## OpenPOWER Power ISA End User License Agreement

“*Power ISA*” means the microprocessor instruction set architecture specification version provided to you with this document. By exercising any right under this End User License Agreement, you (“Recipient”) agree to be bound by the terms and conditions of this Power ISA End User License (“Agreement”).

All information contained in the Power ISA is subject to change without notice. The products described in the Power ISA are NOT intended for use in applications such as implantation, life support, or other hazardous uses where malfunction could result in death, bodily injury, or catastrophic property damage.

### Definitions

“*Architectural Resources*” means assignable resources necessary for elements of the Power ISA to interoperate, including, but not limited to: opcodes, special purpose registers, defined registers, reserved bits in existing defined registers, control table fields and bits, and interrupt vectors.

“*Compliance Subset*” means a portion of the Power ISA, defined within the Power ISA, which must be implemented to ensure software compatibility across Power ISA compliant devices.

“*Contribution*” means any work of authorship that is intentionally submitted to OPF for inclusion in the Power ISA by the copyright owner or by an individual or entity authorized to submit on behalf of the copyright owner. Without limiting the generality of the preceding sentence, RFCs will be considered Contributions.

“*Custom Extensions*” means additions to the Power ISA in a designated subset of Architectural Resources defined by the Power ISA. For clarity, Custom Extensions are not Contributions.

“*Integrated Circuit*” shall mean an integral unit including a plurality of active and passive circuit elements formed at least in part of semiconductor material arranged on or in a chip(s) or substrate.

“*OPF*” means The OpenPOWER Foundation.

“*Licensed Patent Claims*” means patent claims:

(a) licensable by or through OPF; and

(b) which, but for this Agreement, would be necessarily infringed by the use of the Power ISA in making, using, or otherwise implementing a Power Compliant Chip.

“*Party(ies)*” means Recipient or OPF or both.

“*OpenPOWER ISA Compliance Definition*” means the validation procedures associated with architectural compliance developed, delivered, and maintained by and available from OPF.

“*Power Compliant*” means an implementation of (i) one of the Compliance Subsets alone or (ii) one of the Compliance Subsets together with selected permitted combinations of additional instructions and/or facilities within the Power ISA, in the case of clauses (i) and (ii), provided that such implementation meets the corresponding portions of the OpenPOWER ISA Compliance Definition.

“*Power ISA Core*” means an implementation of the Power ISA that is represented by software, a hardware description language (HDL), or an Integrated Circuit design, but excluding physically implemented chips (such as microprocessors, system on a chips, or field-programmable gate arrays (FPGAs)); provided that such implementation is primarily designed to be included as part of software, a hardware description language (HDL), or an Integrated Circuit design that are in each case Power Compliant, regardless of whether such implementation, independently, is Power Compliant.

“*Power Compliant Chip*” means a Power Compliant physical implementation of one or more Power ISA Cores into one or more Integrated Circuits, including, for example, in a microprocessor, system on a chip, or a field-programmable gate array (FPGA), provided that all portions of such physical implementation are Power Compliant.

“*Request for Change (RFC)*” means any request for change in the Power ISA as a whole or a change in the definition of a Compliance Subset provided in the Power ISA.

## 1. Grant of Rights

Solely for the purposes of developing and expanding the Power ISA and the POWER ecosystem, and subject to the terms of this Agreement:

1.1 OPF grants to Recipient a nonexclusive, worldwide, perpetual, royalty-free, non-transferable license under all copyrights licensable by OPF and contained in the Power ISA to a) develop technology products compatible with the Power ISA, and b) create, use, reproduce, perform, display, and distribute Power ISA Cores.

1.2 OPF grants to Recipient the right to license Recipient Power ISA Cores under the Creative Commons Attribution 4.0 license.

1.3 OPF grants to Recipient the right to sell or license Recipient Power ISA Cores under independent terms that are consistent with the rights and licenses granted under this Agreement. As a condition of the license grant under this section 1.3, the Recipient must either provide the Power ISA with this Agreement to the downstream recipient, or provide notification for the downstream recipient to obtain the Power ISA and this Agreement to have appropriate patent licenses to implement the Power ISA Core as a Power Compliant Chip. It is clarified that no rights are to be granted under this Section 1.3 beyond what is expressly permitted by this Agreement.

1.4 Notwithstanding Sections 1.1 through 1.3 above, Recipient shall not have the right or license to create, use, reproduce, perform, display, distribute, sell, or license the Power ISA Core in a physically implemented chip (including a microprocessor, system on a chip, or a field-programmable gate array [FPGA]) that is not Power Compliant, nor to license others to do so.

1.5 OPF grants to Recipient a nonexclusive, worldwide, perpetual, royalty-free, non-transferable license under Licensed Patent Claims to make, use, import, export, sell, offer for sale, and distribute Power Compliant Chips.

1.6 If Recipient institutes patent litigation or an administrative proceeding (including a cross-claim or counterclaim in a lawsuit, or a United States International Trade Commission proceeding) against OPF, OPF members, or any third-party entity (including but not limited to any third party that made a Contribution) alleging infringement of any Recipient patent by any version of the Power ISA, or the implementation thereof in a CPU design, IP core, or chip, then all rights, covenants, and licenses granted by OPF to Recipient under this Agreement shall terminate as of the date such litigation or proceeding is initiated.

1.7 Without limiting any other rights or remedies of OPF, if Recipient materially breaches the terms of this Agreement, OPF may terminate this Agreement at its discretion.

## 2. Modifications to the Power ISA

2.1 Recipient shall have the right to submit Contributions to the Power ISA through a prospectively authorized process by OPF but shall not implement such Contributions until fully approved through the prospectively authorized OPF process.

2.2 Recipient may create Custom Extensions as described and permitted in the Power ISA. Recipient is encouraged, but not required, to bring their Custom Extensions through the authorized OPF process for contributions. For clarity, Custom Extensions cannot be guaranteed to be compatible with another third-party's Custom Extensions.

## 3. Ownership

3.1 Nothing in this Agreement shall be deemed to transfer to Recipient any ownership interest in any intellectual property of OPF or of any contributor to the Power ISA, including but not limited to any copyrights, trade secrets, know-how, trademarks associated with the Power ISA or any patents, registrations or applications for protection of such intellectual property.

3.2 Recipient retains ownership of all incremental work done by Recipient to create Power ISA Cores and Power Compliant Chips, subject to the ownership rights of OPF and any contributors to the Power ISA. Nothing in this Agreement shall be deemed to transfer to OPF any ownership interest in any intellectual property of Recipient, including but not limited to any copyrights, trade secrets, know-how, trademarks, patents, registrations, or applications for protection of such intellectual property.

## 4. Limitation of Liability

4.1 THE POWER ISA AND ANY OTHER INFORMATION CONTAINED IN OR PROVIDED UNDER THIS DOCUMENT ARE PROVIDED ON AN "AS IS" BASIS. OPF makes no representations or warranties, either express or implied, including but not limited to, warranties of merchantability, fitness for a particular purpose, or non-infringement, or that any practice or implementation of the Power ISA or other OPF documentation will not infringe any third-party patents, copyrights, trade secrets, or other rights. In no event will OPF or any other person or entity submitting any Contribution to OPF be liable for damages arising directly or indirectly from any use of the Power ISA or any other information contained in or provided under this document.

**5. Compliance with Law**

5.1 Recipient shall be responsible for compliance with all applicable laws, regulations and ordinances, and will obtain all necessary permits and authorizations applicable to the future conduct of its business involving the Power ISA. Recipient agrees to comply with all applicable international trade laws and regulations such as export controls, embargo/sanctions, antiboycott, and customs laws related to the future conduct of the business involving the Power ISA to be transferred under this Agreement. Recipient warrants that it is knowledgeable with, and will remain in full compliance with, all applicable export controls and embargo/sanctions laws, regulations or rules, orders, and policies, including but not limited to, the U.S. International Traffic in Arms Regulations (“ITAR”), the U.S. Export Administration Regulations (“EAR”), and the regulations of the Office of Foreign Assets Control (“OFAC”), U.S. Department of Treasury.

**6. Choice of Law**

6.1 This Agreement is governed by the laws of the State of New York, without regard to the conflict of law provisions thereof.

**7. Publicity**

7.1 Nothing contained in these terms shall be construed as conferring any right to use in advertising, publicity or other promotional activities any name, trade name, trademark or other designation of any Party hereto (including any contraction, abbreviation or simulation of any of the foregoing).

All capitalized terms in the following text have the meanings assigned to them in the OpenPOWER Intellectual Property Rights Policy (the “OpenPOWER IPR Policy”). The full Policy may be found at the OpenPOWER website.

OpenPOWER requests that any OpenPOWER Party or any other party that believes it has patent claims that would necessarily be infringed by implementations of this OpenPOWER Standards Final Deliverable, to notify OpenPOWER WG Administrator and provide an indication of its willingness to grant patent licenses to such patent claims in a manner consistent with the IPR Mode of the OpenPOWER Work Group that produced this deliverable.

OpenPOWER invites any party to contact the OpenPOWER WG Administrator if it is aware of a claim of ownership of any patent claims that would necessarily be infringed by implementations of this OpenPOWER Standards Final Deliverable by a patent holder that is not willing to provide a license to such patent claims in a manner consistent with the IPR Mode of the OpenPOWER Work Group that produced this OpenPOWER Standards Final Deliverable. OpenPOWER may include such claims on its website but disclaims any obligation to do so.

OpenPOWER takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this OpenPOWER Standards Final Deliverable or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on OpenPOWER procedures with respect to rights in any document or deliverable produced by an OpenPOWER Work Group can be found on the OpenPOWER website. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this OpenPOWER Standards Final Deliverable, can be obtained from the OpenPOWER WG Administrator. OpenPOWER makes no representation that any information or list of intellectual property rights will at any time be complete, or that any claims in such list are, in fact, Essential Claims.

## Preface

The roots of the Power ISA (Instruction Set Architecture) extend back 30 years, to IBM Research. The POWER (Performance Optimization With Enhanced RISC) Architecture was introduced with the RISC System/6000 product family in early 1990. In 1991, Apple, IBM, and Motorola began the collaboration to evolve to the PowerPC Architecture, expanding the architecture's applicability. In 1997, Motorola and IBM began another collaboration, focused on optimizing PowerPC for embedded systems, which produced Book E.

In 2006, Freescale and IBM collaborated on the creation of the Power ISA Version 2.03, which represented the reunification of the architecture by combining Book E content with the more general purpose PowerPC Version 2.02. The resulting architecture included environment-specific privileged architecture optimizations (two Book IIIs) and optional application-specific facilities (categories) as extensions to a pervasive base architecture.

In support of the OpenPOWER Foundation's standardization of server architecture, Power ISA Version 3.0 streamlined this integration by choosing a single Book III and a set of widely used categories to become part of the base architecture for all forward-looking Power implementations. All other optional architecture categories were eliminated to ensure increased application portability between Power processors. Legacy embedded applications that require the eliminated material will continue to use V. 2.07B.

Power ISA Version 3.0C took the first step in re-introducing optionality into the architecture as the Power ISA moves to an "open" model governed by the OpenPOWER Foundation. Material later in the preface identifies compliancy subsets of the architecture and the optional features which they comprise.

The Power ISA Version 3.1B consists of three books and a set of appendices.

