ Enhanced Intel SpeedStep Technology Enable bit.</li> </ul> <p>The bit must be set before an Enhanced Intel SpeedStep Technology transition is requested. This bit is cleared on reset.</p>
		21		Reserved.
		22	Unique	<b>Limit CPUID Maxval (R/W)</b> See Table 35-2.
		23	Shared	<b>xTPR Message Disable (R/W)</b> See Table 35-2.
		33:24		Reserved.
		34	Unique	<b>XD Bit Disable (R/W)</b> See Table 35-2.
		63:35		Reserved.
1C9H	457	MSR_LASTBRANCH_TOS	Unique	<p><b>Last Branch Record Stack TOS (R/W)</b></p> <p>Contains an index (bits 0-2) that points to the MSR containing the most recent branch record.</p> <p>See MSR_LASTBRANCH_0_FROM_IP (at 40H).</p>
1D9H	473	IA32_DEBUGCTL	Unique	<p><b>Debug Control (R/W)</b></p> <p>See Table 35-2.</p>
1DDH	477	MSR_LER_FROM_LIP	Unique	<p><b>Last Exception Record From Linear IP (R)</b></p> <p>Contains a pointer to the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.</p>

**Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
1DEH	478	MSR_LER_TO_LIP	Unique	<b>Last Exception Record To Linear IP (R)</b> This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.
200H	512	IA32_MTRR_PHYSBASE0	Shared	See Table 35-2.

		0		Enable PEBS on IA32_PMC0. (R/W)
400H	1024	IA32_MCO_CTL	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
401H	1025	IA32_MCO_STATUS	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
402H	1026	IA32_MCO_ADDR	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MCO_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MCO_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
404H	1028	IA32_MC1_CTL	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
405H	1029	IA32_MC1_STATUS	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
408H	1032	IA32_MC2_CTL	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
409H	1033	IA32_MC2_STATUS	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40AH	1034	IA32_MC2_ADDR	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	MSR_MC3_CTL	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
40DH	1037	MSR_MC3_STATUS	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40EH	1038	MSR_MC3_ADDR	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC3_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	MSR_MC4_CTL	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
411H	1041	MSR_MC4_STATUS	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."

**Table 35-4. MSRs in Intel® Atom™ Processor Family (Contd.)**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
412H	1042	MSR_MC4_ADDR	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
480H	1152	IA32_VMX_BASIC	Unique	<b>Reporting Register of Basic VMX Capabilities (R/O)</b> See Table 35-2. See Appendix A.1, "Basic VMX Information."
481H	1153	IA32_VMX_PINBASED_CTL	Unique	<b>Capability Reporting Register of Pin-based VM-execution Controls (R/O)</b> See Table 35-2. See Appendix A.3, "VM-Execution Controls."
482H	1154	IA32_VMX_PROCBASED_CTL	Unique	<b>Capability Reporting Register of Primary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, "VM-Execution Controls."
483H	1155	IA32_VMX_EXIT_CTL	Unique	<b>Capability Reporting Register of VM-exit Controls (R/O)</b> See Table 35-2. See Appendix A.4, "VM-Exit Controls."
484H	1156	IA32_VMX_ENTRY_CTL	Unique	<b>Capability Reporting Register of VM-entry Controls (R/O)</b> See Table 35-2. See Appendix A.5, "VM-Entry Controls."
485H	1157	IA32_VMX_MISC	Unique	<b>Reporting Register of Miscellaneous VMX Capabilities (R/O)</b> See Table 35-2. See Appendix A.6, "Miscellaneous Data."
486H	1158	IA32_VMX_CR0_FIXED0	Unique	<b>Capability Reporting Register of CR0 Bits Fixed to 0 (R/O)</b> See Table 35-2. See Appendix A.7, "VMX-Fixed Bits in CR0."
487H	1159	IA32_VMX_CR0_FIXED1	Unique	<b>Capability Reporting Register of CR0 Bits Fixed to 1 (R/O)</b> See Table 35-2. See Appendix A.7, "VMX-Fixed Bits in CR0."
488H	1160	IA32_VMX_CR4_FIXED0	Unique	<b>Capability Reporting Register of CR4 Bits Fixed to 0 (R/O)</b> See Table 35-2. See Appendix A.8, "VMX-Fixed Bits in CR4."
489H	1161	IA32_VMX_CR4_FIXED1	Unique	<b>Capability Reporting Register of CR4 Bits Fixed to 1 (R/O)</b> See Table 35-2. See Appendix A.8, "VMX-Fixed Bits in CR4."
48AH	1162	IA32_VMX_VMCS_ENUM	Unique	<b>Capability Reporting Register of VMCS Field Enumeration (R/O)</b> See Table 35-2. See Appendix A.9, "VMCS Enumeration."

C000_0101H		IA32_GS_BASE	Unique	<b>Map of BASE Address of GS (R/W)</b> See Table 35-2.
C000_0102H		IA32_KERNEL_GSBASE	Unique	<b>Swap Target of BASE Address of GS (R/W)</b> See Table 35-2.

Table 35-5 lists model-specific registers (MSRs) that are specific to Intel® Atom™ processor with the CPUID signature with DisplayFamily\_DisplayModel of 06\_27H.

**Table 35-5. MSRs Supported by Intel® Atom™ Processors with CPUID Signature 06\_27H**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
3F8H	1016	MSR_PKG_C2_RESIDENCY	Package	<b>Package C2 Residency</b> Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States
		63:0	Package	Package C2 Residency Counter. (R/O) Time that this package is in processor-specific C2 states since last reset. Counts at 1 Mhz frequency.
3F9H	1017	MSR_PKG_C4_RESIDENCY	Package	<b>Package C4 Residency</b> Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States
		63:0	Package	Package C4 Residency Counter. (R/O) Time that this package is in processor-specific C4 states since last reset. Counts at 1 Mhz frequency.
3FAH	1018	MSR_PKG_C6_RESIDENCY	Package	<b>Package C6 Residency</b> Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States
		63:0	Package	Package C6 Residency Counter. (R/O) Time that this package is in processor-specific C6 states since last reset. Counts at 1 Mhz frequency.

### 35.4 MSRS IN THE PROCESSORS BASED ON SILVERMONT MICROARCHITECTURE

Table 35-6 lists model-specific registers (MSRs) for Intel processors based on the Silvermont microarchitecture. These processors have a CPUID signature with DisplayFamily\_DisplayModel of 06\_37H and 06\_4DH, see Table 35-1.

The column “Scope” lists the core/shared/package granularity of sharing in the Silvermont microarchitecture. “Core” means each processor core has a separate MSR, or a bit field not shared with another processor core. “Shared” means the MSR or the bit field is shared by more than one processor cores in the physical package. “Package” means all processor cores in the physical package share the same MSR or bit interface.

**Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture**

Address		Register Name	Scope	Bit Description
Hex	Dec			
0H	0	IA32_P5_MC_ADDR	Shared	See Section 35.16, “MSRs in Pentium Processors.”
1H	1	IA32_P5_MC_TYPE	Shared	See Section 35.16, “MSRs in Pentium Processors.”
6H	6	IA32_MONITOR_FILTER_SIZE	Core	See Section 8.10.5, “Monitor/Mwait Address Range Determination.” and Table 35-2
10H	16	IA32_TIME_STAMP_COUNTER	Core	See Section 17.13, “Time-Stamp Counter,” and see Table 35-2.
17H	23	IA32_PLATFORM_ID	Shared	<b>Platform ID (R)</b> See Table 35-2.

Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)

Address		Register Name	Scope	Bit Description
Hex	Dec			
17H	23	MSR_PLATFORM_ID	Shared	<b>Model Specific Platform ID (R)</b>
		7:0		Reserved.
		12:8		<b>Maximum Qualified Ratio (R)</b> The maximum allowed bus ratio.
		49:13		Reserved.
		52:50		<b>See Table 35-2</b>
		63:33		Reserved.
1BH	27	IA32_APIC_BASE	Core	See Section 10.4.4, "Local APIC Status and Location," and Table 35-2.
2AH	42	MSR_EBL_CR_POWERON	Shared	<b>Processor Hard Power-On Configuration (R/W)</b> Enables and disables processor features; <b>(R)</b> indicates current processor configuration.
		0		Reserved.
		1		<b>Data Error Checking Enable (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		2		<b>Response Error Checking Enable (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		3		<b>AERR# Drive Enable (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		4		<b>BERR# Enable for initiator bus requests (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		5		Reserved.
		6		Reserved.
		7		<b>BINIT# Driver Enable (R/W)</b> 1 = Enabled; 0 = Disabled Always 0.
		8		Reserved.
		9		<b>Execute BIST (R/O)</b> 1 = Enabled; 0 = Disabled
		10		<b>AERR# Observation Enabled (R/O)</b> 1 = Enabled; 0 = Disabled Always 0.
		11		Reserved.
		12		<b>BINIT# Observation Enabled (R/O)</b> 1 = Enabled; 0 = Disabled Always 0.

**Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)**

Address		Register Name	Scope	Bit Description
Hex	Dec			
		13		<b>Reserved.</b>
		14		<b>1 MByte Power on Reset Vector (R/O)</b> 1 = 1 MByte; 0 = 4 GBytes
		15		Reserved
		17:16		<b>APIC Cluster ID (R/O)</b> Always OOB.
		19: 18		Reserved.
		21: 20		<b>Symmetric Arbitration ID (R/O)</b> Always OOB.
		26:22		<b>Integer Bus Frequency Ratio (R/O)</b>
34H	52	MSR_SMI_COUNT	Core	<b>SMI Counter (R/O)</b>
		31:0		<b>SMI Count (R/O)</b> Running count of SMI events since last RESET.
		63:32		Reserved.
3AH	58	IA32_FEATURE_CONTROL	Core	<b>Control Features in Intel 64Processor (R/W)</b> See Table 35-2.
40H	64	MSR_LASTBRANCH_0_FROM_IP	Core	<b>Last Branch Record 0 From IP (R/W)</b> One of eight pairs of last branch record registers on the last branch record stack. This part of the stack contains pointers to the <b>source instruction</b> for one of the last eight branches, exceptions, or interrupts taken by the processor. See also: <ul style="list-style-type: none"> <li>▪ Last Branch Record Stack TOS at 1C9H</li> <li>▪ Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)."</li> </ul>
41H	65	MSR_LASTBRANCH_1_FROM_IP	Core	<b>Last Branch Record 1 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
42H	66	MSR_LASTBRANCH_2_FROM_IP	Core	<b>Last Branch Record 2 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
43H	67	MSR_LASTBRANCH_3_FROM_IP	Core	<b>Last Branch Record 3 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
44H	68	MSR_LASTBRANCH_4_FROM_IP	Core	<b>Last Branch Record 4 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
45H	69	MSR_LASTBRANCH_5_FROM_IP	Core	<b>Last Branch Record 5 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
46H	70	MSR_LASTBRANCH_6_FROM_IP	Core	<b>Last Branch Record 6 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.
47H	71	MSR_LASTBRANCH_7_FROM_IP	Core	<b>Last Branch Record 7 From IP (R/W)</b> See description of MSR_LASTBRANCH_0_FROM_IP.

Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)

Address		Register Name	Scope	Bit Description
Hex	Dec			
60H	96	MSR_LASTBRANCH_0_TO_IP	Core	<b>Last Branch Record 0 To IP (R/W)</b> One of eight pairs of last branch record registers on the last branch record stack. This part of the stack contains pointers to the destination instruction for one of the last eight branches, exceptions, or interrupts taken by the processor.
61H	97	MSR_LASTBRANCH_1_TO_IP	Core	<b>Last Branch Record 1 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
62H	98	MSR_LASTBRANCH_2_TO_IP	Core	<b>Last Branch Record 2 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
63H	99	MSR_LASTBRANCH_3_TO_IP	Core	<b>Last Branch Record 3 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
64H	100	MSR_LASTBRANCH_4_TO_IP	Core	<b>Last Branch Record 4 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
65H	101	MSR_LASTBRANCH_5_TO_IP	Core	<b>Last Branch Record 5 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
66H	102	MSR_LASTBRANCH_6_TO_IP	Core	<b>Last Branch Record 6 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
67H	103	MSR_LASTBRANCH_7_TO_IP	Core	<b>Last Branch Record 7 To IP (R/W)</b> See description of MSR_LASTBRANCH_0_TO_IP.
79H	121	IA32_BIOS_UPDT_TRIG	Core	<b>BIOS Update Trigger Register (W)</b> See Table 35-2.
8BH	139	IA32_BIOS_SIGN_ID	Core	<b>BIOS Update Signature ID (RO)</b> See Table 35-2.
C1H	193	IA32_PMC0	Core	<b>Performance counter register</b> See Table 35-2.
C2H	194	IA32_PMC1	Core	<b>Performance Counter Register</b> See Table 35-2.
CDH	205	MSR_FSB_FREQ	Shared	<b>Scaleable Bus Speed(RO)</b> This field indicates the intended scaleable bus clock speed for processors based on Silvermont microarchitecture:
		2:0		<ul style="list-style-type: none"> <li>▪ 100B: 080.0 MHz</li> <li>▪ 000B: 083.3 MHz</li> <li>▪ 001B: 100.0 MHz</li> <li>▪ 010B: 133.3 MHz</li> <li>▪ 011B: 116.7 MHz</li> </ul>
		63:3		Reserved.
E2H	226	MSR_PKG_CST_CONFIG_CONTROL	Shared	<b>C-State Configuration Control (R/W)</b> Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States. See <a href="http://biosbits.org">http://biosbits.org</a> .

**Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)**

Address		Register Name	Scope	Bit Description
Hex	Dec			
		2:0		<b>Package C-State Limit (R/W)</b> Specifies the lowest processor-specific C-state code name (consuming the least power), for the package. The default is set as factory-configured package C-state limit. The following C-state code name encodings are supported: 000b: C0 (no package C-sate support) 001b: C1 (Behavior is the same as 000b) 100b: C4 110b: C6 111b: C7 (Silvermont only).
		9:3		Reserved.
		10		<b>I/O MWAIT Redirection Enable (R/W)</b> When set, will map IO_read instructions sent to IO register specified by MSR_PMG_IO_CAPTURE_BASE to MWAIT instructions
		14:11		Reserved.
		15		<b>CFG Lock (R/WO)</b> When set, lock bits 15:0 of this register until next reset.
		63:16		Reserved.
E4H	228	MSR_PMG_IO_CAPTURE_BASE	Shared	<b>Power Management IO Redirection in C-state (R/W)</b> See <a href="http://biosbits.org">http://biosbits.org</a> .
		15:0		<b>LVL_2 Base Address (R/W)</b> Specifies the base address visible to software for IO redirection. If IO MWAIT Redirection is enabled, reads to this address will be consumed by the power management logic and decoded to MWAIT instructions. When IO port address redirection is enabled, this is the IO port address reported to the OS/software.
		18:16		<b>C-state Range (R/W)</b> Specifies the encoding value of the maximum C-State code name to be included when IO read to MWAIT redirection is enabled by MSR_PMG_CST_CONFIG_CONTROL[bit10]: 100b - C4 is the max C-State to include 110b - C6 is the max C-State to include 111b - C7 is the max C-State to include
		63:19		Reserved.
E7H	231	IA32_MPERF	Core	<b>Maximum Performance Frequency Clock Count (RW)</b> See Table 35-2.
E8H	232	IA32_APERF	Core	<b>Actual Performance Frequency Clock Count (RW)</b> See Table 35-2.
FEH	254	IA32_MTRRCAP	Core	<b>Memory Type Range Register (R)</b> See Table 35-2.
11EH	281	MSR_BBL_CR_CTL3	Shared	

Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)

Address		Register Name	Scope	Bit Description
Hex	Dec			
		0		<b>L2 Hardware Enabled (RO)</b> 1 = If the L2 is hardware-enabled 0 = Indicates if the L2 is hardware-disabled
		7:1		Reserved.
		8		<b>L2 Enabled. (R/W)</b> 1 = L2 cache has been initialized 0 = Disabled (default) Until this bit is set the processor will not respond to the WBINVD instruction or the assertion of the FLUSH# input.
		22:9		Reserved.
		23		<b>L2 Not Present (RO)</b> 0 = L2 Present 1 = L2 Not Present
		63:24		Reserved.
		174H	372	IA32_SYSENTER_CS
175H	373	IA32_SYSENTER_ESP	Core	See Table 35-2.
176H	374	IA32_SYSENTER_EIP	Core	See Table 35-2.
179H	377	IA32_MCG_CAP	Core	See Table 35-2.
17AH	378	IA32_MCG_STATUS	Core	
		0		<b>RIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If cleared, the program cannot be reliably restarted
		1		<b>EIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.
		2		<b>MCIP</b> When set, bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.
		63:3		Reserved.
186H	390	IA32_PERFEVTSELO	Core	See Table 35-2.
187H	391	IA32_PERFEVTSEL1	Core	See Table 35-2.
198H	408	IA32_PERF_STATUS	Shared	See Table 35-2.
199H	409	IA32_PERF_CTL	Core	See Table 35-2.
19AH	410	IA32_CLOCK_MODULATION	Core	<b>Clock Modulation (R/W)</b> See Table 35-2. IA32_CLOCK_MODULATION MSR was originally named IA32_THERM_CONTROL MSR.

Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)

Address		Register Name	Scope	Bit Description
Hex	Dec			
		38	Shared	<b>Turbo Mode Disable (R/W)</b> When set to 1 on processors that support Intel Turbo Boost Technology, the turbo mode feature is disabled and the IDA_Enable feature flag will be clear (CPUID.06H: EAX[1]=0). When set to a 0 on processors that support IDA, CPUID.06H: EAX[1] reports the processor's support of turbo mode is enabled. <b>Note:</b> the power-on default value is used by BIOS to detect hardware support of turbo mode. If power-on default value is 1, turbo mode is available in the processor. If power-on default value is 0, turbo mode is not available.
		63:39		Reserved.
1A2H	418	MSR_TEMPERATURE_TARGET	Package	
		15:0		Reserved.
		23:16		<b>Temperature Target (R)</b> The minimum temperature at which PROCHOT# will be asserted. The value is degree C.
		63:24		Reserved.
1A6H	422	MSR_OFFCORE_RSP_0	Shared	<b>Offcore Response Event Select Register (R/W)</b>
1A7H	423	MSR_OFFCORE_RSP_1	Shared	<b>Offcore Response Event Select Register (R/W)</b>
1ADH	429	MSR_TURBO_RATIO_LIMIT	Package	<b>Maximum Ratio Limit of Turbo Mode</b> <b>RO</b> if MSR_PLATFORM_INFO.[28] = 0, <b>RW</b> if MSR_PLATFORM_INFO.[28] = 1
		7:0	Package	<b>Maximum Ratio Limit for 1C</b> Maximum turbo ratio limit of 1 core active.
		15:8	Package	<b>Maximum Ratio Limit for 2C</b> Maximum turbo ratio limit of 2 core active.
		23:16	Package	<b>Maximum Ratio Limit for 3C</b> Maximum turbo ratio limit of 3 core active.
		31:24	Package	<b>Maximum Ratio Limit for 4C</b> Maximum turbo ratio limit of 4 core active.
		39:32	Package	<b>Maximum Ratio Limit for 5C</b> Maximum turbo ratio limit of 5 core active.
		47:40	Package	<b>Maximum Ratio Limit for 6C</b> Maximum turbo ratio limit of 6 core active.
		55:48	Package	<b>Maximum Ratio Limit for 7C</b> Maximum turbo ratio limit of 7 core active.
		63:56	Package	<b>Maximum Ratio Limit for 7C</b> Maximum turbo ratio limit of 7 core active.
1B0H	432	IA32_ENERGY_PERF_BIAS	Core	See Table 35-2.

Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)

Address		Register Name	Scope	Bit Description
Hex	Dec			
1C9H	457	MSR_LASTBRANCH_TOS	Core	<b>Last Branch Record Stack TOS (R/W)</b> Contains an index (bits 0-2) that points to the MSR containing the most recent branch record. See MSR_LASTBRANCH_O_FROM_IP (at 40H).
1D9H	473	IA32_DEBUGCTL	Core	<b>Debug Control (R/W)</b> See Table 35-2.
1DDH	477	MSR_LER_FROM_LIP	Core	<b>Last Exception Record From Linear IP (R)</b> Contains a pointer to the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.
1DEH	478	MSR_LER_TO_LIP	Core	<b>Last Exception Record To Linear IP (R)</b> This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.
1F2H	498	IA32_SMRR_PHYSBASE	Core	See Table 35-2.
1F3H	499	IA32_SMRR_PHYSMASK	Core	See Table 35-2.
200H	512	IA32_MTRR_PHYSBASE0	Core	See Table 35-2.
201H	513	IA32_MTRR_PHYSMASK0	Core	See Table 35-2.
202H	514	IA32_MTRR_PHYSBASE1	Core	See Table 35-2.
203H	515	IA32_MTRR_PHYSMASK1	Core	See Table 35-2.
204H	516	IA32_MTRR_PHYSBASE2	Core	See Table 35-2.
205H	517	IA32_MTRR_PHYSMASK2	Core	See Table 35-2.
206H	518	IA32_MTRR_PHYSBASE3	Core	See Table 35-2.
207H	519	IA32_MTRR_PHYSMASK3	Core	See Table 35-2.
208H	520	IA32_MTRR_PHYSBASE4	Core	See Table 35-2.
209H	521	IA32_MTRR_PHYSMASK4	Core	See Table 35-2.
20AH	522	IA32_MTRR_PHYSBASE5	Core	See Table 35-2.
20BH	523	IA32_MTRR_PHYSMASK5	Core	See Table 35-2.
20CH	524	IA32_MTRR_PHYSBASE6	Core	See Table 35-2.
20DH	525	IA32_MTRR_PHYSMASK6	Core	See Table 35-2.
20EH	526	IA32_MTRR_PHYSBASE7	Core	See Table 35-2.
20FH	527	IA32_MTRR_PHYSMASK7	Core	See Table 35-2.
250H	592	IA32_MTRR_FIX64K_00000	Core	See Table 35-2.
258H	600	IA32_MTRR_FIX16K_80000	Core	See Table 35-2.
259H	601	IA32_MTRR_FIX16K_A0000	Core	See Table 35-2.
268H	616	IA32_MTRR_FIX4K_C0000	Core	See Table 35-2.
269H	617	IA32_MTRR_FIX4K_C8000	Core	See Table 35-2.
26AH	618	IA32_MTRR_FIX4K_D0000	Core	See Table 35-2.

Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)

Address		Register Name	Scope	Bit Description
Hex	Dec			
26BH	619	IA32_MTRR_FIX4K_D8000	Core	See Table 35-2.
26CH	620	IA32_MTRR_FIX4K_E0000	Core	See Table 35-2.
26DH	621	IA32_MTRR_FIX4K_E8000	Core	See Table 35-2.
26EH	622	IA32_MTRR_FIX4K_F0000	Core	See Table 35-2.
26FH	623	IA32_MTRR_FIX4K_F8000	Core	See Table 35-2.
277H	631	IA32_PAT	Core	See Table 35-2.
2FFH	767	IA32_MTRR_DEF_TYPE	Core	<b>Default Memory Types (R/W)</b> See Table 35-2.
309H	777	IA32_FIXED_CTR0	Core	<b>Fixed-Function Performance Counter Register 0 (R/W)</b> See Table 35-2.
30AH	778	IA32_FIXED_CTR1	Core	<b>Fixed-Function Performance Counter Register 1 (R/W)</b> See Table 35-2.
30BH	779	IA32_FIXED_CTR2	Core	<b>Fixed-Function Performance Counter Register 2 (R/W)</b> See Table 35-2.
345H	837	IA32_PERF_CAPABILITIES	Core	See Table 35-2. See Section 17.4.1, "IA32_DEBUGCTL MSR."
38DH	909	IA32_FIXED_CTR_CTRL	Core	<b>Fixed-Function-Counter Control Register (R/W)</b> See Table 35-2.
38EH	910	IA32_PERF_GLOBAL_STAUS	Core	See Table 35-2. See Section 18.4.2, "Global Counter Control Facilities."
38FH	911	IA32_PERF_GLOBAL_CTRL	Core	See Table 35-2. See Section 18.4.2, "Global Counter Control Facilities."
390H	912	IA32_PERF_GLOBAL_OVF_CTRL	Core	See Table 35-2. See Section 18.4.2, "Global Counter Control Facilities."
3F1H	1009	MSR_PEBS_ENABLE	Core	See Table 35-2. See Section 18.4.4, "Precise Event Based Sampling (PEBS)."
		0		Enable PEBS on IA32_PMC0. (R/W)
3F8H	1016	MSR_PKG_C4_RESIDENCY	Package	Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.
		63:0		Package C4 Residency Counter. (R/O) Value since last reset that this package is in processor-specific C4 states. Counts at P1 clock frequency (Guaranteed Maximum Frequency).
3F9H	1017	MSR_PKG_C6C_RESIDENCY	Package	Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.
		63:0		Package C6C Residency Counter. (R/O) Value since last reset that this package is in processor-specific C6C states. Counts at P1 clock frequency (Guaranteed Maximum Frequency)
3FAH	1018	MSR_PKG_C6_RESIDENCY	Package	Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.

**Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)**

Address		Register Name	Scope	Bit Description
Hex	Dec			
		63:0		Package C6 Residency Counter. (R/O) Value since last reset that this package is in processor-specific C6 states. Counts at P1 clock frequency (Guaranteed Maximum Frequency)
3FCH	1020	MSR_CORE_C4_RESIDENCY	Core	Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.
		63:0		CORE C4 Residency Counter. (R/O) Value since last reset that this core is in processor-specific C4 states. Counts at P1 clock frequency (Guaranteed Maximum Frequency)
3FDH	1021	MSR_CORE_C6_RESIDENCY	Core	Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.
		63:0		CORE C6 Residency Counter. (R/O) Value since last reset that this core is in processor-specific C6 states. Counts at P1 clock frequency (Guaranteed Maximum Frequency)
400H	1024	IA32_MCO_CTL	Shared	See Section 15.3.2.1, "IA32_MCI_CTL MSRs."
401H	1025	IA32_MCO_STATUS	Shared	See Section 15.3.2.2, "IA32_MCI_STATUS MSRS."
402H	1026	IA32_MCO_ADDR	Shared	See Section 15.3.2.3, "IA32_MCI_ADDR MSRs." The IA32_MCO_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MCO_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
404H	1028	IA32_MC1_CTL	Shared	See Section 15.3.2.1, "IA32_MCI_CTL MSRs."
405H	1029	IA32_MC1_STATUS	Shared	See Section 15.3.2.2, "IA32_MCI_STATUS MSRS."
408H	1032	IA32_MC2_CTL	Shared	See Section 15.3.2.1, "IA32_MCI_CTL MSRs."
409H	1033	IA32_MC2_STATUS	Shared	See Section 15.3.2.2, "IA32_MCI_STATUS MSRS."
40AH	1034	IA32_MC2_ADDR	Shared	See Section 15.3.2.3, "IA32_MCI_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	MSR_MC3_CTL	Core	See Section 15.3.2.1, "IA32_MCI_CTL MSRs."
40DH	1037	MSR_MC3_STATUS	Core	See Section 15.3.2.2, "IA32_MCI_STATUS MSRS."
40EH	1038	MSR_MC3_ADDR	Core	See Section 15.3.2.3, "IA32_MCI_ADDR MSRs." The MSR_MC3_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	MSR_MC4_CTL	Core	See Section 15.3.2.1, "IA32_MCI_CTL MSRs."

Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)

Address		Register Name	Scope	Bit Description
Hex	Dec			
411H	1041	MSR_MC4_STATUS	Core	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
412H	1042	MSR_MC4_ADDR	Core	See Section 15.3.2.3, "IA32_MCi_ADDR MSRS." The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
414H	1044	MSR_MC5_CTL	Package	See Section 15.3.2.1, "IA32_MCi_CTL MSRS."
415H	1045	MSR_MC5_STATUS	Package	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
416H	1046	MSR_MC5_ADDR	Package	See Section 15.3.2.3, "IA32_MCi_ADDR MSRS." The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
480H	1152	IA32_VMX_BASIC	Core	<b>Reporting Register of Basic VMX Capabilities (R/O)</b> See Table 35-2. See Appendix A.1, "Basic VMX Information."
481H	1153	IA32_VMX_PINBASED_CTLS	Core	<b>Capability Reporting Register of Pin-based VM-execution Controls (R/O)</b> See Table 35-2. See Appendix A.3, "VM-Execution Controls."
482H	1154	IA32_VMX_PROCBASED_CTLS	Core	<b>Capability Reporting Register of Primary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, "VM-Execution Controls."
483H	1155	IA32_VMX_EXIT_CTLS	Core	<b>Capability Reporting Register of VM-exit Controls (R/O)</b> See Table 35-2. See Appendix A.4, "VM-Exit Controls."
484H	1156	IA32_VMX_ENTRY_CTLS	Core	<b>Capability Reporting Register of VM-entry Controls (R/O)</b> See Table 35-2. See Appendix A.5, "VM-Entry Controls."
485H	1157	IA32_VMX_MISC	Core	<b>Reporting Register of Miscellaneous VMX Capabilities (R/O)</b> See Table 35-2. See Appendix A.6, "Miscellaneous Data."
486H	1158	IA32_VMX_CRO_FIXED0	Core	<b>Capability Reporting Register of CRO Bits Fixed to 0 (R/O)</b> See Table 35-2. See Appendix A.7, "VMX-Fixed Bits in CRO."
487H	1159	IA32_VMX_CRO_FIXED1	Core	<b>Capability Reporting Register of CRO Bits Fixed to 1 (R/O)</b> See Table 35-2. See Appendix A.7, "VMX-Fixed Bits in CRO."
488H	1160	IA32_VMX_CR4_FIXED0	Core	<b>Capability Reporting Register of CR4 Bits Fixed to 0 (R/O)</b> See Table 35-2. See Appendix A.8, "VMX-Fixed Bits in CR4."

Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)

Address		Register Name	Scope	Bit Description
Hex	Dec			
489H	1161	IA32_VMX_CR4_FIXED1	Core	<b>Capability Reporting Register of CR4 Bits Fixed to 1 (R/O)</b> See Table 35-2. See Appendix A.8, "VMX-Fixed Bits in CR4."
48AH	1162	IA32_VMX_VMCS_ENUM	Core	<b>Capability Reporting Register of VMCS Field Enumeration (R/O)</b> See Table 35-2. See Appendix A.9, "VMCS Enumeration."
48BH	1163	IA32_VMX_PROCBASED_CTLDS2	Core	<b>Capability Reporting Register of Secondary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, "VM-Execution Controls."
48CH	1164	IA32_VMX_EPT_VPID_ENUM	Core	<b>Capability Reporting Register of EPT and VPID (R/O)</b> See Table 35-2
48DH	1165	IA32_VMX_TRUE_PINBASED_CTLDS	Core	<b>Capability Reporting Register of Pin-based VM-execution Flex Controls (R/O)</b> See Table 35-2
48EH	1166	IA32_VMX_TRUE_PROCBASED_CTLDS	Core	<b>Capability Reporting Register of Primary Processor-based VM-execution Flex Controls (R/O)</b> See Table 35-2
48FH	1167	IA32_VMX_TRUE_EXIT_CTLDS	Core	<b>Capability Reporting Register of VM-exit Flex Controls (R/O)</b> See Table 35-2
490H	1168	IA32_VMX_TRUE_ENTRY_CTLDS	Core	<b>Capability Reporting Register of VM-entry Flex Controls (R/O)</b> See Table 35-2
491H	1169	IA32_VMX_FMFUNC	Core	<b>Capability Reporting Register of VM-function Controls (R/O)</b> See Table 35-2
4C1H	1217	IA32_A_PMC0	Core	See Table 35-2.
4C2H	1218	IA32_A_PMC1	Core	See Table 35-2.
600H	1536	IA32_DS_AREA	Core	<b>DS Save Area (R/W)</b> See Table 35-2. See Section 18.12.4, "Debug Store (DS) Mechanism."
606H	1542	MSR_RAPL_POWER_UNIT	Package	<b>Unit Multipliers used in RAPL Interfaces (R/O)</b> See Section 14.7.1, "RAPL Interfaces."
610H	1552	MSR_PKG_POWER_LIMIT	Package	<b>PKG RAPL Power Limit Control (R/W)</b> See Section 14.7.3, "Package RAPL Domain."
611H	1553	MSR_PKG_ENERGY_STATUS	Package	<b>PKG Energy Status (R/O)</b> See Section 14.7.3, "Package RAPL Domain."
638H	1592	MSR_PPO_POWER_LIMIT	Package	<b>PPO RAPL Power Limit Control (R/W)</b> See Section 14.7.4, "PPO/PP1 RAPL Domains."
639H	1593	MSR_PPO_ENERGY_STATUS	Package	<b>PPO Energy Status (R/O)</b> See Section 14.7.4, "PPO/PP1 RAPL Domains."
660H	1632	MSR_CORE_C1_RESIDENCY	Core	Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.

**Table 35-6. MSRs in Intel Processors Based on the Silvermont Microarchitecture (Contd.)**

Address		Register Name	Scope	Bit Description
Hex	Dec			
		63:0		CORE C1 Residency Counter. (R/O) Value since last reset that this core is in processor-specific C1 states. Counts at P1 clock frequency (Guaranteed Maximum Frequency)
6E0H	1760	IA32_TSC_DEADLINE	Core	<b>TSC Target of Local APIC's TSC Deadline Mode (R/W)</b> See Table 35-2
C000_0080H		IA32_EFER	Core	<b>Extended Feature Enables</b> See Table 35-2.
C000_0081H		IA32_STAR	Core	<b>System Call Target Address (R/W)</b> See Table 35-2.
C000_0082H		IA32_LSTAR	Core	<b>IA-32e Mode System Call Target Address (R/W)</b> See Table 35-2.
C000_0084H		IA32_FMASK	Core	<b>System Call Flag Mask (R/W)</b> See Table 35-2.
C000_0100H		IA32_FS_BASE	Core	<b>Map of BASE Address of FS (R/W)</b> See Table 35-2.
C000_0101H		IA32_GS_BASE	Core	<b>Map of BASE Address of GS (R/W)</b> See Table 35-2.
C000_0102H		IA32_KERNEL_GSBASE	Core	<b>Swap Target of BASE Address of GS (R/W)</b> See Table 35-2.
C000_0103H		IA32_TSC_AUX	Core	<b>AUXILIARY TSC Signature. (R/W)</b> See Table 35-2

## 35.5 MSRS IN THE INTEL® MICROARCHITECTURE CODE NAME NEHALEM

Table 35-7 lists model-specific registers (MSRs) that are common for Intel® microarchitecture code name Nehalem. These include Intel Core i7 and i5 processor family. Architectural MSR addresses are also included in Table 35-7. These processors have a CPUID signature with DisplayFamily\_DisplayModel of 06\_1AH, 06\_1EH, 06\_1FH, 06\_2EH, see Table 35-1. Additional MSRs specific to 06\_1AH, 06\_1EH, 06\_1FH are listed in Table 35-8. Some MSRs listed in these tables are used by BIOS. More information about these MSR can be found at <http://bios-bits.org>.

The column "Scope" represents the package/core/thread scope of individual bit field of an MSR. "Thread" means this bit field must be programmed on each logical processor independently. "Core" means the bit field must be programmed on each processor core independently, logical processors in the same core will be affected by change of this bit on the other logical processor in the same core. "Package" means the bit field must be programmed once for each physical package. Change of a bit filed with a package scope will affect all logical processors in that physical package.

**Table 35-7. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
0H	0	IA32_P5_MC_ADDR	Thread	See Section 35.16, "MSRs in Pentium Processors."
1H	1	IA32_P5_MC_TYPE	Thread	See Section 35.16, "MSRs in Pentium Processors."
6H	6	IA32_MONITOR_FILTER_SIZE	Thread	See Section 8.10.5, "Monitor/Mwait Address Range Determination," and Table 35-2.
10H	16	IA32_TIME_STAMP_COUNTER	Thread	See Section 17.13, "Time-Stamp Counter," and see Table 35-2.
17H	23	IA32_PLATFORM_ID	Package	<b>Platform ID (R)</b> See Table 35-2.
17H	23	MSR_PLATFORM_ID	Package	<b>Model Specific Platform ID (R)</b>
		49:0		Reserved.
		52:50		See Table 35-2.
		63:53		Reserved.
1BH	27	IA32_APIC_BASE	Thread	See Section 10.4.4, "Local APIC Status and Location," and Table 35-2.
34H	52	MSR_SMI_COUNT	Thread	<b>SMI Counter (R/O)</b>
		31:0		<b>SMI Count (R/O)</b> Running count of SMI events since last RESET.
		63:32		Reserved.
3AH	58	IA32_FEATURE_CONTROL	Thread	<b>Control Features in Intel 64 Processor (R/W)</b> See Table 35-2.
79H	121	IA32_BIOS_UPDT_TRIG	Core	<b>BIOS Update Trigger Register (W)</b> See Table 35-2.
8BH	139	IA32_BIOS_SIGN_ID	Thread	<b>BIOS Update Signature ID (R0)</b> See Table 35-2.
C1H	193	IA32_PMC0	Thread	<b>Performance Counter Register</b> See Table 35-2.
C2H	194	IA32_PMC1	Thread	<b>Performance Counter Register</b> See Table 35-2.
C3H	195	IA32_PMC2	Thread	<b>Performance Counter Register</b> See Table 35-2.
C4H	196	IA32_PMC3	Thread	<b>Performance Counter Register</b> See Table 35-2.
CEH	206	MSR_PLATFORM_INFO	Package	see <a href="http://biosbits.org">http://biosbits.org</a> .
		7:0		Reserved.

Table 35-7. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem (Contd.)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		15:8	Package	<b>Maximum Non-Turbo Ratio (R/O)</b> The is the ratio of the frequency that invariant TSC runs at. The invariant TSC frequency can be computed by multiplying this ratio by 133.33 MHz.
		27:16		Reserved.
		28	Package	<b>Programmable Ratio Limit for Turbo Mode (R/O)</b> When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled.
		29	Package	<b>Programmable TDC-TDP Limit for Turbo Mode (R/O)</b> When set to 1, indicates that TDC/TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDC and TDP Limits for Turbo mode are not programmable.
		39:30		Reserved.
		47:40	Package	<b>Maximum Efficiency Ratio (R/O)</b> The is the minimum ratio (maximum efficiency) that the processor can operates, in units of 133.33MHz.
		63:48		Reserved.
E2H	226	MSR_PKG_CST_CONFIG_CONTROL	Core	<b>C-State Configuration Control (R/W)</b> Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States. See <a href="http://biosbits.org">http://biosbits.org</a> .
		2:0		<b>Package C-State Limit (R/W)</b> Specifies the lowest processor-specific C-state code name (consuming the least power), for the package. The default is set as factory-configured package C-state limit. The following C-state code name encodings are supported: 000b: C0 (no package C-sate support) 001b: C1 (Behavior is the same as 000b) 010b: C3 011b: C6 100b: C7 101b and 110b: Reserved 111: No package C-state limit. Note: This field cannot be used to limit package C-state to C3.
		9:3		Reserved.
		10		<b>I/O MWAIT Redirection Enable (R/W)</b> When set, will map IO_read instructions sent to IO register specified by MSR_PMG_IO_CAPTURE_BASE to MWAIT instructions.
		14:11		Reserved.
		15		<b>CFG Lock (R/WO)</b> When set, lock bits 15:0 of this register until next reset.

**Table 35-7. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		23:16		Reserved.
		24		<b>Interrupt filtering enable (R/W)</b> When set, processor cores in a deep C-State will wake only when the event message is destined for that core. When 0, all processor cores in a deep C-State will wake for an event message.
		25		<b>C3 state auto demotion enable (R/W)</b> When set, the processor will conditionally demote C6/C7 requests to C3 based on uncore auto-demote information.
		26		<b>C1 state auto demotion enable (R/W)</b> When set, the processor will conditionally demote C3/C6/C7 requests to C1 based on uncore auto-demote information.
		63:27		Reserved.
E4H	228	MSR_PMG_IO_CAPTURE_BASE	Core	<b>Power Management IO Redirection in C-state (R/W)</b> See <a href="http://biosbits.org">http://biosbits.org</a> .
		15:0		<b>LVL_2 Base Address (R/W)</b> Specifies the base address visible to software for IO redirection. If IO MWAIT Redirection is enabled, reads to this address will be consumed by the power management logic and decoded to MWAIT instructions. When IO port address redirection is enabled, this is the IO port address reported to the OS/software.
		18:16		<b>C-state Range (R/W)</b> Specifies the encoding value of the maximum C-State code name to be included when IO read to MWAIT redirection is enabled by MSR_PMG_CST_CONFIG_CONTROL[bit10]: 000b - C3 is the max C-State to include 001b - C6 is the max C-State to include 010b - C7 is the max C-State to include

Table 35-7. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem (Contd.)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		0		<b>RIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If cleared, the program cannot be reliably restarted.
		1		<b>EIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.
		2		<b>MCIP</b> When set, bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.

825H	2085	IA32_X2APIC_IRR5	Thread	x2APIC Interrupt Request register bits [191:160] (R/O)
826H	2086	IA32_X2APIC_IRR6	Thread	x2APIC Interrupt Request register bits [223:192] (R/O)

Table 35-7. MSRs in Processors Based on Intel® Microarchitecture Code Name Nehalem (Contd.)

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
827H	2087	IA32_X2APIC_IRR7	Thread	x2APIC Interrupt Request register bits [255:224] (R/O)
828H	2088	IA32_X2APIC_ESR	Thread	x2APIC Error Status register (R/W)
82FH	2095	IA32_X2APIC_LVT_CMCI	Thread	x2APIC LVT Corrected Machine Check Interrupt register (R/W)
830H	2096	IA32_X2APIC_ICR	Thread	x2APIC Interrupt Command register (R/W)
832H	2098	IA32_X2APIC_LVT_TIMER	Thread	x2APIC LVT Timer Interrupt register (R/W)
833H	2099	IA32_X2APIC_LVT_THERMAL	Thread	x2APIC LVT Thermal Sensor Interrupt register (R/W)
834H	2100	IA32_X2APIC_LVT_PMI	Thread	x2APIC LVT Performance Monitor register (R/W)
835H	2101	IA32_X2APIC_LVT_LINT0	Thread	x2APIC LVT LINT0 register (R/W)
836H	2102	IA32_X2APIC_LVT_LINT1	Thread	x2APIC LVT LINT1 register (R/W)
837H	2103	IA32_X2APIC_LVT_ERROR	Thread	x2APIC LVT Error register (R/W)
838H	2104	IA32_X2APIC_INIT_COUNT	Thread	x2APIC Initial Count register (R/W)
839H	2105	IA32_X2APIC_CUR_COUNT	Thread	x2APIC Current Count register (R/O)
83EH	2110	IA32_X2APIC_DIV_CONF	Thread	x2APIC Divide Configuration register (R/W)
83FH	2111	IA32_X2APIC_SELF_IPI	Thread	x2APIC Self IPI register (W/O)
C000_0080H		IA32_EFER	Thread	<b>Extended Feature Enables</b> See Table 35-2.
C000_0081H		IA32_STAR	Thread	<b>System Call Target Address (R/W)</b> See Table 35-2.
C000_0082H		IA32_LSTAR	Thread	<b>IA-32e Mode System Call Target Address (R/W)</b> See Table 35-2.
C000_0084H		IA32_FMASK	Thread	<b>System Call Flag Mask (R/W)</b> See Table 35-2.
C000_0100H		IA32_FS_BASE	Thread	<b>Map of BASE Address of FS (R/W)</b> See Table 35-2.
C000_0101H		IA32_GS_BASE	Thread	<b>Map of BASE Address of GS (R/W)</b> See Table 35-2.
C000_0102H		IA32_KERNEL_GSBASE	Thread	<b>Swap Target of BASE Address of GS (R/W)</b> See Table 35-2.
C000_0103H		IA32_TSC_AUX	Thread	<b>AUXILIARY TSC Signature. (R/W)</b> See Table 35-2 and Section 17.13.2, "IA32_TSC_AUX Register and RDTSCP Support."

### 35.5.1 Additional MSRs in the Intel® Xeon® Processor 5500 and 3400 Series

Intel Xeon Processor 5500 and 3400 series support additional model-specific registers listed in Table 35-8. These MSRs also apply to Intel Core i7 and i5 processor family CPUID signature with DisplayFamily\_DisplayModel of 06\_1AH, 06\_1EH and 06\_1FH, see Table 35-1.

**Table 35-8. Additional MSRs in Intel® Xeon® Processor 5500 and 3400 Series**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
1ADH	429	MSR_TURBO_RATIO_LIMIT	Package	Actual maximum turbo frequency is multiplied by 133.33MHz. (not available to model 06_2EH)
		7:0		<b>Maximum Turbo Ratio Limit 1C (R/O)</b> Maximum Turbo mode ratio limit with 1 core active.
		15:8		<b>Maximum Turbo Ratio Limit 2C (R/O)</b> Maximum Turbo mode ratio limit with 2cores active.
		23:16		<b>Maximum Turbo Ratio Limit 3C (R/O)</b> Maximum Turbo mode ratio limit with 3cores active.
		31:24		<b>Maximum Turbo Ratio Limit 4C (R/O)</b> Maximum Turbo mode ratio limit with 4 cores active.
		63:32		Reserved.

## 35.6 MSRS IN THE INTEL® XEON® PROCESSOR 5600 SERIES (BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE)

Intel® Xeon® Processor 5600 Series (based on Intel® microarchitecture code name Westmere) supports the MSR interfaces listed in Table 35-7, Table 35-8, plus additional MSR listed in Table 35-10. These MSRs also apply to Intel Core i7, i5 and i3 processor family with CPUID signature DisplayFamily\_DisplayModel of 06\_25H and 06\_2CH, see Table 35-1.

**Table 35-10. Additional MSRs Supported by Intel Processors  
(Based on Intel® Microarchitecture Code Name Westmere)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
1A7H	423	MSR_OFFCORE_RSP_1	Thread	<b>Offcore Response Event Select Register (R/W)</b>
1ADH	429	MSR_TURBO_RATIO_LIMIT	Package	<b>Maximum Ratio Limit of Turbo Mode</b> RO if MSR_PLATFORM_INFO.[28] = 0, RW if MSR_PLATFORM_INFO.[28] = 1
		7:0	Package	<b>Maximum Ratio Limit for 1C</b> Maximum turbo ratio limit of 1 core active.
		15:8	Package	<b>Maximum Ratio Limit for 2C</b> Maximum turbo ratio limit of 2 core active.
		23:16	Package	<b>Maximum Ratio Limit for 3C</b> Maximum turbo ratio limit of 3 core active.
		31:24	Package	<b>Maximum Ratio Limit for 4C</b> Maximum turbo ratio limit of 4 core active.
		39:32	Package	<b>Maximum Ratio Limit for 5C</b> Maximum turbo ratio limit of 5 core active.
		47:40	Package	<b>Maximum Ratio Limit for 6C</b> Maximum turbo ratio limit of 6 core active.
		63:48		Reserved.
1B0H	432	IA32_ENERGY_PERF_BIAS	Package	See Table 35-2.

## 35.7 MSRS IN THE INTEL® XEON® PROCESSOR E7 FAMILY (BASED ON INTEL® MICROARCHITECTURE CODE NAME WESTMERE)

Intel® Xeon® Processor E7 Family (based on Intel® microarchitecture code name Westmere) supports the MSR interfaces listed in Table 35-7 (except MSR address 1ADH), Table 35-8, plus additional MSR listed in Table 35-11.

**Table 35-11. Additional MSRs Supported by Intel® Xeon® Processor E7 Family**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
1A7H	423	MSR_OFFCORE_RSP_1	Thread	<b>Offcore Response Event Select Register (R/W)</b>
1ADH	429	MSR_TURBO_RATIO_LIMIT	Package	<b>Reserved</b> Attempt to read/write will cause #UD.
1B0H	432	IA32_ENERGY_PERF_BIAS	Package	See Table 35-2.
F40H	3904	MSR_C8_PMON_BOX_CTRL	Package	Uncore C-box 8 perfmon local box control MSR.
F41H	3905	MSR_C8_PMON_BOX_STATUS	Package	Uncore C-box 8 perfmon local box status MSR.
F42H	3906	MSR_C8_PMON_BOX_OVF_CTRL	Package	Uncore C-box 8 perfmon local box overflow control MSR.

FDBH	4059	MSR_C9_PMON_CTRL5	Package	Uncore C-box 9 perfmon counter MSR.

## 35.8 MSRS IN INTEL® PROCESSOR FAMILY BASED ON INTEL® MICROARCHITECTURE CODE NAME SANDY BRIDGE

Table 35-12 lists model-specific registers (MSRs) that are common to Intel® processor family based on Intel micro-architecture code name Sandy Bridge. All architectural MSRs listed in Table 35-2 are supported. These processors have a CPUID signature with DisplayFamily\_DisplayModel of 06\_2AH, 06\_2DH, see Table 35-1. Additional MSRs specific to 06\_2AH are listed in Table 35-13.

**Table 35-12. MSRs Supported by Intel® Processors based on Intel® microarchitecture code name Sandy Bridge**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
0H	0	IA32_P5_MC_ADDR	Thread	See Section 35.16, “MSRs in Pentium Processors.”
1H	1	IA32_P5_MC_TYPE	Thread	See Section 35.16, “MSRs in Pentium Processors.”
6H	6	IA32_MONITOR_FILTER_SIZE	Thread	See Section 8.10.5, “Monitor/Mwait Address Range Determination,” and Table 35-2.
10H	16	IA32_TIME_STAMP_COUNTER	Thread	See Section 17.13, “Time-Stamp Counter,” and see Table 35-2.
17H	23	IA32_PLATFORM_ID	Package	<b>Platform ID (R)</b> See Table 35-2.

**Table 35-12. MSRs Supported by Intel® Processors  
based on Intel® microarchitecture code name Sandy Bridge (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
1BH	27	IA32_APIC_BASE	Thread	See Section 10.4.4, "Local APIC Status and Location," and Table 35-2.
34H	52	MSR_SMI_COUNT	Thread	<b>SMI Counter (R/O)</b>
		31:0		<b>SMI Count (R/O)</b> Count SMIs.
		63:32		Reserved.
3AH	58	IA32_FEATURE_CONTROL	Thread	<b>Control Features in Intel 64 Processor (R/W)</b> See Table 35-2.
79H	121	IA32_BIOS_UPDT_TRIG	Core	<b>BIOS Update Trigger Register (W)</b> See Table 35-2.
8BH	139	IA32_BIOS_SIGN_ID	Thread	<b>BIOS Update Signature ID (RO)</b> See Table 35-2.
C1H	193	IA32_PMC0	Thread	<b>Performance Counter Register</b> See Table 35-2.
C2H	194	IA32_PMC1	Thread	<b>Performance Counter Register</b> See Table 35-2.
C3H	195	IA32_PMC2	Thread	<b>Performance Counter Register</b> See Table 35-2.
C4H	196	IA32_PMC3	Thread	<b>Performance Counter Register</b> See Table 35-2.
C5H	197	IA32_PMC4	Core	<b>Performance Counter Register</b> See Table 35-2.
C6H	198	IA32_PMC5	Core	<b>Performance Counter Register</b> See Table 35-2.
C7H	199	IA32_PMC6	Core	<b>Performance Counter Register</b> See Table 35-2.
C8H	200	IA32_PMC7	Core	<b>Performance Counter Register</b> See Table 35-2.
CEH	206	MSR_PLATFORM_INFO	Package	See <a href="http://biosbits.org">http://biosbits.org</a> .
		7:0		Reserved.
		15:8	Package	<b>Maximum Non-Turbo Ratio (R/O)</b> This is the ratio of the frequency that invariant TSC runs at. Frequency = ratio * 100 MHz.
		27:16		Reserved.
		28	Package	<b>Programmable Ratio Limit for Turbo Mode (R/O)</b> When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled.

**Table 35-12. MSRs Supported by Intel® Processors based on Intel® microarchitecture code name Sandy Bridge (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		29	Package	<b>Programmable TDP Limit for Turbo Mode (R/O)</b> When set to 1, indicates that TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDP Limit for Turbo mode is not programmable.
		39:30		Reserved.
		47:40	Package	<b>Maximum Efficiency Ratio (R/O)</b> The is the minimum ratio (maximum efficiency) that the processor can operates, in units of 100MHz.
		63:48		Reserved.
E2H	226	MSR_PKG_CST_CONFIG_CONTROL	Core	<b>C-State Configuration Control (R/W)</b> Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States. See <a href="http://biosbits.org">http://biosbits.org</a> .
		2:0		<b>Package C-State Limit (R/W)</b> Specifies the lowest processor-specific C-state code name (consuming the least power), for the package. The default is set as factory-configured package C-state limit. The following C-state code name encodings are supported: 000b: C0/C1 (no package C-sate support) 001b: C2 010b: C6 no retention 011b: C6 retention 100b: C7 101b: C7s 111: No package C-state limit. Note: This field cannot be used to limit package C-state to C3.
		9:3		Reserved.
		10		<b>I/O MWAIT Redirection Enable (R/W)</b> When set, will map IO_read instructions sent to IO register specified by MSR_PMG_IO_CAPTURE_BASE to MWAIT instructions
		14:11		Reserved.
		15		<b>CFG Lock (R/WO)</b> When set, lock bits 15:0 of this register until next reset.
		24:16		Reserved.
		25		<b>C3 state auto demotion enable (R/W)</b> When set, the processor will conditionally demote C6/C7 requests to C3 based on uncore auto-demote information.
		26		<b>C1 state auto demotion enable (R/W)</b> When set, the processor will conditionally demote C3/C6/C7 requests to C1 based on uncore auto-demote information.

**Table 35-12. MSRs Supported by Intel® Processors  
based on Intel® microarchitecture code name Sandy Bridge (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		27		<b>Enable C3 undemotion (R/W)</b> When set, enables undemotion from demoted C3.
		28		<b>Enable C1 undemotion (R/W)</b> When set, enables undemotion from demoted C1.
		63:29		Reserved.
E4H	228	MSR_PMG_IO_CAPTURE_BASE	Core	<b>Power Management IO Redirection in C-state (R/W)</b> See <a href="http://biosbits.org">http://biosbits.org</a> .
		15:0		<b>LVL_2 Base Address (R/W)</b> Specifies the base address visible to software for IO redirection. If IO MWAIT Redirection is enabled, reads to this address will be consumed by the power management logic and decoded to MWAIT instructions. When IO port address redirection is enabled, this is the IO port address reported to the OS/software.
		18:16		<b>C-state Range (R/W)</b> Specifies the encoding value of the maximum C-State code name to be included when IO read to MWAIT redirection is enabled by MSR_PMG_CST_CONFIG_CONTROL[bit10]: 000b - C3 is the max C-State to include 001b - C6 is the max C-State to include 010b - C7 is the max C-State to include
		63:19		Reserved.
E7H	231	IA32_MPERF	Thread	<b>Maximum Performance Frequency Clock Count (RW)</b> See Table 35-2.
E8H	232	IA32_APERF	Thread	<b>Actual Performance Frequency Clock Count (RW)</b> See Table 35-2.
FEH	254	IA32_MTRRCAP	Thread	See Table 35-2.
174H	372	IA32_SYSENTER_CS	Thread	See Table 35-2.
175H	373	IA32_SYSENTER_ESP	Thread	See Table 35-2.
176H	374	IA32_SYSENTER_EIP	Thread	See Table 35-2.
179H	377	IA32_MCG_CAP	Thread	See Table 35-2.
17AH	378	IA32_MCG_STATUS	Thread	
		0		<b>RIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If cleared, the program cannot be reliably restarted.
		1		<b>EIPV</b> When set, bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.

**Table 35-12. MSRs Supported by Intel® Processors  
based on Intel® microarchitecture code name Sandy Bridge (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		2		<b>MCIP</b> When set, bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.
		63:3		Reserved.
186H	390	IA32_PERFEVTSEL0	Thread	See Table 35-2.
187H	391	IA32_PERFEVTSEL1	Thread	See Table 35-2.
188H	392	IA32_PERFEVTSEL2	Thread	See Table 35-2.
189H	393	IA32_PERFEVTSEL3	Thread	See Table 35-2.
18AH	394	IA32_PERFEVTSEL4	Core	See Table 35-2; If CPUID.0AH:EAX[15:8] = 8
18BH	395	IA32_PERFEVTSEL5	Core	See Table 35-2; If CPUID.0AH:EAX[15:8] = 8
18CH	396	IA32_PERFEVTSEL6	Core	See Table 35-2; If CPUID.0AH:EAX[15:8] = 8
18DH	397	IA32_PERFEVTSEL7	Core	See Table 35-2; If CPUID.0AH:EAX[15:8] = 8
198H	408	IA32_PERF_STATUS	Package	See Table 35-2.
		15:0		Current Performance State Value.
		63:16		Reserved.
198H	408	MSR_PERF_STATUS	Package	
		47:32		Core Voltage (R/O) P-state core voltage can be computed by MSR_PERF_STATUS[37:32] * (float) 1/(2 <sup>13</sup> ).
199H	409	IA32_PERF_CTL	Thread	See Table 35-2.
19AH	410	IA32_CLOCK_MODULATION	Thread	<b>Clock Modulation (R/W)</b> See Table 35-2 IA32_CLOCK_MODULATION MSR was originally named IA32_THERM_CONTROL MSR.
		3:0		<b>On demand Clock Modulation Duty Cycle (R/W)</b> In 6.25% increment
		4		<b>On demand Clock Modulation Enable (R/W)</b>
		63:5		Reserved.
19BH	411	IA32_THERM_INTERRUPT	Core	<b>Thermal Interrupt Control (R/W)</b> See Table 35-2.

**Table 35-12. MSRs Supported by Intel® Processors  
based on Intel® microarchitecture code name Sandy Bridge (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
19CH	412	IA32_THERM_STATUS	Core	<b>Thermal Monitor Status (R/W)</b> See Table 35-2.
1A0	416	IA32_MISC_ENABLE		<b>Enable Misc. Processor Features (R/W)</b> Allows a variety of processor functions to be enabled and disabled.
		0	Thread	<b>Fast-Strings Enable</b> See Table 35-2
		6:1		Reserved.
		7	Thread	<b>Performance Monitoring Available (R)</b> See Table 35-2.
		10:8		Reserved.
		11	Thread	<b>Branch Trace Storage Unavailable (RO)</b> See Table 35-2.
		12	Thread	<b>Precise Event Based Sampling Unavailable (RO)</b> See Table 35-2.
		15:13		Reserved.
		16	Package	<b>Enhanced Intel SpeedStep Technology Enable (R/W)</b> See Table 35-2.
		18	Thread	ENABLE MONITOR FSM. (R/W) See Table 35-2.
		21:19		Reserved.
		22	Thread	<b>Limit CPUID Maxval (R/W)</b> See Table 35-2.
		23	Thread	<b>xTPR Message Disable (R/W)</b> See Table 35-2.
		33:24		Reserved.
		34	Thread	<b>XD Bit Disable (R/W)</b> See Table 35-2.
		37:35		Reserved.
38	Package	<b>Turbo Mode Disable (R/W)</b> When set to 1 on processors that support Intel Turbo Boost Technology, the turbo mode feature is disabled and the IDA_Enable feature flag will be clear (CPUID.06H: EAX[1]=0). When set to a 0 on processors that support IDA, CPUID.06H: EAX[1] reports the processor's support of turbo mode is enabled. <b>Note:</b> the power-on default value is used by BIOS to detect hardware support of turbo mode. If power-on default value is 1, turbo mode is available in the processor. If power-on default value is 0, turbo mode is not available.		
63:39		Reserved.		
1A2H	418	MSR_TEMPERATURE_TARGET	Unique

600H	1536	IA32_DS_AREA	Thread	<b>DS Save Area (R/W)</b> See Table 35-2. See Section 18.12.4, "Debug Store (DS) Mechanism."
606H	1542	MSR_RAPL_POWER_UNIT	Package	<b>Unit Multipliers used in RAPL Interfaces (R/O)</b> See Section 14.7.1, "RAPL Interfaces."
60AH	1546	MSR_PKGC3_IRTL	Package	<b>Package C3 Interrupt Response Limit (R/W)</b> Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.
		9:0		<b>Interrupt response time limit (R/W)</b> Specifies the limit that should be used to decide if the package should be put into a package C3 state.
		12:10		<b>Time Unit (R/W)</b> Specifies the encoding value of time unit of the interrupt response time limit. The following time unit encodings are supported: 000b: 1 ns 001b: 32 ns 010b: 1024 ns 011b: 32768 ns 100b: 1048576 ns 101b: 33554432 ns
		14:13		Reserved.
		15		<b>Valid (R/W)</b> Indicates whether the values in bits 12:0 are valid and can be used by the processor for package C-state management.
		63:16		Reserved.
60BH	1547	MSR_PKGC6_IRTL	Package	<b>Package C6 Interrupt Response Limit (R/W)</b> This MSR defines the budget allocated for the package to exit from C6 to a C0 state, where interrupt request can be delivered to the core and serviced. Additional core-exit latency may be applicable depending on the actual C-state the core is in. Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.
		9:0		<b>Interrupt response time limit (R/W)</b> Specifies the limit that should be used to decide if the package should be put into a package C6 state.

727H	1831	MSR_UNC_CBO_2_PER_CTR1	Package	Uncore C-Box 2, performance counter 1
730H	1840	MSR_UNC_CBO_3_PERFEVTSELO	Package	Uncore C-Box 3, counter 0 event select MSR
731H	1841	MSR_UNC_CBO_3_PERFEVTSEL1	Package	Uncore C-Box 3, counter 1 event select MSR.
736H	1846	MSR_UNC_CBO_3_PER_CTR0	Package	Uncore C-Box 3, performance counter 0.
737H	1847	MSR_UNC_CBO_3_PER_CTR1	Package	Uncore C-Box 3, performance counter 1.

### 35.8.2 MSRs In Intel® Xeon® Processor E5 Family (Based on Intel® Microarchitecture Code Name Sandy Bridge)

Table 35-14 lists selected model-specific registers (MSRs) that are specific to the Intel® Xeon® Processor E5 Family (based on Intel® microarchitecture code name Sandy Bridge). These processors have a CPUID signature with DisplayFamily\_DisplayModel of 06\_2DH, see Table 35-1.

**Table 35-14. Selected MSRs Supported by Intel® Xeon® Processors E5 Family (based on Intel® microarchitecture code name Sandy Bridge)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
17FH	383	MSR_ERROR_CONTROL	Package	<b>MC Bank Error Configuration (R/W)</b>
		0		Reserved
		1		<b>MemError Log Enable (R/W)</b> When set, enables IMC status bank to log additional info in bits 36:32.
		63:2		Reserved.
1ADH	429	MSR_TURBO_RATIO_LIMIT	Package	<b>Maximum Ratio Limit of Turbo Mode</b> RO if MSR_PLATFORM_INFO.[28] = 0, RW if MSR_PLATFORM_INFO.[28] = 1

**Table 35-14. Selected MSRs Supported by Intel® Xeon® Processors E5 Family (based on Intel® microarchitecture code name Sandy Bridge) (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		7:0	Package	<b>Maximum Ratio Limit for 1C</b> Maximum turbo ratio limit of 1 core active.
		15:8	Package	<b>Maximum Ratio Limit for 2C</b> Maximum turbo ratio limit of 2 core active.
		23:16	Package	<b>Maximum Ratio Limit for 3C</b> Maximum turbo ratio limit of 3 core active.
		31:24	Package	<b>Maximum Ratio Limit for 4C</b> Maximum turbo ratio limit of 4 core active.
		39:32	Package	<b>Maximum Ratio Limit for 5C</b> Maximum turbo ratio limit of 5 core active.
		47:40	Package	<b>Maximum Ratio Limit for 6C</b> Maximum turbo ratio limit of 6 core active.
		55:48	Package	<b>Maximum Ratio Limit for 7C</b> Maximum turbo ratio limit of 7 core active.
		63:56	Package	<b>Maximum Ratio Limit for 8C</b> Maximum turbo ratio limit of 8 core active.
285H	645	IA32_MC5_CTL2	Package	See Table 35-2.
286H	646	IA32_MC6_CTL2	Package	See Table 35-2.
287H	647	IA32_MC7_CTL2	Package	See Table 35-2.
288H	648	IA32_MC8_CTL2	Package	See Table 35-2.
289H	649	IA32_MC9_CTL2	Package	See Table 35-2.
28AH	650	IA32_MC10_CTL2	Package	See Table 35-2.
28BH	651	IA32_MC11_CTL2	Package	See Table 35-2.
28CH	652	IA32_MC12_CTL2	Package	See Table 35-2.
28DH	653	IA32_MC13_CTL2	Package	See Table 35-2.
28EH	654	IA32_MC14_CTL2	Package	See Table 35-2.
28FH	655	IA32_MC15_CTL2	Package	See Table 35-2.
290H	656	IA32_MC16_CTL2	Package	See Table 35-2.
291H	657	IA32_MC17_CTL2	Package	See Table 35-2.
292H	658	IA32_MC18_CTL2	Package	See Table 35-2.
293H	659	IA32_MC19_CTL2	Package	See Table 35-2.
39CH	924	MSR_PEBS_NUM_ALT	Package	
		0		<b>ENABLE_PEBS_NUM_ALT (RW)</b> Write 1 to enable alternate PEBS counting logic for specific events requiring additional configuration, see Table 19-9
		63:1		Reserved (must be zero).
414H	1044	MSR_MC5_CTL	Package	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."

**Table 35-14. Selected MSRs Supported by Intel® Xeon® Processors E5 Family (based on Intel® microarchitecture code name Sandy Bridge) (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
415H	1045	MSR_MC5_STATUS	Package	See Section 15.3.2.2, "IA32_MCI_STATUS MSRS," and Chapter 16.

## 35.9 MSRS IN THE 3RD GENERATION INTEL® CORE™ PROCESSOR FAMILY (BASED ON INTEL® MICROARCHITECTURE CODE NAME IVY BRIDGE)

The 3rd generation Intel® Core™ processor family and Intel Xeon processor E3-1200v2 product family (based on Intel microarchitecture code name Ivy Bridge) supports the MSR interfaces listed in Table 35-12, Table 35-13 and Table 35-15.

**Table 35-15. Additional MSRs Supported by 3rd Generation Intel® Core™ Processors (based on Intel® microarchitecture code name Ivy Bridge)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
CEH	206	MSR_PLATFORM_INFO	Package	See <a href="http://biosbits.org">http://biosbits.org</a> .
		7:0		Reserved.
		15:8	Package	<b>Maximum Non-Turbo Ratio (R/O)</b> The is the ratio of the frequency that invariant TSC runs at. Frequency = ratio * 100 MHz.
		27:16		Reserved.
		28	Package	<b>Programmable Ratio Limit for Turbo Mode (R/O)</b> When set to 1, indicates that Programmable Ratio Limits for Turbo mode is enabled, and when set to 0, indicates Programmable Ratio Limits for Turbo mode is disabled.
		29	Package	<b>Programmable TDP Limit for Turbo Mode (R/O)</b> When set to 1, indicates that TDP Limits for Turbo mode are programmable, and when set to 0, indicates TDP Limit for Turbo mode is not programmable.
		31:30		Reserved.
		32	Package	<b>Low Power Mode Support (LPM) (R/O)</b> When set to 1, indicates that LPM is supported, and when set to 0, indicates LPM is not supported.
		34:33	Package	<b>Number of ConfigTDP Levels (R/O)</b> 00: Only nominal TDP level available. 01: One additional TDP level available. 02: Two additional TDP level available. 11: Reserved
		39:35		Reserved.
		47:40	Package	<b>Maximum Efficiency Ratio (R/O)</b> The is the minimum ratio (maximum efficiency) that the processor can operate, in units of 100MHz.
		55:48	Package	<b>Minimum Operating Ratio (R/O)</b> Contains the minimum supported operating ratio in units of 100 MHz.
63:56		Reserved.		
E2H	226	MSR_PKG_CST_CONFIG_CONTROL	Core	<b>C-State Configuration Control (R/W)</b> Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States. See <a href="http://biosbits.org">http://biosbits.org</a> .

**Table 35-15. Additional MSRs Supported by 3rd Generation Intel® Core™ Processors (based on Intel® microarchitecture code name Ivy Bridge) (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		2:0		<b>Package C-State Limit (R/W)</b> Specifies the lowest processor-specific C-state code name (consuming the least power), for the package. The default is set as factory-configured package C-state limit. The following C-state code name encodings are supported: 000b: C0/C1 (no package C-state support) 001b: C2 010b: C6 no retention 011b: C6 retention 100b: C7 101b: C7s 111: No package C-state limit. Note: This field cannot be used to limit package C-state to C3.
		9:3		Reserved.
		10		<b>I/O MWAIT Redirection Enable (R/W)</b> When set, will map IO_read instructions sent to IO register specified by MSR_PMG_IO_CAPTURE_BASE to MWAIT instructions
		14:11		Reserved.
		15		<b>CFG Lock (R/WO)</b> When set, lock bits 15:0 of this register until next reset.
		24:16		Reserved.
		25		<b>C3 state auto demotion enable (R/W)</b> When set, the processor will conditionally demote C6/C7 requests to C3 based on uncore auto-demote information.
		26		<b>C1 state auto demotion enable (R/W)</b> When set, the processor will conditionally demote C3/C6/C7 requests to C1 based on uncore auto-demote information.
		27		<b>Enable C3 undemotion (R/W)</b> When set, enables undemotion from demoted C3.
		28		<b>Enable C1 undemotion (R/W)</b> When set, enables undemotion from demoted C1.
		63:29		Reserved.
648H	1608	MSR_CONFIG_TDP_NOMINAL	Package	<b>Nominal TDP Ratio (R/O)</b>
		7:0		<b>Config_TDP_Nominal</b> Nominal TDP level ratio to be used for this specific processor (in units of 100 MHz).
		63:8		Reserved.
649H	1609	MSR_CONFIG_TDP_LEVEL1	Package	ConfigTDP Level 1 ratio and power level (R/O)
		14:0		PKG_TDP_LVL1. Power setting for ConfigTDP Level 1.

**Table 35-15. Additional MSRs Supported by 3rd Generation Intel® Core™ Processors (based on Intel® microarchitecture code name Ivy Bridge) (Contd.)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
		15		Reserved
		23:16		Config_TDP_LVL1_Ratio. ConfigTDP level 1 ratio to be used for this specific processor.
		31:24		Reserved
		46:32		PKG_MAX_PWR_LVL1. Max Power setting allowed for ConfigTDP Level 1.
		47		Reserved
		62:48		PKG_MIN_PWR_LVL1. MIN Power setting allowed for ConfigTDP Level 1.
		63		Reserved.
64AH	1610	MSR_CONFIG_TDP_LEVEL2	Package	ConfigTDP Level 2 ratio and power level (R/O)
		14:0		PKG_TDP_LVL2. Power setting for ConfigTDP Level 2.
		15		Reserved
		23:16		Config_TDP_LVL2_Ratio. ConfigTDP level 2 ratio to be used for this specific processor.
		31:24		Reserved
		46:32		PKG_MAX_PWR_LVL2. Max Power setting allowed for ConfigTDP Level 2.
		47		Reserved
		62:48		PKG_MIN_PWR_LVL2. MIN Power setting allowed for ConfigTDP Level 2.
		63		Reserved.
64BH	1611	MSR_CONFIG_TDP_CONTROL	Package	<b>ConfigTDP Control (R/W)</b>
		1:0		<b>TDP_LEVEL (RW/L)</b> System BIOS can program this field.
		30:2		Reserved.
		31		<b>Config_TDP_Lock (RW/L)</b> When this bit is set, the content of this register is locked until a reset.
		63:32		Reserved.
64CH	1612	MSR_TURBO_ACTIVATION_RATIO	Package	<b>ConfigTDP Control (R/W)</b>
		7:0		<b>MAX_NON_TURBO_RATIO (RW/L)</b> System BIOS can program this field.
		30:8		Reserved.
		31		<b>TURBO_ACTIVATION_RATIO_Lock (RW/L)</b> When this bit is set, the content of this register is locked until a reset.

### 35.9.1 MSRs In Intel® Xeon® Processor E5 v2 Product Family (Based on Intel® Microarchitecture Code Name Ivy Bridge-EP)

Table 35-16 lists model-specific registers (MSRs) that are specific to the Intel® Xeon® Processor E5 v2 Product Family (based on Intel microarchitecture code name Ivy Bridge-EP). These processors have a CPUID signature with DisplayFamily\_DisplayModel of 06\_3EH, see Table 35-1. These processors supports the MSR interfaces listed in Table 35-12, and Table 35-16.

**Table 35-16. MSRs Supported by Intel® Xeon® Processors E5 v2 Product Family (based on Intel® microarchitecture code name Ivy Bridge-EP)**

Register Address		Register Name	Scope	Bit Description

631H	1585	MSR_PKG_C9_RESIDENCY	Package	Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.
		59:0		Package C9 Residency Counter. (R/O) Value since last reset that this package is in processor-specific C9 states. Count at the same frequency as the TSC.
		63:60		Reserved
632H	1586	MSR_PKG_C10_RESIDENCY	Package	Note: C-state values are processor specific C-state code names, unrelated to MWAIT extension C-state parameters or ACPI C-States.
		59:0		Package C10 Residency Counter. (R/O) Value since last reset that this package is in processor-specific C10 states. Count at the same frequency as the TSC.
		63:60		Reserved

### 35.10.2 MSRs in 4th Generation Intel® Core™ Processor Family (based on Intel® Microarchitecture Code Name Haswell)

Table 35-20 lists model-specific registers (MSRs) that are specific to 4th generation Intel® Core™ processor family and Intel Xeon processor E3-1200 v3 product family (based on Intel microarchitecture code name Haswell). These processors have a CPUID signature with DisplayFamily\_DisplayModel of 06\_3CH/06\_45H/06\_46H, see Table 35-1.

**Table 35-20. MSRs Supported by 4th Generation Intel® Core™ Processors (Intel® microarchitecture code name Haswell)**

Register Address		Register Name	Scope	Bit Description
Hex	Dec			
17DH	390	MSR_SMM_MCA_CAP	THREAD	<b>Enhanced SMM Capabilities (SMM-RO)</b> Reports SMM capability Enhancement. Accessible only while in SMM.
		57:0		<b>Reserved</b>
		58		<b>SMM_Code_Access_Chk (SMM-RO)</b> If set to 1 indicates that the SMM code access restriction is supported and the MSR_SMM_FEATURE_CONTROL is supported.
		59		<b>Long_Flow_Indication (SMM-RO)</b> If set to 1 indicates that the SMM long flow indicator is supported and the MSR_SMM_DELAYED is supported.
		63:60		Reserved

		61:0		<b>Resource Monitored Data</b>
		62		<b>Unavailable:</b> If 1, indicates data for this RMID is not available or not monitored for this resource or RMID.
		63		<b>Error:</b> If 1, indicates and unsupported RMID or event type was written to IA32_PQR_QM_EVTSEL.
C8FH	3115	IA32_PQR_ASSOC	THREAD	<b>QoS Resource Association Register (R/W).</b>
		9:0		<b>RMID</b>
		63: 10		<b>Reserved</b>

### 35.12 MSRS IN THE PENTIUM® 4 AND INTEL® XEON® PROCESSORS

Table 35-22 lists MSRs (architectural and model-specific) that are defined across processor generations based on Intel NetBurst microarchitecture. The processor can be identified by its CPUID signatures of DisplayFamily encoding of 0FH, see Table 35-1.

- MSRs with an "IA32\_" prefix are designated as "architectural." This means that the functions of these MSRs and their addresses remain the same for succeeding families of IA-32 processors.
- MSRs with an "MSR\_" prefix are model specific with respect to address functionalities. The column "Model Availability" lists the model encoding value(s) within the Pentium 4 and Intel Xeon processor family at the specified register address. The model encoding value of a processor can be queried using CPUID. See "CPUID—CPU Identification" in Chapter 3 of the *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2A*.

**Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors**

Register Address		Register Name Fields and Flags	Model Availability	Shared/ Unique <sup>1</sup>	Bit Description
Hex	Dec				
0H	0	IA32_P5_MC_ADDR	0, 1, 2, 3, 4, 6	Shared	See Section 35.16, "MSRs in Pentium Processors."
1H	1	IA32_P5_MC_TYPE	0, 1, 2, 3, 4, 6	Shared	See Section 35.16, "MSRs in Pentium Processors."
6H	6	IA32_MONITOR_FILTER_LINE_SIZE	3, 4, 6	Shared	See Section 8.10.5, "Monitor/Mwait Address Range Determination."
10H	16	IA32_TIME_STAMP_COUNTER	0, 1, 2, 3, 4, 6	Unique	<b>Time Stamp Counter</b> See Table 35-2.
					On earlier processors, only the lower 32 bits are writable. On any write to the lower 32 bits, the upper 32 bits are cleared. For processor family 0FH, models 3 and 4: all 64 bits are writable.

Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>1</sup>	Bit Description
Hex	Dec				
17H	23	IA32_PLATFORM_ID	0, 1, 2, 3, 4, 6	Shared	<b>Platform ID (R)</b> See Table 35-2. The operating system can use this MSR to determine “slot” information for the processor and the proper microcode update to load.
1BH	27	IA32_APIC_BASE	0, 1, 2, 3, 4, 6	Unique	<b>APIC Location and Status (R/W)</b> See Table 35-2. See Section 10.4.4, “Local APIC Status and Location.”
2AH	42	MSR_EBC_HARD_POWERON	0, 1, 2, 3, 4, 6	Shared	<b>Processor Hard Power-On Configuration (R/W)</b> Enables and disables processor features; <b>(R)</b> indicates current processor configuration.
		0			<b>Output Tri-state Enabled (R)</b> Indicates whether tri-state output is enabled (1) or disabled (0) as set by the strapping of SMI#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		1			<b>Execute BIST (R)</b> Indicates whether the execution of the BIST is enabled (1) or disabled (0) as set by the strapping of INIT#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		2			<b>In Order Queue Depth (R)</b> Indicates whether the in order queue depth for the system bus is 1 (1) or up to 12 (0) as set by the strapping of A7#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		3			<b>MCERR# Observation Disabled (R)</b> Indicates whether MCERR# observation is enabled (0) or disabled (1) as determined by the strapping of A9#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		4			<b>BINIT# Observation Enabled (R)</b> Indicates whether BINIT# observation is enabled (0) or disabled (1) as determined by the strapping of A10#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		6:5			<b>APIC Cluster ID (R)</b> Contains the logical APIC cluster ID value as set by the strapping of A12# and A11#. The logical cluster ID value is written into the field on the deassertion of RESET#; the field is set to 1 when the address bus signal is asserted.

**Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)**

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>7</sup>	Bit Description
Hex	Dec				
		7			<b>Bus Park Disable (R)</b> Indicates whether bus park is enabled (0) or disabled (1) as set by the strapping of A15#. The value in this bit is written on the deassertion of RESET#; the bit is set to 1 when the address bus signal is asserted.
		11:8			Reserved.
		13:12			<b>Agent ID (R)</b> Contains the logical agent ID value as set by the strapping of BR[3:0]. The logical ID value is written into the field on the deassertion of RESET#; the field is set to 1 when the address bus signal is asserted.
		63:14			Reserved.
2BH	43	MSR_EBC_SOFT_POWERON	0, 1, 2, 3, 4, 6	Shared	<b>Processor Soft Power-On Configuration (R/W)</b> Enables and disables processor features.
		0			<b>RCNT/SCNT On Request Encoding Enable (R/W)</b> Controls the driving of RCNT/SCNT on the request encoding. Set to enable (1); clear to disabled (0, default).
		1			<b>Data Error Checking Disable (R/W)</b> Set to disable system data bus parity checking; clear to enable parity checking.
		2			<b>Response Error Checking Disable (R/W)</b> Set to disable (default); clear to enable.
		3			<b>Address/Request Error Checking Disable (R/W)</b> Set to disable (default); clear to enable.
		4			<b>Initiator MCERR# Disable (R/W)</b> Set to disable MCERR# driving for initiator bus requests (default); clear to enable.
		5			<b>Internal MCERR# Disable (R/W)</b> Set to disable MCERR# driving for initiator internal errors (default); clear to enable.
		6			<b>BINIT# Driver Disable (R/W)</b> Set to disable BINIT# driver (default); clear to enable driver.
		63:7			Reserved.

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>7</sup>	Bit Description
Hex	Dec				
		63-0			Registers R8-15 (and the associated state-save MSRs) exist only in Intel 64 processors. These registers contain valid information only when the processor is operating in 64-bit mode at the time of the error.
198H	408	IA32_PERF_STATUS	3, 4, 6	Unique	See Table 35-2. See Section 14.1, "Enhanced Intel Speedstep® Technology."
199H	409	IA32_PERF_CTL	3, 4, 6	Unique	See Table 35-2. See Section 14.1, "Enhanced Intel Speedstep® Technology."
19AH	410	IA32_CLOCK_MODULATION	0, 1, 2, 3, 4, 6	Unique	<b>Thermal Monitor Control (R/W)</b> See Table 35-2. See Section 14.5.3, "Software Controlled Clock Modulation."
19BH	411	IA32_THERM_INTERRUPT	0, 1, 2, 3, 4, 6	Unique	<b>Thermal Interrupt Control (R/W)</b> See Section 14.5.2, "Thermal Monitor," and see Table 35-2.
19CH	412	IA32_THERM_STATUS	0, 1, 2, 3, 4, 6	Shared	<b>Thermal Monitor Status (R/W)</b> See Section 14.5.2, "Thermal Monitor," and see Table 35-2.
19DH	413	MSR_THERM2_CTL			Thermal Monitor 2 Control.
			3,	Shared	For Family F, Model 3 processors: When read, specifies the value of the target TM2 transition last written. When set, it sets the next target value for TM2 transition.
			4, 6	Shared	For Family F, Model 4 and Model 6 processors: When read, specifies the value of the target TM2 transition last written. Writes may cause #GP exceptions.
1A0H	416	IA32_MISC_ENABLE	0, 1, 2, 3, 4, 6	Shared	<b>Enable Miscellaneous Processor Features (R/W)</b>
		0			Fast-Strings Enable. See Table 35-2.
		1			Reserved.
		2			<b>x87 FPU Fopcode Compatibility Mode Enable</b>
		3			<b>Thermal Monitor 1 Enable</b> See Section 14.5.2, "Thermal Monitor," and see Table 35-2.
		4			<b>Split-Lock Disable</b> When set, the bit causes an #AC exception to be issued instead of a split-lock cycle. Operating systems that set this bit must align system structures to avoid split-lock scenarios. When the bit is clear (default), normal split-locks are issued to the bus.

Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Availability	Shared/Unique <sup>1</sup>	Bit Description
Hex	Dec				
					This debug feature is specific to the Pentium 4 processor.
		5			Reserved.
		6			<p><b>Third-Level Cache Disable (R/W)</b></p> <p>When set, the third-level cache is disabled; when clear (default) the third-level cache is enabled. This flag is reserved for processors that do not have a third-level cache.</p> <p>Note that the bit controls only the third-level cache; and only if overall caching is enabled through the CD flag of control register CR0, the page-level cache controls, and/or the MTRRs. See Section 11.5.4, "Disabling and Enabling the L3 Cache."</p>
		7			<p><b>Performance Monitoring Available (R)</b></p> <p>See Table 35-2.</p>
		8			<p><b>Suppress Lock Enable</b></p> <p>When set, assertion of LOCK on the bus is suppressed during a Split Lock access. When clear (default), LOCK is not suppressed.</p>
		9			<p><b>Prefetch Queue Disable</b></p> <p>When set, disables the prefetch queue. When clear (default), enables the prefetch queue.</p>
		10			<p><b>FERR# Interrupt Reporting Enable (R/W)</b></p> <p>When set, interrupt reporting through the FERR# pin is enabled; when clear, this interrupt reporting function is disabled.</p> <p>When this flag is set and the processor is in the stop-clock state (STPCLK# is asserted), asserting the FERR# pin signals to the processor that an interrupt (such as, INIT#, BINIT#, INTR, NMI, SMI#, or RESET#) is pending and that the processor should return to normal operation to handle the interrupt.</p> <p>This flag does not affect the normal operation of the FERR# pin (to indicate an unmasked floating-point error) when the STPCLK# pin is not asserted.</p>
		11			<p><b>Branch Trace Storage Unavailable (BTS_UNAVAILABLE) (R)</b></p> <p>See Table 35-2.</p> <p>When set, the processor does not support branch trace storage (BTS); when clear, BTS is supported.</p>

**Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)**

Register Address		Register Name Fields and Flags	Model Availability	Shared/Unique <sup>7</sup>	Bit Description
Hex	Dec				
		12			<p><b>PEBS_UNAVAILABLE: Precise Event Based Sampling Unavailable (R)</b></p> <p>See Table 35-2.</p> <p>When set, the processor does not support precise event-based sampling (PEBS); when clear, PEBS is supported.</p>
		13	3		<p><b>TM2 Enable (R/W)</b></p> <p>When this bit is set (1) and the thermal sensor indicates that the die temperature is at the pre-determined threshold, the Thermal Monitor 2 mechanism is engaged. TM2 will reduce the bus to core ratio and voltage according to the value last written to MSR_THERM2_CTL bits 15:0.</p> <p>When this bit is clear (0, default), the processor does not change the VID signals or the bus to core ratio when the processor enters a thermal managed state.</p> <p>If the TM2 feature flag (ECX[8]) is not set to 1 after executing CPUID with EAX = 1, then this feature is not supported and BIOS must not alter the contents of this bit location. The processor is operating out of spec if both this bit and the TM1 bit are set to disabled states.</p>
		17:14			Reserved.
		18	3, 4, 6		<p><b>ENABLE MONITOR FSM (R/W)</b></p> <p>See Table 35-2.</p>
		19			<p><b>Adjacent Cache Line Prefetch Disable (R/W)</b></p> <p>When set to 1, the processor fetches the cache line of the 128-byte sector containing currently required data. When set to 0, the processor fetches both cache lines in the sector.</p>
					<p>Single processor platforms should not set this bit. Server platforms should set or clear this bit based on platform performance observed in validation and testing.</p> <p>BIOS may contain a setup option that controls the setting of this bit.</p>
		21:20			Reserved.
		22	3, 4, 6		<p><b>Limit CPUID MAXVAL (R/W)</b></p> <p>See Table 35-2.</p> <p>Setting this can cause unexpected behavior to software that depends on the availability of CPUID leaves greater than 3.</p>
		23		Shared	<p><b>xTPR Message Disable (R/W)</b></p> <p>See Table 35-2.</p>

Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>1</sup>	Bit Description
Hex	Dec				
		24			<p><b>L1 Data Cache Context Mode (R/W)</b></p> <p>When set, the L1 data cache is placed in shared mode; when clear (default), the cache is placed in adaptive mode. This bit is only enabled for IA-32 processors that support Intel Hyper-Threading Technology. See Section 11.5.6, "L1 Data Cache Context Mode."</p> <p>When L1 is running in adaptive mode and CR3s are identical, data in L1 is shared across logical processors. Otherwise, L1 is not shared and cache use is competitive.</p> <p>If the Context ID feature flag (ECX[10]) is set to 0 after executing CPUID with EAX = 1, the ability to switch modes is not supported. BIOS must not alter the contents of IA32_MISC_ENABLE[24].</p>
		33:25			Reserved.
		34		Unique	<p><b>XD Bit Disable (R/W)</b></p> <p>See Table 35-2.</p>
		63:35			Reserved.
1A1H	417	MSR_PLATFORM_BRV	3, 4, 6	Shared	<p><b>Platform Feature Requirements (R)</b></p>
		17:0			Reserved.
		18			<p><b>PLATFORM Requirements</b></p> <p>When set to 1, indicates the processor has specific platform requirements. The details of the platform requirements are listed in the respective data sheets of the processor.</p>
		63:19			Reserved.
1D7H	471	MSR_LER_FROM_LIP	0, 1, 2, 3, 4, 6	Unique	<p><b>Last Exception Record From Linear IP (R)</b></p> <p>Contains a pointer to the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.</p> <p>See Section 17.9.3, "Last Exception Records."</p>
		31:0			<p><b>From Linear IP</b></p> <p>Linear address of the last branch instruction.</p>
		63:32			Reserved.
1D7H	471	63:0		Unique	<p><b>From Linear IP</b></p> <p>Linear address of the last branch instruction (If IA-32e mode is active).</p>
1D8H	472	MSR_LER_TO_LIP	0, 1, 2, 3, 4, 6	Unique	<p><b>Last Exception Record To Linear IP (R)</b></p> <p>This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled.</p> <p>See Section 17.9.3, "Last Exception Records."</p>

**Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)**

Register Address		Register Name Fields and Flags	Model Availability	Shared/Unique <sup>7</sup>	Bit Description
Hex	Dec				
		31:0			<b>From Linear IP</b> Linear address of the target of the last branch instruction.
		63:32			Reserved.
1D8H	472	63:0		Unique	<b>From Linear IP</b> Linear address of the target of the last branch instruction (If IA-32e mode is active).
1D9H	473	MSR_DEBUGCTLA	0, 1, 2, 3, 4, 6	Unique	<b>Debug Control (R/W)</b> Controls how several debug features are used. Bit definitions are discussed in the referenced section. See Section 17.9.1, "MSR_DEBUGCTLA MSR."
1DAH	474	MSR_LASTBRANCH_TOS	0, 1, 2, 3, 4, 6	Unique	<b>Last Branch Record Stack TOS (R/W)</b> Contains an index (0-3 or 0-15) that points to the top of the last branch record stack (that is, that points the index of the MSR containing the most recent branch record). See Section 17.9.2, "LBR Stack for Processors Based on Intel NetBurst® Microarchitecture"; and addresses 1DBH-1DEH and 680H-68FH.
1DBH	475	MSR_LASTBRANCH_0	0, 1, 2	Unique	<b>Last Branch Record 0 (R/W)</b> One of four last branch record registers on the last branch record stack. It contains pointers to the source and destination instruction for one of the last four branches, exceptions, or interrupts that the processor took. MSR_LASTBRANCH_0 through MSR_LASTBRANCH_3 at 1DBH-1DEH are available only on family 0FH, models 0H-02H. They have been replaced by the MSRs at 680H-68FH and 6C0H-6CFH. See Section 17.9, "Last Branch, Interrupt, and Exception Recording (Processors based on Intel NetBurst® Microarchitecture)."
1DDH	477	MSR_LASTBRANCH_2	0, 1, 2	Unique	<b>Last Branch Record 2</b> See description of the MSR_LASTBRANCH_0 MSR at 1DBH.
1DEH	478	MSR_LASTBRANCH_3	0, 1, 2	Unique	<b>Last Branch Record 3</b> See description of the MSR_LASTBRANCH_0 MSR at 1DBH.
200H	512	IA32_MTRR_PHYSBASE0	0, 1, 2, 3, 4, 6	Shared	<b>Variable Range Base MTRR</b> See Section 11.11.2.3, "Variable Range MTRRs."

3AFH	943	MSR_SAAT_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B0H	944	MSR_U2L_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B1H	945	MSR_U2L_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B2H	946	MSR_BPU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B3H	947	MSR_BPU_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."

Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>1</sup>	Bit Description
Hex	Dec				
3B4H	948	MSR_IS_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B5H	949	MSR_IS_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B6H	950	MSR_ITLB_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B7H	951	MSR_ITLB_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B8H	952	MSR_CRU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3B9H	953	MSR_CRU_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3BAH	954	MSR_IQ_ESCR0	0, 1, 2	Shared	See Section 18.12.1, "ESCR MSRs." This MSR is not available on later processors. It is only available on processor family 0FH, models 01H-02H.
3BBH	955	MSR_IQ_ESCR1	0, 1, 2	Shared	See Section 18.12.1, "ESCR MSRs." This MSR is not available on later processors. It is only available on processor family 0FH, models 01H-02H.
3BCH	956	MSR_RAT_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3BDH	957	MSR_RAT_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3BEH	958	MSR_SSU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3C0H	960	MSR_MS_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3C1H	961	MSR_MS_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3C2H	962	MSR_TBPU_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3C3H	963	MSR_TBPU_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3C4H	964	MSR_TC_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3C5H	965	MSR_TC_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3C8H	968	MSR_IX_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3C9H	969	MSR_IX_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3CAH	970	MSR_ALF_ESCR0	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."

**Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)**

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>7</sup>	Bit Description
Hex	Dec				
3CBH	971	MSR_ALF_ESCR1	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3CCH	972	MSR_CRU_ESCR2	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3CDH	973	MSR_CRU_ESCR3	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3E0H	992	MSR_CRU_ESCR4	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3E1H	993	MSR_CRU_ESCR5	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3FOH	1008	MSR_TC_PRECISE_EVENT	0, 1, 2, 3, 4, 6	Shared	See Section 18.12.1, "ESCR MSRs."
3F1H	1009	MSR_PEBS_ENABLE	0, 1, 2, 3, 4, 6	Shared	<b>Precise Event-Based Sampling (PEBS) (R/W)</b> Controls the enabling of precise event sampling and replay tagging.
		12:0			See Table 19-26.
		23:13			Reserved.
		24			<b>UOP Tag</b> Enables replay tagging when set.
		25			<b>ENABLE_PEBS_MY_THR (R/W)</b> Enables PEBS for the target logical processor when set; disables PEBS when clear (default). See Section 18.13.3, "IA32_PEBS_ENABLE MSR," for an explanation of the target logical processor. This bit is called ENABLE_PEBS in IA-32 processors that do not support Intel Hyper-Threading Technology.
		26			<b>ENABLE_PEBS_OTH_THR (R/W)</b> Enables PEBS for the target logical processor when set; disables PEBS when clear (default). See Section 18.13.3, "IA32_PEBS_ENABLE MSR," for an explanation of the target logical processor. This bit is reserved for IA-32 processors that do not support Intel Hyper-Threading Technology.
		63:27			Reserved.
3F2H	1010	MSR_PEBS_MATRIX_VERT	0, 1, 2, 3, 4, 6	Shared	See Table 19-26.
400H	1024	IA32_MCO_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCI_CTL MSRs."
401H	1025	IA32_MCO_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCI_STATUS MSRs."

Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>1</sup>	Bit Description
Hex	Dec				
402H	1026	IA32_MCO_ADDR	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MCO_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MCO_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
403H	1027	IA32_MCO_MISC	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MCO_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MCO_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
404H	1028	IA32_MC1_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
405H	1029	IA32_MC1_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRs."
406H	1030	IA32_MC1_ADDR	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC1_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
407H	1031	IA32_MC1_MISC		Shared	See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC1_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
408H	1032	IA32_MC2_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
409H	1033	IA32_MC2_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRs."
40AH	1034	IA32_MC2_ADDR			See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.

**Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)**

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>7</sup>	Bit Description
Hex	Dec				
40BH	1035	IA32_MC2_MISC			See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC2_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	IA32_MC3_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
40DH	1037	IA32_MC3_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40EH	1038	IA32_MC3_ADDR	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC3_ADDR register is either not implemented or contains no address if the ADDRIV flag in the IA32_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40FH	1039	IA32_MC3_MISC	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC3_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	IA32_MC4_CTL	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
411H	1041	IA32_MC4_STATUS	0, 1, 2, 3, 4, 6	Shared	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
412H	1042	IA32_MC4_ADDR			See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDRIV flag in the IA32_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
413H	1043	IA32_MC4_MISC			See Section 15.3.2.4, "IA32_MCi_MISC MSRs." The IA32_MC2_MISC MSR is either not implemented or does not contain additional information if the MISCV flag in the IA32_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.

Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>1</sup>	Bit Description
Hex	Dec				
480H	1152	IA32_VMX_BASIC	3, 4, 6	Unique	<b>Reporting Register of Basic VMX Capabilities (R/O)</b> See Table 35-2. See Appendix A.1, "Basic VMX Information."
481H	1153	IA32_VMX_PINBASED_CTLDS	3, 4, 6	Unique	<b>Capability Reporting Register of Pin-based VM-execution Controls (R/O)</b> See Table 35-2. See Appendix A.3, "VM-Execution Controls."
482H	1154	IA32_VMX_PROCBASED_CTLDS	3, 4, 6	Unique	<b>Capability Reporting Register of Primary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, "VM-Execution Controls," and see Table 35-2.
483H	1155	IA32_VMX_EXIT_CTLDS	3, 4, 6	Unique	<b>Capability Reporting Register of VM-exit Controls (R/O)</b> See Appendix A.4, "VM-Exit Controls," and see Table 35-2.
484H	1156	IA32_VMX_ENTRY_CTLDS	3, 4, 6	Unique	<b>Capability Reporting Register of VM-entry Controls (R/O)</b> See Appendix A.5, "VM-Entry Controls," and see Table 35-2.
485H	1157	IA32_VMX_MISC	3, 4, 6	Unique	<b>Reporting Register of Miscellaneous VMX Capabilities (R/O)</b> See Appendix A.6, "Miscellaneous Data," and see Table 35-2.
486H	1158	IA32_VMX_CR0_FIXED0	3, 4, 6	Unique	<b>Capability Reporting Register of CR0 Bits Fixed to 0 (R/O)</b> See Appendix A.7, "VMX-Fixed Bits in CR0," and see Table 35-2.
487H	1159	IA32_VMX_CR0_FIXED1	3, 4, 6	Unique	<b>Capability Reporting Register of CR0 Bits Fixed to 1 (R/O)</b> See Appendix A.7, "VMX-Fixed Bits in CR0," and see Table 35-2.
488H	1160	IA32_VMX_CR4_FIXED0	3, 4, 6	Unique	<b>Capability Reporting Register of CR4 Bits Fixed to 0 (R/O)</b> See Appendix A.8, "VMX-Fixed Bits in CR4," and see Table 35-2.
489H	1161	IA32_VMX_CR4_FIXED1	3, 4, 6	Unique	<b>Capability Reporting Register of CR4 Bits Fixed to 1 (R/O)</b> See Appendix A.8, "VMX-Fixed Bits in CR4," and see Table 35-2.
48AH	1162	IA32_VMX_VMCS_ENUM	3, 4, 6	Unique	<b>Capability Reporting Register of VMCS Field Enumeration (R/O)</b> See Appendix A.9, "VMCS Enumeration," and see Table 35-2.

**Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)**

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>7</sup>	Bit Description
Hex	Dec				
48BH	1163	IA32_VMX_PROCBASED_CTLSS2	3, 4, 6	Unique	<b>Capability Reporting Register of Secondary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, "VM-Execution Controls," and see Table 35-2.
600H	1536	IA32_DS_AREA	0, 1, 2, 3, 4, 6	Unique	<b>DS Save Area (R/W)</b> See Table 35-2. See Section 18.12.4, "Debug Store (DS) Mechanism."
680H	1664	MSR_LASTBRANCH_0_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 0 (R/W)</b> One of 16 pairs of last branch record registers on the last branch record stack (680H-68FH). This part of the stack contains pointers to the <b>source instruction</b> for one of the last 16 branches, exceptions, or interrupts taken by the processor.
					The MSRs at 680H-68FH, 6C0H-6CfH are not available in processor releases before family 0FH, model 03H. These MSRs replace MSRs previously located at 1DBH-1DEH, which performed the same function for early releases.  See Section 17.9, "Last Branch, Interrupt, and Exception Recording (Processors based on Intel NetBurst® Microarchitecture)."
681H	1665	MSR_LASTBRANCH_1_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 1</b> See description of MSR_LASTBRANCH_0 at 680H.
682H	1666	MSR_LASTBRANCH_2_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 2</b> See description of MSR_LASTBRANCH_0 at 680H.
683H	1667	MSR_LASTBRANCH_3_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 3</b> See description of MSR_LASTBRANCH_0 at 680H.
684H	1668	MSR_LASTBRANCH_4_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 4</b> See description of MSR_LASTBRANCH_0 at 680H.
685H	1669	MSR_LASTBRANCH_5_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 5</b> See description of MSR_LASTBRANCH_0 at 680H.
686H	1670	MSR_LASTBRANCH_6_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 6</b> See description of MSR_LASTBRANCH_0 at 680H.
687H	1671	MSR_LASTBRANCH_7_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 7</b> See description of MSR_LASTBRANCH_0 at 680H.
688H	1672	MSR_LASTBRANCH_8_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 8</b> See description of MSR_LASTBRANCH_0 at 680H.
689H	1673	MSR_LASTBRANCH_9_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 9</b> See description of MSR_LASTBRANCH_0 at 680H.
68AH	1674	MSR_LASTBRANCH_10_FROM_IP	3, 4, 6	Unique	<b>Last Branch Record 10</b> See description of MSR_LASTBRANCH_0 at 680H.

Table 35-22. MSRs in the Pentium® 4 and Intel® Xeon® Processors (Contd.)

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique <sup>1</sup>	Bit Description

C000_0080H		IA32_EFER	3, 4, 6	Unique	<b>Extended Feature Enables</b> See Table 35-2.
C000_0081H		IA32_STAR	3, 4, 6	Unique	<b>System Call Target Address (R/W)</b> See Table 35-2.
C000_0082H		IA32_LSTAR	3, 4, 6	Unique	<b>IA-32e Mode System Call Target Address (R/W)</b> See Table 35-2.
C000_0084H		IA32_FMASK	3, 4, 6	Unique	<b>System Call Flag Mask (R/W)</b> See Table 35-2.
C000_0100H		IA32_FS_BASE	3, 4, 6	Unique	<b>Map of BASE Address of FS (R/W)</b> See Table 35-2.
C000_0101H		IA32_GS_BASE	3, 4, 6	Unique	<b>Map of BASE Address of GS (R/W)</b> See Table 35-2.
C000_0102H		IA32_KERNEL_GSBASE	3, 4, 6	Unique	<b>Swap Target of BASE Address of GS (R/W)</b> See Table 35-2.

**NOTES**

1. For HT-enabled processors, there may be more than one logical processors per physical unit. If an MSR is Shared, this means that one MSR is shared between logical processors. If an MSR is unique, this means that each logical processor has its own MSR.

**35.12.1 MSRs Unique to Intel® Xeon® Processor MP with L3 Cache**

The MSRs listed in Table 35-23 apply to Intel Xeon Processor MP with up to 8MB level three cache. These processors can be detected by enumerating the deterministic cache parameter leaf of CPUID instruction (with EAX = 4 as input) to detect the presence of the third level cache, and with CPUID reporting family encoding 0FH, model encoding 3 or 4 (see CPUID instruction for more details).

**Table 35-23. MSRs Unique to 64-bit Intel® Xeon® Processor MP with Up to an 8 MB L3 Cache**

Register Address	Register Name Fields and Flags	Model Avail- ability	Shared/ Unique	Bit Description
107CCH	MSR_IFSB_BUSQ0	3, 4	Shared	<b>IFSB BUSQ Event Control and Counter Register (R/W)</b> See Section 18.17, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."
107CDH	MSR_IFSB_BUSQ1	3, 4	Shared	<b>IFSB BUSQ Event Control and Counter Register (R/W)</b>
107CEH	MSR_IFSB_SNPQ0	3, 4	Shared	<b>IFSB SNPQ Event Control and Counter Register (R/W)</b> See Section 18.17, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."
107CFH	MSR_IFSB_SNPQ1	3, 4	Shared	<b>IFSB SNPQ Event Control and Counter Register (R/W)</b>
107D0H	MSR_EFSB_DRDY0	3, 4	Shared	<b>EFSB DRDY Event Control and Counter Register (R/W)</b> See Section 18.17, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache" for details.
107D1H	MSR_EFSB_DRDY1	3, 4	Shared	<b>EFSB DRDY Event Control and Counter Register (R/W)</b>
107D2H	MSR_IFSB_CTL6	3, 4	Shared	<b>IFSB Latency Event Control Register (R/W)</b> See Section 18.17, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache" for details.
107D3H	MSR_IFSB_CNTR7	3, 4	Shared	<b>IFSB Latency Event Counter Register (R/W)</b> See Section 18.17, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."

The MSRs listed in Table 35-24 apply to Intel Xeon Processor 7100 series. These processors can be detected by enumerating the deterministic cache parameter leaf of CPUID instruction (with EAX = 4 as input) to detect the presence of the third level cache, and with CPUID reporting family encoding 0FH, model encoding 6 (See CPUID instruction for more details.). The performance monitoring MSRs listed in Table 35-24 are shared between logical processors in the same core, but are replicated for each core.

**Table 35-24. MSRs Unique to Intel Xeon Processor 7100 Series**

Register Address		Register Name Fields and Flags	Model Avail- ability	Shared/ Unique	Bit Description
107CCH		MSR_EMON_L3_CTR_CTL0	6	Shared	<b>GBUSQ Event Control and Counter Register (R/W)</b> See Section 18.17, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."
107CDH		MSR_EMON_L3_CTR_CTL1	6	Shared	<b>GBUSQ Event Control and Counter Register (R/W)</b>
107CEH		MSR_EMON_L3_CTR_CTL2	6	Shared	<b>GSNPQ Event Control and Counter Register (R/W)</b> See Section 18.17, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache."
107CFH		MSR_EMON_L3_CTR_CTL3	6	Shared	<b>GSNPQ Event Control and Counter Register (R/W)</b>
107D0H		MSR_EMON_L3_CTR_CTL4	6	Shared	<b>FSB Event Control and Counter Register (R/W)</b> See Section 18.17, "Performance Monitoring on 64-bit Intel Xeon Processor MP with Up to 8-MByte L3 Cache" for details.
107D1H		MSR_EMON_L3_CTR_CTL5	6	Shared	<b>FSB Event Control and Counter Register (R/W)</b>
107D2H		MSR_EMON_L3_CTR_CTL6	6	Shared	<b>FSB Event Control and Counter Register (R/W)</b>
107D3H		MSR_EMON_L3_CTR_CTL7	6	Shared	<b>FSB Event Control and Counter Register (R/W)</b>

### 35.13 MSRS IN INTEL® CORE™ SOLO AND INTEL® CORE™ DUO PROCESSORS

Model-specific registers (MSRs) for Intel Core Solo, Intel Core Duo processors, and Dual-core Intel Xeon processor LV are listed in Table 35-25. The column "Shared/Unique" applies to Intel Core Duo processor. "Unique" means each processor core has a separate MSR, or a bit field in an MSR governs only a core independently. "Shared" means the MSR or the bit field in an MSR address governs the operation of both processor cores.

**Table 35-25. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
0H	0	P5_MC_ADDR	Unique	See Section 35.16, "MSRs in Pentium Processors," and see Table 35-2.
1H	1	P5_MC_TYPE	Unique	See Section 35.16, "MSRs in Pentium Processors," and see Table 35-2.
6H	6	IA32_MONITOR_FILTER_SIZE	Unique	See Section 8.10.5, "Monitor/Mwait Address Range Determination," and see Table 35-2.

**Table 35-25. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV**

Register Address		Register Name	Shared/ Unique	Bit Description	
Hex	Dec				
10H	16	IA32_TIME_STAMP_COUNTER	Unique	See Section 17.13, "Time-Stamp Counter," and see Table 35-2.	
17H	23	IA32_PLATFORM_ID	Shared	<b>Platform ID (R)</b> See Table 35-2. The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load.	
1BH	27	IA32_APIC_BASE	Unique	See Section 10.4.4, "Local APIC Status and Location," and see Table 35-2.	
2AH	42	MSR_EBL_CR_POWERON	Shared	<b>Processor Hard Power-On Configuration (R/W)</b> Enables and disables processor features; (R) indicates current processor configuration.	
				0	Reserved.
				1	<b>Data Error Checking Enable (R/W)</b> 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
				2	<b>Response Error Checking Enable (R/W)</b> 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
				3	<b>MCERR# Drive Enable (R/W)</b> 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
				4	<b>Address Parity Enable (R/W)</b> 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
				6: 5	Reserved
				7	<b>BINIT# Driver Enable (R/W)</b> 1 = Enabled; 0 = Disabled Note: Not all processor implements R/W.
				8	<b>Output Tri-state Enabled (R/O)</b> 1 = Enabled; 0 = Disabled
				9	<b>Execute BIST (R/O)</b> 1 = Enabled; 0 = Disabled
				10	<b>MCERR# Observation Enabled (R/O)</b> 1 = Enabled; 0 = Disabled
				11	Reserved
				12	<b>BINIT# Observation Enabled (R/O)</b> 1 = Enabled; 0 = Disabled
				13	Reserved
				14	<b>1 MByte Power on Reset Vector (R/O)</b> 1 = 1 MByte; 0 = 4 GBytes

**Table 35-25. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		15		Reserved
		17:16		<b>APIC Cluster ID (R/O)</b>
		18		<b>System Bus Frequency (R/O)</b> 0 = 100 MHz 1 = Reserved
		19		Reserved.
		21:20		<b>Symmetric Arbitration ID (R/O)</b>
		26:22		<b>Clock Frequency Ratio (R/O)</b>
3AH	58	IA32_FEATURE_CONTROL	Unique	<b>Control Features in IA-32 Processor (R/W)</b> See Table 35-2.
40H	64	MSR_LASTBRANCH_0	Unique	<b>Last Branch Record 0 (R/W)</b> One of 8 last branch record registers on the last branch record stack: bits 31-0 hold the 'from' address and bits 63-32 hold the 'to' address. See also: <ul style="list-style-type: none"> <li>▪ Last Branch Record Stack TOS at 1C9H</li> <li>▪ Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)."</li> </ul>
41H	65	MSR_LASTBRANCH_1	Unique	<b>Last Branch Record 1 (R/W)</b> See description of MSR_LASTBRANCH_0.
42H	66	MSR_LASTBRANCH_2	Unique	<b>Last Branch Record 2 (R/W)</b> See description of MSR_LASTBRANCH_0.
43H	67	MSR_LASTBRANCH_3	Unique	<b>Last Branch Record 3 (R/W)</b> See description of MSR_LASTBRANCH_0.
44H	68	MSR_LASTBRANCH_4	Unique	<b>Last Branch Record 4 (R/W)</b> See description of MSR_LASTBRANCH_0.
45H	69	MSR_LASTBRANCH_5	Unique	<b>Last Branch Record 5 (R/W)</b> See description of MSR_LASTBRANCH_0.
46H	70	MSR_LASTBRANCH_6	Unique	<b>Last Branch Record 6 (R/W)</b> See description of MSR_LASTBRANCH_0.
47H	71	MSR_LASTBRANCH_7	Unique	<b>Last Branch Record 7 (R/W)</b> See description of MSR_LASTBRANCH_0.
79H	121	IA32_BIOS_UPDT_TRIG	Unique	<b>BIOS Update Trigger Register (W)</b> See Table 35-2.
8BH	139	IA32_BIOS_SIGN_ID	Unique	<b>BIOS Update Signature ID (RO)</b> See Table 35-2.
C1H	193	IA32_PMC0	Unique	<b>Performance counter register</b> See Table 35-2.
C2H	194	IA32_PMC1	Unique	<b>Performance counter register</b> See Table 35-2.

**Table 35-25. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
CDH	205	MSR_FSB_FREQ	Shared	<b>Scaleable Bus Speed (RO)</b> This field indicates the scaleable bus clock speed:
		2:0		<ul style="list-style-type: none"> <li>▪ 101B: 100 MHz (FSB 400)</li> <li>▪ 001B: 133 MHz (FSB 533)</li> <li>▪ 011B: 167 MHz (FSB 667)</li> </ul> <p>133.33 MHz should be utilized if performing calculation with System Bus Speed when encoding is 101B. 166.67 MHz should be utilized if performing calculation with System Bus Speed when encoding is 001B.</p>
		63:3		Reserved.
E7H	231	IA32_MPERF	Unique	<b>Maximum Performance Frequency Clock Count. (RW)</b> See Table 35-2.
E8H	232	IA32_APERF	Unique	<b>Actual Performance Frequency Clock Count. (RW)</b> See Table 35-2.
FEH	254	IA32_MTRRCAP	Unique	See Table 35-2.
11EH	281	MSR_BBL_CR_CTL3	Shared	
		0		<b>L2 Hardware Enabled (RO)</b> 1 = If the L2 is hardware-enabled 0 = Indicates if the L2 is hardware-disabled
		7:1		Reserved.
		8		<b>L2 Enabled (R/W)</b> 1 = L2 cache has been initialized 0 = Disabled (default) Until this bit is set the processor will not respond to the WBINVD instruction or the assertion of the FLUSH# input.
		22:9		Reserved.
		23		<b>L2 Not Present (RO)</b> 0 = L2 Present 1 = L2 Not Present
		63:24		Reserved.
174H	372	IA32_SYSENTER_CS	Unique	See Table 35-2.
175H	373	IA32_SYSENTER_ESP	Unique	See Table 35-2.
176H	374	IA32_SYSENTER_EIP	Unique	See Table 35-2.
179H	377	IA32_MCG_CAP	Unique	See Table 35-2.
17AH	378	IA32_MCG_STATUS	Unique	

**Table 35-25. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		0		<b>RIPV</b> When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If this bit is cleared, the program cannot be reliably restarted.
		1		<b>EIPV</b> When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.
		2		<b>MCIP</b> When set, this bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.
		63:3		Reserved.
186H	390	IA32_PERFEVTSELO	Unique	See Table 35-2.
187H	391	IA32_PERFEVTSEL1	Unique	See Table 35-2.
198H	408	IA32_PERF_STATUS	Shared	See Table 35-2.
199H	409	IA32_PERF_CTL	Unique	See Table 35-2.
19AH	410	IA32_CLOCK_MODULATION	Unique	<b>Clock Modulation (R/W)</b> See Table 35-2.
19BH	411	IA32_THERM_INTERRUPT	Unique	<b>Thermal Interrupt Control (R/W)</b> See Table 35-2. See Section 14.5.2, "Thermal Monitor."
19CH	412	IA32_THERM_STATUS	Unique	<b>Thermal Monitor Status (R/W)</b> See Table 35-2. See Section 14.5.2, "Thermal Monitor".
19DH	413	MSR_THERM2_CTL	Unique	
		15:0		Reserved.
		16		<b>TM_SELECT (R/W)</b> Mode of automatic thermal monitor: 0 = Thermal Monitor 1 (thermally-initiated on-die modulation of the stop-clock duty cycle) 1 = Thermal Monitor 2 (thermally-initiated frequency transitions) If bit 3 of the IA32_MISC_ENABLE register is cleared, TM_SELECT has no effect. Neither TM1 nor TM2 will be enabled.
		63:16		Reserved.
1A0	416	IA32_MISC_ENABLE		<b>Enable Miscellaneous Processor Features (R/W)</b> Allows a variety of processor functions to be enabled and disabled.
		2:0		Reserved.

**Table 35-25. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
		3	Unique	<b>Automatic Thermal Control Circuit Enable (R/W)</b> See Table 35-2.
		6:4		Reserved.
		7	Shared	<b>Performance Monitoring Available (R)</b> See Table 35-2.
		9:8		Reserved.
		10	Shared	<b>FERR# Multiplexing Enable (R/W)</b> 1 = FERR# asserted by the processor to indicate a pending break event within the processor 0 = Indicates compatible FERR# signaling behavior This bit must be set to 1 to support XAPIC interrupt model usage.
		11	Shared	<b>Branch Trace Storage Unavailable (RO)</b> See Table 35-2.
		12		Reserved.
		13	Shared	<b>TM2 Enable (R/W)</b> When this bit is set (1) and the thermal sensor indicates that the die temperature is at the pre-determined threshold, the Thermal Monitor 2 mechanism is engaged. TM2 will reduce the bus to core ratio and voltage according to the value last written to MSR_THERM2_CTL bits 15:0.
				When this bit is clear (0, default), the processor does not change the VID signals or the bus to core ratio when the processor enters a thermal managed state. If the TM2 feature flag (ECX[8]) is not set to 1 after executing CPUID with EAX = 1, then this feature is not supported and BIOS must not alter the contents of this bit location. The processor is operating out of spec if both this bit and the TM1 bit are set to disabled states.
		15:14		Reserved.
		16	Shared	<b>Enhanced Intel SpeedStep Technology Enable (R/W)</b> 1 = Enhanced Intel SpeedStep Technology enabled
		18	Shared	<b>ENABLE MONITOR FSM (R/W)</b> See Table 35-2.
		19		<b>Reserved.</b>
		22	Shared	<b>Limit CPUID Maxval (R/W)</b> See Table 35-2. Setting this bit may cause behavior in software that depends on the availability of CPUID leaves greater than 3.
		33:23		Reserved.
		34	Shared	<b>XD Bit Disable (R/W)</b> See Table 35-2.
		63:35		Reserved.

2FFH	767	IA32_MTRR_DEF_TYPE	Unique	<b>Default Memory Types (R/W)</b> See Table 35-2. See Section 11.11.2.1, "IA32_MTRR_DEF_TYPE MSR."
400H	1024	IA32_MC0_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
401H	1025	IA32_MC0_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRs."
402H	1026	IA32_MC0_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC0_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC0_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
404H	1028	IA32_MC1_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
405H	1029	IA32_MC1_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRs."
406H	1030	IA32_MC1_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC1_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
408H	1032	IA32_MC2_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
409H	1033	IA32_MC2_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRs."
40AH	1034	IA32_MC2_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	MSR_MC4_CTL	Unique	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
40DH	1037	MSR_MC4_STATUS	Unique	See Section 15.3.2.2, "IA32_MCi_STATUS MSRs."
40EH	1038	MSR_MC4_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	MSR_MC3_CTL		See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
411H	1041	MSR_MC3_STATUS		See Section 15.3.2.2, "IA32_MCi_STATUS MSRs."

**Table 35-25. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
412H	1042	MSR_MC3_ADDR	Unique	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC3_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
413H	1043	MSR_MC3_MISC	Unique	
414H	1044	MSR_MC5_CTL	Unique	
415H	1045	MSR_MC5_STATUS	Unique	
416H	1046	MSR_MC5_ADDR	Unique	
417H	1047	MSR_MC5_MISC	Unique	
480H	1152	IA32_VMX_BASIC	Unique	<b>Reporting Register of Basic VMX Capabilities (R/O)</b> See Table 35-2. See Appendix A.1, "Basic VMX Information" (If CPUID.01H:ECX.[bit 9])
481H	1153	IA32_VMX_PINBASED_CTL	Unique	<b>Capability Reporting Register of Pin-based VM-execution Controls (R/O)</b> See Appendix A.3, "VM-Execution Controls" (If CPUID.01H:ECX.[bit 9])
482H	1154	IA32_VMX_PROCBASED_CTL	Unique	<b>Capability Reporting Register of Primary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, "VM-Execution Controls" (If CPUID.01H:ECX.[bit 9])
483H	1155	IA32_VMX_EXIT_CTL	Unique	<b>Capability Reporting Register of VM-exit Controls (R/O)</b> See Appendix A.4, "VM-Exit Controls" (If CPUID.01H:ECX.[bit 9])
484H	1156	IA32_VMX_ENTRY_CTL	Unique	<b>Capability Reporting Register of VM-entry Controls (R/O)</b> See Appendix A.5, "VM-Entry Controls" (If CPUID.01H:ECX.[bit 9])
485H	1157	IA32_VMX_MISC	Unique	<b>Reporting Register of Miscellaneous VMX Capabilities (R/O)</b> See Appendix A.6, "Miscellaneous Data" (If CPUID.01H:ECX.[bit 9])
486H	1158	IA32_VMX_CR0_FIXED0	Unique	<b>Capability Reporting Register of CR0 Bits Fixed to 0 (R/O)</b> See Appendix A.7, "VMX-Fixed Bits in CR0" (If CPUID.01H:ECX.[bit 9])
487H	1159	IA32_VMX_CR0_FIXED1	Unique	<b>Capability Reporting Register of CR0 Bits Fixed to 1 (R/O)</b> See Appendix A.7, "VMX-Fixed Bits in CR0" (If CPUID.01H:ECX.[bit 9])
488H	1160	IA32_VMX_CR4_FIXED0	Unique	<b>Capability Reporting Register of CR4 Bits Fixed to 0 (R/O)</b> See Appendix A.8, "VMX-Fixed Bits in CR4" (If CPUID.01H:ECX.[bit 9])

**Table 35-25. MSRs in Intel® Core™ Solo, Intel® Core™ Duo Processors, and Dual-Core Intel® Xeon® Processor LV**

Register Address		Register Name	Shared/ Unique	Bit Description
Hex	Dec			
489H	1161	IA32_VMX_CR4_FIXED1	Unique	<b>Capability Reporting Register of CR4 Bits Fixed to 1 (R/O)</b> See Appendix A.8, “VMX-Fixed Bits in CR4” (If CPUID.01H:ECX.[bit 9])
48AH	1162	IA32_VMX_VMCS_ENUM	Unique	<b>Capability Reporting Register of VMCS Field Enumeration (R/O)</b> See Appendix A.9, “VMCS Enumeration” (If CPUID.01H:ECX.[bit 9])
48BH	1163	IA32_VMX_PROCBASED_CTLS2	Unique	<b>Capability Reporting Register of Secondary Processor-based VM-execution Controls (R/O)</b> See Appendix A.3, “VM-Execution Controls” (If CPUID.01H:ECX.[bit 9] and IA32_VMX_PROCBASED_CTLS[bit 63])
600H	1536	IA32_DS_AREA	Unique	<b>DS Save Area (R/W)</b> See Table 35-2. See Section 18.12.4, “Debug Store (DS) Mechanism.”
		31:0		<b>DS Buffer Management Area</b> Linear address of the first byte of the DS buffer management area.
		63:32		Reserved.
C000_0080H		IA32_EFER	Unique	See Table 35-2.
		10:0		Reserved.
		11		<b>Execute Disable Bit Enable</b>
		63:12		Reserved.

## 35.14 MSRS IN THE PENTIUM M PROCESSOR

Model-specific registers (MSRs) for the Pentium M processor are similar to those described in Section 35.15 for P6 family processors. The following table describes new MSRs and MSRs whose behavior has changed on the Pentium M processor.

**Table 35-26. MSRs in Pentium M Processors**

Register Address		Register Name	Bit Description
Hex	Dec		
0H	0	P5_MC_ADDR	See Section 35.16, “MSRs in Pentium Processors.”
1H	1	P5_MC_TYPE	See Section 35.16, “MSRs in Pentium Processors.”
10H	16	IA32_TIME_STAMP_COUNTER	See Section 17.13, “Time-Stamp Counter,” and see Table 35-2.
17H	23	IA32_PLATFORM_ID	<b>Platform ID (R)</b> See Table 35-2. The operating system can use this MSR to determine “slot” information for the processor and the proper microcode update to load.

**Table 35-26. MSRs in Pentium M Processors (Contd.)**

Register Address		Register Name	Bit Description
Hex	Dec		
2AH	42	MSR_EBL_CR_POWERON	<b>Processor Hard Power-On Configuration (R/W)</b> Enables and disables processor features. <b>(R)</b> Indicates current processor configuration.
		0	Reserved.
		1	<b>Data Error Checking Enable (R)</b> 0 = Disabled Always 0 on the Pentium M processor.
		2	<b>Response Error Checking Enable (R)</b> 0 = Disabled Always 0 on the Pentium M processor.
		3	<b>MCERR# Drive Enable (R)</b> 0 = Disabled Always 0 on the Pentium M processor.
		4	<b>Address Parity Enable (R)</b> 0 = Disabled Always 0 on the Pentium M processor.
		6:5	Reserved.
		7	<b>BINIT# Driver Enable (R)</b> 1 = Enabled; 0 = Disabled Always 0 on the Pentium M processor.
		8	<b>Output Tri-state Enabled (R/O)</b> 1 = Enabled; 0 = Disabled
		9	<b>Execute BIST (R/O)</b> 1 = Enabled; 0 = Disabled
		10	<b>MCERR# Observation Enabled (R/O)</b> 1 = Enabled; 0 = Disabled Always 0 on the Pentium M processor.
		11	Reserved.
		12	<b>BINIT# Observation Enabled (R/O)</b> 1 = Enabled; 0 = Disabled Always 0 on the Pentium M processor.
		13	Reserved.
		14	<b>1 MByte Power on Reset Vector (R/O)</b> 1 = 1 MByte; 0 = 4 GBytes Always 0 on the Pentium M processor.
		15	Reserved.
17:16	<b>APIC Cluster ID (R/O)</b> Always 00B on the Pentium M processor.		