Book I, *Power ISA User Instruction Set Architecture*, covers the base instruction set and related facilities available to the application programmer.

Book II, *Power ISA Virtual Environment Architecture*, defines the storage model and other instructions and facilities that enable the application programmer to create multithreaded programs and programs that interact with certain physical realities of the computing environment.

Book III, *Power ISA Operating Environment Architecture*, defines the supervisor instructions and related facilities.

As used in this document, the term "Power ISA" refers to the instructions and facilities described in Books I, II, and III.

Change bars have been included in the body of this document to indicate changes from the Power ISA Version 3.0C.

## Summary of Changes in Power ISA Version 3.1B

This document is Version 3.1B of the Power ISA. It is intended to supersede and replace version 3.0C. Any product descriptions that reference a version of the architecture are understood to reference the latest version. This version was created by making miscellaneous corrections and by applying the following requests for change (RFCs) to Power ISA Version 3.0C. In contrast to change bars elsewhere in the document, change bars in this summary of changes indicate changes relative to v3.1.

### Byte-Reverse Instructions:

Added new GPR-based byte-reverse instructions.

### Vector Integer Multiply/Divide/Modulo Instructions:

Added SIMD-equivalent forms of FXU multiply, divide, and modulo instructions to increase synergy with FXU instruction set for auto-vectorization.

### Instruction Prefix Support:

Added a 32-bit instruction prefix to support PC-relative addressing, up to 34-bit immediate operands, additional operand fields, and additional opcode space.

### BHRB Filtering:

Added new BHRB Filtering fields and defined associated terminology.

### VSX 32-byte Storage Access Operations:

Added new 32-byte VSR load and store instructions.

### Multiple DEAW:

Added a second Data Address Watchpoint. [H]DAR is set to the first byte of overlap. 512B boundary is removed. Match detection is on DW granularity independent of operand size. SIAR/SDAR are not altered by the Trace interrupt when TE=0b00.

### 128-bit Binary Integer Operations:

Added new 128-bit integer instructions for comparison, divide, modulo, rotate, shift, DFP and QFP format conversion operations. Also added 128-bit integer multiply assist operations.

### SIMD Permute-Class Operations:

New permute-class instructions for element extraction and insertion operations, 32-bit immediate splat operations, doublewide bit shift left/right operations, element mask-based blend operations, and an arbitrary-wide permute assist operation.

### Reduced-Precision: Outer Product Operations:

Added new outer-product instructions to accelerate matrix multiplication, supporting 4-bit, 8-bit, and 16-bit integer and 16-bit, 32-bit, and 64-bit floating-point datatypes.

### Bit-Manipulation Operations:

Added new bit-manipulation instructions.

### Set Boolean Extension:

Added four new instructions that convert a condition code bit (any CR bit) into a Boolean (0/1), the negation of a Boolean (1/0), a field mask (all 0s/all 1s), and the negation of a field mask (all 1s/all 0s) that is placed into a GPR.

### String Operations:

Added new string isolate instructions to support null-terminated and explicit-length strings.

### Test LSB by Byte Operation:

Added new instruction to set any CR field to reflect predicate compare summary status, not just CR field 6 which Rc=1 is limited to.

### VSX Load/Store Rightmost Element Operations:

Added new load and store instructions that transfer the rightmost vector element between VSR and storage.

### Prefixed addi Instruction and Prefixed Load/Store Instructions and Addressing:

Using new instruction prefix, added support for extended immediate displacements and PC-relative addressing for a specific set of GPR and VSR load and store operations.

### VSX Scalar Minimum/Maximum/Compare Quad-Precision Operations:

Add new quad-precision minimum, maximum, and predicate comparison instructions.

### CMODX Extension for Prefix:

The quasi patch class of unsynchronized updates to instruction storage is made architecture. Language is changed and rules are added to account for the addition of prefixed instructions to the architecture.

### Reduced-Precision - bfloat16 Outer Product & Format Conversion Operations:

Added new instructions to accelerate matrix multiplication and format conversions for the bfloat16 datatype.

### Processor Control Register Extensions:

The PCR is updated to accommodate new problem-state instructions added in v3.1.

### Reduced-Precision: Missing Integer-based Outer Product Operations:

Added additional new instructions to accelerate matrix multiplication for 8-bit and 16-bit integer datatypes.

### VSX Mask Manipulation Operations:

Added new vector instructions to manipulate vector masks.

### VSX PCV Generate Operations:

Added new permute control vector generate instructions to support efficient emulation of load expand and store compress operations.

New Performance Monitor SPRs:

Added three new performance monitor SPRs. SIER2 and SIER3 are added to provide additional information about the sampled instruction. MMCR3 is added for further sampling related configuration control.

Translation Management Extensions:

Added an L bit for sbiag, where L=1 indicates an invalidation by LPID. tlbil with SET=0 and IS=1, 2, or 3 invalidate all congruence classes and tlbil with SET !=0 is a noop except when RIC=1, which becomes an invalid form. Made ISL apply in hypervisor state.

Copy/Paste Extensions:

Added memory move functionality.

Persistent Storage / Store Sync:

Added pushes and synchronization for persistent storage and variants of sync optimized for store ordering.

Dynamic Execution Control Facility:

Added support for dynamic software control of security vs performance aspect during execution of a hardware thread.

Pause / Wait-reserve:

Added two new variants of the wait instruction; removed platform notify, TIDR, and CIR.

Performance Monitor Facility Sampling Security:

Changes the definition of MMCR0<sub>PMCC</sub>=0b00 case to allow for a new secure mode of access with regards to sampling registers which is available conditional on new MMCR<sub>PMCC</sub><sub>EXT</sub> bit. Introduces a new freeze mode for ultravisor privilege state differentiating it from hypervisor privilege state freeze mode. Restricts BHRB to only record in problem state. Also MMCR0<sub>PMACQ</sub>, bit 52 of MMCR0 is removed.

Hash-based Pointer Authentication: Added support for hash-based pointer authentication scheme. Primary application of this scheme is protection against return-oriented programming (ROP).

Hypervisor Interrupt Location Control:

Added HAIL for the hypervisor to specify its interrupt behavior independent from guest state.

Changes and Clarifications to Data Cache Management Instructions:

Specifies that the number of software data prefetch streams guaranteed to be available to a thread varies by degree of multithreading in the processor. Clarifies when a new software data prefetch stream will overwrite an existing one. Redefines when a thread's software data prefetch streams are cleared.

BHRB Disable Control:

Adds an additional control on BHRB recording via MMCR<sub>A</sub> bit 26 namely MMCR<sub>A</sub><sub>BHRBRD</sub>.

Translation Management Extensions #2:

Added SW bit to the radix PDE. Added the term "effR" in an attempt to clarify tlbie[] function. Allowed for the TLB entry not to have the base (or actual) page size(s).

Exception related fixes for MMA:

When underflow is enabled, simple underflow (when the result is not also inexact) causes an exception. Exception behavior for bfloat16 converts is made similar to other converts instead of similar to the GERS. Underflow and overflow trap enabled exception bit setting is corrected. The name and mnemonic for xvcvbf16sp are changed to indicate it generates no floating-point exceptions.

Storage Interrupt Cleanup:

Cleaned up the presentations of [H]DSI and [H]ISI and makes related changes elsewhere. Also removed application access to Radix Quadrant 3.

Performance Monitor Threshold Counter Multiplier Width:

Extended the Threshold Event Counter Multiplier field (TECM) specified by MMCRA SPR from 7 bits [38:44] to 8 bits [37:44]. Added the interpretation of Sampled Instruction Type SITYPE=0b111 encoding given by SIER[46:48].

VSX Load/Store with Length Atomicity:

Defined circumstances under which the accesses caused by the VSX load/store with length instructions are single copy atomic. Removed the special case exclusion for single copy atomicity of accesses to the individual words or doublewords of load/store multiple. Applied Java decomposition rules to the VSX load/store with length instructions and the individual word/doubleword accesses of load/store multiple.

Synchronization Clarifications:

Made various clarifications related to the synchronization of translation table updates and invalidations.

## OpenISA Compliancy Subset Methodology and Requirements

The PowerISA comprises the base architecture (that which is never optional - not part of any optional or deprecated feature), four groups of optional features, and a group of deprecated features. (See the next two pages.) Authorized implementations of the Power ISA must support one of the four *Compliancy Subsets* defined below. Support of a subset means that a design includes the base architecture and all features that are not optional for that subset. A supporting design may also include any features that are optional for the supported subset (including deprecated features), subject to stated pre-requisites, and *Custom Extensions* created using the *architecture sandbox* defined below. “Inclusion” of the base architecture, of an optional feature, or of a custom extension can be accomplished using a combination of hardware and firmware, provided that the firmware is implemented using other elements of the base architecture and of the included features, and elements of the architecture

sandbox; invoked using the second and third pages of real storage (see the second bullet of Section 6.7.5 of Book III); and subject to the prohibitions against the use of firmware given in Section 7.4.4 of Book III. Each optional or deprecated feature must be implemented in its entirety. Attempted execution of an instruction associated with a feature that is not included must cause a Hypervisor Emulation Assistance Interrupt (HEAI). The result of an attempted access to an SPR associated with a feature that is not included using *mtspr* or *mfspr* must be that described for “an SPR number that is undefined for the implementation” in the respective instruction description. See Section 5.4.4 of Book III. For Scalar Fixed-Point + Floating-Point and Scalar Fixed-Point Compliancy Subset implementations that do not include the logical partitioning feature, an Illegal Instruction type Program Interrupt as described in the penultimate Programming Note in Section 7.5.9 of Book III may be substituted for the HEAI.

---

## OpenPOWER Compliancy Subsets

### 1. AIX Compliancy Subset (ACS)

The following features are optional for this compliancy subset. The rest of PowerISA v3.1B must be included.

Always Optional Features listed below

Deprecated Features listed below

### 2. Linux Compliancy Subset (LCS)

The following features are optional for this compliancy subset. The rest of PowerISA v3.1B must be included.

Linux Optional Features listed below

Always Optional Features listed below

Deprecated Features listed below

### 3. Scalar Fixed-Point + Floating-Point Compliancy Subset (SFFS)

The following features are optional for this compliancy subset. The rest of PowerISA v3.1B must be included.

Scalar Float Optional Features listed below,

Linux Optional Features listed below

Always Optional Features listed below

Deprecated Features listed below

### 4. Scalar Fixed-Point Compliancy Subset (SFS)

The following features are optional for this compliancy subset. The rest of PowerISA v3.1B must be included.

Scalar Fixed Optional Features listed below

Scalar Float Optional Features listed below

Linux Optional Features listed below

Always Optional Features listed below

Deprecated Features listed below

## OpenPOWER Optional and Deprecated Features

### Always Optional Features

The following features are optional for all compliancy subsets.

Feature	Reference
Copy/Paste for accelerator invocation and memory copy (CPA)	See Section 4.4 of Book II.
Secure Memory Facility (SMF) <sup>1</sup>	See Chapter 3 of Book III.
Hardware and software data stream prefetching (STM) (DSCR state not optional)	See Section 4.2 and Section 4.3.2 of Book II.
M=0 (M) (non-coherent memory)	See Section 1.6.3 of Book II.
W=1 (W) (write through-required memory)	See Section 1.6.1 of Book II.
Power management (PM) <sup>2</sup>	See Section 4.2.2, Section 4.3.2, and the description of the PECE field(s) of the LPCR in Section 2.2 of Book III.
MMA <sup>3</sup>	See Section 7.2.1.3 and Section 7.6.1.12 of Book I.