Table 35-26. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
		18	<b>System Bus Frequency (R/O)</b> 0 = 100 MHz 1 = Reserved Always 0 on the Pentium M processor.
		19	Reserved.
		21:20	<b>Symmetric Arbitration ID (R/O)</b> Always 00B on the Pentium M processor.
		26:22	Clock Frequency Ratio (R/O)
40H	64	MSR_LASTBRANCH_0	<b>Last Branch Record 0 (R/W)</b> One of 8 last branch record registers on the last branch record stack: bits 31-0 hold the 'from' address and bits 63-32 hold the to address. See also: <ul style="list-style-type: none"> <li>Last Branch Record Stack TOS at 1C9H</li> <li>Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)"</li> </ul>
41H	65	MSR_LASTBRANCH_1	<b>Last Branch Record 1 (R/W)</b> See description of MSR_LASTBRANCH_0.
42H	66	MSR_LASTBRANCH_2	<b>Last Branch Record 2 (R/W)</b> See description of MSR_LASTBRANCH_0.
43H	67	MSR_LASTBRANCH_3	<b>Last Branch Record 3 (R/W)</b> See description of MSR_LASTBRANCH_0.
44H	68	MSR_LASTBRANCH_4	<b>Last Branch Record 4 (R/W)</b> See description of MSR_LASTBRANCH_0.
45H	69	MSR_LASTBRANCH_5	<b>Last Branch Record 5 (R/W)</b> See description of MSR_LASTBRANCH_0.
46H	70	MSR_LASTBRANCH_6	<b>Last Branch Record 6 (R/W)</b> See description of MSR_LASTBRANCH_0.
47H	71	MSR_LASTBRANCH_7	<b>Last Branch Record 7 (R/W)</b> See description of MSR_LASTBRANCH_0.
119H	281	MSR_BBL_CR_CTL	
		63:0	Reserved.
11EH	281	MSR_BBL_CR_CTL3	
		0	<b>L2 Hardware Enabled (R/O)</b> 1 = If the L2 is hardware-enabled 0 = Indicates if the L2 is hardware-disabled
		4:1	Reserved.

**Table 35-26. MSRs in Pentium M Processors (Contd.)**

Register Address		Register Name	Bit Description
Hex	Dec		
		5	<b>ECC Check Enable (RO)</b> This bit enables ECC checking on the cache data bus. ECC is always generated on write cycles. 0 = Disabled (default) 1 = Enabled For the Pentium M processor, ECC checking on the cache data bus is always enabled.
		7:6	Reserved.
		8	<b>L2 Enabled (R/W)</b> 1 = L2 cache has been initialized 0 = Disabled (default) Until this bit is set the processor will not respond to the WBINVD instruction or the assertion of the FLUSH# input.
		22:9	Reserved.
		23	<b>L2 Not Present (RO)</b> 0 = L2 Present 1 = L2 Not Present
		63:24	Reserved.
179H	377	IA32_MCG_CAP	
		7:0	<b>Count (RO)</b> Indicates the number of hardware unit error reporting banks available in the processor.
		8	<b>IA32_MCG_CTL Present (RO)</b> 1 = Indicates that the processor implements the MSR_MCG_CTL register found at MSR 17BH. 0 = Not supported.
		63:9	Reserved.
17AH	378	IA32_MCG_STATUS	
		0	<b>RIPV</b> When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) can be used to restart the program. If this bit is cleared, the program cannot be reliably restarted.
		1	<b>EIPV</b> When set, this bit indicates that the instruction addressed by the instruction pointer pushed on the stack (when the machine check was generated) is directly associated with the error.
		2	<b>MCIP</b> When set, this bit indicates that a machine check has been generated. If a second machine check is detected while this bit is still set, the processor enters a shutdown state. Software should write this bit to 0 after processing a machine check exception.
		63:3	Reserved.

Table 35-26. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
198H	408	IA32_PERF_STATUS	See Table 35-2.
199H	409	IA32_PERF_CTL	See Table 35-2.
19AH	410	IA32_CLOCK_MODULATION	<b>Clock Modulation (R/W).</b> See Table 35-2. See Section 14.5.3, "Software Controlled Clock Modulation."
19BH	411	IA32_THERM_INTERRUPT	<b>Thermal Interrupt Control (R/W)</b> See Table 35-2. See Section 14.5.2, "Thermal Monitor."
19CH	412	IA32_THERM_STATUS	<b>Thermal Monitor Status (R/W)</b> See Table 35-2. See Section 14.5.2, "Thermal Monitor."
19DH	413	MSR_THERM2_CTL	
		15:0	Reserved.
		16	<b>TM_SELECT (R/W)</b> Mode of automatic thermal monitor: 0 = Thermal Monitor 1 (thermally-initiated on-die modulation of the stop-clock duty cycle) 1 = Thermal Monitor 2 (thermally-initiated frequency transitions) If bit 3 of the IA32_MISC_ENABLE register is cleared, TM_SELECT has no effect. Neither TM1 nor TM2 will be enabled.
		63:16	Reserved.
1A0	416	IA32_MISC_ENABLE	<b>Enable Miscellaneous Processor Features (R/W)</b> Allows a variety of processor functions to be enabled and disabled.
		2:0	Reserved.
		3	<b>Automatic Thermal Control Circuit Enable (R/W)</b> 1 = Setting this bit enables the thermal control circuit (TCC) portion of the Intel Thermal Monitor feature. This allows processor clocks to be automatically modulated based on the processor's thermal sensor operation. 0 = Disabled (default). The automatic thermal control circuit enable bit determines if the thermal control circuit (TCC) will be activated when the processor's internal thermal sensor determines the processor is about to exceed its maximum operating temperature. When the TCC is activated and TM1 is enabled, the processors clocks will be forced to a 50% duty cycle. BIOS must enable this feature. The bit should not be confused with the on-demand thermal control circuit enable bit.
		6:4	Reserved.
		7	<b>Performance Monitoring Available (R)</b> 1 = Performance monitoring enabled 0 = Performance monitoring disabled

**Table 35-26. MSRs in Pentium M Processors (Contd.)**

Register Address		Register Name	Bit Description
Hex	Dec		
		9:8	Reserved.
		10	<b>FERR# Multiplexing Enable (R/W)</b> 1 = FERR# asserted by the processor to indicate a pending break event within the processor 0 = Indicates compatible FERR# signaling behavior This bit must be set to 1 to support XAPIC interrupt model usage.
			<b>Branch Trace Storage Unavailable (RO)</b> 1 = Processor doesn't support branch trace storage (BTS) 0 = BTS is supported
		12	<b>Precise Event Based Sampling Unavailable (RO)</b> 1 = Processor does not support precise event-based sampling (PEBS); 0 = PEBS is supported. The Pentium M processor does not support PEBS.
		15:13	Reserved.
		16	<b>Enhanced Intel SpeedStep Technology Enable (R/W)</b> 1 = Enhanced Intel SpeedStep Technology enabled. On the Pentium M processor, this bit may be configured to be read-only.
		22:17	Reserved.
		23	<b>xTPR Message Disable (R/W)</b> When set to 1, xTPR messages are disabled. xTPR messages are optional messages that allow the processor to inform the chipset of its priority. The default is processor specific.
		63:24	Reserved.
1C9H	457	MSR_LASTBRANCH_TOS	<b>Last Branch Record Stack TOS (R/W)</b> Contains an index (bits 0-3) that points to the MSR containing the most recent branch record. See also: <ul style="list-style-type: none"> <li>▪ MSR_LASTBRANCH_O_FROM_IP (at 40H)</li> <li>▪ Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)"</li> </ul>
1D9H	473	MSR_DEBUGCTLB	<b>Debug Control (R/W)</b> Controls how several debug features are used. Bit definitions are discussed in the referenced section. See Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)."
1DDH	477	MSR_LER_TO_LIP	<b>Last Exception Record To Linear IP (R)</b> This area contains a pointer to the target of the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled. See Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)" and Section 17.12.2, "Last Branch and Last Exception MSRs."

Table 35-26. MSRs in Pentium M Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
1DEH	478	MSR_LER_FROM_LIP	<b>Last Exception Record From Linear IP (R)</b> Contains a pointer to the last branch instruction that the processor executed prior to the last exception that was generated or the last interrupt that was handled. See Section 17.11, "Last Branch, Interrupt, and Exception Recording (Pentium M Processors)" and Section 17.12.2, "Last Branch and Last Exception MSRs."
2FFH	767	IA32_MTRR_DEF_TYPE	<b>Default Memory Types (R/W)</b> Sets the memory type for the regions of physical memory that are not mapped by the MTRRs. See Section 11.11.2.1, "IA32_MTRR_DEF_TYPE MSR."
400H	1024	IA32_MCO_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
401H	1025	IA32_MCO_STATUS	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
402H	1026	IA32_MCO_ADDR	See Section 14.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MCO_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MCO_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
404H	1028	IA32_MC1_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
405H	1029	IA32_MC1_STATUS	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
406H	1030	IA32_MC1_ADDR	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC1_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC1_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
408H	1032	IA32_MC2_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
409H	1033	IA32_MC2_STATUS	See Chapter 15.3.2.2, "IA32_MCi_STATUS MSRS."
40AH	1034	IA32_MC2_ADDR	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The IA32_MC2_ADDR register is either not implemented or contains no address if the ADDR_V flag in the IA32_MC2_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
40CH	1036	MSR_MC4_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
40DH	1037	MSR_MC4_STATUS	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."
40EH	1038	MSR_MC4_ADDR	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC4_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC4_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
410H	1040	MSR_MC3_CTL	See Section 15.3.2.1, "IA32_MCi_CTL MSRs."
411H	1041	MSR_MC3_STATUS	See Section 15.3.2.2, "IA32_MCi_STATUS MSRS."

**Table 35-26. MSRs in Pentium M Processors (Contd.)**

Register Address		Register Name	Bit Description
Hex	Dec		
412H	1042	MSR_MC3_ADDR	See Section 15.3.2.3, "IA32_MCi_ADDR MSRs." The MSR_MC3_ADDR register is either not implemented or contains no address if the ADDR_V flag in the MSR_MC3_STATUS register is clear. When not implemented in the processor, all reads and writes to this MSR will cause a general-protection exception.
600H	1536	IA32_DS_AREA	<b>DS Save Area (R/W)</b> See Table 35-2. Points to the DS buffer management area, which is used to manage the BTS and PEBS buffers. See Section 18.1.2.4, "Debug Store (DS) Mechanism."
		31:0	<b>DS Buffer Management Area</b> Linear address of the first byte of the DS buffer management area.
		63:32	Reserved.

### 35.15 MSRS IN THE P6 FAMILY PROCESSORS

The following MSRs are defined for the P6 family processors. The MSRs in this table that are shaded are available only in the Pentium II and Pentium III processors. Beginning with the Pentium 4 processor, some of the MSRs in this list have been designated as "architectural" and have had their names changed. See Table 35-2 for a list of the architectural MSRs.

**Table 35-27. MSRs in the P6 Family Processors**

Register Address		Register Name	Bit Description
Hex	Dec		
0H	0	P5_MC_ADDR	See Section 35.16, "MSRs in Pentium Processors."
1H	1	P5_MC_TYPE	See Section 35.16, "MSRs in Pentium Processors."
10H	16	TSC	See Section 17.13, "Time-Stamp Counter."
17H	23	IA32_PLATFORM_ID	<b>Platform ID (R)</b> The operating system can use this MSR to determine "slot" information for the processor and the proper microcode update to load.
		49:0	Reserved.
		52:50	<b>Platform Id (R)</b> Contains information concerning the intended platform for the processor.  52 51 50 0 0 0 Processor Flag 0 0 0 1 Processor Flag 1 0 1 0 Processor Flag 2 0 1 1 Processor Flag 3 1 0 0 Processor Flag 4 1 0 1 Processor Flag 5 1 1 0 Processor Flag 6 1 1 1 Processor Flag 7
		56:53	L2 Cache Latency Read.
		59:57	Reserved.

Table 35-27. MSRs in the P6 Family Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
		60	Clock Frequency Ratio Read.
		63:61	Reserved.
1BH	27	APIC_BASE	Section 10.4.4, "Local APIC Status and Location."
		7:0	Reserved.
		8	<b>Boot Strap Processor indicator Bit</b> 1 = BSP
		10:9	Reserved.
		11	<b>APIC Global Enable Bit - Permanent till reset</b> 1 = Enabled 0 = Disabled
		31:12	APIC Base Address.
		63:32	Reserved.
2AH	42	EBL_CR_POWERON	<b>Processor Hard Power-On Configuration (R/W)</b> Enables and disables processor features; <b>(R)</b> indicates current processor configuration.
		0	Reserved. <sup>1</sup>
		1	<b>Data Error Checking Enable (R/W)</b> 1 = Enabled 0 = Disabled
		2	<b>Response Error Checking Enable FRCERR Observation Enable (R/W)</b> 1 = Enabled 0 = Disabled
		3	<b>AERR# Drive Enable (R/W)</b> 1 = Enabled 0 = Disabled
		4	<b>BERR# Enable for Initiator Bus Requests (R/W)</b> 1 = Enabled 0 = Disabled
		5	Reserved.
		6	<b>BERR# Driver Enable for Initiator Internal Errors (R/W)</b> 1 = Enabled 0 = Disabled
		7	<b>BINIT# Driver Enable (R/W)</b> 1 = Enabled 0 = Disabled
		8	<b>Output Tri-state Enabled (R)</b> 1 = Enabled 0 = Disabled

**Table 35-27. MSRs in the P6 Family Processors (Contd.)**

Register Address		Register Name	Bit Description
Hex	Dec		
		9	<b>Execute BIST (R)</b> 1 = Enabled 0 = Disabled
		10	<b>AERR# Observation Enabled (R)</b> 1 = Enabled 0 = Disabled
		11	Reserved.
		12	<b>BINIT# Observation Enabled (R)</b> 1 = Enabled 0 = Disabled
		13	<b>In Order Queue Depth (R)</b> 1 = 1 0 = 8
		14	<b>1-MByte Power on Reset Vector (R)</b> 1 = 1MByte 0 = 4GBytes
		15	<b>FRC Mode Enable (R)</b> 1 = Enabled 0 = Disabled
		17:16	<b>APIC Cluster ID (R)</b>
		19:18	<b>System Bus Frequency (R)</b> 00 = 66MHz 10 = 100Mhz 01 = 133MHz 11 = Reserved
		21:20	<b>Symmetric Arbitration ID (R)</b>
		25:22	<b>Clock Frequency Ratio (R)</b>
		26	<b>Low Power Mode Enable (R/W)</b>
		27	<b>Clock Frequency Ratio</b>
		63:28	Reserved. <sup>1</sup>
		33H	51
29:0	Reserved.		
30	<b>Streaming Buffer Disable</b>		
31	<b>Disable LOCK#</b> Assertion for split locked access.		
79H	121	BIOS_UPDT_TRIG	BIOS Update Trigger Register.
88	136	BBL_CR_D0[63:0]	Chunk 0 data register D[63:0]: used to write to and read from the L2
89	137	BBL_CR_D1[63:0]	Chunk 1 data register D[63:0]: used to write to and read from the L2
8A	138	BBL_CR_D2[63:0]	Chunk 2 data register D[63:0]: used to write to and read from the L2

Table 35-27. MSRs in the P6 Family Processors (Contd.)

Register Address		Register Name	Bit Description
Hex	Dec		
8BH	139	BIOS_SIGN/BBL_CR_D3[63:0]	<b>BIOS Update Signature Register or Chunk 3 data register D[63:0]</b> Used to write to and read from the L2 depending on the usage model.
C1H	193	PerfCtr0 (PERFCTR0)	
C2H	194	PerfCtr1 (PERFCTR1)	
FEH	254	MTRRcap

412H	1042	MC3_ADDR	
413H	1043	MC3_MISC	Defined in MCA architecture but not implemented in the P6 family processors.

**NOTES**

1. Bit 0 of this register has been redefined several times, and is no longer used in P6 family processors.
2. The processor number feature may be disabled by setting bit 21 of the BBL\_CR\_CTL MSR (model-specific register address 119h) to "1". Once set, bit 21 of the BBL\_CR\_CTL may not be cleared. This bit is write-once. The processor number feature will be disabled until the processor is reset.
3. The Pentium III processor will prevent FSB frequency overclocking with a new shutdown mechanism. If the FSB frequency selected is greater than the internal FSB frequency the processor will shutdown. If the FSB selected is less than the internal FSB frequency the BIOS may choose to use bit 11 to implement its own shutdown policy.

## 35.16 MSRS IN PENTIUM PROCESSORS

The following MSRs are defined for the Pentium processors. The P5\_MC\_ADDR, P5\_MC\_TYPE, and TSC MSRs (named IA32\_P5\_MC\_ADDR, IA32\_P5\_MC\_TYPE, and IA32\_TIME\_STAMP\_COUNTER in the Pentium 4 processor) are architectural; that is, code that accesses these registers will run on Pentium 4 and P6 family processors without generating exceptions (see Section 35.1, "Architectural MSRs"). The CESR, CTR0, and CTR1 MSRs are unique to

Pentium processors; code that accesses these registers will generate exceptions on Pentium 4 and P6 family processors.

**Table 35-28. MSRs in the Pentium Processor**

Register Address		Register Name	Bit Description
Hex	Dec		
0H	0	P5_MC_ADDR	See Section 15.10.2, "Pentium Processor Machine-Check Exception Handling."
1H	1	P5_MC_TYPE	See Section 15.10.2, "Pentium Processor Machine-Check Exception Handling."
10H	16	TSC	See Section 17.13, "Time-Stamp Counter."
11H	17	CESR	See Section 18.20.1, "Control and Event Select Register (CESR)."
12H	18	CTR0	Section 18.20.3, "Events Counted."
13H	19	CTR1	Section 18.20.3, "Events Counted."

# APPENDIX A

## VMX CAPABILITY REPORTING FACILITY

The ability of a processor to support VMX operation and related instructions is indicated by `CPUID.1:ECX.VMX[bit 5] = 1`. A value 1 in this bit indicates support for VMX features.

Support for specific features detailed in Chapter 26 and other VMX chapters is determined by reading values from a set of capability MSR. These MSRs are indexed starting at MSR address 480H. VMX capability MSRs are read-only; an attempt to write them (with `WRMSR`) produces a general-protection exception (`#GP(0)`). They do not exist on processors that do not support VMX operation; an attempt to read them (with `RDMSR`) on such processors produces a general-protection exception (`#GP(0)`).

### A.1 BASIC VMX INFORMATION

The `IA32_VMX_BASIC` MSR (index 480H) consists of the following fields:

- Bits 30:0 contain the 31-bit VMCS revision identifier used by the processor. Processors that use the same VMCS revision identifier use the same size for VMCS regions (see subsequent item on bits 44:32).<sup>1</sup>
- Bit 31 is always 0.
- Bits 44:32 report the number of bytes that software should allocate for the VMXON region and any VMCS region. It is a value greater than 0 and at most 4096 (bit 44 is set if and only if bits 43:32 are clear).
- Bit 48 indicates the width of the physical addresses that may be used for the VMXON region, each VMCS, and data structures referenced by pointers in a VMCS (I/O bitmaps, virtual-APIC page, MSR areas for VMX transitions). If the bit is 0, these addresses are limited to the processor's physical-address width.<sup>2</sup> If the bit is 1, these addresses are limited to 32 bits. This bit is always 0 for processors that support Intel 64 architecture.
- If bit 49 is read as 1, the logical processor supports the dual-monitor treatment of system-management interrupts and system-management mode. See Section 34.15 for details of this treatment.
- Bits 53:50 report the memory type that the logical processor uses to access the VMCS for `VMREAD` and `VMWRITE` and to access the VMCS, data structures referenced by pointers in the VMCS (I/O bitmaps, virtual-APIC page, MSR areas for VMX transitions), and the MSEG header during VM entries, VM exits, and in VMX non-root operation.<sup>3</sup>

The first processors to support VMX operation use the write-back type. The values used are given in Table A-1.

**Table A-1. Memory Types Used For VMCS Access**

Value(s)	Field
0	Uncacheable (UC)
1-5	Not used
6	Write Back (WB)
7-15	Not used

1. Earlier versions of this manual specified that the VMCS revision identifier was a 32-bit field in bits 31:0 of this MSR. For all processors produced prior to this change, bit 31 of this MSR was read as 0.

2. On processors that support Intel 64 architecture, the pointer must not set bits beyond the processor's physical address width.

3. If the MTRRs are disabled by clearing the `E` bit (bit 11) in the `IA32_MTRR_DEF_TYPE` MSR, the logical processor uses the UC memory type to access the indicated data structures, regardless of the value reported in bits 53:50 in the `IA32_VMX_BASIC` MSR. The processor will also use the UC memory type if the setting of `CR0.CD` on this logical processor (or another logical processor on the same physical processor) would cause it to do so for all memory accesses. The values of `IA32_MTRR_DEF_TYPE.E` and `CR0.CD` do not affect the value reported in `IA32_VMX_BASIC[53:50]`.

If software needs to access these data structures (e.g., to modify the contents of the MSR bitmaps), it can configure the paging structures to map them into the linear-address space. If it does so, it should establish mappings that use the memory type reported in this MSR.<sup>1</sup>

- If bit 54 is read as 1, the logical processor reports information in the VM-exit instruction-information field on VM exits due to execution of the INS and OUTS instructions. This reporting is done only if this bit is read as 1.
- Bit 55 is read as 1 if any VMX controls that default to 1 may be cleared to 0. See Appendix A.2 for details. It also reports support for the VMX capability MSRs IA32\_VMX\_TRUE\_PINBASED\_CTLTS, IA32\_VMX\_TRUE\_PROCBASED\_CTLTS, IA32\_VMX\_TRUE\_EXIT\_CTLTS, and IA32\_VMX\_TRUE\_ENTRY\_CTLTS. See Appendix A.3.1, Appendix A.3.2, Appendix A.4, and Appendix A.5 for details.
- The values of bits 47:45 and bits 63:56 are reserved and are read as 0.

## A.2 RESERVED CONTROLS AND DEFAULT SETTINGS

As noted in Chapter 26, “VM Entries”, certain VMX controls are reserved and must be set to a specific value (0 or 1) determined by the processor. The specific value to which a reserved control must be set is its **default setting**. Software can discover the default setting of a reserved control by consulting the appropriate VMX capability MSR (see Appendix A.3 through Appendix A.5).

Future processors may define new functionality for one or more reserved controls. Such processors would allow each newly defined control to be set either to 0 or to 1. Software that does not desire a control’s new functionality should set the control to its default setting. For that reason, it is useful for software to know the default settings of the reserved controls.

Default settings partition the various controls into the following classes:

- **Always-flexible.** These have never been reserved.
- **Default0.** These are (or have been) reserved with a default setting of 0.
- **Default1.** They are (or have been) reserved with a default setting of 1.

As noted in Appendix A.1, a logical processor uses bit 55 of the IA32\_VMX\_BASIC MSR to indicate whether any of the default1 controls may be 0:

- If bit 55 of the IA32\_VMX\_BASIC MSR is read as 0, all the default1 controls are reserved and must be 1. VM entry will fail if any of these controls are 1 (see Section 26.2.1).
- If bit 55 of the IA32\_VMX\_BASIC MSR is read as 1, not all the default1 controls are reserved, and some (but not necessarily all) may be 0. The CPU supports four (4) new VMX capability MSRs: IA32\_VMX\_TRUE\_PINBASED\_CTLTS, IA32\_VMX\_TRUE\_PROCBASED\_CTLTS, IA32\_VMX\_TRUE\_EXIT\_CTLTS, and IA32\_VMX\_TRUE\_ENTRY\_CTLTS. See Appendix A.3 through Appendix A.5 for details. (These MSRs are not supported if bit 55 of the IA32\_VMX\_BASIC MSR is read as 0.)

See Section 31.5.1 for recommended software algorithms for proper capability detection of the default1 controls.

## A.3 VM-EXECUTION CONTROLS

There are separate capability MSRs for the pin-based VM-execution controls, the primary processor-based VM-execution controls, and the secondary processor-based VM-execution controls. These are described in Appendix A.3.1, Appendix A.3.2, and Appendix A.3.3, respectively.

---

1. Alternatively, software may map any of these regions or structures with the UC memory type. (This may be necessary for the MSEG header.) Doing so is discouraged unless necessary as it will cause the performance of software accesses to those structures to suffer. The processor will continue to use the memory type reported in the VMX capability MSR IA32\_VMX\_BASIC with the exceptions noted.

### A.3.1 Pin-Based VM-Execution Controls

The IA32\_VMX\_PINBASED\_CTLMSR (index 481H) reports on the allowed settings of **most** of the pin-based VM-execution controls (see Section 24.6.1):

- Bits 31:0 indicate the **allowed 0-settings** of these controls. VM entry allows control X (bit X of the pin-based VM-execution controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

Exceptions are made for the pin-based VM-execution controls in the default1 class (see Appendix A.2). These are bits 1, 2, and 4; the corresponding bits of the IA32\_VMX\_PINBASED\_CTLMSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32\_VMX\_BASIC MSR:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, VM entry fails if any pin-based VM-execution control in the default1 class is 0.
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_PINBASED\_CTLMSR (see below) reports which of the pin-based VM-execution controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the **allowed 1-settings** of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_PINBASED\_CTLMSR (index 48DH) reports on the allowed settings of **all** of the pin-based VM-execution controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the pin-based VM-execution controls:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, all information about the allowed settings of the pin-based VM-execution controls is contained in the IA32\_VMX\_PINBASED\_CTLMSR. (The IA32\_VMX\_TRUE\_PINBASED\_CTLMSR is not supported.)
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, all information about the allowed settings of the pin-based VM-execution controls is contained in the IA32\_VMX\_TRUE\_PINBASED\_CTLMSR. Assuming that software knows that the default1 class of pin-based VM-execution controls contains bits 1, 2, and 4, there is no need for software to consult the IA32\_VMX\_PINBASED\_CTLMSR.

### A.3.2 Primary Processor-Based VM-Execution Controls

The IA32\_VMX\_PROCBASED\_CTLMSR (index 482H) reports on the allowed settings of **most** of the primary processor-based VM-execution controls (see Section 24.6.2):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the primary processor-based VM-execution controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0.

Exceptions are made for the primary processor-based VM-execution controls in the default1 class (see Appendix A.2). These are bits 1, 4–6, 8, 13–16, and 26; the corresponding bits of the IA32\_VMX\_PROCBASED\_CTLMSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32\_VMX\_BASIC MSR:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, VM entry fails if any of the primary processor-based VM-execution controls in the default1 class is 0.
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_PROCBASED\_CTLMSR (see below) reports which of the primary processor-based VM-execution controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_PROCBASED\_CTLMSR (index 48EH) reports on the allowed settings of **all** of the primary processor-based VM-execution controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the primary processor-based VM-execution controls:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, all information about the allowed settings of the primary processor-based VM-execution controls is contained in the IA32\_VMX\_PROCBASED\_CTLMSR. (The IA32\_VMX\_TRUE\_PROCBASED\_CTLMSR is not supported.)
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, all information about the allowed settings of the processor-based VM-execution controls is contained in the IA32\_VMX\_TRUE\_PROCBASED\_CTLMSR. Assuming that software knows that the default1 class of processor-based VM-execution controls contains bits 1, 4–6, 8, 13–16, and 26, there is no need for software to consult the IA32\_VMX\_PROCBASED\_CTLMSR.

### A.3.3 Secondary Processor-Based VM-Execution Controls

The IA32\_VMX\_PROCBASED\_CTLMSR2 (index 48BH) reports on the allowed settings of the secondary processor-based VM-execution controls (see Section 24.6.2). VM entries perform the following checks:

- Bits 31:0 indicate the allowed 0-settings of these controls. These bits are always 0. This fact indicates that VM entry allows each bit of the secondary processor-based VM-execution controls to be 0 (reserved bits must be 0)
- Bits 63:32 indicate the allowed 1-settings of these controls; the 1-setting is not allowed for any reserved bit. VM entry allows control X (bit X of the secondary processor-based VM-execution controls) to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X and the “activate secondary controls” primary processor-based VM-execution control are both 1.

The IA32\_VMX\_PROCBASED\_CTLMSR2 MSR exists only on processors that support the 1-setting of the “activate secondary controls” VM-execution control (only if bit 63 of the IA32\_VMX\_PROCBASED\_CTLMSR is 1).

## A.4 VM-EXIT CONTROLS

The IA32\_VMX\_EXIT\_CTLMSR (index 483H) reports on the allowed settings of **most** of the VM-exit controls (see Section 24.7.1):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the VM-exit controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. Exceptions are made for the VM-exit controls in the default1 class (see Appendix A.2). These are bits 0–8, 10, 11, 13, 14, 16, and 17; the corresponding bits of the IA32\_VMX\_EXIT\_CTLMSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32\_VMX\_BASIC MSR:
  - If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, VM entry fails if any VM-exit control in the default1 class is 0.
  - If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_EXIT\_CTLMSR (see below) reports which of the VM-exit controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control 32+X to be 1 if bit X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_EXIT\_CTLMSR (index 48FH) reports on the allowed settings of **all** of the VM-exit controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.

- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control X to be 1 if bit 32+X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the VM-exit controls:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, all information about the allowed settings of the VM-exit controls is contained in the IA32\_VMX\_EXIT\_CTLMS MSR. (The IA32\_VMX\_TRUE\_EXIT\_CTLMS MSR is not supported.)
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, all information about the allowed settings of the VM-exit controls is contained in the IA32\_VMX\_TRUE\_EXIT\_CTLMS MSR. Assuming that software knows that the default1 class of VM-exit controls contains bits 0–8, 10, 11, 13, 14, 16, and 17, there is no need for software to consult the IA32\_VMX\_EXIT\_CTLMS MSR.

## A.5 VM-ENTRY CONTROLS

The IA32\_VMX\_ENTRY\_CTLMS MSR (index 484H) reports on the allowed settings of **most** of the VM-entry controls (see Section 24.8.1):

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X (bit X of the VM-entry controls) to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. Exceptions are made for the VM-entry controls in the default1 class (see Appendix A.2). These are bits 0–8 and 12; the corresponding bits of the IA32\_VMX\_ENTRY\_CTLMS MSR are always read as 1. The treatment of these controls by VM entry is determined by bit 55 in the IA32\_VMX\_BASIC MSR:
  - If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, VM entry fails if any VM-entry control in the default1 class is 0.
  - If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_ENTRY\_CTLMS MSR (see below) reports which of the VM-entry controls in the default1 class can be 0 on VM entry.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry fails if bit X is 1 in the VM-entry controls and bit 32+X is 0 in this MSR.