Notes:

1. LPAR is a pre-requisite for SMF.
2. If Power management is implemented by an ACS- or LCS-compliant design, it must be implemented as the architecture describes. If Power management is implemented by an SFFS- or SFS-compliant design, it need not be implemented as the architecture describes, and may include different interfaces created from the architecture sandbox.
3. SIMD is a requirement for MMA.

## Linux Optional Features

The following features are optional for the Linux Compliancy Subset, the Scalar Fixed-Point + Floating-Point Compliancy Subset, and the Scalar Fixed-Point Compliancy Subset.

Feature	Reference
AIL/HAIL programmability (AIL) (AIL=3 and HAIL=1 required)	See the description of the AIL and HAIL fields of the LPCR in Section 2.2 of Book III.
Atomic Memory Operations (AMO)	See Section 4.5 of Book II.
Big Endian (BE) (LE is required for LCS. Linux supporting LCS is 64b LE Linux.)	See Section 1.10 of Book I and its first two subsections. Also see the description of the ILE field of the LPCR in Section 2.2 of Book III and the description of the LE bit of the MSR in Section 4.2.1 of Book III.
Branch History Rolling Buffer (BHRB)	See Chapter 7 of Book II.
Decimal floating-point (DFP) <sup>1</sup>	See Chapter 5 of Book I.
Event-Based Branching (EBB)	See Chapter 6 of Book II.
EVIRT programmability (EVIRT) <sup>2</sup> (EVIRT=1 required)	See the description of the EVIRT field of the LPCR in Section 2.2 of Book III.
SLB / HPT translation (HPT) (includes VPM, ISL, KBV)	See Section 6.7.7 through Section 6.7.9 of Book III. Also see the description of the VPM, ISL, and KBV fields of the LPCR in Section 2.2 of Book III.
Load/Store Multiple instructions (LM)	See Section 3.3.6 of Book I.
Load/Store String instructions (LS)	See Section 3.3.7 of Book I.
Processor Compatibility Register (PCR) <sup>2</sup>	See Section 2.5 of Book III.
Quad-precision floating-point (QFP) <sup>3</sup>	See Chapter 7 of Book I.
Broadcast TLB shutdown (TLBIE) (tlbiel not optional)	See Section 6.9.3.3 of Book III.
Control Register (CTRL)	See Section 5.3.4 of Book III.
SMT (SMT) <sup>4</sup> (includes PURR/SPURR, PSPB, RPR, PPR, processor control) (PPR and hyper-visor/ultravisor messaging not optional)	See Chapter 3 of Book II. Also see Section 5.3.5 through Section 5.3.7, Section 8.6, Section 8.7, and Chapter 12 of Book III.

### Notes:

1. FP is a pre-requisite for DFP.
2. LPAR is a pre-requisite for EVIRT and PCR.
3. SIMD is a pre-requisite for QFP.
4. If SMT is implemented by an LCS-compliant design, it must be implemented as the architecture describes. If SMT is not implemented by an LCS-compliant design, the design must not except on PPR accesses and must implement *msgsnd[u]*, *msgclr[u]*, and *msgsync*. If SMT is implemented by an SFFS- or SFS-compliant design, it need not be implemented as the architecture describes, and may include different interfaces created from the architecture sandbox.

### Scalar Float Optional Features

The following features are optional for the Scalar Fixed-Point + Floating-Point Compliancy Subset and the Scalar Fixed-Point Compliancy Subset.

Feature	Reference
SIMD (SIMD) <sup>1</sup> (VMX and VSX)	See Chapter 6 and Chapter 7 of Book I.
SF=1 (64-bit) <sup>2</sup>	See Section 1.5 and Section 1.10.3 of Book I and the description of the SF field of the MSR in Section 4.2.1 of Book III.
Little Endian (LE) (BE is required for SFFS and SFS. Linux supporting SFFS and SFS is 32b BE Linux.)	See Section 1.10 of Book I and its first two subsections. Also see the description of the ILE field of the LPCR in Section 2.2 of Book III and the description of the LE bit of the MSR in Section 4.2.1 of Book III.
Logical partitioning (LPAR) <sup>3,4</sup>	See Chapter 2 of Book III.
Fixed-point instructions that modify OV to indicate whether overflow occurred (OV) (addex and instructions with OE=1 such as addo, subfo, etc.)	See Section 3.3.9 of Book I.
Nested radix translation (ROR) <sup>5</sup> (single-level radix translation not optional)	See Section 6.7.7 and Section 6.7.10 of Book III.

Notes:

1. FP is a pre-requisite for SIMD.
2. When 64-bit is not included, a single radix tree will be used to map both application and OS address spaces (no quadrant structure).
3. 64-bit is a pre-requisite for LPAR.
4. When LPAR is not included, MSR<sub>HV</sub>=1 always.
5. LPAR is a pre-requisite for ROR.

### Scalar Fixed Optional Features

The following features are optional for the Scalar Fixed-Point Compliancy Subset

Feature	Reference
Scalar binary floating-point (FP)	See Chapter 4 of Book I.

### Deprecated Features

There are no deprecated features in Power ISA v3.1B.

## OpenPOWER Architecture Sandbox

OpenPOWER compliancy subsets permit Custom Extensions. Any architectural resources used for Custom Extensions must use only the resources described below and any instructions and SPRs that the architecture describes as implementation-dependent.

Development of Custom Extensions using the architecture sandbox is appropriate for facilities that benefit a small portion of the processor design space. For facilities with broad applicability, developers are strongly encouraged to submit a proposal for adoption into the architecture. Adopted proposals will become optional or required features of the architecture, and will be assigned resources that are not in the architecture sandbox to avoid fragmentation of the architecture. Facilities described in proposals that are not adopted into the architecture may be implemented as Custom Extensions using the architecture sandbox.

System software and toolchain support of Custom Extensions is not guaranteed. Developers are encouraged to provide a means to disable custom extensions to present an architecture that is supported by standard system software and toolchain.

The architecture sandbox consists of the following.

- The designated opcode sandbox is instructions having a primary opcode of 22. Note that primary opcode 22 is reserved by AIX. As a result, Custom Extensions that use primary opcode 22 are not compatible with ACS.
- The designated SPR sandbox consists of non-privileged SPRs 704-719 and privileged SPRs 720-735.
- The designated [H]FSCR sandbox consists of [H]FSCR bits 8-9 and their corresponding IC values.
- The designated XER bit sandbox consists of XER bits 54:55.
- The designated FPSCR bit sandbox consists of FPSCR bits 14-15.
- The designated VSCR bit sandbox consists of VSCR bits 96 & 112. VSCR bit 96 is provided for Vector Facility control & VSCR bit 112 is provided for Vector Facility status.
- The designated interrupt vector sandbox consists of interrupt vector 0x0000\_0000\_0000\_OFEO.

## Preface . . . . . vii

Summary of Changes in Power ISA Version 3.1B . . . . .	viii
OpenISA Compliancy Subset Methodology and Requirements . . . . .	x

## Table of Contents . . . . . xv

### Book I:

#### Power ISA User Instruction Set Architecture . . . . . 1

#### Chapter 1. Introduction . . . . . 3

1.1 Overview . . . . .	3
1.2 Instruction Mnemonics and Operands	3
1.3 Document Conventions . . . . .	3
1.3.1 Definitions . . . . .	3
1.3.2 Notation . . . . .	4
1.3.3 Reserved Fields, Reserved Values, and Reserved SPRs . . . . .	5
1.3.4 Description of Instruction Operation	6
1.3.5 Phased-Out Facilities . . . . .	8
1.4 Processor Overview . . . . .	9
1.5 Computation modes . . . . .	10
1.6 Instruction Formats . . . . .	11
1.6.1 Word Instruction Formats . . . . .	12
1.6.1.1 A-FORM . . . . .	12
1.6.1.2 B-FORM . . . . .	12
1.6.1.3 D-FORM . . . . .	12
1.6.1.4 DQ-FORM . . . . .	12
1.6.1.5 DS-FORM . . . . .	12
1.6.1.6 DX-FORM . . . . .	12
1.6.1.7 I-FORM . . . . .	12
1.6.1.8 M-FORM . . . . .	12
1.6.1.9 MD-FORM . . . . .	12
1.6.1.10 MDS-FORM . . . . .	12
1.6.1.11 SC-FORM . . . . .	12
1.6.1.12 VA-FORM . . . . .	12
1.6.1.13 VC-FORM . . . . .	12
1.6.1.14 VX-FORM . . . . .	13
1.6.1.15 X-FORM . . . . .	13

1.6.1.16 XFL-FORM . . . . .	15
1.6.1.17 XFX-FORM . . . . .	15
1.6.1.18 XL-FORM . . . . .	15
1.6.1.19 XO-FORM . . . . .	15
1.6.1.20 XS-FORM . . . . .	15
1.6.1.21 XX2-FORM . . . . .	15
1.6.1.22 XX3-FORM . . . . .	15
1.6.1.23 XX4-FORM . . . . .	15
1.6.1.24 Z22-FORM . . . . .	15
1.6.1.25 Z23-FORM . . . . .	16
1.6.2 Word Instruction Fields . . . . .	16
1.6.3 Instruction Prefix Formats . . . . .	23
1.6.3.1 Type 00 Prefix – Eight-Byte Load/Store Instructions . . . . .	23
1.6.3.2 Type 01 Prefix – Eight-Byte Register-to-Register Instructions . . . . .	23
1.6.3.3 Type 10 - Modified Load/Store Instructions . . . . .	23
1.6.3.4 Type 11 - Modified Register-to-Register Instructions . . . . .	23
1.6.4 Instruction Prefix Fields . . . . .	24
1.7 Classes of Instructions . . . . .	24
1.7.1 Defined Instruction Class . . . . .	24
1.7.2 Illegal Instruction Class . . . . .	25
1.7.3 Reserved Instruction Class . . . . .	25
1.8 Forms of Defined Instructions . . . . .	25
1.8.1 Preferred Instruction Forms . . . . .	25
1.8.2 Invalid Instruction Forms . . . . .	25
1.8.3 Reserved-no-op Instructions . . . . .	25
1.9 Exceptions . . . . .	25
1.10 Storage Addressing . . . . .	26
1.10.1 Storage Operands . . . . .	26
1.10.2 Instruction Fetches . . . . .	29
1.10.3 Effective Address Calculation . . . . .	30

#### Chapter 2. Branch Facility . . . . . 33

2.1 Branch Facility Overview . . . . .	33
2.2 Instruction Execution Order . . . . .	33
2.3 Branch Facility Registers . . . . .	34
2.3.1 Condition Register . . . . .	34
2.3.2 Link Register . . . . .	35
2.3.3 Count Register . . . . .	35
2.3.4 Target Address Register . . . . .	35
2.4 Branch Instructions . . . . .	37
2.5 Condition Register Instructions . . . . .	44

2.5.1	Condition Register Logical Instructions	44
2.5.2	Condition Register Field Instruction	46
2.6	System Call Instructions	47

## Chapter 3. Fixed-Point Facility . . . 49

3.1	Fixed-Point Facility Overview	49
3.2	Fixed-Point Facility Registers	49
3.2.1	General Purpose Registers	49
3.2.2	Fixed-Point Exception Register	49
3.2.3	VR Save Register	50
3.3	Fixed-Point Facility Instructions	51
3.3.1	Fixed-Point Storage Access Instructions	51
3.3.1.1	Storage Access Exceptions	51
3.3.2	Fixed-Point Load Instructions	51
3.3.2.1	64-bit Fixed-Point Load Instructions	56
3.3.3	Fixed-Point Store Instructions	58
3.3.3.1	64-bit Fixed-Point Store Instructions	62
3.3.4	Fixed Point Load and Store Quadword Instructions	64
3.3.5	Fixed-Point Load and Store with Byte Reversal Instructions	67
3.3.5.1	64-Bit Load and Store with Byte Reversal Instructions	69
3.3.6	Fixed-Point Load and Store Multiple Instructions	70
3.3.7	Fixed-Point Move Assist Instructions [Phased Out]	71
3.3.8	Other Fixed-Point Instructions	74
3.3.9	Fixed-Point Arithmetic Instructions	75
3.3.9.1	64-bit Fixed-Point Arithmetic Instructions	87
3.3.10	Fixed-Point Compare Instructions	92
3.3.10.1	Character-Type Compare Instructions	94
3.3.11	Fixed-Point Trap Instructions	96
3.3.11.1	64-bit Fixed-Point Trap Instructions	98
3.3.12	Fixed-Point Select	98
3.3.13	Fixed-Point Logical Instructions	99
3.3.13.1	64-bit Fixed-Point Logical Instructions	104
3.3.14	Fixed-Point Rotate and Shift Instructions	107
3.3.14.1	Fixed-Point Rotate Instructions	107
3.3.14.1.1	64-bit Fixed-Point Rotate Instructions	110
3.3.14.2	Fixed-Point Shift Instructions	113

3.3.14.2.1	64-bit Fixed-Point Shift Instructions	115
3.3.15	Binary Coded Decimal (BCD) Assist Instructions	117
3.3.16	Byte-Reverse Instructions	119
3.3.17	Fixed-Point Hash Instructions	120
3.3.17.1	Hash Function Description	120
3.3.17.2	Fixed-Point Hash Instructions	121
3.3.18	Move To/From Vector-Scalar Register Instructions	123
3.3.19	Move To/From System Register Instructions	127
3.3.20	Prefixed No-Operation Instruction	133

## Chapter 4. Floating-Point Facility 135

4.1	Floating-Point Facility Overview	135
4.2	Floating-Point Facility Registers	136
4.2.1	Floating-Point Registers	136
4.2.2	Floating-Point Status and Control Register	136
4.3	Floating-Point Data	139
4.3.1	Data Format	139
4.3.2	Value Representation	139
4.3.3	Sign of Result	141
4.3.4	Normalization and Denormalization	141
4.3.5	Data Handling and Precision	141
4.3.5.1	Single-Precision Operands	141
4.3.5.2	Integer-Valued Operands	142
4.3.6	Rounding	143
4.4	Floating-Point Exceptions	144
4.4.1	Invalid Operation Exception	146
4.4.1.1	Definition	146
4.4.1.2	Action	146
4.4.2	Zero Divide Exception	146
4.4.2.1	Definition	146
4.4.2.2	Action	147
4.4.3	Overflow Exception	147
4.4.3.1	Definition	147
4.4.3.2	Action	147
4.4.4	Underflow Exception	148
4.4.4.1	Definition	148
4.4.4.2	Action	148
4.4.5	Inexact Exception	148
4.4.5.1	Definition	148
4.4.5.2	Action	148
4.5	Floating-Point Execution Models	149
4.5.1	Execution Model for IEEE Operations	149
4.5.2	Execution Model for Multiply-Add Type Instructions	151
4.6	Floating-Point Facility Instructions	152
4.6.1	Floating-Point Storage Access Instructions	152
4.6.1.1	Storage Access Exceptions	152

4.6.2	Floating-Point Load Instructions	153	5.5.10.1	Invalid Operation Exception	203
4.6.3	Floating-Point Store Instructions	158	5.5.10.2	Zero Divide Exception	204
4.6.4	Floating-Point Load and Store Double Pair Instructions [Phased-Out]	163	5.5.10.3	Overflow Exception	205
4.6.5	Floating-Point Move Instructions	165	5.5.10.4	Underflow Exception	205
4.6.6	Floating-Point Arithmetic Instructions	167	5.5.10.5	Inexact Exception	206
4.6.6.1	Floating-Point Elementary Arithmetic Instructions	167	5.5.11	Summary of Normal Rounding And Range Actions	207
4.6.6.2	Floating-Point Multiply-Add Instructions	172	5.6	DFP Instruction Descriptions	209
4.6.7	Floating-Point Rounding and Conversion Instructions	174	5.6.1	DFP Arithmetic Instructions	209
4.6.7.1	Floating-Point Rounding Instruction	174	5.6.2	DFP Compare Instructions	214
4.6.7.2	Floating-Point Convert To/From Integer Instructions	174	5.6.3	DFP Test Instructions	217
4.6.7.3	Floating Round to Integer Instructions	181	5.6.4	DFP Quantum Adjustment Instructions	221
4.6.8	Floating-Point Compare Instructions	183	5.6.5	DFP Conversion Instructions	232
4.6.9	Floating-Point Select Instruction	184	5.6.5.1	DFP Data-Format Conversion Instructions	232
4.6.10	Floating-Point Status and Control Register Instructions	186	5.6.5.2	DFP Data-Type Conversion Instructions	235
<b>Chapter 5. Decimal Floating-Point</b>			5.6.6	DFP Format Instructions	239
<b>191</b>			5.6.7	DFP Instruction Summary	243
5.1	Decimal Floating-Point (DFP) Facility Overview	191	<b>Chapter 6. Vector Facility</b>		
5.2	DFP Register Handling	192	<b>247</b>		
5.2.1	DFP Usage of Floating-Point Registers	192	6.1	Vector Facility Overview	247
5.3	DFP Support for Non-DFP Data Types	194	6.2	Chapter Conventions	247
5.4	DFP Number Representation	195	6.2.1	Description of Instruction Operation	247
5.4.1	DFP Data Format	195	6.3	Vector Facility Registers	262
5.4.1.1	Fields Within the Data Format	195	6.3.1	Vector-Scalar Registers	262
5.4.1.2	Summary of DFP Data Formats	196	6.3.2	Vector Status and Control Register	262
5.4.1.3	Preferred DPD Encoding	197	6.3.3	VR Save Register	263
5.4.2	Classes of DFP Data	197	6.4	Vector Storage Access Operations	264
5.5	DFP Execution Model	198	6.4.1	Accessing Unaligned Storage Operands	266
5.5.1	Rounding	198	6.5	Vector Integer Operations	268
5.5.2	Rounding Mode Specification	199	6.5.1	Integer Saturation	269
5.5.3	Formation of Final Result	199	6.6	Vector Floating-Point Operations	270
5.5.3.1	Use of Ideal Exponent	199	6.6.1	Floating-Point Overview	270
5.5.4	Arithmetic Operations	200	6.6.2	Floating-Point Exceptions	270
5.5.4.1	Sign of Arithmetic Result	200	6.6.2.1	NaN Operand Exception	270
5.5.5	Compare Operations	200	6.6.2.2	Invalid Operation Exception	271
5.5.6	Test Operations	200	6.6.2.3	Zero Divide Exception	271
5.5.7	Quantum Adjustment Operations	200	6.6.2.4	Log of Zero Exception	271
5.5.8	Conversion Operations	201	6.6.2.5	Overflow Exception	271
5.5.8.1	Data-Format Conversion	201	6.6.2.6	Underflow Exception	271
5.5.8.2	Data-Type Conversion	201	6.7	Vector Storage Access Instructions	272
5.5.9	Format Operations	201	6.7.1	Storage Access Exceptions	272
5.5.10	DFP Exceptions	201	6.7.2	Vector Load Instructions	273
			6.7.3	Vector Store Instructions	277
			6.7.4	Vector Alignment Support Instructions	281
			6.8	Vector Permute and Formatting Instructions	283
			6.8.1	Vector Pack Instructions	283
			6.8.2	Vector Unpack Instructions	290
			6.8.3	Vector Merge Instructions	294

6.8.4	Vector Splat Instructions . . . . .	298	6.9.2.2	Vector Integer Minimum Instructions . . . . .	389
6.8.5	Vector Permute Instruction . . . . .	301	6.9.3	Vector Integer Compare Instructions	393
6.8.6	Vector Select Instruction . . . . .	302	6.9.4	Vector Logical Instructions . . . . .	407
6.8.7	Vector Shift Instructions . . . . .	303	6.9.5	Vector Integer Rotate Instructions . . . . .	409
6.8.8	Vector Extract Element Instructions . . . . .	309	6.9.5.1	Vector Integer Rotate Left Instructions . . . . .	409
6.8.8.1	Vector Extract Element to VSR using Immediate-specified Index Instructions . . . . .	309	6.9.5.2	Vector Integer Rotate Left then AND with Mask Instructions . . . . .	412
6.8.8.2	Vector Extract Element to GPR using GPR-specified Index Instructions	311	6.9.5.3	Vector Integer Rotate Left then Mask Insert Instructions . . . . .	415
6.8.8.3	Vector Extract Double Element to VSR Using GPR-specified Index Instructions . . . . .	314	6.9.6	Vector Integer Shift Instructions . . . . .	418
6.8.9	Vector Insert Element Instructions . . . . .	318	6.9.6.1	Vector Integer Shift Left Instructions . . . . .	418
6.8.9.1	Vector Insert Element from VSR Using Immediate-specified Index Instructions . . . . .	318	6.9.6.2	Vector Integer Shift Right Instructions . . . . .	421
6.8.9.2	Vector Insert Element from GPR Using GPR-specified Index Instructions . . . . .	320	6.9.6.3	Vector Integer Shift Right Algebraic Instructions . . . . .	424
6.8.9.3	Vector Insert Element from GPR Using Immediate-specified Index Instructions . . . . .	324	6.10	Vector Floating-Point Instruction Set	427
6.8.9.4	Vector Insert Element from VSR Using GPR-specified Index Instructions . . . . .	325	6.10.1	Vector Floating-Point Arithmetic Instructions . . . . .	427
6.9	Vector Integer Instructions . . . . .	328	6.10.2	Vector Floating-Point Maximum/Minimum Instructions . . . . .	429
6.9.1	Vector Integer Arithmetic Instructions	328	6.10.3	Vector Floating-Point Rounding and Conversion Instructions . . . . .	430
6.9.1.1	Vector Integer Add Instructions	328	6.10.3.1	Vector Floating-Point Conversion Instructions . . . . .	430
6.9.1.2	Vector Integer Subtract Instructions	336	6.10.3.2	Vector Floating-Point Round to Integral Instructions . . . . .	432
6.9.1.3	Vector Integer Multiply Instructions	344	6.10.4	Vector Floating-Point Compare Instructions . . . . .	434
6.9.1.4	Vector Integer Multiply-Add/Sum Instructions . . . . .	356	6.10.5	Vector Floating-Point Estimate Instructions . . . . .	437
6.9.1.5	Vector Integer Divide Instructions . . . . .	363	6.11	Vector Exclusive-OR-based Instructions . . . . .	440
6.9.1.6	Vector Integer Modulo Instructions . . . . .	369	6.11.1	Vector AES Instructions . . . . .	440
6.9.1.7	Vector Integer Sum-Across Instructions . . . . .	372	6.11.2	Vector SHA-256 and SHA-512 Sigma Instructions . . . . .	443
6.9.1.8	Vector Integer Negate Instructions . . . . .	376	6.11.3	Vector Binary Polynomial Multiplication Instructions . . . . .	445
6.9.1.9	Vector Extend Sign Instructions . . . . .	377	6.11.4	Vector Permute & Exclusive-OR Instruction . . . . .	449
6.9.1.10	Vector Integer Average Instructions . . . . .	380	6.12	Vector Bit Manipulation Instructions . . . . .	450
6.9.1.11	Vector Integer Absolute Difference Instructions . . . . .	383	6.12.1	Vector Gather Bits Instructions	450
6.9.2	Vector Integer Maximum/Minimum Instructions . . . . .	385	6.12.2	Vector Count Leading Zeros Instructions . . . . .	452
6.9.2.1	Vector Integer Maximum Instructions . . . . .	385	6.12.3	Vector Count Trailing Zeros Instructions . . . . .	455
			6.12.4	Vector Count Leading/Trailing Zero LSB Instructions . . . . .	458
			6.12.5	Vector Bit Insert/Extract Instructions	459