If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, the IA32\_VMX\_TRUE\_ENTRY\_CTLMS MSR (index 490H) reports on the allowed settings of **all** of the VM-entry controls:

- Bits 31:0 indicate the allowed 0-settings of these controls. VM entry allows control X to be 0 if bit X in the MSR is cleared to 0; if bit X in the MSR is set to 1, VM entry fails if control X is 0. There are no exceptions.
- Bits 63:32 indicate the allowed 1-settings of these controls. VM entry allows control 32+X to be 1 if bit X in the MSR is set to 1; if bit 32+X in the MSR is cleared to 0, VM entry fails if control X is 1.

It is necessary for software to consult only one of the capability MSRs to determine the allowed settings of the VM-entry controls:

- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 0, all information about the allowed settings of the VM-entry controls is contained in the IA32\_VMX\_ENTRY\_CTLMS MSR. (The IA32\_VMX\_TRUE\_ENTRY\_CTLMS MSR is not supported.)
- If bit 55 in the IA32\_VMX\_BASIC MSR is read as 1, all information about the allowed settings of the VM-entry controls is contained in the IA32\_VMX\_TRUE\_ENTRY\_CTLMS MSR. Assuming that software knows that the default1 class of VM-entry controls contains bits 0–8 and 12, there is no need for software to consult the IA32\_VMX\_ENTRY\_CTLMS MSR.

## A.6 MISCELLANEOUS DATA

The IA32\_VMX\_MISC MSR (index 485H) consists of the following fields:

- Bits 4:0 report a value X that specifies the relationship between the rate of the VMX-preemption timer and that of the timestamp counter (TSC). Specifically, the VMX-preemption timer (if it is active) counts down by 1 every time bit X in the TSC changes due to a TSC increment.

- If bit 5 is read as 1, VM exits store the value of IA32\_EFER.LMA into the “IA-32e mode guest” VM-entry control; see Section 27.2 for more details. This bit is read as 1 on any logical processor that supports the 1-setting of the “unrestricted guest” VM-execution control.
- Bits 8:6 report, as a bitmap, the activity states supported by the implementation:
  - Bit 6 reports (if set) the support for activity state 1 (HLT).
  - Bit 7 reports (if set) the support for activity state 2 (shutdown).
  - Bit 8 reports (if set) the support for activity state 3 (wait-for-SIPI).
 If an activity state is not supported, the implementation causes a VM entry to fail if it attempts to establish that activity state. All implementations support VM entry to activity state 0 (active).
- If bit 15 is read as 1, the RDMSR instruction can be used in system-management mode (SMM) to read the IA32\_SMBASE MSR (MSR address 9EH). See Section 34.15.6.4.
- Bits 24:16 indicate the number of CR3-target values supported by the processor. This number is a value between 0 and 256, inclusive (bit 24 is set if and only if bits 23:16 are clear).
- Bits 27:25 is used to compute the recommended maximum number of MSRs that should appear in the VM-exit MSR-store list, the VM-exit MSR-load list, or the VM-entry MSR-load list. Specifically, if the value bits 27:25 of IA32\_VMX\_MISC is N, then  $512 * (N + 1)$  is the recommended maximum number of MSRs to be included in each list. If the limit is exceeded, undefined processor behavior may result (including a machine check during the VMX transition).
- If bit 28 is read as 1, bit 2 of the IA32\_SMM\_MONITOR\_CTL can be set to 1. VMXOFF unblocks SMIs unless IA32\_SMM\_MONITOR\_CTL[bit 2] is 1 (see Section 34.14.4).
- If bit 29 is read as 1, software can use VMWRITE to write to any supported field in the VMCS; otherwise, VMWRITE cannot be used to modify VM-exit information fields.
- Bits 63:32 report the 32-bit MSEG revision identifier used by the processor.
- Bits 14:9 and bits 31:30 are reserved and are read as 0.

## A.7 VMX-FIXED BITS IN CR0

The IA32\_VMX\_CR0\_FIXED0 MSR (index 486H) and IA32\_VMX\_CR0\_FIXED1 MSR (index 487H) indicate how bits in CR0 may be set in VMX operation. They report on bits in CR0 that are allowed to be 0 and to be 1, respectively, in VMX operation. If bit X is 1 in IA32\_VMX\_CR0\_FIXED0, then that bit of CR0 is fixed to 1 in VMX operation. Similarly, if bit X is 0 in IA32\_VMX\_CR0\_FIXED1, then that bit of CR0 is fixed to 0 in VMX operation. It is always the case that, if bit X is 1 in IA32\_VMX\_CR0\_FIXED0, then that bit is also 1 in IA32\_VMX\_CR0\_FIXED1; if bit X is 0 in IA32\_VMX\_CR0\_FIXED1, then that bit is also 0 in IA32\_VMX\_CR0\_FIXED0. Thus, each bit in CR0 is either fixed to 0 (with value 0 in both MSRs), fixed to 1 (1 in both MSRs), or flexible (0 in IA32\_VMX\_CR0\_FIXED0 and 1 in IA32\_VMX\_CR0\_FIXED1).

## A.8 VMX-FIXED BITS IN CR4

The IA32\_VMX\_CR4\_FIXED0 MSR (index 488H) and IA32\_VMX\_CR4\_FIXED1 MSR (index 489H) indicate how bits in CR4 may be set in VMX operation. They report on bits in CR4 that are allowed to be 0 and 1, respectively, in VMX operation. If bit X is 1 in IA32\_VMX\_CR4\_FIXED0, then that bit of CR4 is fixed to 1 in VMX operation. Similarly, if bit X is 0 in IA32\_VMX\_CR4\_FIXED1, then that bit of CR4 is fixed to 0 in VMX operation. It is always the case that, if bit X is 1 in IA32\_VMX\_CR4\_FIXED0, then that bit is also 1 in IA32\_VMX\_CR4\_FIXED1; if bit X is 0 in IA32\_VMX\_CR4\_FIXED1, then that bit is also 0 in IA32\_VMX\_CR4\_FIXED0. Thus, each bit in CR4 is either fixed to 0 (with value 0 in both MSRs), fixed to 1 (1 in both MSRs), or flexible (0 in IA32\_VMX\_CR4\_FIXED0 and 1 in IA32\_VMX\_CR4\_FIXED1).

## A.9 VMCS ENUMERATION

The IA32\_VMX\_VMCS\_ENUM MSR (index 48AH) provides information to assist software in enumerating fields in the VMCS.

As noted in Section 24.11.2, each field in the VMCS is associated with a 32-bit encoding which is structured as follows:

- Bits 31:15 are reserved (must be 0).
- Bits 14:13 indicate the field's width.
- Bit 12 is reserved (must be 0).
- Bits 11:10 indicate the field's type.
- Bits 9:1 is an index field that distinguishes different fields with the same width and type.
- Bit 0 indicates access type.

IA32\_VMX\_VMCS\_ENUM indicates to software the highest index value used in the encoding of any field supported by the processor:

- Bits 9:1 contain the highest index value used for any VMCS encoding.
- Bit 0 and bits 63:10 are reserved and are read as 0.

## A.10 VPID AND EPT CAPABILITIES

The IA32\_VMX\_EPT\_VPID\_CAP MSR (index 48CH) reports information about the capabilities of the logical processor with regard to virtual-processor identifiers (VPIDs, Section 28.1) and extended page tables (EPT, Section 28.2):

- If bit 0 is read as 1, the logical processor allows software to configure EPT paging-structure entries in which bits 2:0 have value 100b (indicating an execute-only translation).
- Bit 6 indicates support for a page-walk length of 4.
- If bit 8 is read as 1, the logical processor allows software to configure the EPT paging-structure memory type to be uncacheable (UC); see Section 24.6.11.
- If bit 14 is read as 1, the logical processor allows software to configure the EPT paging-structure memory type to be write-back (WB).
- If bit 16 is read as 1, the logical processor allows software to configure a EPT PDE to map a 2-Mbyte page (by setting bit 7 in the EPT PDE).
- If bit 17 is read as 1, the logical processor allows software to configure a EPT PDPTE to map a 1-Gbyte page (by setting bit 7 in the EPT PDPTE).
- Support for the INVEPT instruction (see Chapter 30 and Section 28.3.3.1).
  - If bit 20 is read as 1, the INVEPT instruction is supported.
  - If bit 25 is read as 1, the single-context INVEPT type is supported.
  - If bit 26 is read as 1, the all-context INVEPT type is supported.
- If bit 21 is read as 1, accessed and dirty flags for EPT are supported (see Section 28.2.4).
- Support for the INVVPID instruction (see Chapter 30 and Section 28.3.3.1).
  - If bit 32 is read as 1, the INVVPID instruction is supported.
  - If bit 40 is read as 1, the individual-address INVVPID type is supported.
  - If bit 41 is read as 1, the single-context INVVPID type is supported.
  - If bit 42 is read as 1, the all-context INVVPID type is supported.
  - If bit 43 is read as 1, the single-context-retaining-globals INVVPID type is supported.
- Bits 5:1, bit 7, bits 13:9, bit 15, bits 19:17, bits 24:21, bits 31:27, bits 39:33, and bits 63:44 are reserved and are read as 0.

The IA32\_VMX\_EPT\_VPID\_CAP MSR exists only on processors that support the 1-setting of the “activate secondary controls” VM-execution control (only if bit 63 of the IA32\_VMX\_PROCBASED\_CTL5 MSR is 1) and that support either the 1-setting of the “enable EPT” VM-execution control (only if bit 33 of the IA32\_VMX\_PROCBASED\_CTL52 MSR is 1) or the 1-setting of the “enable VPID” VM-execution control (only if bit 37 of the IA32\_VMX\_PROCBASED\_CTL52 MSR is 1).

### A.11 VM FUNCTIONS

The IA32\_VMX\_VMFUNC MSR (index 491H) reports on the allowed settings of the VM-function controls (see Section 24.6.14). VM entry allows bit X of the VM-function controls to be 1 if bit X in the MSR is set to 1; if bit X in the MSR is cleared to 0, VM entry fails if bit X of the VM-function controls, the “activate secondary controls” primary processor-based VM-execution control, and the “enable VM functions” secondary processor-based VM-execution control are all 1.

The IA32\_VMX\_VMFUNC MSR exists only on processors that support the 1-setting of the “activate secondary controls” VM-execution control (only if bit 63 of the IA32\_VMX\_PROCBASED\_CTL5 MSR is 1) and the 1-setting of the “enable VM functions” secondary processor-based VM-execution control (only if bit 45 of the IA32\_VMX\_PROCBASED\_CTL52 MSR is 1).

# APPENDIX B

## FIELD ENCODING IN VMCS

Every component of the VMCS is encoded by a 32-bit field that can be used by VMREAD and VMWRITE. Section 24.11.2 describes the structure of the encoding space (the meanings of the bits in each 32-bit encoding).

This appendix enumerates all fields in the VMCS and their encodings. Fields are grouped by width (16-bit, 32-bit, etc.) and type (guest-state, host-state, etc.)

### B.1 16-BIT FIELDS

A value of 0 in bits 14:13 of an encoding indicates a 16-bit field. Only guest-state areas and the host-state area contain 16-bit fields. As noted in Section 24.11.2, each 16-bit field allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

#### B.1.1 16-Bit Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-1 enumerates the 16-bit control fields.

**Table B-1. Encoding for 16-Bit Control Fields (0000\_00xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Virtual-processor identifier (VPID) <sup>1</sup>	000000000B	00000000H
Posted-interrupt notification vector <sup>2</sup>	000000001B	00000002H
EPTP index <sup>3</sup>	000000010B	00000004H

#### NOTES:

1. This field exists only on processors that support the 1-setting of the "enable VPID" VM-execution control.
2. This field exists only on processors that support the 1-setting of the "process posted interrupts" VM-execution control.
3. This field exists only on processors that support the 1-setting of the "EPT-violation #VE" VM-execution control.

#### B.1.2 16-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-2 enumerates 16-bit guest-state fields.

**Table B-2. Encodings for 16-Bit Guest-State Fields (0000\_10xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Guest ES selector	000000000B	00000800H
Guest CS selector	000000001B	00000802H
Guest SS selector	0000000010B	00000804H
Guest DS selector	0000000011B	00000806H
Guest FS selector	000000100B	00000808H
Guest GS selector	000000101B	0000080AH
Guest LDTR selector	000000110B	0000080CH
Guest TR selector	000000111B	0000080EH

**Table B-2. Encodings for 16-Bit Guest-State Fields (0000\_10xx\_xxxx\_xxx0B) (Contd.)**

Field Name	Index	Encoding
Guest interrupt status <sup>1</sup>	000001000B	00000810H

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “virtual-interrupt delivery” VM-execution control.

**B.1.3 16-Bit Host-State Fields**

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-3 enumerates the 16-bit host-state fields.

**Table B-3. Encodings for 16-Bit Host-State Fields (0000\_11xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Host ES selector	000000000B	00000C00H
Host CS selector	000000001B	00000C02H
Host SS selector	000000010B	00000C04H
Host DS selector	000000011B	00000C06H
Host FS selector	000000100B	00000C08H
Host GS selector	000000101B	00000C0AH
Host TR selector	000000110B	00000C0CH

**B.2 64-BIT FIELDS**

A value of 1 in bits 14:13 of an encoding indicates a 64-bit field. There are 64-bit fields only for controls and for guest state. As noted in Section 24.11.2, every 64-bit field has two encodings, which differ on bit 0, the access type. Thus, each such field has an even encoding for full access and an odd encoding for high access.

**B.2.1 64-Bit Control Fields**

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-4 enumerates the 64-bit control fields.

**Table B-4. Encodings for 64-Bit Control Fields (0010\_00xx\_xxxx\_xxxAb)**

Field Name	Index	Encoding
Address of I/O bitmap A (full)	000000000B	00002000H
Address of I/O bitmap A (high)		00002001H
Address of I/O bitmap B (full)	000000001B	00002002H

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “use MSR bitmaps” VM-execution control.
2. This field exists only on processors that support either the 1-setting of the “use TPR shadow” VM-execution control.
3. This field exists only on processors that support the 1-setting of the “virtualize APIC accesses” VM-execution control.
4. This field exists only on processors that support the 1-setting of the “process posted interrupts” VM-execution control.
5. This field exists only on processors that support the 1-setting of the “enable VM functions” VM-execution control.
6. This field exists only on processors that support the 1-setting of the “enable EPT” VM-execution control.

7. This field exists only on processors that support the 1-setting of the “virtual-interrupt delivery” VM-execution control.
8. This field exists only on processors that support the 1-setting of the “EPTP switching” VM-function control.
9. This field exists only on processors that support the 1-setting of the “VMCS shadowing” VM-execution control.
10. This field exists only on processors that support the 1-setting of the “EPT-violation #VE” VM-execution control.

## B.2.2 64-Bit Read-Only Data Field

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. There is only one such 64-bit field as given in Table B-5. (As with other 64-bit fields, this one has two encodings.)

**Table B-5. Encodings for 64-Bit Read-Only Data Field (0010\_01xx\_xxxx\_xxxAb)**

Field Name	Index	Encoding
Guest-physical address (full) <sup>1</sup>	000000000B	00002400H
Guest-physical address (high) <sup>1</sup>		00002401H

### NOTES:

1. This field exists only on processors that support the 1-setting of the “enable EPT” VM-execution control.

## B.2.3 64-Bit Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-6 enumerates the 64-bit guest-state fields.

**Table B-6. Encodings for 64-Bit Guest-State Fields (0010\_10xx\_xxxx\_xxxAb)**

Field Name	Index	Encoding
VMCS link pointer (full)	000000000B	00002800H

**NOTES:**

1. This field exists only on processors that support either the 1-setting of the “load IA32\_PAT” VM-entry control or that of the “save IA32\_PAT” VM-exit control.
2. This field exists only on processors that support either the 1-setting of the “load IA32\_EFER” VM-entry control or that of the “save IA32\_EFER” VM-exit control.
3. This field exists only on processors that support the 1-setting of the “load IA32\_PERF\_GLOBAL\_CTRL” VM-entry control.
4. This field exists only on processors that support the 1-setting of the “enable EPT” VM-execution control.

**B.2.4 64-Bit Host-State Fields**

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-7 enumerates the 64-bit control fields.

**Table B-7. Encodings for 64-Bit Host-State Fields (0010\_11xx\_xxxx\_xxxAb)**

Field Name	Index	Encoding

Host IA32_PERF_GLOBAL_CTRL (high) <sup>3</sup>		00002C05H

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “load IA32\_PAT” VM-exit control.
2. This field exists only on processors that support the 1-setting of the “load IA32\_EFER” VM-exit control.
3. This field exists only on processors that support the 1-setting of the “load IA32\_PERF\_GLOBAL\_CTRL” VM-exit control.

**B.3 32-BIT FIELDS**

A value of 2 in bits 14:13 of an encoding indicates a 32-bit field. As noted in Section 24.11.2, each 32-bit field allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

**B.3.1 32-Bit Control Fields**

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-8 enumerates the 32-bit control fields.

**Table B-8. Encodings for 32-Bit Control Fields (0100\_00xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Pin-based VM-execution controls	000000000B	00004000H

PLE_Window <sup>3</sup>	000010001b	00004022H

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “use TPR shadow” VM-execution control.
2. This field exists only on processors that support the 1-setting of the “activate secondary controls” VM-execution control.
3. This field exists only on processors that support the 1-setting of the “PAUSE-loop exiting” VM-execution control.

**B.3.2 32-Bit Read-Only Data Fields**

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. Table B-9 enumerates the 32-bit read-only data fields.

**Table B-9. Encodings for 32-Bit Read-Only Data Fields (0100\_01xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
VM-instruction error	000000000B	00004400H
Exit reason	000000001B	00004402H

VM-exit interruption error code	000000011B	00004406H
IDT-vectoring information field	000000100B	00004408H
IDT-vectoring error code	000000101B	0000440AH
VM-exit instruction length	000000110B	0000440CH
VM-exit instruction information	000000111B	0000440EH

**B.3.3 32-Bit Guest-State Fields**

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-10 enumerates the 32-bit guest-state fields.

**Table B-10. Encodings for 32-Bit Guest-State Fields (0100\_10xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Guest ES limit	000000000B	00004800H
Guest CS limit	000000001B	00004802H

**Table B-10. Encodings for 32-Bit Guest-State Fields  
(0100\_10xx\_xxxx\_xxx0B) (Contd.)**

Field Name	Index	Encoding
Guest SS limit	000000010B	00004804H
Guest DS limit	000000011B	00004806H
Guest FS limit	000000100B	00004808H
Guest GS limit	000000101B	0000480AH
Guest LDTR limit	000000110B	0000480CH
Guest TR limit	000000111B	0000480EH
Guest GDTR limit	000001000B	00004810H
Guest IDTR limit	000001001B	00004812H
Guest ES access rights	000001010B	00004814H
Guest CS access rights	000001011B	00004816H
Guest SS access rights	000001100B	00004818H
Guest DS access rights	000001101B	0000481AH
Guest FS access rights	000001110B	0000481CH
Guest GS access rights	000001111B	0000481EH
Guest LDTR access rights	000010000B	00004820H
Guest TR access rights	000010001B	00004822H
Guest interruptibility state	000010010B	00004824H
Guest activity state	000010011B	00004826H
Guest SMBASE	000010100B	00004828H
Guest IA32_SYSENTER_CS	000010101B	0000482AH
VMX-preemption timer value <sup>1</sup>	000010111B	0000482EH

**NOTES:**

1. This field exists only on processors that support the 1-setting of the “activate VMX-preemption timer” VM-execution control.

The limit fields for GDTR and IDTR are defined to be 32 bits in width even though these fields are only 16-bits wide in the Intel 64 and IA-32 architectures. VM entry ensures that the high 16 bits of both these fields are cleared to 0.

### B.3.4 32-Bit Host-State Field

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. There is only one such 32-bit field as given in Table B-11.

**Table B-11. Encoding for 32-Bit Host-State Field (0100\_11xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Host IA32_SYSENTER_CS	000000000B	00004C00H

## B.4 NATURAL-WIDTH FIELDS

A value of 3 in bits 14:13 of an encoding indicates a natural-width field. As noted in Section 24.11.2, each of these fields allows only full access, meaning that bit 0 of its encoding is 0. Each such encoding is thus an even number.

## B.4.1 Natural-Width Control Fields

A value of 0 in bits 11:10 of an encoding indicates a control field. These fields are distinguished by their index value in bits 9:1. Table B-12 enumerates the natural-width control fields.

**Table B-12. Encodings for Natural-Width Control Fields (0110\_00xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
CR0 guest/host mask	000000000B	00006000H
CR4 guest/host mask	000000001B	00006002H
CR0 read shadow	000000010B	00006004H
CR4 read shadow	000000011B	00006006H
CR3-target value 0	000000100B	00006008H
CR3-target value 1	000000101B	0000600AH
CR3-target value 2	000000110B	0000600CH
CR3-target value 3 <sup>1</sup>	000000111B	0000600EH

### NOTES:

1. If a future implementation supports more than 4 CR3-target values, they will be encoded consecutively following the 4 encodings given here.

## B.4.2 Natural-Width Read-Only Data Fields

A value of 1 in bits 11:10 of an encoding indicates a read-only data field. These fields are distinguished by their index value in bits 9:1. Table B-13 enumerates the natural-width read-only data fields.

**Table B-13. Encodings for Natural-Width Read-Only Data Fields (0110\_01xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Exit qualification	000000000B	00006400H
I/O RCX	000000001B	00006402H
I/O RSI	000000010B	00006404H
I/O RDI	000000011B	00006406H
I/O RIP	000000100B	00006408H
Guest-linear address	000000101B	0000640AH

## B.4.3 Natural-Width Guest-State Fields

A value of 2 in bits 11:10 of an encoding indicates a field in the guest-state area. These fields are distinguished by their index value in bits 9:1. Table B-14 enumerates the natural-width guest-state fields.

**Table B-14. Encodings for Natural-Width Guest-State Fields (0110\_10xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Guest CR0	000000000B	00006800H
Guest CR3	000000001B	00006802H
Guest CR4	000000010B	00006804H
Guest ES base	000000011B	00006806H
Guest CS base	000000100B	00006808H

**Table B-14. Encodings for Natural-Width Guest-State Fields (0110\_10xx\_xxxx\_xxx0B) (Contd.)**

Field Name	Index	Encoding
Guest SS base	000000101B	0000680AH
Guest DS base	000000110B	0000680CH
Guest FS base	000000111B	0000680EH
Guest GS base	000001000B	00006810H
Guest LDTR base	000001001B	00006812H
Guest TR base	000001010B	00006814H
Guest GDTR base	000001011B	00006816H
Guest IDTR base	000001100B	00006818H
Guest DR7	000001101B	0000681AH
Guest RSP	000001110B	0000681CH
Guest RIP	000001111B	0000681EH
Guest RFLAGS	000010000B	00006820H
Guest pending debug exceptions	000010001B	00006822H
Guest IA32_SYSENTER_ESP	000010010B	00006824H
Guest IA32_SYSENTER_EIP	000010011B	00006826H

The base-address fields for ES, CS, SS, and DS in the guest-state area are defined to be natural-width (with 64 bits on processors supporting Intel 64 architecture) even though these fields are only 32-bits wide in the Intel 64 architecture. VM entry ensures that the high 32 bits of these fields are cleared to 0.

#### B.4.4 Natural-Width Host-State Fields

A value of 3 in bits 11:10 of an encoding indicates a field in the host-state area. These fields are distinguished by their index value in bits 9:1. Table B-15 enumerates the natural-width host-state fields.

**Table B-15. Encodings for Natural-Width Host-State Fields (0110\_11xx\_xxxx\_xxx0B)**

Field Name	Index	Encoding
Host CR0	00000000B	00006C00H
Host CR3	00000001B	00006C02H
Host CR4	000000010B	00006C04H
Host FS base	000000011B	00006C06H
Host GS base	000000100B	00006C08H
Host TR base	000000101B	00006C0AH
Host GDTR base	000000110B	00006C0CH
Host IDTR base	000000111B	00006C0EH
Host IA32_SYSENTER_ESP	000001000B	00006C10H
Host IA32_SYSENTER_EIP	000001001B	00006C12H
Host RSP	000001010B	00006C14H
Host RIP	000001011B	00006C16H

## APPENDIX C VMX BASIC EXIT REASONS

Every VM exit writes a 32-bit exit reason to the VMCS (see Section 24.9.1). Certain VM-entry failures also do this (see Section 26.7). The low 16 bits of the exit-reason field form the basic exit reason which provides basic information about the cause of the VM exit or VM-entry failure.

Table C-1 lists values for basic exit reasons and explains their meaning. Entries apply to VM exits, unless otherwise noted.

**Table C-1. Basic Exit Reasons**

Basic Exit Reason	Description
0	<b>Exception or non-maskable interrupt (NMI).</b> Either: 1: Guest software caused an exception and the bit in the exception bitmap associated with exception's vector was 1. 2: An NMI was delivered to the logical processor and the "NMI exiting" VM-execution control was 1. This case includes executions of BOUND that cause #BR, executions of INT3 (they cause #BP), executions of INTO that cause #OF, and executions of UD2 (they cause #UD).
1	<b>External interrupt.</b> An external interrupt arrived and the "external-interrupt exiting" VM-execution control was 1.
2	<b>Triple fault.</b> The logical processor encountered an exception while attempting to call the double-fault handler and that exception did not itself cause a VM exit due to the exception bitmap.
3	<b>INIT signal.</b> An INIT signal arrived
4	<b>Start-up IPI (SIPI).</b> A SIPI arrived while the logical processor was in the "wait-for-SIPI" state.
5	<b>I/O system-management interrupt (SMI).</b> An SMI arrived immediately after retirement of an I/O instruction and caused an SMM VM exit (see Section 34.15.2).
6	<b>Other SMI.</b> An SMI arrived and caused an SMM VM exit (see Section 34.15.2) but not immediately after retirement of an I/O instruction.
7	<b>Interrupt window.</b> At the beginning of an instruction, RFLAGS.IF was 1; events were not blocked by STI or by MOV SS; and the "interrupt-window exiting" VM-execution control was 1.
8	<b>NMI window.</b> At the beginning of an instruction, there was no virtual-NMI blocking; events were not blocked by MOV SS; and the "NMI-window exiting" VM-execution control was 1.
9	<b>Task switch.</b> Guest software attempted a task switch.
10	<b>CPUID.</b> Guest software attempted to execute CPUID.
11	<b>GETSEC.</b> Guest software attempted to execute GETSEC.
12	<b>HLT.</b> Guest software attempted to execute HLT and the "HLT exiting" VM-execution control was 1.
13	<b>INVD.</b> Guest software attempted to execute INVD.
14	<b>INVLPG.</b> Guest software attempted to execute INVLPG and the "INVLPG exiting" VM-execution control was 1.
15	<b>RDPMC.</b> Guest software attempted to execute RDPMC and the "RDPMC exiting" VM-execution control was 1.
16	<b>RDTSC.</b> Guest software attempted to execute RDTSC and the "RDTSC exiting" VM-execution control was 1.
17	<b>RSM.</b> Guest software attempted to execute RSM in SMM.
18	<b>VMCALL.</b> VMCALL was executed either by guest software (causing an ordinary VM exit) or by the executive monitor (causing an SMM VM exit; see Section 34.15.2).
19	<b>VMCLEAR.</b> Guest software attempted to execute VMCLEAR.
20	<b>VMLAUNCH.</b> Guest software attempted to execute VMLAUNCH.
21	<b>VMPTRLD.</b> Guest software attempted to execute VMPTRLD.
22	<b>VMPTRST.</b> Guest software attempted to execute VMPTRST.
23	<b>VMREAD.</b> Guest software attempted to execute VMREAD.

**Table C-1. Basic Exit Reasons (Contd.)**

Basic Exit Reason	Description
24	<b>VMRESUME.</b> Guest software attempted to execute VMRESUME.
25	<b>VMWRITE.</b> Guest software attempted to execute VMWRITE.
26	<b>VMXOFF.</b> Guest software attempted to execute VMXOFF.
27	<b>VMXON.</b> Guest software attempted to execute VMXON.
28	<b>Control-register accesses.</b> Guest software attempted to access CR0, CR3, CR4, or CR8 using CLTS, LMSW, or MOV CR and the VM-execution control fields indicate that a VM exit should occur (see Section 25.1 for details). This basic exit reason is not used for trap-like VM exits following executions of the MOV to CR8 instruction when the “use TPR shadow” VM-execution control is 1.
29	<b>MOV DR.</b> Guest software attempted a MOV to or from a debug register and the “MOV-DR exiting” VM-execution control was 1.
30	<b>I/O instruction.</b> Guest software attempted to execute an I/O instruction and either: 1: The “use I/O bitmaps” VM-execution control was 0 and the “unconditional I/O exiting” VM-execution control was 1. 2: The “use I/O bitmaps” VM-execution control was 1 and a bit in the I/O bitmap associated with one of the ports accessed by the I/O instruction was 1.
31	<b>RDMSR.</b> Guest software attempted to execute RDMSR and either: 1: The “use MSR bitmaps” VM-execution control was 0. 2: The value of RCX is neither in the range 00000000H - 00001FFFH nor in the range C0000000H - C0001FFFH. 3: The value of RCX was in the range 00000000H - 00001FFFH and the $n^{\text{th}}$ bit in read bitmap for low MSRs is 1, where $n$ was the value of RCX. 4: The value of RCX is in the range C0000000H - C0001FFFH and the $n^{\text{th}}$ bit in read bitmap for high MSRs is 1, where $n$ is the value of RCX & 00001FFFH.
32	<b>WRMSR.</b> Guest software attempted to execute WRMSR and either: 1: The “use MSR bitmaps” VM-execution control was 0. 2: The value of RCX is neither in the range 00000000H - 00001FFFH nor in the range C0000000H - C0001FFFH. 3: The value of RCX was in the range 00000000H - 00001FFFH and the $n^{\text{th}}$ bit in write bitmap for low MSRs is 1, where $n$ was the value of RCX. 4: The value of RCX is in the range C0000000H - C0001FFFH and the $n^{\text{th}}$ bit in write bitmap for high MSRs is 1, where $n$ is the value of RCX & 00001FFFH.
33	<b>VM-entry failure due to invalid guest state.</b> A VM entry failed one of the checks identified in Section 26.3.1.
34	<b>VM-entry failure due to MSR loading.</b> A VM entry failed in an attempt to load MSRs. See Section 26.4.
36	<b>MWAIT.</b> Guest software attempted to execute MWAIT and the “MWAIT exiting” VM-execution control was 1.
37	<b>Monitor trap flag.</b> A VM entry occurred due to the 1-setting of the “monitor trap flag” VM-execution control and injection of an MTF VM exit as part of VM entry. See Section 25.5.2.
39	<b>MONITOR.</b> Guest software attempted to execute MONITOR and the “MONITOR exiting” VM-execution control was 1.
40	<b>PAUSE.</b> Either guest software attempted to execute PAUSE and the “PAUSE exiting” VM-execution control was 1 or the “PAUSE-loop exiting” VM-execution control was 1 and guest software executed a PAUSE loop with execution time exceeding PLE_Window (see Section 25.1.3).
41	<b>VM-entry failure due to machine-check event.</b> A machine-check event occurred during VM entry (see Section 26.8).
43	<b>TPR below threshold.</b> The logical processor determined that the value of bits 7:4 of the byte at offset 080H on the virtual-APIC page was below that of the TPR threshold VM-execution control field while the “use TPR shadow” VM-execution control was 1 either as part of TPR virtualization (Section 29.1.2) or VM entry (Section 26.6.7).
44	<b>APIC access.</b> Guest software attempted to access memory at a physical address on the APIC-access page and the “virtualize APIC accesses” VM-execution control was 1 (see Section 29.4).
45	<b>Virtualized EOI.</b> EOI virtualization was performed for a virtual interrupt whose vector indexed a bit set in the EOI-exit bitmap.