6.12.6	Vector Centrifuge Instruction . .	461	7.3.2.4	Normalization and Denormalization	519
6.12.7	Vector Population Count Instructions . . . . .	462	7.3.2.5	Data Handling and Precision. .	519
6.12.8	Vector Parity Byte Instructions.	464	7.3.2.6	Rounding. . . . .	524
6.12.9	Vector Bit Permute Instructions	466	7.3.3	VSX Floating-Point Execution Models . . . . .	527
6.13	Vector Mask Manipulation Instructions . . . . .	468	7.3.3.1	VSX Execution Model for IEEE Operations. . . . .	527
6.13.1	Vector Mask Move Instructions	468	7.3.3.2	VSX Execution Model for Multiply-Add Type Instructions . . . . .	528
6.13.2	Vector Expand Mask Instructions .	471	7.4	VSX Floating-Point Exceptions . .	530
6.13.3	Vector Count Mask Bits Instructions	474	7.4.1	Floating-Point Invalid Operation Exception. . . . .	533
6.13.4	Vector Extract Mask Instructions . .	476	7.4.1.1	Definition . . . . .	533
6.14	Vector String Instructions . . . . .	479	7.4.1.2	Action for VE=1 . . . . .	533
6.14.1	Vector String Isolate Instructions . .	479	7.4.1.3	Action for VE=0 . . . . .	536
6.14.2	Vector Clear Bytes Instructions	481	7.4.2	Floating-Point Zero Divide Exception	545
6.15	Decimal Integer Instructions . . . .	482	7.4.2.1	Definition . . . . .	545
6.15.1	Decimal Integer Arithmetic Instructions . . . . .	482	7.4.2.2	Action for ZE=1 . . . . .	545
6.15.2	Decimal Integer Format Conversion Instructions . . . . .	485	7.4.2.3	Action for ZE=0 . . . . .	546
6.15.3	Decimal Integer Sign Manipulation Instructions . . . . .	494	7.4.3	Floating-Point Overflow Exception . .	548
6.15.4	Decimal Integer Shift and Round Instructions . . . . .	496	7.4.3.1	Definition . . . . .	548
6.15.5	Decimal Integer Truncate Instructions . . . . .	499	7.4.3.2	Action for OE=1 . . . . .	548
6.16	Vector Status and Control Register Instructions . . . . .	501	7.4.3.3	Action for OE=0. . . . .	551
<b>Chapter 7. Vector-Scalar Extension Facility . . . . . 503</b>			7.4.4	Floating-Point Underflow Exception .	554
7.1	Introduction. . . . .	503	7.4.4.1	Definition . . . . .	554
7.1.1	Overview of the Vector-Scalar Extension . . . . .	503	7.4.4.2	Action for UE=1 . . . . .	554
7.1.1.1	Compatibility with Floating-Point and Decimal Floating-Point Operations	503	7.4.4.3	Action for UE=0. . . . .	557
7.1.1.2	Compatibility with Vector Operations . . . . .	503	7.4.5	Floating-Point Inexact Exception	560
7.2	VSX Registers . . . . .	504	7.4.5.1	Definition . . . . .	560
7.2.1	Vector-Scalar Registers . . . . .	504	7.4.5.2	Action for XE=1 . . . . .	560
7.2.1.1	Floating-Point Registers . . . . .	504	7.4.5.3	Action for XE=0 . . . . .	564
7.2.1.2	Vector Registers . . . . .	506	7.5	VSX Storage Access Operations .	567
7.2.1.3	VSX Accumulators . . . . .	507	7.5.1	Accessing Aligned Storage Operands. . . . .	567
7.2.2	Floating-Point Status and Control Register. . . . .	509	7.5.2	Accessing Unaligned Storage Operands. . . . .	568
7.3	VSX Operations . . . . .	514	7.5.3	Storage Access Exceptions . . . .	569
7.3.1	VSX Floating-Point Arithmetic Overview. . . . .	514	7.6	VSX Instruction Set . . . . .	570
7.3.2	VSX Floating-Point Data . . . . .	515	7.6.1	VSX Instruction Set Summary . .	570
7.3.2.1	Data Format . . . . .	515	7.6.1.1	VSX Storage Access Instructions .	570
7.3.2.2	Value Representation . . . . .	517	7.6.1.2	VSX Binary Floating-Point Sign Manipulation Instructions. . . . .	573
7.3.2.3	Sign of Result . . . . .	518	7.6.1.3	VSX Binary Floating-Point Arithmetic Instructions . . . . .	573
			7.6.1.4	VSX Binary Floating-Point Compare Instructions . . . . .	576
			7.6.1.5	VSX Binary Floating-Point Round to Shorter Precision Instructions . . . . .	577
			7.6.1.6	VSX Binary Floating-Point Convert to Shorter Precision Instructions . . . . .	577

7.6.1.7	VSX Binary Floating-Point Convert to Longer Precision Instructions . . . . .	577
7.6.1.8	VSX Binary Floating-Point Round to Integral Instructions . . . . .	578
7.6.1.9	VSX Binary Floating-Point Convert To Integer Instructions . . . . .	578
7.6.1.10	VSX Binary Floating-Point Convert From Integer Instructions. . . . .	579
7.6.1.11	VSX Binary Floating-Point Math Support Instructions . . . . .	579
7.6.1.12	VSX Matrix-Multiply Assist (MMA) Instructions . . . . .	580
7.6.1.12.1	VSX Accumulator Move Instructions . . . . .	580
7.6.1.12.2	VSX Binary Integer Outer-Product Instructions . . . . .	580
7.6.1.12.3	VSX Binary Floating-Point Outer-Product Instructions . . . . .	581
7.6.1.13	VSX Vector Logical Instructions. . . . .	582
7.6.1.14	VSX Vector Permute-class Instructions . . . . .	583
7.6.1.15	VSX Vector Load Special Value Instruction. . . . .	584
7.6.1.16	VSX Vector Test Least-Significant Bit by Byte Instruction. . . . .	584
7.6.2	VSX Instruction Description Conventions . . . . .	585
7.6.2.1	VSX Instruction RTL Operators	585
7.6.2.2	VSX Instruction RTL Function Calls . . . . .	586
7.6.3	VSX Instruction Descriptions. . . . .	618

## Appendix A. Suggested Floating-Point Models . . . . . 1005

A.1	Floating-Point Round to Single-Precision Model . . . . .	1005
A.2	Floating-Point Convert to Integer Model . . . . .	1009
A.3	Floating-Point Convert from Integer Model . . . . .	1012
A.4	Floating-Point Round to Integer Model . . . . .	1014

## Appendix B. Densely Packed Decimal. . . . . 1017

B.1	BCD-to-DPD Translation . . . . .	1017
B.2	DPD-to-BCD Translation . . . . .	1017
B.3	Preferred DPD encoding . . . . .	1018

## Appendix C. Assembler Extended Mnemonics. . . . . 1021

C.1	Symbols. . . . .	1021
C.2	Branch Mnemonics . . . . .	1022
C.2.1	BO and BI Fields . . . . .	1022

C.2.2	Simple Branch Mnemonics . . . . .	1022
C.2.3	Branch Mnemonics Incorporating Conditions . . . . .	1023
C.2.4	Branch Prediction . . . . .	1024
C.3	Condition Register Logical Mnemonics . . . . .	1025
C.4	Subtract Mnemonics . . . . .	1025
C.4.1	Subtract Immediate. . . . .	1025
C.4.2	Subtract. . . . .	1025
C.5	Compare Mnemonics. . . . .	1026
C.5.1	Doubleword Comparisons. . . . .	1026
C.5.2	Word Comparisons . . . . .	1026
C.6	Trap Mnemonics . . . . .	1027
C.7	Integer Select Mnemonics . . . . .	1028
C.8	Rotate and Shift Mnemonics . . . . .	1029
C.8.1	Operations on Doublewords . . . . .	1029
C.8.2	Operations on Words . . . . .	1030
C.9	Move To/From Special Purpose Register Mnemonics . . . . .	1031
C.10	Miscellaneous Mnemonics. . . . .	1032

## Book II:

### Power ISA Virtual Environment Architecture . . . . . 1037

### Chapter 1. Storage Model . . . . . 1039

1.1	Definitions. . . . .	1039
1.2	Introduction. . . . .	1040
1.3	Virtual Storage . . . . .	1041
1.4	Single-Copy Atomicity . . . . .	1041
1.5	Cache Model . . . . .	1042
1.6	Storage Control Attributes . . . . .	1043
1.6.1	Write Through Required . . . . .	1043
1.6.2	Caching Inhibited . . . . .	1043
1.6.3	Memory Coherence Required . . . . .	1043
1.6.4	Guarded . . . . .	1044
1.7	Shared Storage . . . . .	1044
1.7.1	Storage Access Ordering . . . . .	1044
1.7.1.1	Storage Ordering of Copy/Paste-Initiated Data Transfers . . . . .	1047
1.7.1.2	Storage Ordering of Stores to Persistent Storage . . . . .	1047
1.7.1.3	Storage Ordering of I/O Accesses . . . . .	1048
1.7.2	Atomic Update. . . . .	1048
1.7.2.1	Reservations . . . . .	1049
1.7.2.2	Forward Progress . . . . .	1050
1.8	Instruction Storage . . . . .	1051
1.8.1	Concurrent Modification and Execution of Instructions. . . . .	1053

**Chapter 2. Instruction Restart . . . 1055****Chapter 3. Management of Shared Resources . . . . . 1057**

- 3.1 Program Priority Registers . . . . . 1057
- 3.2 “or” Instruction . . . . . 1058

**Chapter 4. Storage Control Instructions . . . . . 1059**

- 4.1 Parameters Useful to Application Programs . . . . . 1059
- 4.2 Data Stream Control Register (DSCR) 1059
- 4.3 Cache Management Instructions 1061
  - 4.3.1 Instruction Cache Instructions . 1062
  - 4.3.2 Data Cache Instructions . . . . . 1063
    - 4.3.2.1 Obsolete Data Cache Instructions 1075
    - 4.3.3 “or” Instruction . . . . . 1076
- 4.4 Copy-Paste Facility. . . . . 1077
- 4.5 Atomic Memory Operations . . . . . 1080
  - 4.5.1 Load Atomic. . . . . 1080
  - 4.5.2 Store Atomic . . . . . 1084
- 4.6 Synchronization Instructions. . . . . 1086
  - 4.6.1 Instruction Synchronize Instruction . 1086
  - 4.6.2 Load And Reserve and Store Conditional Instructions . . . . . 1086
    - 4.6.2.1 64-Bit Load And Reserve and Store Conditional Instructions . . . . . 1092
    - 4.6.2.2 128-bit Load And Reserve and Store Conditional Instructions . . . . . 1094
  - 4.6.3 Memory Barrier Instructions. . . . . 1096
  - 4.6.4 Wait Instruction . . . . . 1100

**Chapter 5. Time Base . . . . . 1103**

- 5.1 Time Base Instructions . . . . . 1104

**Chapter 6. Event-Based Branch Facility . . . . . 1107**

- 6.1 Event-Based Branch Overview. . 1107
- 6.2 Event-Based Branch Registers. . 1107
  - 6.2.1 Branch Event Status and Control Register. . . . . 1107
  - 6.2.2 Event-Based Branch Handler Register . . . . . 1109
  - 6.2.3 Event-Based Branch Return Register 1109
- 6.3 Event-Based Branch Instructions .1110

**Chapter 7. Branch History Rolling Buffer . . . . . 1111**

- 7.1 Branch History Rolling Buffer Entry Format. . . . . 1112

- 7.2 Branch History Rolling Buffer Instructions . . . . . 1113

**Appendix A. Assembler Extended Mnemonics . . . . . 1115**

- A.1 Data Cache Block Touch [for Store] Mnemonics . . . . . 1115
- A.2 Data Cache Block Flush Mnemonics . 1115
- A.3 Or Mnemonics . . . . . 1115
- A.4 Load And Reserve Mnemonics . . . . . 1115
- A.5 Synchronize Mnemonics. . . . . 1116
- A.6 Wait Mnemonics . . . . . 1116
- A.7 Move To/From Time Base Mnemonics 1116
- A.8 Return From Event-Based Branch Mnemonic . . . . . 1116

**Appendix B. Programming Examples for Sharing Storage . . . . . 1117**

- B.1 Atomic Update Primitives . . . . . 1117
- B.2 Lock Acquisition and Release, and Related Techniques. . . . . 1119
  - B.2.1 Lock Acquisition and Import Barriers 1119
    - B.2.1.1 Acquire Lock and Import Shared Storage . . . . . 1119
    - B.2.1.2 Obtain Pointer and Import Shared Storage . . . . . 1119
  - B.2.2 Lock Release and Export Barriers . . 1120
    - B.2.2.1 Export Shared Storage and Release Lock. . . . . 1120
    - B.2.2.2 Export Shared Storage and Release Lock using lwsync . . . . . 1120
  - B.2.3 Safe Fetch . . . . . 1120
- B.3 List Insertion . . . . . 1121
- B.4 Notes . . . . . 1121

**Book III:****Power ISA Operating Environment Architecture . . . . . 1123****Chapter 1. Introduction. . . . . 1125**

- 1.1 Overview . . . . . 1125
- 1.2 Document Conventions. . . . . 1125
  - 1.2.1 Definitions and Notation. . . . . 1125
  - 1.2.2 Reserved Fields . . . . . 1126
  - 1.2.3 Deviations from the Sequential Execution Model . . . . . 1127
  - 1.2.4 Restricting Out-of-Order Execution . 1127

1.3	General Systems Overview . . . . .	1127
1.4	Exceptions . . . . .	1127
1.5	Synchronization . . . . .	1128
1.5.1	Context Synchronization . . . . .	1128
1.5.2	Execution Synchronization . . . . .	1129
<b>Chapter 2. Logical Partitioning (LPAR) and Thread Control . . . . 1131</b>		
2.1	Overview . . . . .	1131
2.2	Logical Partitioning Control Register (LPCR) . . . . .	1131
2.3	Hypervisor Real Mode Offset Register (HRMOR) . . . . .	1136
2.4	Logical Partition Identification Register (LPIDR) . . . . .	1136
2.5	Processor Compatibility Register (PCR) . . . . .	1136
2.6	Other Hypervisor Resources . . . . .	1146
2.7	Sharing Hypervisor and Ultravisor Resources . . . . .	1147
2.8	Sub-Processors . . . . .	1147
2.9	Thread Identification Register (TIR) . . . . .	1147
2.10	Hypervisor Interrupt Little-Endian (HILE) Bit . . . . .	1148
<b>Chapter 3. Ultravisor and Secure Memory Facility (SMF) . . . . . 1149</b>		
3.1	Overview . . . . .	1149
3.2	Ultravisor Real Mode Offset Register (URMOR) . . . . .	1150
3.3	Ultravisor Interrupt Little-Endian (UILE) Bit . . . . .	1150
3.4	Secure Memory Facility Control Register (SMFCTRL) . . . . .	1150
3.4.1	Enabling SMF and Secure Memory Enforcement . . . . .	1151
<b>Chapter 4. Branch Facility . . . . . 1153</b>		
4.1	Branch Facility Overview . . . . .	1153
4.2	Branch Facility Registers . . . . .	1153
4.2.1	Machine State Register . . . . .	1153
4.2.2	Processor Stop Status and Control Register (PSSCR) . . . . .	1157
4.3	Branch Facility Instructions . . . . .	1160
4.3.1	System Linkage Instructions . . . . .	1160
4.3.2	Power-Saving Mode . . . . .	1164
4.3.2.1	Power-Saving Mode Instruction . . . . .	1165
4.3.2.2	Entering and Exiting Power-Saving Mode . . . . .	1165
4.4	Event-Based Branch Facility and Instruction . . . . .	1167
<b>Chapter 5. Fixed-Point Facility . . 1169</b>		
5.1	Fixed-Point Facility Overview . . . . .	1169
5.2	Special Purpose Registers . . . . .	1169
5.3	Fixed-Point Facility Registers . . . . .	1169
5.3.1	Processor Version Register . . . . .	1169
5.3.2	Processor Identification Register . . . . .	1169
5.3.3	Process Identification Register . . . . .	1170
5.3.4	Control Register . . . . .	1170
5.3.5	Program Priority Register . . . . .	1170
5.3.6	Problem State Priority Boost Register . . . . .	1170
5.3.7	Relative Priority Register . . . . .	1171
5.3.8	Hash Key Registers . . . . .	1171
5.3.9	Software-use SPRs . . . . .	1171
5.4	Fixed-Point Facility Instructions . . . . .	1173
5.4.1	Fixed-Point Load and Store Caching Inhibited Instructions . . . . .	1173
5.4.2	Fixed-Point Hash Instructions . . . . .	1175
5.4.3	OR Instruction . . . . .	1177
5.4.4	Move To/From System Register Instructions . . . . .	1177
<b>Chapter 6. Storage Control . . . . . 1189</b>		
6.1	Overview . . . . .	1189
6.2	Storage Exceptions . . . . .	1189
6.3	Instruction Fetch . . . . .	1189
6.3.1	Implicit Branch . . . . .	1189
6.3.2	Address Wrapping Combined with Changing MSR Bit SF . . . . .	1189
6.4	Data Access . . . . .	1190
6.5	Performing Operations Out-of-Order . . . . .	1190
6.6	Invalid Real Address . . . . .	1190
6.7	Storage Addressing . . . . .	1191
6.7.1	32-Bit Mode . . . . .	1191
6.7.2	Virtualized Partition Memory (VPM) Mode . . . . .	1192
6.7.3	Ultravisor Real, Hypervisor Real, and Virtual Real Addressing Modes . . . . .	1192
6.7.3.1	Ultravisor/Hypervisor Offset Real Mode Address . . . . .	1192
6.7.3.2	Storage Control Attributes for Accesses in Ultravisor and Hypervisor Real Addressing Modes . . . . .	1193
6.7.3.2.1	Hypervisor Real Mode Storage Control . . . . .	1193
6.7.3.3	Virtual Real Mode Addressing Mechanism . . . . .	1194
6.7.3.4	Storage Control Attributes for Implicit Storage Accesses . . . . .	1195
6.7.4	Definitions . . . . .	1195
6.7.5	Address Ranges Having Defined Uses . . . . .	1196
6.7.5.1	Effective Address Space Structure for Radix-using Partitions . . . . .	1196

6.7.6	In-Memory Tables . . . . .	1197	6.9.1	Cache Management Instructions . . .	1231
6.7.6.1	Partition Table . . . . .	1197	6.9.2	Synchronize Instruction . . . . .	1231

## Chapter 8. Timer Facilities . . . . .1311

8.1	Overview. . . . .	1311
8.2	Time Base (TB). . . . .	1311
8.2.1	Writing the Time Base . . . . .	1312
8.3	Virtual Time Base . . . . .	1312
8.4	Decrementer. . . . .	1313
8.4.1	Writing and Reading the Decrementer. . . . .	1314
8.5	Hypervisor Decrementer. . . . .	1314
8.6	Processor Utilization of Resources Register (PURR). . . . .	1314
8.7	Scaled Processor Utilization of Resources Register (SPURR) . . . . .	1315
8.8	Instruction Counter . . . . .	1316

## Chapter 9. Dynamic Execution

### Control Facility . . . . . 1317

9.1	Overview. . . . .	1317
9.2	Dynamic Execution Control Instructions . . . . .	1317
9.2.1	Execution Serializing No-op Instruction . . . . .	1317
9.3	Dynamic Execution Control Registers . . . . .	1317
9.3.1	Dynamic Execution Control Register (DEXCR). . . . .	1317
9.3.2	Hypervisor Dynamic Execution Control Register (HDEXCR) . . . . .	1318
9.3.3	Ultravisor Dynamic Execution Control Register (UDEXCR) . . . . .	1318
9.4	Dynamic Execution Control Operation . . . . .	1318

## Chapter 10. Debug Facilities. . . 1321

10.1	Overview. . . . .	1321
10.2	Come-From Address Register . . . . .	1321
10.3	Completed Instruction Address Breakpoint. . . . .	1321
10.4	Data Address Watchpoint . . . . .	1322

## Chapter 11. Performance Monitor

### Facility . . . . . 1325

11.1	Overview. . . . .	1325
11.2	Performance Monitor Operation . . . . .	1325
11.3	No-op Instructions Reserved for the Performance Monitor . . . . .	1326
11.4	Performance Monitor Facility Registers . . . . .	1326
11.4.1	Performance Monitor SPR Numbers . . . . .	1327
11.4.2	Performance Monitor Counters . . . . .	1327
11.4.2.1	Event Counting and Sampling . . . . .	1327
11.4.3	Threshold Event Counter . . . . .	1328