Table C-1. Basic Exit Reasons (Contd.)

Basic Exit Reason	Description
46	<b>Access to GDTR or IDTR.</b> Guest software attempted to execute LGDT, LIDT, SGDT, or SIDT and the “descriptor-table exiting” VM-execution control was 1.
47	<b>Access to LDTR or TR.</b> Guest software attempted to execute LLDT, LTR, SLDT, or STR and the “descriptor-table exiting” VM-execution control was 1.
48	<b>EPT violation.</b> An attempt to access memory with a guest-physical address was disallowed by the configuration of the EPT paging structures.
49	<b>EPT misconfiguration.</b> An attempt to access memory with a guest-physical address encountered a misconfigured EPT paging-structure entry.
50	<b>INVEPT.</b> Guest software attempted to execute INVEPT.
51	<b>RDTSCP.</b> Guest software attempted to execute RDTSCP and the “enable RDTSCP” and “RDTSC exiting” VM-execution controls were both 1.
52	<b>VMX-preemption timer expired.</b> The preemption timer counted down to zero.
53	<b>INNVPID.</b> Guest software attempted to execute INNVPID.
54	<b>WBINVD.</b> Guest software attempted to execute WBINVD and the “WBINVD exiting” VM-execution control was 1.
55	<b>XSETBV.</b> Guest software attempted to execute XSETBV.
56	<b>APIC write.</b> Guest software completed a write to the virtual-APIC page that must be virtualized by VMM software (see Section 29.4.3.3).
57	<b>RDRAND.</b> Guest software attempted to execute RDRAND and the “RDRAND exiting” VM-execution control was 1.
58	<b>INVPCID.</b> Guest software attempted to execute INVPCID and the “enable INVPCID” and “INVLPG exiting” VM-execution controls were both 1.
59	<b>VMFUNC.</b> Guest software invoked a VM function with the VMFUNC instruction and the VM function either was not enabled or generated a function-specific condition causing a VM exit.

## Numerics

- 0000, Vol.2-B-41
- 128-bit
  - packed byte integers data type, Vol.1-4-9, Vol.1-11-4
  - packed double-precision floating-point data type, Vol.1-4-9, Vol.1-11-4
  - packed doubleword integers data type, Vol.1-4-9
  - packed quadword integers data type, Vol.1-4-9
  - packed SIMD data types, Vol.1-4-8
  - packed single-precision floating-point data type, Vol.1-4-9, Vol.1-10-5
  - packed word integers data type, Vol.1-4-9, Vol.1-11-4
- 16-bit
  - address size, Vol.1-3-8
  - operand size, Vol.1-3-8
- 16-bit code, mixing with 32-bit code, Vol.3-21-1
- 286 processor, Vol.1-2-1
- 32-bit
  - address size, Vol.1-3-8
  - operand size, Vol.1-3-8
- 32-bit code, mixing with 16-bit code, Vol.3-21-1
- 32-bit physical addressing
  - overview, Vol.3-3-6
- 36-bit physical addressing
  - overview, Vol.3-3-6
- 64-bit
  - packed byte integers data type, Vol.1-4-8, Vol.1-9-3
  - packed doubleword integers data type, Vol.1-4-8
  - packed doubleword integers data types, Vol.1-9-3
  - packed word integers data type, Vol.1-4-8, Vol.1-9-3
- 64-bit mode
  - sub-mode of IA-32e, Vol.1-3-1
  - address calculation, Vol.1-3-9
  - address size, Vol.1-3-18
  - address space, Vol.1-3-4
  - BOUND instruction, Vol.1-7-18
  - branch behavior, Vol.1-6-8
  - byte register limitation, Vol.1-3-12
  - call gates, Vol.3-5-14
  - CALL instruction, Vol.1-6-8, Vol.1-7-17
  - canonical address, Vol.1-3-9
  - CMPS instruction, Vol.1-7-20
  - CMPXCHG16B instruction, Vol.1-7-5
  - code segment descriptors, Vol.3-5-3, Vol.3-9-11
  - control and debug registers, Vol.2-2-11
  - control registers, Vol.3-2-13
  - CR8 register, Vol.3-2-13
  - D flag, Vol.3-5-4
  - data types, Vol.1-7-2
  - debug registers, Vol.3-2-7
  - DEC instruction, Vol.1-7-8
  - decimal arithmetic instructions, Vol.1-7-10
  - default operand and address sizes, Vol.1-3-2
  - default operand size, Vol.2-2-11
  - descriptors, Vol.3-5-3, Vol.3-5-5
  - direct memory-offset MOVs, Vol.2-2-10
  - DPL field, Vol.3-5-4
  - exception handling, Vol.3-6-16
  - exceptions, Vol.1-6-13
  - external interrupts, Vol.3-10-31
  - far pointer, Vol.1-4-7
  - fast system calls, Vol.3-5-22

 BLSMSK - Get Mask Up to Lowest Set Bit, Vol.2-3-76  
 bootstrap processor, Vol.2-5-15, Vol.2-5-20, Vol.2-5-27, Vol.2-5-29  
 BOUND instruction, Vol.1-6-12, Vol.1-7-18, Vol.1-7-23, Vol.2-3-78,  
   Vol.2-4-425, Vol.3-2-5, Vol.3-6-4, Vol.3-6-25  
 BOUND range exceeded exception (#BR), Vol.1-6-13, Vol.2-3-78,  
   Vol.2-4-425, Vol.3-6-25  
 BP register, Vol.1-3-11  
 BP0#, BP1#, BP2#, and BP3# pins, Vol.3-17-32, Vol.3-17-34  
 Branch  
   control transfer instructions, Vol.1-7-14  
   hints, Vol.1-11-13  
   on EFLAGS register status flags, Vol.1-7-15, Vol.1-8-6  
   on x87 FPU condition codes, Vol.1-8-6, Vol.1-8-19  
   prediction, Vol.1-2-7  
 Branch hints, Vol.2-2-2  
 Branch record  
   branch trace message, Vol.3-17-12  
   IA-32e mode, Vol.3-17-18  
   saving, Vol.3-17-13, Vol.3-17-22, Vol.3-17-29  
   saving as a branch trace message, Vol.3-17-12  
   structure, Vol.3-17-29  
   structure of in BTS buffer, Vol.3-17-17  
 Branch trace message (see BTM)  
 Branch trace store (see BTS)  
 Brand information, Vol.2-3-177  
   processor brand index, Vol.2-3-179  
   processor brand string, Vol.2-3-177  
 Breakpoint exception (#BP), Vol.3-6-4, Vol.3-6-23, Vol.3-17-9  
 Breakpoints  
   data breakpoint, Vol.3-17-5  
   data breakpoint exception conditions, Vol.3-17-8

  description of, Vol.3-17-1  
 DR0-DR3 debug registers, Vol.3-17-3  
 example, Vol.3-17-5  
 exception, Vol.3-6-23  
 field recognition, Vol.3-17-5, Vol.3-17-6  
 general-detect exception condition, Vol.3-17-9  
 instruction breakpoint, Vol.3-17-5  
 instruction breakpoint exception condition, Vol.3-17-7  
 I/O breakpoint exception conditions, Vol.3-17-8  
 LENO - LEN3 (Length) fields  
   DR7 register, Vol.3-17-5  
 R/W0-R/W3 (read/write) fields  
   DR7 register, Vol.3-17-4  
   single-step exception condition, Vol.3-17-9  
   task-switch exception condition, Vol.3-17-9  
 BS (single step) flag, DR6 register, Vol.3-17-3  
 BSF instruction, Vol.1-7-14, Vol.2-3-80  
 BSP flag, IA32\_APIC\_BASE MSR, Vol.3-10-8  
 BSR instruction, Vol.1-7-14, Vol.2-3-82  
 BSWAP instruction, Vol.1-7-4, Vol.2-3-84, Vol.3-22-4  
 BT instruction, Vol.1-3-14, Vol.1-3-15, Vol.1-7-14, Vol.2-3-85  
 BT (task switch) flag, DR6 register, Vol.3-17-3, Vol.3-17-9  
 BTC instruction, Vol.1-3-14, Vol.1-3-15, Vol.1-7-14, Vol.2-3-87,  
   Vol.2-3-465, Vol.3-8-3  
 BTF (single-step on branches) flag  
   DEBUGCTLMR MSR, Vol.3-17-34  
 BTMs (branch trace messages)  
   description of, Vol.3-17-12  
   enabling, Vol.3-17-10, Vol.3-17-20, Vol.3-17-21, Vol.3-17-28,  
     Vol.3-17-31, Vol.3-17-32  
   TR (trace message enable) flag  
     MSR\_DEBUGCTLA MSR, Vol.3-17-28  
     MSR\_DEBUGCTLB MSR, Vol.3-17-10, Vol.3-17-31, Vol.3-17-32  
 BTR instruction, Vol.1-3-14, Vol.1-3-15, Vol.1-7-14, Vol.2-3-89,  
   Vol.2-3-465, Vol.3-8-3  
 BTS buffer  
   description of, Vol.3-17-15  
   introduction to, Vol.3-17-10, Vol.3-17-12  
   records in, Vol.3-17-17  
   setting up, Vol.3-17-20  
   structure of, Vol.3-17-16, Vol.3-17-18, Vol.3-18-27  
 BTS instruction, Vol.1-3-14, Vol.1-3-15, Vol.1-7-14, Vol.2-3-91,  
   Vol.2-3-465, Vol.3-8-3  
 BTS (branch trace store) facilities  
   availability of, Vol.3-17-27  
   BTS\_UNAVAILABLE flag,  
     IA32\_MISC\_ENABLE MSR, Vol.3-17-15, Vol.1-35-151  
   introduction to, Vol.3-17-10

   cache management instructions, Vol.3-11-17, Vol.3-11-18

## INDEX

- cache mechanisms in IA-32 processors, Vol.3-22-29
  - caching terminology, Vol.3-11-5
  - CD flag, CR0 control register, Vol.3-11-10, Vol.3-22-18
  - choosing a memory type, Vol.3-11-8
  - CPUID feature flag, Vol.3-11-18
  - flags and fields, Vol.3-11-10
  - flushing TLBs, Vol.3-11-19
  - G (global) flag
    - page-directory entries, Vol.3-11-13
    - page-table entries, Vol.3-11-13
  - internal caches, Vol.3-11-1
  - MemTypeGet() function, Vol.3-11-29
  - MemTypeSet() function, Vol.3-11-31
  - MESI protocol, Vol.3-11-5, Vol.3-11-9
  - methods of caching available, Vol.3-11-6
  - MTRR initialization, Vol.3-11-29
  - MTRR precedences, Vol.3-11-28
  - MTRRs, description of, Vol.3-11-20
  - multiple-processor considerations, Vol.3-11-32
  - NW flag, CR0 control register, Vol.3-11-13, Vol.3-22-18
  - operating modes, Vol.3-11-12
  - overview of, Vol.3-11-1
  - page attribute table (PAT), Vol.3-11-33
  - PCD flag
    - CR3 control register, Vol.3-11-13
    - page-directory entries, Vol.3-11-13, Vol.3-11-33
    - page-table entries, Vol.3-11-13, Vol.3-11-33
  - PGE (page global enable) flag, CR4 control register, Vol.3-11-13
  - precedence of controls, Vol.3-11-13
  - preventing caching, Vol.3-11-16
  - protocol, Vol.3-11-9
  - PWT flag
    - CR3 control register, Vol.3-11-13
    - page-directory entries, Vol.3-11-33
    - page-table entries, Vol.3-11-33
  - remapping memory types, Vol.3-11-29
  - setting up memory ranges with MTRRs, Vol.3-11-22
  - shared mode, L1 Data Cache, Vol.3-11-18
  - variable-range MTRRs, Vol.3-11-23, Vol.3-11-25
- Cache Inclusiveness, Vol.2-3-159
- Caches, Vol.3-2-7
- cache hit, Vol.3-11-5
  - cache line, Vol.3-11-5
  - cache line fill, Vol.3-11-5
  - cache write hit, Vol.3-11-5
  - description of, Vol.3-11-1
  - effects of a locked operation on internal processor caches, Vol.3-8-5
  - enabling, Vol.3-9-7
  - management, instructions, Vol.3-2-22, Vol.3-11-17
- Caches, invalidating (flushing), Vol.2-3-413, Vol.2-4-548
- cache, smart, Vol.1-2-4
- Caching
- cache control protocol, Vol.3-11-9
  - cache line, Vol.3-11-5
  - cache management instructions, Vol.3-11-17
  - cache mechanisms in IA-32 processors, Vol.3-22-29
  - caching terminology, Vol.3-11-5
  - choosing a memory type, Vol.3-11-8
  - flushing TLBs, Vol.3-11-19
  - implicit caching, Vol.3-11-19
  - internal caches, Vol.3-11-1
  - L1 (level 1) cache, Vol.3-11-4
  - L2 (level 2) cache, Vol.3-11-4
  - L3 (level 3) cache, Vol.3-11-4
  - methods of caching available, Vol.3-11-6
  - MTRRs, description of, Vol.3-11-20
  - operating modes, Vol.3-11-12
  - overview of, Vol.3-11-1
  - self-modifying code, effect on, Vol.3-11-18, Vol.3-22-29
  - snooping, Vol.3-11-6
  - store buffer, Vol.3-11-20
  - TLBs, Vol.3-11-5
- UC (strong uncacheable) memory type, Vol.3-11-6
  - UC- (uncacheable) memory type, Vol.3-11-6
  - WB (write back) memory type, Vol.3-11-7
  - WC (write combining) memory type, Vol.3-11-7
  - WP (write protected) memory type, Vol.3-11-7
  - write-back caching, Vol.3-11-6
  - WT (write through) memory type, Vol.3-11-7
- Call gate, Vol.1-6-6
- Call gates
- 16-bit, interlevel return from, Vol.3-22-32
  - accessing a code segment through, Vol.3-5-15
  - description of, Vol.3-5-13
  - for 16-bit and 32-bit code modules, Vol.3-21-1
  - IA-32e mode, Vol.3-5-14
  - introduction to, Vol.3-2-4
  - mechanism, Vol.3-5-15
  - privilege level checking rules, Vol.3-5-16
- CALL instruction, Vol.1-3-17, Vol.1-6-3, Vol.1-6-4, Vol.1-6-7, Vol.1-7-15, Vol.1-7-22, Vol.2-3-95, Vol.3-2-5, Vol.3-3-9, Vol.3-5-10, Vol.3-5-15, Vol.3-5-20, Vol.3-7-2, Vol.3-7-9, Vol.3-7-10, Vol.3-21-5
- Caller access privileges, checking, Vol.3-5-26
- Calls
- 16 and 32-bit code segments, Vol.3-21-3
  - controlling operand-size attribute, Vol.3-21-5
  - returning from, Vol.3-5-20
- Calls (see Procedure calls)
- Canonical address, Vol.1-3-9
- GETSEC, Vol.2-5-2
- Capability MSRs
- See VMX capability MSRs
- Catastrophic shutdown detector
- Thermal monitoring
    - catastrophic shutdown detector, Vol.3-14-8
- catastrophic shutdown detector, Vol.3-14-7
- CBW instruction, Vol.1-7-7, Vol.2-3-108
- CC0 and CC1 (counter control) fields, CESR MSR (Pentium processor), Vol.3-18-95
- CD (cache disable) flag, CR0 control register, Vol.3-2-14, Vol.3-9-7, Vol.3-11-10, Vol.3-11-12, Vol.3-11-13, Vol.3-11-16, Vol.3-11-32, Vol.3-22-17, Vol.3-22-18, Vol.3-22-29
- CDQ instruction, Vol.1-7-7, Vol.2-3-225
- CDQE instruction, Vol.2-3-108
- Celeron processor
- description of, Vol.1-2-3
- CESR (control and event select) MSR (Pentium processor), Vol.3-18-94, Vol.3-18-95
- CF (carry) flag, EFLAGS register, Vol.1-3-15, Vol.1-A-1, Vol.2-3-27, Vol.2-3-85, Vol.2-3-87, Vol.2-3-89, Vol.2-3-91, Vol.2-3-109, Vol.2-3-116, Vol.2-3-230, Vol.2-3-388, Vol.2-3-393, Vol.2-3-586, Vol.2-4-279, Vol.2-4-340, Vol.2-4-352, Vol.2-4-355, Vol.2-4-376, Vol.2-4-388
- CH register, Vol.1-3-11
- CL register, Vol.1-3-11
- CLC instruction, Vol.1-3-15, Vol.1-7-21, Vol.2-3-109
- CLD instruction, Vol.1-3-16, Vol.1-7-21, Vol.2-3-110
- CLFLSH feature flag, CPUID instruction, Vol.3-9-8
- CLFLUSH instruction, Vol.1-11-12, Vol.2-3-111, Vol.3-2-15, Vol.3-8-6, Vol.3-9-8, Vol.3-11-17
- CPUID flag, Vol.2-3-171
- CLI instruction, Vol.1-16-3, Vol.2-3-113, Vol.3-6-7
- Clocks
- counting processor clocks, Vol.3-18-79
  - Hyper-Threading Technology, Vol.3-18-79
  - nominal CPI, Vol.3-18-79
  - non-halted clockticks, Vol.3-18-79
  - non-halted CPI, Vol.3-18-79
  - non-sleep Clockticks, Vol.3-18-79
  - time stamp counter, Vol.3-18-79
- CLTS instruction, Vol.2-3-115, Vol.3-2-21, Vol.3-5-24, Vol.3-25-2, Vol.3-25-6
- Cluster model, local APIC, Vol.3-10-24

- CMC instruction, Vol.1-3-15, Vol.1-7-21, Vol.2-3-116
- CMOVcc flag, Vol.2-3-171
- CMOVcc instructions, Vol.1-7-3, Vol.1-7-4, Vol.2-3-117, Vol.3-22-4
  - CPUID flag, Vol.2-3-171
- CMP instruction, Vol.1-7-8, Vol.2-3-121
- CMPPD instruction, Vol.1-11-7, Vol.2-3-123
- CMPPS instruction, Vol.1-10-9, Vol.2-3-130
- CMPS instruction, Vol.1-3-16, Vol.1-7-18, Vol.2-3-136, Vol.2-4-301
- CMPSB instruction, Vol.2-3-136
- CMPSD instruction, Vol.1-11-7, Vol.2-3-136, Vol.2-3-140
- CMPSQ instruction, Vol.2-3-136
- CMPSS instruction, Vol.1-10-9, Vol.2-3-144
- CMPSW instruction, Vol.2-3-136
- CMPXCHG instruction, Vol.1-7-4, Vol.2-3-148, Vol.2-3-465, Vol.3-8-3, Vol.3-22-4
- CMPXCHG16B instruction, Vol.1-7-5, Vol.2-3-150
  - CPUID bit, Vol.2-3-169
- CMPXCHG8B instruction, Vol.1-7-4, Vol.2-3-150, Vol.3-8-3, Vol.3-22-4
  - CPUID flag, Vol.2-3-171
- Code modules
  - 16 bit vs. 32 bit, Vol.3-21-1
  - mixing 16-bit and 32-bit code, Vol.3-21-1
  - sharing data, mixed-size code segs, Vol.3-21-3
  - transferring control, mixed-size code segs, Vol.3-21-3
- Code segment, Vol.1-3-13
- Code segments
  - accessing data in, Vol.3-5-9
  - accessing through a call gate, Vol.3-5-15
  - description of, Vol.3-3-12
  - descriptor format, Vol.3-5-2
  - descriptor layout, Vol.3-5-2
  - direct calls or jumps to, Vol.3-5-10
  - paging of, Vol.3-2-6
  - pointer size, Vol.3-21-4
  - privilege level checks
    - transferring control between code segs, Vol.3-5-10
- COMISD instruction, Vol.1-11-7, Vol.2-3-153
- COMISS instruction, Vol.1-10-9, Vol.2-3-155
- Compare
  - compare and exchange, Vol.1-7-4
  - integers, Vol.1-7-8
  - real numbers, x87 FPU, Vol.1-8-19
  - strings, Vol.1-7-18
- Compatibility
  - IA-32 architecture, Vol.3-22-1
  - software, Vol.3-1-5
- Compatibility mode
  - address space, Vol.1-3-1
  - branch functions, Vol.1-6-8
  - call gate descriptors, Vol.1-6-8
  - code segment descriptor, Vol.3-5-3
  - code segment descriptors, Vol.3-9-11
  - control registers, Vol.3-2-13
  - CS.L and CS.D, Vol.3-9-11
  - debug registers, Vol.3-2-22
  - EFLAGS register, Vol.3-2-11
  - exception handling, Vol.3-2-5
  - gates, Vol.3-2-4
  - GDTR register, Vol.3-2-12, Vol.3-2-13
  - global and local descriptor tables, Vol.3-2-4
  - IDTR register, Vol.3-2-12
  - interrupt handling, Vol.3-2-5
  - introduction, Vol.1-2-21, Vol.1-3-1, Vol.2-2-6
  - L flag, Vol.3-3-12, Vol.3-5-4
  - memory management, Vol.3-2-6
  - memory models, Vol.1-3-8
  - MMX technology, Vol.1-9-2
  - operation, Vol.3-9-11
  - see 64-bit mode
  - segment loading instructions, Vol.3-3-9
  - segmentation, Vol.1-3-21
  - segments, Vol.3-3-5
- SSE extensions, Vol.1-10-3
- SSE2 extensions, Vol.1-11-3
- SSE3 extensions, Vol.1-12-1
- SSSE3 extensions, Vol.1-12-1
- summary table notation, Vol.2-3-7
- switching to, Vol.3-9-12
- SYSCALL and SYSRET, Vol.3-5-22
- SYSENTER and SYSEXIT, Vol.3-5-21
- system flags, Vol.3-2-11
- system registers, Vol.3-2-7
- task register, Vol.3-2-13
- x87 FPU, Vol.1-8-1
  - See also: 64-bit mode, IA-32e mode
  - See also: IA-32e mode, 64-bit mode
- Compatibility, software, Vol.1-1-4, Vol.2-1-4
- Condition code flags, EFLAGS register, Vol.2-3-117
- Condition code flags, x87 FPU status word
  - branching on, Vol.1-8-6
  - compatibility information, Vol.3-22-7
  - conditional moves on, Vol.1-8-6
  - description of, Vol.1-8-4
  - flags affected by instructions, Vol.2-3-13
  - interpretation of, Vol.1-8-5
  - setting, Vol.2-3-346, Vol.2-3-348, Vol.2-3-350
  - use of, Vol.1-8-18
- Conditional jump, Vol.2-3-428
- Conditional moves, x87 FPU condition codes, Vol.1-8-6
- Conforming code segment, Vol.2-3-442
- Conforming code segments
  - accessing, Vol.3-5-12
  - C (conforming) flag, Vol.3-5-11
  - description of, Vol.3-3-13
- Constants (floating point), Vol.1-8-17
- Constants (floating point), loading, Vol.2-3-300
- Context, task (see Task state)
- Control registers
  - 64-bit mode, Vol.1-3-4, Vol.3-2-13
  - CR0, Vol.3-2-13
  - CR1 (reserved), Vol.3-2-13
  - CR2, Vol.3-2-13
  - CR3 (PDBR), Vol.3-2-6, Vol.3-2-13
  - CR4, Vol.3-2-13
  - description of, Vol.3-2-13
  - introduction to, Vol.3-2-6
  - overview of, Vol.1-3-4
  - VMX operation, Vol.3-31-17
- Control registers, moving values to and from, Vol.2-3-507
- Coprocessor segment
  - overflow exception, Vol.3-6-30, Vol.3-22-11
- Core microarchitecture, Vol.1-2-10, Vol.1-2-12, Vol.1-2-14
- core microarchitecture, Vol.1-2-10, Vol.1-2-12
- Core Solo and Core Duo, Vol.1-2-4
- Cosine, x87 FPU operation, Vol.1-8-20, Vol.2-3-276, Vol.2-3-328
- Counter mask field
  - PerfEvtSel0 and PerfEvtSel1 MSRs (P6 family processors), Vol.3-18-4, Vol.3-18-93
- CPL, Vol.2-3-113, Vol.2-4-434
  - description of, Vol.3-5-7
  - field, CS segment selector, Vol.3-5-2
- CPUID instruction, Vol.2-3-157, Vol.2-3-171
  - 36-bit page size extension, Vol.2-3-171
  - AP-485, Vol.1-1-7, Vol.2-1-7, Vol.3-1-8
  - APIC on-chip, Vol.2-3-171
  - availability, Vol.3-22-4
  - basic CPUID information, Vol.2-3-158
  - cache and TLB characteristics, Vol.2-3-158
  - CLFLUSH flag, Vol.1-11-12, Vol.2-3-171
  - CLFLUSH instruction cache line size, Vol.2-3-167
  - CMOVcc feature flag, Vol.1-7-3
  - CMPXCHG16B flag, Vol.2-3-169
  - CMPXCHG8B flag, Vol.2-3-171
  - control register flags, Vol.3-2-18

## INDEX

- CPL qualified debug store, Vol.2-3-168
  - debug extensions, CR4.DE, Vol.2-3-171
  - debug store supported, Vol.2-3-172
  - detecting features, Vol.3-22-2
  - determine support for, Vol.1-3-16
  - deterministic cache parameters leaf, Vol.2-3-158, Vol.2-3-160, Vol.2-3-161, Vol.2-3-162, Vol.2-3-163
  - extended function information, Vol.2-3-163
  - feature information, Vol.2-3-170
  - FPU on-chip, Vol.2-3-171
  - FSAVE flag, Vol.2-3-172
  - FXRSTOR flag, Vol.2-3-172
  - FXSAVE-FXRSTOR flag, Vol.1-10-14
  - IA-32e mode available, Vol.2-3-164
  - input limits for EAX, Vol.2-3-165
  - L1 Context ID, Vol.2-3-169
  - local APIC physical ID, Vol.2-3-167
  - machine check architecture, Vol.2-3-171
  - machine check exception, Vol.2-3-171
  - memory type range registers, Vol.2-3-171
  - MMX feature flag, Vol.1-9-8
  - MONITOR feature information, Vol.2-3-176
  - MONITOR/MWAIT flag, Vol.2-3-168
  - MONITOR/MWAIT leaf, Vol.2-3-159, Vol.2-3-160, Vol.2-3-161
  - MWAIT feature information, Vol.2-3-176
  - page attribute table, Vol.2-3-171
  - page size extension, Vol.2-3-171
  - performance monitoring features, Vol.2-3-176
  - physical address bits, Vol.2-3-165
  - physical address extension, Vol.2-3-171
  - power management, Vol.2-3-176, Vol.2-3-177
  - processor brand index, Vol.2-3-167, Vol.2-3-177
  - processor brand string, Vol.2-3-164, Vol.2-3-177
  - processor serial number, Vol.2-3-158, Vol.2-3-171
  - processor type field, Vol.2-3-167
  - RDMSR flag, Vol.2-3-171
  - returned in EBX, Vol.2-3-167
  - returned in ECX & EDX, Vol.2-3-167
  - self snoop, Vol.2-3-172
  - serializing instructions, Vol.3-8-17
  - serializing use, Vol.1-16-5
  - SpeedStep technology, Vol.2-3-168
  - SS2 extensions flag, Vol.2-3-172
  - SSE extensions flag, Vol.2-3-172
  - SSE feature flag, Vol.1-10-1, Vol.1-10-6
  - SSE2 feature flag, Vol.1-11-1, Vol.1-12-5
  - SSE3 extensions flag, Vol.2-3-168
  - SSE3 feature flag, Vol.1-12-5
  - SSSE2 feature flag, Vol.1-12-9, Vol.1-12-20, Vol.1-12-26
  - SSSE3 extensions flag, Vol.2-3-168
  - summary of, Vol.1-7-23
  - syntax for data, Vol.3-1-7
  - SYSENTER flag, Vol.2-3-171
  - SYSEXIT flag, Vol.2-3-171
  - thermal management, Vol.2-3-176, Vol.2-3-177
  - thermal monitor, Vol.2-3-168, Vol.2-3-172
  - time stamp counter, Vol.2-3-171
  - using CPUID, Vol.2-3-157
  - vendor ID string, Vol.2-3-165
  - version information, Vol.2-3-158, Vol.2-3-176
  - virtual 8086 Mode flag, Vol.2-3-171
  - virtual address bits, Vol.2-3-165
  - WRMSR flag, Vol.2-3-171
  - CQO instruction, Vol.2-3-225
  - CR0 control register, Vol.2-4-368, Vol.3-22-7
    - description of, Vol.3-2-13
    - introduction to, Vol.3-2-6
    - state following processor reset, Vol.3-9-2
  - CR1 control register (reserved), Vol.3-2-13
  - CR2 control register
    - description of, Vol.3-2-13
    - introduction to, Vol.3-2-6
  - CR3 control register (PDBR)
    - associated with a task, Vol.3-7-1, Vol.3-7-3
    - description of, Vol.3-2-13
    - in TSS, Vol.3-7-4, Vol.3-7-14
    - introduction to, Vol.3-2-6
    - loading during initialization, Vol.3-9-10
    - memory management, Vol.3-2-6
    - page directory base address, Vol.3-2-6
    - page table base address, Vol.3-2-5
  - CR4 control register
    - description of, Vol.3-2-13
    - enabling control functions, Vol.3-22-2
    - inclusion in IA-32 architecture, Vol.3-22-17
    - introduction to, Vol.3-2-6
    - VMX usage of, Vol.3-23-3
  - CR8 register, Vol.3-2-7
    - 64-bit mode, Vol.3-2-13
    - compatibility mode, Vol.3-2-13
    - description of, Vol.3-2-13
    - task priority level bits, Vol.3-2-18
    - when available, Vol.3-2-13
  - CS register, Vol.1-3-12, Vol.1-3-13, Vol.2-3-96, Vol.2-3-401, Vol.2-3-420, Vol.2-3-434, Vol.2-3-503, Vol.2-4-183, Vol.3-22-10
    - state following initialization, Vol.3-9-5
  - C-state, Vol.3-14-7
  - CTI instruction, Vol.1-7-22
  - CTRO and CTR1 (performance counters) MSRs (Pentium processor), Vol.3-18-94, Vol.3-18-96
  - Current privilege level (see CPL)
  - Current stack, Vol.1-6-1, Vol.1-6-3
  - CVTDQ2PD instruction, Vol.1-11-10, Vol.2-3-185
  - CVTDQ2PS instruction, Vol.1-11-10, Vol.2-3-190
  - CVTPD2DQ instruction, Vol.1-11-10, Vol.2-3-192
  - CVTPD2PI instruction, Vol.1-11-10, Vol.2-3-194
  - CVTPD2PS instruction, Vol.1-11-9, Vol.2-3-195
  - CVTPI2PD instruction, Vol.1-11-10, Vol.2-3-197
  - CVTPI2PS instruction, Vol.1-10-11, Vol.2-3-198
  - CVTPS2DQ instruction, Vol.1-11-10, Vol.2-3-199, Vol.2-3-200
  - CVTPS2PD instruction, Vol.1-11-9, Vol.2-3-201
  - CVTPS2PI instruction, Vol.1-10-11, Vol.2-3-203
  - CVTSD2SI instruction, Vol.1-11-10, Vol.2-3-204
  - CVTSD2SS instruction, Vol.1-11-9, Vol.2-3-206
  - CVTSI2SD instruction, Vol.1-11-10, Vol.2-3-208
  - CVTSI2SS instruction, Vol.1-10-11, Vol.2-3-210
  - CVTSS2SD instruction, Vol.1-11-9, Vol.2-3-212
  - CVTSS2SI instruction, Vol.1-10-11, Vol.2-3-213
  - CVTTPD2DQ instruction, Vol.1-11-10, Vol.2-3-215
  - CVTTPD2PI instruction, Vol.1-11-10, Vol.2-3-215, Vol.2-3-217
  - CVTTPS2DQ instruction, Vol.1-11-10, Vol.2-3-218
  - CVTTPS2PI instruction, Vol.1-10-11, Vol.2-3-220
  - CVTTSD2SI instruction, Vol.1-11-10, Vol.2-3-221
  - CVTTSS2SI instruction, Vol.1-10-11, Vol.2-3-223