11.4.4	Monitor Mode Control Register 0 . . . . .	1329	<b>Appendix B. Illegal Instructions</b>	<b>1367</b>
11.4.5	Monitor Mode Control Register 1 . . . . .	1333	<b>Appendix C. Reserved Instructions</b>	<b>. 1369</b>
11.4.6	Monitor Mode Control Register 2 . . . . .	1336	<b>Appendix D. Opcode Maps . . . . .</b>	<b>1371</b>
11.4.7	Monitor Mode Control Register A . . . . .	1337	<b>Appendix E. Power ISA Instruction Set Sorted by Opcode . . . . .</b>	<b>1407</b>
11.4.8	Sampled Instruction Address Register . . . . .	1340	<b>Appendix F. Power ISA Instruction Set Sorted by Version . . . . .</b>	<b>1439</b>
11.4.9	Sampled Data Address Register . . . . .	1340	<b>Appendix G. Power ISA Instruction Set Sorted by OpenPOWER Compiancy Subset . . . . .</b>	<b>1471</b>
11.4.10	Sampled Instruction Event Register . . . . .	1340	<b>Appendix H. Power ISA Instruction Set Sorted by Mnemonic . . . . .</b>	<b>1503</b>
11.4.11	Other Performance Monitor Registers . . . . .	1342	<b>Last Page - End of Document . . . . .</b>	<b>1536</b>
11.5	Branch History Rolling Buffer . . . . .	1343		
11.5.1	BHRB Filtering . . . . .	1343		
<b>Chapter 12. Processor Control . 1345</b>				
12.1	Overview . . . . .	1345		
12.2	Programming Model . . . . .	1345		
12.3	Processor Control Registers . . . . .	1345		
12.3.1	Directed Privileged Doorbell Exception State . . . . .	1345		
12.4	Processor Control Instructions . . . . .	1347

## **Book I:**

# **Power ISA User Instruction Set Architecture**

# Chapter 1. Introduction

## 1.1 Overview

This chapter describes computation modes, document conventions, a processor overview, instruction formats, storage addressing, and instruction fetching.

## 1.2 Instruction Mnemonics and Operands

The description of each instruction includes the mnemonic and a formatted list of operands. Some examples are the following.

```
stw      RS,D(RA)
addis   RT,RA,SI
```

Power ISA-compliant Assemblers will support the mnemonics and operand lists exactly as shown. They should also provide certain extended mnemonics, such as the ones described either in Appendix C of Book I or in the instruction description, if extended mnemonics are provided for the instruction. Assemblers will support extended mnemonics having a reduced number of operands using the specified default values for any operands omitted from the base form.

## 1.3 Document Conventions

### 1.3.1 Definitions

The following definitions are used throughout this document.

- **program**  
A sequence of related instructions.
- **application program**  
A program that uses only the instructions and resources described in Books I and II.
- **processor**  
The hardware component that implements the instruction set, storage model, and other facilities defined in the Power ISA architecture, and executes the instructions specified in a program.

- **octword, quadword, doubleword, word, half-word, byte, and nibble**  
256 bits, 128 bits, 64 bits, 32 bits, 16 bits, 8 bits, and 4 bits, respectively.
- **positive**  
Means greater than zero.
- **negative**  
Means less than zero.
- **floating-point single format** (or simply **single format**)  
Refers to the representation of a single-precision binary floating-point value in a register or storage.
- **floating-point double format** (or simply **double format**)  
Refers to the representation of a double-precision binary floating-point value in a register or storage.
- **system library program**  
A component of the system software that can be called by an application program using a *Branch* instruction.
- **system service program**  
A component of the system software that can be called by an application program using a *System Call* or *System Call Vectored* instruction.
- **system trap handler**  
A component of the system software that receives control when the conditions specified in a *Trap* instruction are satisfied.
- **system error handler**  
A component of the system software that receives control when an error occurs. The system error handler includes a component for each of the various kinds of error. These error-specific components are referred to as the system alignment error handler, the system data storage error handler, etc.
- **latency**  
Refers to the interval from the time an instruction begins execution until it produces a result that is available for use by a subsequent instruction.

- **unavailable**  
Refers to a resource that cannot be used by the program. For example, storage is unavailable if access to it is denied. See Book III.
- **undefined value**  
May vary between implementations, and between different executions on the same implementation, and similarly for register contents, storage contents, etc., that are specified as being undefined.
- **boundedly undefined**  
The results of executing a given instruction are said to be boundedly undefined if they could have been achieved by executing an arbitrary finite sequence of instructions (none of which yields boundedly undefined results) in the state the processor was in before executing the given instruction. Boundedly undefined results may include the presentation of inconsistent state to the system error handler as described in Section 1.8.1 of Book II. Boundedly undefined results for a given instruction may vary between implementations, and between different executions on the same implementation.
- **“must”**  
If software violates a rule that is stated using the word “must” (e.g., “this field must be set to 0”), the results are boundedly undefined unless otherwise stated.
- **sequential execution model**  
The model of program execution described in Section 2.2, “Instruction Execution Order” on page 33.

## 1.3.2 Notation

The following notation is used throughout the Power ISA documents.

- All numbers are decimal unless specified in some special way.
  - 0bnnnn means a number expressed in binary format.
  - 0xnxxx means a number expressed in hexadecimal format.

Underscores may be used between digits.
- RT, RA, R1, ... refer to General Purpose Registers.
- FRT, FRA, FR1, ... refer to Floating-Point Registers.
- FRT<sub>p</sub>, FR<sub>A</sub><sub>p</sub>, FR<sub>B</sub><sub>p</sub>, ... refer to an even-odd pair of Floating-Point Registers. Values must be even, otherwise the instruction form is invalid.
- VRT, VRA, VR1, ... refer to Vector Registers.
- (x) means the contents of register x, where x is the name of an instruction field. For example, (RA) means the contents of register RA, and (FRA) means the contents of register FRA, where RA and FRA are instruction fields. Names such as LR and CTR denote registers, not fields, so parentheses are not used with them. Parentheses are also omitted when register x is the register into which the result of an operation is placed.
- (RA|0) means the contents of register RA if the RA field has the value 1-31, or the value 0 if the RA field is 0.
- Bytes in registers, instructions, fields, and bit strings are numbered from left to right, starting with byte 0 (most significant).
- Bits in registers, instructions, fields, and bit strings are specified as follows. In the last three items (definition of X<sub>p</sub> etc.), if X is a field that specifies a GPR, FPR, or VR (e.g., the RS field of an instruction), the definitions apply to the register, not to the field.
  - Bits in instructions, fields, and bit strings are numbered from left to right, starting with bit 0
  - For all registers except the Vector registers, bits in registers that are less than 64 bits start with bit number 64-L, where L is the register length; for the Vector registers, bits in registers that are less than 128 bits start with bit number 128-L.
  - The leftmost bit of a sequence of bits is the most significant bit of the sequence.
  - X<sub>p</sub> means bit p of register/instruction/field/bit\_string X.
  - X<sub>p:q</sub> means bits p through q of register/instruction/field/bit\_string X.
  - X<sub>p q ...</sub> means bits p, q, ... of register/instruction/field/bit\_string X.
- ¬(RA) means the one's complement of the contents of register RA.
- A period (.) as the last character of an instruction mnemonic means that the instruction records status information in certain fields of the Condition Register as a side effect of execution.
- The symbol || is used to describe the concatenation of two values. For example, 010 || 111 is the same as 010111.
- x<sup>n</sup> means x raised to the n<sup>th</sup> power.
- <sup>n</sup>x means the replication of x, n times (i.e., x concatenated to itself n-1 times). <sup>0</sup>0 and <sup>1</sup>1 are special cases:
  - <sup>0</sup>0 means a field of n bits with each bit equal to 0. Thus <sup>5</sup>0 is equivalent to 0b00000.
  - <sup>1</sup>1 means a field of n bits with each bit equal to 1. Thus <sup>5</sup>1 is equivalent to 0b11111.
- Each bit and field in instructions, and in status and control registers (e.g., XER, FPSCR) and Special

Purpose Registers, is either defined or reserved. Some defined fields contain reserved values. In such cases when this document refers to the specific field, it refers only to the defined values, unless otherwise specified.

- */, //, ///, ...* denotes a reserved field, in a register, instruction, field, or bit string.
- *?, ??, ???, ...* denotes an implementation-dependent field in a register, instruction, field or bit string.

### 1.3.3 Reserved Fields, Reserved Values, and Reserved SPRs

Reserved fields in instructions are ignored by the processor.

In some cases a defined field of an instruction has certain values that are reserved. This includes cases in which the field is shown in the instruction layout as containing a particular value; in such cases all other values of the field are reserved. In general, if an instruction is coded such that a defined field contains a reserved value the instruction form is invalid; see Section 1.8.2 on page 25. The only exception to the preceding rule is that it does not apply to Reserved and Illegal classes of instructions (see Section 1.6.3) or to portions of defined fields that are specified, in the instruction description, as being treated as reserved fields.

To maximize compatibility with future architecture extensions, software must ensure that reserved fields in instructions contain zero and that defined fields of instructions do not contain reserved values.

The handling of reserved bits in System Registers (e.g., XER, FPSCR) depends on whether the processor is in problem state. Unless otherwise stated, software is permitted to write any value to such a bit. In problem state, a subsequent reading of the bit returns 0 regardless of the value written; in privileged states, a subsequent reading of the bit returns 0 if the value last written to the bit was 0 and returns an undefined value (0 or 1) otherwise.

In some cases, a defined field of a System Register has certain values that are reserved. Software must not set a defined field of a System Register to a reserved value. References elsewhere in this document to a defined field (in an instruction or System Register) that has reserved values assume the field does not contain a reserved value, unless otherwise stated or obvious from context.

In some cases, a given bit of a System Register is specified to be set to a constant value by a given instruction or event. Unless otherwise stated or obvious from context, software should not depend on this constant value because the bit may be assigned a meaning in a future version of the architecture.

The reserved SPRs include SPRs 808, 809, 810, and 811. *mtspr* and *mfspr* instructions specifying these SPRs are treated as no-ops. Reserved SPRs are provided in the architecture to anticipate the eventual adoption of performance hint functionality that must be controlled by SPRs. Control of these capabilities using reserved SPRs will allow software to use these new capabilities on new implementations that support them while remaining compatible with existing implementations that may not support the new functionality.

Reserved SPRs are not assigned names. There are no individual descriptions of reserved SPRs in this document.

#### Assembler Note

Assemblers should report uses of reserved values of defined fields of instructions as errors.

#### Programming Note

It is the responsibility of software to preserve bits that are now reserved in System Registers, because they may be assigned a meaning in some future version of the architecture.

In order to accomplish this preservation in implementation-independent fashion, software should do the following.

- Initialize each such register supplying zeros for all reserved bits.
- Alter (defined) bit(s) in the register by reading the register, altering only the desired bit(s), and then writing the new value back to the register.

The XER and FPSCR are partial exceptions to this recommendation. Software can alter the status bits in these registers, preserving the reserved bits, by executing instructions that have the side effect of altering the status bits. Similarly, software can alter any defined bit in the FPSCR by executing a Floating-Point Status and Control Register instruction. Using such instructions is likely to yield better performance than using the method described in the second item above.

### 1.3.4 Description of Instruction Operation

Instruction descriptions (including related material such as the introduction to the section describing the instructions) mention that the instruction may cause a system error handler to be invoked, under certain conditions, if and only if the system error handler may treat the case as a programming error. (An instruction may cause a system error handler to be invoked under other conditions as well; see Chapter 7 of Book III).