G (global) flag  
     page-directory entries, Vol.3-11-13  
     page-table entries, Vol.3-11-13  
 G (granularity) flag  
     segment descriptor, Vol.3-3-10, Vol.3-3-11, Vol.3-5-2, Vol.3-5-4  
 GO-G3 (global breakpoint enable) flags  
     DR7 register, Vol.3-17-4  
 Gate descriptors  
     call gates, Vol.3-5-13  
     description of, Vol.3-5-13  
     IA-32e mode, Vol.3-5-14  
 Gates, Vol.3-2-4  
     IA-32e mode, Vol.3-2-4  
 GD (general detect enable) flag  
     DR7 register, Vol.3-17-4, Vol.3-17-9  
 GDT  
     description of, Vol.3-2-3, Vol.3-3-15  
     IA-32e mode, Vol.3-2-4  
     index field of segment selector, Vol.3-3-7  
     initializing, Vol.3-9-9  
     paging of, Vol.3-2-6  
     pointers to exception/interrupt handlers, Vol.3-6-11  
     segment descriptors in, Vol.3-3-9  
     selecting with TI flag of segment selector, Vol.3-3-7  
     task switching, Vol.3-7-9  
     task-gate descriptor, Vol.3-7-8  
     TSS descriptors, Vol.3-7-5  
     use in address translation, Vol.3-3-6  
 GDT (global descriptor table), Vol.2-3-458, Vol.2-3-461  
 GDTR register, Vol.1-3-4, Vol.1-3-5  
     description of, Vol.3-2-3, Vol.3-2-6, Vol.3-2-12, Vol.3-3-15  
     IA-32e mode, Vol.3-2-4, Vol.3-2-12  
     limit, Vol.3-5-5  
     loading during initialization, Vol.3-9-9  
     storing, Vol.3-3-15  
 GDTR (global descriptor table register), Vol.2-3-458, Vol.2-4-350  
 GE (global exact breakpoint enable) flag  
     DR7 register, Vol.3-17-4, Vol.3-17-8

General purpose registers  
     64-bit mode, Vol.1-3-4, Vol.1-3-12  
     description of, Vol.1-3-10  
     overview of, Vol.1-3-2, Vol.1-3-4  
     parameter passing, Vol.1-6-5  
     part of basic programming environment, Vol.1-7-1  
     using REX prefix, Vol.1-3-12  
 General-detect exception condition, Vol.3-17-9  
 General-protection exception (#GP), Vol.3-3-12, Vol.3-5-6, Vol.3-5-7,  
     Vol.3-5-11, Vol.3-5-12, Vol.3-6-9, Vol.3-6-13, Vol.3-6-37,  
     Vol.3-7-5, Vol.3-17-2, Vol.3-22-11, Vol.3-22-20, Vol.3-22-33,  
     Vol.3-22-34  
 General-purpose instructions  
     64-bit encodings, Vol.2-B-18  
     64-bit mode, Vol.1-7-1  
     basic programming environment, Vol.1-7-1  
     data types operated on, Vol.1-7-1, Vol.1-7-2  
     description of, Vol.1-7-1  
     non-64-bit encodings, Vol.2-B-7  
     origin of, Vol.1-7-1  
     programming with, Vol.1-7-1  
     summary of, Vol.1-5-2, Vol.1-7-2  
 General-purpose registers  
     moving value to and from, Vol.2-3-503  
     popping all, Vol.2-4-187  
     pushing all, Vol.2-4-271  
 General-purpose registers, saved in TSS, Vol.3-7-4  
 GETSEC, Vol.2-5-1, Vol.2-5-2, Vol.2-5-5  
 Global control MSRs, Vol.3-15-2  
 Global descriptor table register (see GDTR)  
 Global descriptor table (see GDT)  
 GS register, Vol.1-3-12, Vol.1-3-13, Vol.2-3-448

## H

HADDPD instruction, Vol.1-5-20, Vol.1-12-4, Vol.2-3-371, Vol.2-3-372  
 HADDPs instruction, Vol.1-5-20, Vol.1-12-4, Vol.2-3-374  
 HALT state  
     relationship to SMI interrupt, Vol.3-34-3, Vol.3-34-13  
 Hardware Lock Elision (HLE), Vol.1-15-2  
 Hardware reset  
     description of, Vol.3-9-1  
     processor state after reset, Vol.3-9-2  
     state of MTRRs following, Vol.3-11-20  
     value of SMBASE following, Vol.3-34-4  
 Hexadecimal numbers, Vol.1-1-5, Vol.2-1-5, Vol.3-1-6  
 high-temperature interrupt enable bit, Vol.3-14-15, Vol.3-14-18  
 HITM# line, Vol.3-11-6  
 HLT instruction, Vol.2-3-377, Vol.3-2-23, Vol.3-5-24, Vol.3-6-29,  
     Vol.3-25-2, Vol.3-34-13, Vol.3-34-14  
 Horizontal processing model, Vol.1-12-1  
 HSUBPD instruction, Vol.1-5-20, Vol.1-12-5, Vol.2-3-378  
 HSUBPS instruction, Vol.1-5-20, Vol.1-12-4, Vol.2-3-381  
 HT Technology  
     first processor, Vol.1-2-3  
     implementing, Vol.1-2-17  
     introduction, Vol.1-2-17  
 Hyper-Threading Technology  
     architectural state of a logical processor, Vol.3-8-32  
     architecture description, Vol.3-8-26  
     caches, Vol.3-8-30  
     counting clockticks, Vol.3-18-80  
     debug registers, Vol.3-8-29  
     description of, Vol.3-8-24, Vol.3-22-3, Vol.3-22-4  
     detecting, Vol.3-8-35, Vol.3-8-39, Vol.3-8-40  
     executing multiple threads, Vol.3-8-25  
     execution-based timing loops, Vol.3-8-52  
     external signal compatibility, Vol.3-8-31  
     halting logical processors, Vol.3-8-50  
     handling interrupts, Vol.3-8-25  
     HLT instruction, Vol.3-8-46  
     IA32\_MISC\_ENABLE MSR, Vol.3-8-29, Vol.3-8-32

- P6 family processors
  - compatibility with FP software, Vol.3-22-6
  - description of, Vol.1-1-1, Vol.2-1-1, Vol.3-1-1
  - history of, Vol.1-2-2
  - last branch, interrupt, and exception recording, Vol.3-17-33
  - list of performance-monitoring events, Vol.3-19-181
  - machine encodings, Vol.2-B-41
  - MSR supported by, Vol.1-35-184
  - P6 family microarchitecture, Vol.1-2-6
- PASB instruction, Vol.1-5-21, Vol.1-12-7, Vol.2-4-23
- PABSD instruction, Vol.1-12-8, Vol.2-4-23
- PABSW instruction, Vol.1-5-21, Vol.1-12-8, Vol.2-4-23
- Packed
  - BCD integer indefinite, Vol.1-4-11
  - BCD integers, Vol.1-4-10
  - bytes, Vol.1-9-3
  - doublewords, Vol.1-9-3
  - SIMD data types, Vol.1-4-8
  - SIMD floating-point values, Vol.1-4-8
  - SIMD integers, Vol.1-4-8
  - words, Vol.1-9-3
- PACKSSDw instruction, Vol.2-4-27
- PACKSSWB instruction, Vol.1-9-7, Vol.2-4-27
- PACKUSWB instruction, Vol.1-9-7, Vol.2-4-35
- PADD instruction, Vol.1-9-6, Vol.2-4-38
- PADD instruction, Vol.1-9-6, Vol.2-4-38
- PADDQ instruction, Vol.1-11-11, Vol.2-4-42
- PADDSB instruction, Vol.1-9-7, Vol.2-4-44
- PADDSW instruction, Vol.1-9-7, Vol.2-4-44
- PADDUSB instruction, Vol.1-9-7, Vol.2-4-47
- PADDUSW instruction, Vol.1-9-7, Vol.2-4-47
- PADDW instruction, Vol.1-9-6, Vol.2-4-38
- PAE paging
  - feature flag, CR4 register, Vol.3-2-17
  - flag, CR4 control register, Vol.3-3-6, Vol.3-22-17, Vol.3-22-18
- Page attribute table (PAT)
  - compatibility with earlier IA-32 processors, Vol.3-11-36
  - detecting support for, Vol.3-11-34
  - IA32\_CR\_PAT MSR, Vol.3-11-34
  - introduction to, Vol.3-11-33
  - memory types that can be encoded with, Vol.3-11-34
  - MSR, Vol.3-11-13
  - precedence of cache controls, Vol.3-11-14
  - programming, Vol.3-11-35
  - selecting a memory type with, Vol.3-11-35
- Page directories, Vol.3-2-6
- Page directory
  - base address (PDBR), Vol.3-7-5
  - introduction to, Vol.3-2-6
  - overview, Vol.3-3-2
  - setting up during initialization, Vol.3-9-10
- Page directory pointers, Vol.3-2-6
- Page frame (see Page)
- Page tables, Vol.3-2-6
  - introduction to, Vol.3-2-6
  - overview, Vol.3-3-2
  - setting up during initialization, Vol.3-9-10
- Page-directory entries, Vol.3-8-3, Vol.3-11-5
- Page-fault exception (#PF), Vol.3-4-44, Vol.3-6-40, Vol.3-22-20
- Pages
  - disabling protection of, Vol.3-5-1
  - enabling protection of, Vol.3-5-1
  - introduction to, Vol.3-2-6
  - overview, Vol.3-3-2
  - PG flag, CRO control register, Vol.3-5-1
  - split, Vol.3-22-14
- Page-table entries, Vol.3-8-3, Vol.3-11-5, Vol.3-11-19
- Paging
  - combining segment and page-level protection, Vol.3-5-29
  - combining with segmentation, Vol.3-3-5
  - defined, Vol.3-3-1
  - IA-32e mode, Vol.3-2-6
  - initializing, Vol.3-9-10
  - introduction to, Vol.3-2-6
  - large page size MTRR considerations, Vol.3-11-33
  - mapping segments to pages, Vol.3-4-45
  - page boundaries regarding TSS, Vol.3-7-5
  - page-fault exception, Vol.3-6-40, Vol.3-6-50
  - page-level protection, Vol.3-5-2, Vol.3-5-3, Vol.3-5-27
  - page-level protection flags, Vol.3-5-28
  - virtual-8086 tasks, Vol.3-20-7
- PALIGNR instruction, Vol.1-5-22, Vol.1-12-8, Vol.2-4-50
- PAND instruction, Vol.1-9-7, Vol.2-4-53
- PANDN instruction, Vol.1-9-7, Vol.2-4-55
- Parameter
  - passing, between 16- and 32-bit call gates, Vol.3-21-6
  - translation, between 16- and 32-bit code segments, Vol.3-21-6
- Parameter passing
  - argument list, Vol.1-6-5
  - on stack, Vol.1-6-5
  - on the stack, Vol.1-6-5
  - through general-purpose registers, Vol.1-6-5
  - x87 FPU register stack, Vol.1-8-3
  - XMM registers, Vol.1-11-23
- GETSEC, Vol.2-5-4
- PAUSE instruction, Vol.1-11-12, Vol.2-4-57, Vol.3-2-15, Vol.3-25-3
- PAVGB instruction, Vol.1-10-11, Vol.2-4-58
- PAVGW instruction, Vol.2-4-58
- PBi (performance monitoring/breakpoint pins) flags, DEBUGCTLMR MSR, Vol.3-17-32, Vol.3-17-34
- PC (pin control) flag, PerfEvtSel0 and PerfEvtSel1 MSRs (P6 family processors), Vol.3-18-4, Vol.3-18-93
- PC (precision) field, x87 FPU control word, Vol.1-8-7
- PC0 and PC1 (pin control) fields, CESR MSR (Pentium processor), Vol.3-18-95
- PCD pin (Pentium processor), Vol.3-11-13
- PCD (page-level cache disable) flag
  - CR3 control register, Vol.3-2-16, Vol.3-11-13, Vol.3-22-17, Vol.3-22-29
  - page-directory entries, Vol.3-9-7, Vol.3-11-13, Vol.3-11-33
  - page-table entries, Vol.3-9-7, Vol.3-11-13, Vol.3-11-33, Vol.3-22-30
- PCE flag, CR4 register, Vol.2-4-291
- PCE (performance monitoring counter enable) flag, CR4 control register, Vol.3-2-17, Vol.3-5-24, Vol.3-18-63, Vol.3-18-93
- PCE (performance-monitoring counter enable) flag, CR4 control register, Vol.3-22-17
- PCMPEQB instruction, Vol.1-9-7, Vol.2-4-71
- PCMPEQD instruction, Vol.1-9-7, Vol.2-4-71
- PCMPEQW instruction, Vol.1-9-7, Vol.2-4-71
- PCMPGTB instruction, Vol.1-9-7, Vol.2-4-81
- PCMPGTD instruction, Vol.1-9-7, Vol.2-4-81
- PCMPGTW instruction, Vol.1-9-7, Vol.2-4-81
- PDBR (see CR3 control register)
- PDEP - Parallel Bits Deposit, Vol.2-4-91
- PE (inexact result exception) flag, Vol.1-11-16
  - MXCSR register, Vol.1-4-18
  - x87 FPU status word, Vol.1-4-18, Vol.1-8-4, Vol.1-8-5, Vol.1-8-29
- PE (protection enable) flag, CRO control register, Vol.3-2-16, Vol.3-5-1, Vol.3-9-10, Vol.3-9-12, Vol.3-34-9
- PE (protection enable) flag, CRO register, Vol.2-3-463
- PEBS records, Vol.3-17-18
- PEBS (precise event-based sampling) facilities
  - availability of, Vol.3-18-74
  - description of, Vol.3-18-61, Vol.3-18-73
  - DS save area, Vol.3-17-15

- IA-32e mode, Vol.3-17-18
- PEBS buffer, Vol.3-17-15, Vol.3-18-74
- PEBS records, Vol.3-17-15, Vol.3-17-17
- writing a PEBS interrupt service routine, Vol.3-18-74
- writing interrupt service routine, Vol.3-17-21
- PEBS\_UNAVAILABLE flag
  - IA32\_MISC\_ENABLE MSR, Vol.3-17-15, Vol.1-35-151
- Pending break enable, Vol.2-3-172
- Pentium 4 processor, Vol.1-1-1, Vol.2-1-1, Vol.3-1-1
  - compatibility with FP software, Vol.3-22-6
  - description of, Vol.1-2-3, Vol.1-2-4
  - last branch, interrupt, and exception recording, Vol.3-17-27
  - list of performance-monitoring events, Vol.3-19-1, Vol.3-19-150
  - MSRs supported, Vol.1-35-29, Vol.1-35-43, Vol.1-35-54, Vol.1-35-142, Vol.1-35-166
  - time-stamp counter, Vol.3-17-35
- Pentium 4 processor supporting Hyper-Threading Technology
  - description of, Vol.1-2-3, Vol.1-2-4
- Pentium II processor, Vol.1-1-2, Vol.2-1-2, Vol.3-1-2
  - description of, Vol.1-2-2
  - P6 family microarchitecture, Vol.1-2-6
- Pentium II Xeon processor
  - description of, Vol.1-2-2
- Pentium III processor, Vol.1-1-2, Vol.2-1-2, Vol.3-1-2
  - description of, Vol.1-2-3
  - P6 family microarchitecture, Vol.1-2-6
- Pentium III Xeon processor
  - description of, Vol.1-2-3
- Pentium M processor
  - description of, Vol.1-2-3
  - instructions supported, Vol.1-2-3
  - last branch, interrupt, and exception recording, Vol.3-17-32
  - MSRs supported by, Vol.1-35-177
  - time-stamp counter, Vol.3-17-35
- Pentium Pro processor, Vol.1-1-2, Vol.2-1-2, Vol.3-1-2
  - description of, Vol.1-2-2
  - P6 family microarchitecture, Vol.1-2-6

- PSUBSW instruction, Vol.1-9-7, Vol.2-4-245

## INDEX

PSUBUSB instruction, Vol.1-9-7, Vol.2-4-248  
PSUBUSW instruction, Vol.1-9-7, Vol.2-4-248  
PSUBW instruction, Vol.1-9-6, Vol.2-4-238  
PUNPCKHBW instruction, Vol.1-9-7, Vol.2-4-253  
PUNPCKHDQ instruction, Vol.1-9-7, Vol.2-4-253  
PUNPCKHQDQ instruction, Vol.1-11-11, Vol.2-4-253  
PUNPCKHWD instruction, Vol.1-9-7, Vol.2-4-253  
PUNPCKLBW instruction, Vol.1-9-7, Vol.2-4-260  
PUNPCKLDQ instruction, Vol.1-9-7, Vol.2-4-260  
PUNPCKLQDQ instruction, Vol.1-11-11, Vol.2-4-260  
PUNPCKLWD instruction, Vol.1-9-7, Vol.2-4-260  
PUSH instruction, Vol.1-6-1, Vol.1-6-2, Vol.1-7-5, Vol.1-7-22,  
Vol.2-4-267, Vol.3-22-6  
PUSHA instruction, Vol.1-6-6, Vol.1-7-5, Vol.2-4-271  
PUSHAD instruction, Vol.2-4-271  
PUSHF instruction, Vol.1-3-14, Vol.1-6-6, Vol.1-7-21, Vol.2-4-273,  
Vol.3-6-7, Vol.3-22-6  
PUSHFD instruction, Vol.1-3-14, Vol.1-6-6, Vol.1-7-21, Vol.2-4-273  
PVI (protected-mode virtual interrupts) flag  
CR4 control register, Vol.3-2-11, Vol.3-2-17, Vol.3-22-17  
PwT pin (Pentium processor), Vol.3-11-13  
PwT (page-level write-through) flag  
CR3 control register, Vol.3-2-16, Vol.3-11-13, Vol.3-22-17,  
Vol.3-22-29  
page-directory entries, Vol.3-9-7, Vol.3-11-13, Vol.3-11-33  
page-table entries, Vol.3-9-7, Vol.3-11-33, Vol.3-22-30  
PXOR instruction, Vol.1-9-7, Vol.2-4-275

**Q**

QNaN floating-point indefinite, Vol.1-4-5, Vol.1-4-16, Vol.1-4-17,  
Vol.1-8-13

QNaNs  
description of, Vol.1-4-15  
effect on COMISD and UCOMISD, Vol.1-11-7  
encodings, Vol.1-4-5  
operating on, Vol.1-4-16  
rules for generating, Vol.1-4-16  
using in applications, Vol.1-4-16

QNaN, compatibility, IA-32 processors, Vol.3-22-8

Quadword, Vol.1-4-1, Vol.1-9-3

Quiet NaN (see QNaN)

**R**

R8D-R15D registers, Vol.1-3-11

R8-R15 registers, Vol.1-3-11

RAX register, Vol.1-3-11

RBP register, Vol.1-3-11, Vol.1-6-4

RBX register, Vol.1-3-11

RC (rounding control) field  
MXCSR register, Vol.1-4-18, Vol.1-10-4  
x87 FPU control word, Vol.1-4-18, Vol.1-8-8

RC (rounding control) field, x87 FPU control word, Vol.2-3-293,  
Vol.2-3-300, Vol.2-3-332

RCL instruction, Vol.1-7-13, Vol.2-4-277

RCPPS instruction, Vol.1-10-8, Vol.2-4-282

RCPPS instruction, Vol.1-10-8, Vol.2-4-284

RCR instruction, Vol.1-7-13, Vol.2-4-277

RCX register, Vol.1-3-11

RDI register, Vol.1-3-11

RDMSR instruction, Vol.2-4-288, Vol.2-4-291, Vol.2-4-296, Vol.3-2-19,  
Vol.3-2-24, Vol.3-5-24, Vol.3-17-29, Vol.3-17-34,  
Vol.3-17-36, Vol.3-18-63, Vol.3-18-92, Vol.3-18-93,  
Vol.3-18-94, Vol.3-22-4, Vol.3-22-35, Vol.3-25-4, Vol.3-25-8  
CPUID flag, Vol.2-3-171

RDPMS instruction, Vol.2-4-290, Vol.3-2-23, Vol.3-5-24, Vol.3-18-63,  
Vol.3-18-92, Vol.3-18-93, Vol.3-22-4, Vol.3-22-17,  
Vol.3-22-36, Vol.3-25-4  
in 64-bit mode, Vol.3-2-24

RDRAND, Vol.1-7-24

RDTSC instruction, Vol.2-4-294, Vol.2-4-296, Vol.2-4-298, Vol.3-2-23,  
Vol.3-5-24, Vol.3-17-36, Vol.3-22-4, Vol.3-25-4, Vol.3-25-8,  
Vol.3-25-9  
in 64-bit mode, Vol.3-2-24

RDX register, Vol.1-3-11

reading sensors, Vol.3-14-13

Read/write  
protection, page level, Vol.3-5-28  
rights, checking, Vol.3-5-25

Real address mode  
handling exceptions in, Vol.1-6-12  
handling interrupts in, Vol.1-6-12  
memory model, Vol.1-3-6, Vol.1-3-7  
memory model used, Vol.1-3-8  
not in 64-bit mode, Vol.1-3-8  
overview, Vol.1-3-1

Real numbers  
continuum, Vol.1-4-11  
encoding, Vol.1-4-13, Vol.1-4-14  
notation, Vol.1-4-12, Vol.1-14-18  
system, Vol.1-4-11

Real-address mode  
8086 emulation, Vol.3-20-1  
address translation in, Vol.3-20-2  
description of, Vol.3-20-1  
exceptions and interrupts, Vol.3-20-6  
IDT initialization, Vol.3-9-8  
IDT, changing base and limit of, Vol.3-20-5  
IDT, structure of, Vol.3-20-5  
IDT, use of, Vol.3-20-4  
initialization, Vol.3-9-8  
instructions supported, Vol.3-20-3  
interrupt and exception handling, Vol.3-20-4  
interrupts, Vol.3-20-6  
introduction to, Vol.3-2-7  
mode switching, Vol.3-9-12  
native 16-bit mode, Vol.3-21-1  
overview of, Vol.3-20-1  
registers supported, Vol.3-20-3  
switching to, Vol.3-9-13

Recursive task switching, Vol.3-7-13

Register operands  
64-bit mode, Vol.1-3-20  
legacy modes, Vol.1-3-19

Register stack, x87 FPU, Vol.1-8-1

Registers  
64-bit mode, Vol.1-3-11, Vol.1-3-14  
control registers, Vol.1-3-4  
CR in 64-bit mode, Vol.1-3-4  
debug registers, Vol.1-3-4  
EFLAGS register, Vol.1-3-10, Vol.1-3-14  
EIP register, Vol.1-3-10, Vol.1-3-17  
general purpose registers, Vol.1-3-10  
instruction pointer, Vol.1-3-10  
machine check registers, Vol.1-3-4  
memory management registers, Vol.1-3-4  
MMX registers, Vol.1-3-2, Vol.1-9-2  
MSRs, Vol.1-3-4  
MTRRs, Vol.1-3-4  
MXCSR register, Vol.1-10-4  
performance monitoring counters, Vol.1-3-4  
REX prefix, Vol.1-3-11  
segment registers, Vol.1-3-10, Vol.1-3-12  
x87 FPU registers, Vol.1-8-1  
XMM registers, Vol.1-3-2, Vol.1-10-3

Reg/opcode field, instruction format, Vol.2-2-3

Related literature, Vol.1-1-7, Vol.2-1-6, Vol.3-1-8

Remainder, x87 FPU operation, Vol.2-3-314

Replay events, Vol.3-19-174

REP/REPE/REPZ/REPNE/REPZ  
prefixes, Vol.1-7-19, Vol.1-16-3

- REP/REPE/REPZ/REPNE/REPNZ prefixes, Vol.2-3-137, Vol.2-3-396, Vol.2-4-20, Vol.2-4-300

 x87 FPU instructions

## INDEX

- arithmetic vs. non-arithmetic instructions, Vol.1-8-24
  - basic arithmetic, Vol.1-8-17
  - comparison and classification, Vol.1-8-18
  - control, Vol.1-8-22
  - data transfer, Vol.1-8-15
  - exponential, Vol.1-8-21
  - instruction set, Vol.1-8-15
  - load constant, Vol.1-8-17
  - logarithmic, Vol.1-8-21
  - operands, Vol.1-8-15
  - overview, Vol.1-8-15
  - save and restore state, Vol.1-8-22
  - scale, Vol.1-8-21
  - transcendental, Vol.1-8-22
  - transitions between x87 FPU and MMX code, Vol.1-9-9
  - trigonometric, Vol.1-8-20
  - unsupported, Vol.1-8-23
  - x87 FPU last opcode, Vol.2-3-304, Vol.2-3-319, Vol.2-3-321, Vol.2-3-336
  - x87 FPU status word
    - condition code flags, Vol.1-8-4, Vol.2-3-270, Vol.2-3-286, Vol.2-3-346, Vol.2-3-348, Vol.2-3-350, Vol.3-22-7
    - DE flag, Vol.1-8-27
    - description of, Vol.1-8-4
    - exception flags, Vol.1-8-5
    - loading, Vol.2-3-304
    - OE flag, Vol.1-8-28
    - PE flag, Vol.1-8-4
    - restoring, Vol.2-3-319
    - saving, Vol.2-3-321, Vol.2-3-336, Vol.2-3-338
    - stack fault flag, Vol.1-8-6
    - TOP field, Vol.1-8-2, Vol.2-3-290
    - top of stack (TOP) pointer, Vol.1-8-4
    - x87 FPU flags affected by instructions, Vol.2-3-13
  - x87 FPU tag word, Vol.1-8-8, Vol.1-9-9, Vol.2-3-304, Vol.2-3-319, Vol.2-3-321, Vol.2-3-336, Vol.3-22-8
  - XABORT - Transaction Abort, Vol.2-4-557
  - XADD instruction, Vol.1-7-4, Vol.2-3-465, Vol.2-4-559, Vol.3-8-3, Vol.3-22-4
  - xAPIC, Vol.3-10-38, Vol.3-10-40
    - determining lowest priority processor, Vol.3-10-25
    - interrupt control register, Vol.3-10-21
    - introduction to, Vol.3-10-4
    - message passing protocol on system bus, Vol.3-10-33
    - new features, Vol.3-22-27
    - spurious vector, Vol.3-10-32
    - using system bus, Vol.3-10-4
  - xAPIC Mode, Vol.3-10-31, Vol.3-10-37, Vol.3-10-41, Vol.3-10-44, Vol.3-10-46
  - XCHG instruction, Vol.1-7-4, Vol.2-3-465, Vol.2-4-564, Vol.3-8-3, Vol.3-8-15
  - XCRO, Vol.1-14-15
  - XEND - Transaction End, Vol.2-4-566
  - XFEATURE\_ENABLED\_MASK, Vol.2-4-568, Vol.2-4-578, Vol.2-4-582, Vol.2-4-585, Vol.2-4-588, Vol.2-4-589, Vol.3-2-18
  - XGETBV, Vol.2-4-568, Vol.2-4-578, Vol.2-B-41, Vol.3-2-18, Vol.3-2-20, Vol.3-2-21
  - XLAB instruction, Vol.2-4-570
  - XLAT instruction, Vol.2-4-570
  - XLAT/XLATB instruction, Vol.1-7-23
  - XMM registers
    - 64-bit mode, Vol.1-3-4
    - description, Vol.1-10-3
    - FXSAVE and FXRSTOR instructions, Vol.1-11-23
    - overview of, Vol.1-3-2
    - parameters passing in, Vol.1-11-23
    - saving on a procedure or function call, Vol.1-11-23
  - XMM registers, saving, Vol.3-13-5
  - XOR instruction, Vol.1-7-10, Vol.2-3-465, Vol.2-4-572, Vol.3-8-3
  - XORPD instruction, Vol.1-11-7, Vol.2-4-574
  - XORPS instruction, Vol.1-10-9, Vol.2-4-576
  - XRSTOR, Vol.1-14-15, Vol.2-4-582, Vol.2-4-585, Vol.2-B-41
  - XSAVE, Vol.1-14-15, Vol.1-14-20, Vol.1-14-25, Vol.1-14-33, Vol.1-14-34, Vol.2-4-568, Vol.2-4-578, Vol.2-4-579, Vol.2-4-580, Vol.2-4-581, Vol.2-4-582, Vol.2-4-583, Vol.2-4-584, Vol.2-4-585, Vol.2-4-587, Vol.2-4-588, Vol.2-4-589, Vol.2-B-41, Vol.3-2-18, Vol.3-13-8
  - XSETBV, Vol.2-4-585, Vol.2-4-588, Vol.2-B-41, Vol.3-2-18, Vol.3-2-19, Vol.3-2-20, Vol.3-2-24
  - XTEST - Test If In Transactional Execution, Vol.2-4-590
- ## Z
- ZE (divide by zero exception) flag
    - x87 FPU status word, Vol.1-8-5, Vol.1-8-27
  - ZE (divide by zero exception) flag bit
    - MXCSR register, Vol.1-11-15
  - Zero, floating-point format, Vol.1-4-5, Vol.1-4-14
  - ZF flag, EFLAGS register, Vol.3-5-25
  - ZF (zero) flag, EFLAGS register, Vol.1-3-15, Vol.1-A-1, Vol.2-3-148, Vol.2-3-442, Vol.2-3-470, Vol.2-3-472, Vol.2-4-301, Vol.2-4-434
  - ZM (divide by zero exception) mask bit
    - MXCSR register, Vol.1-11-15
    - x87 FPU control word, Vol.1-8-7, Vol.1-8-27