A formal description is given of the operation of each instruction. In addition, the operation of most instructions is described by a semiformal language at the register transfer level (RTL). This RTL uses the notation given below, in addition to the notation described in Section 1.3.2. Some of this notation is also used in the formal descriptions of instructions. RTL notation not summarized here should be self-explanatory.

The RTL descriptions cover the normal execution of the instruction, except that “standard” setting of status registers, such as the Condition Register, is not shown.

(“Non-standard” setting of these registers, such as the setting of the Condition Register by the *Compare* instructions, is shown.) The RTL descriptions do not cover cases in which the system error handler is invoked, or for which the results are boundedly undefined.

The RTL descriptions specify the architectural transformation performed by the execution of an instruction. They do not imply any particular implementation.

Notation	Meaning
$\leftarrow$	Assignment
$\leftarrow_{iea}$	Assignment of an instruction effective address. In 32-bit mode the high-order 32 bits of the 64-bit target address are set to 0.
$\neg$	NOT logical operator
$+$	Two's complement addition
$-$	Two's complement subtraction, unary minus
$\times$	Multiplication
$\times_{si}$	Signed-integer multiplication
$\times_{ui}$	Unsigned-integer multiplication
$/$	Division
$\div$	Division, with result truncated to integer
$\%$	Remainder of integer division
$\sqrt{\quad}$	Square root
$=, \neq$	Equals, Not Equals relations
$<, \leq, >, \geq$	Signed comparison relations
$<^u, >^u$	Unsigned comparison relations
$?$	Unordered comparison relation
$\&,  $	AND, OR logical operators
$\oplus, \equiv$	Exclusive OR, Equivalence logical operators (( $a \equiv b$ ) = ( $a \oplus \neg b$ ))
$ABS(x)$	Absolute value of $x$
$BCD\_TO\_DPD(x)$	The low-order 24 bits of $x$ contain six, 4-bit BCD fields which are converted to two deplets; each set of two deplets is placed into the low-order 20 bits of the result. See Section B.1, “BCD-to-DPD Translation”.
$CEIL(x)$	Least integer $\geq x$
$DOUBLE(x)$	Result of converting $x$ from floating-point single format to floating-point double format, using the model shown on page 153
$DPD\_TO\_BCD(x)$	The low-order 20 bits of $x$ contain two deplets which are converted to six, 4-bit BCD fields; each set of six, 4-bit BCD fields is placed into the low-order 24 bits of the result. See Section B.2, “DPD-to-BCD Translation”.
$EXTS(x)$	Result of extending $x$ on the left with sign bits
$FLOOR(x)$	Greatest integer $\leq x$
$GPR(x)$	General Purpose Register $x$
$LENGTH(x)$	Length of $x$ , in bits.

<p>MASK(x, y) Mask having 1s in positions x through y (wrapping if <math>x &gt; y</math>) and 0s elsewhere</p> <p>MEM(x, y) Contents of a sequence of y bytes of storage. The sequence depends on the byte ordering used for storage access, as follows. Big-Endian byte ordering: The sequence starts with the byte at address x and ends with the byte at address <math>x+y-1</math>. Little-Endian byte ordering: The sequence starts with the byte at address <math>x+y-1</math> and ends with the byte at address x.</p> <p>MEM<sub>metadata</sub>(x,y) Metadata associated with MEM(x,y).</p> <p>ROTL<sub>64</sub>(x, y) Result of rotating the 64-bit value x left y positions</p> <p>ROTL<sub>32</sub>(x, y) Result of rotating the 64-bit value x left y positions, where x is 32 bits long</p> <p>SINGLE(x) Result of converting x from floating-point double format to floating-point single format, using the model shown on page 158</p> <p>SPR(x) Special Purpose Register x</p> <p>TRAP Invoke the system trap handler</p> <p>x.bit[y] Return the contents of bit y of x.</p> <p>x.nibble[y] Return the contents of 4-bit nibble element y of x.</p> <p>x.byte[y] Return the contents of 8-bit byte element y of x.</p> <p>x.hword[y] Return the contents of 16-bit halfword element y of x.</p> <p>x.word[y] Return the contents of 32-bit word element y of x.</p> <p>x.dword[y] Return the contents of 64-bit doubleword element y of x.</p> <p>x.qword[y] Return the contents of 128-bit quadword element y of x.</p> <p><math>x \lll y</math> Result of rotating x left by y bits. <math>b \leftarrow \text{LENGTH}(x)</math> <math>\text{result } t \leftarrow x_{y:b-1} \parallel x_{0:y-1}</math></p> <p><math>x \ggg y</math> Result of rotating x right by y bits. <math>b \leftarrow \text{LENGTH}(x)</math> <math>\text{result } t \leftarrow x_{b-y:b-1} \parallel x_{0:b-1-y}</math></p> <p>characterization Reference to the setting of status bits, in a standard way that is explained in the text</p> <p>undefined An undefined value.</p> <p>CIA Current Instruction Address, which is the 64-bit address of the instruction being described by a sequence of RTL. Used by relative branches to set the Next Instruction Address (NIA), and by Branch instructions with LK=1 to set the Link Register. Does not correspond to any architected register. The CIA is sometimes referred to as the Program Counter (PC).</p>	<p>NIA Next Instruction Address, which is the 64-bit address of the next instruction to be executed. For a successful branch, the next instruction address is the branch target address: in RTL, this is indicated by assigning a value to NIA. For other instructions that cause non-sequential instruction fetching (see Book III), the RTL is similar. For instructions that do not branch, and do not otherwise cause instruction fetching to be non-sequential, the next instruction address is CIA+4. Does not correspond to any architected register.</p> <p>if... then... else... Conditional execution, indenting shows range; else is optional.</p> <p>do Do loop, indenting shows range. “To” and/or “by” clauses specify incrementing an iteration variable, and a “while” clause gives termination conditions.</p> <p>leave Leave innermost do loop, or do loop described in leave statement.</p> <p>for For loop, indenting shows range. Clause after “for” specifies the entities for which to execute the body of the loop.</p> <p>switch/case/default switch/case/default statement, indenting shows range. The clause after “switch” specifies the expression to evaluate. The clause after “case” specifies individual values for the expression, followed by a colon, followed by the actions that are taken if the evaluated expression has any of the specified values. “default” is optional. If present, it must follow all the “case” clauses. The clause after “default” starts with a colon, and specifies the actions that are taken if the evaluated expression does not have any of the values specified in the preceding case statements.</p>
---	--

The precedence rules for RTL operators are summarized in Table 1. Operators higher in the table are applied before those lower in the table. Operators at the same level in the table associate from left to right, from right to left, or not at all, as shown. (For example,  $-$  associates from left to right, so  $a-b-c = (a-b)-c$ .) Parentheses are used to override the evaluation order implied by the table or to increase clarity; parenthesized expressions are evaluated before serving as operands.

Table 1: Operator precedence	
Operators	Associativity
subscript, function evaluation	left to right
pre-superscript (replication), post-superscript (exponentiation)	<i>right to left</i>
unary $-$ , $\neg$	<i>right to left</i>
$\times$ , $\div$	left to right
$+$ , $-$	left to right
$\parallel$	left to right
$=$ , $\neq$ , $<$ , $\leq$ , $>$ , $\geq$ , $<^u$ , $>^u$ , $?$	left to right
$\&$ , $\oplus$ , $\equiv$	left to right
$ $	left to right
$:$ (range)	none
$\leftarrow$ , $\leftarrow_{iea}$	none

## 1.3.5 Phased-Out Facilities

### Phased-Out Facilities

These are facilities and instructions that, in some future version of the architecture, will be dropped out of the architecture. System developers should develop a migration plan to eliminate use of them in new systems. These facilities are marked with a [Phased-Out] marker.

Phased-Out facilities and instructions must be implemented.

#### Programming Note

**Warning:** Instructions and facilities being phased out of the architecture are likely to perform poorly on future implementations. New programs should not use them.

## 1.4 Processor Overview

The basic classes of instructions are as follows:

- branch instructions (Chapter 2)
- GPR-based scalar fixed-point instructions (Chapter 3)
- FPR-based scalar floating-point instructions (Chapter 4)
- FPR-based scalar decimal floating-point instructions (Chapter 5)
- VR-based vector fixed-point and floating-point instructions (Chapter 6)
- VSR-based scalar and vector floating-point instructions (Chapter 7)

Scalar fixed-point instructions operate on byte, halfword, word, doubleword, and quadword operands, where each operand is contained in a GPR (or a pair of GPRs for quadword operands). Vector fixed-point instructions operate on vectors of nibble, byte, halfword, word, doubleword, and quadword operands, where each vector is contained in a VR. Scalar binary floating-point instructions operate on single-precision, double-precision, and quad-precision floating-point operands, where each operand is contained in an FPR or VSR. Scalar decimal floating-point instructions operate on short, long, and extended decimal floating-point operands, where each operand is contained in an FPR (or a pair of FPRs for quadword operands).

Vector floating-point instructions operate on vectors of single-precision and double-precision floating-point operands, where each vector is contained in a VR or VSR.

The Power ISA uses instructions that are four or eight bytes long and are word-aligned. It provides for byte, halfword, word, doubleword, and quadword operand loads and stores between storage and a set of 32 General Purpose Registers (GPRs). It provides for byte, halfword, word, doubleword, quadword, and octword operand loads and stores between storage and a set of 64 Vector-Scalar Registers (VSRs).

Signed integers are represented in two's complement form.

There are no computational instructions that modify storage; instructions that reference storage may reformat the data (e.g. load halfword algebraic). To use a storage operand in a computation and then modify the same or another storage location, the contents of the storage operand must be loaded into a register, modified, and then stored back to the target location. Figure 1 is a logical representation of instruction processing. Figure 2 shows the registers that are defined in Book I. (A few additional registers that are available to application programs are defined in other Books, and are not shown in the figure.)

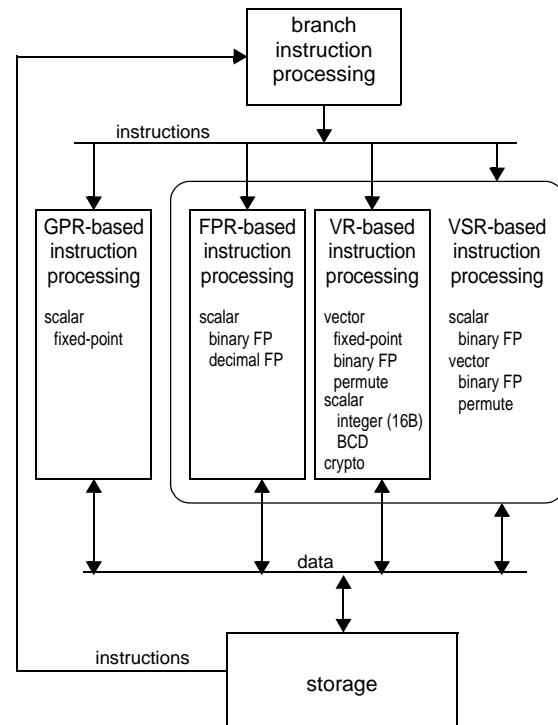

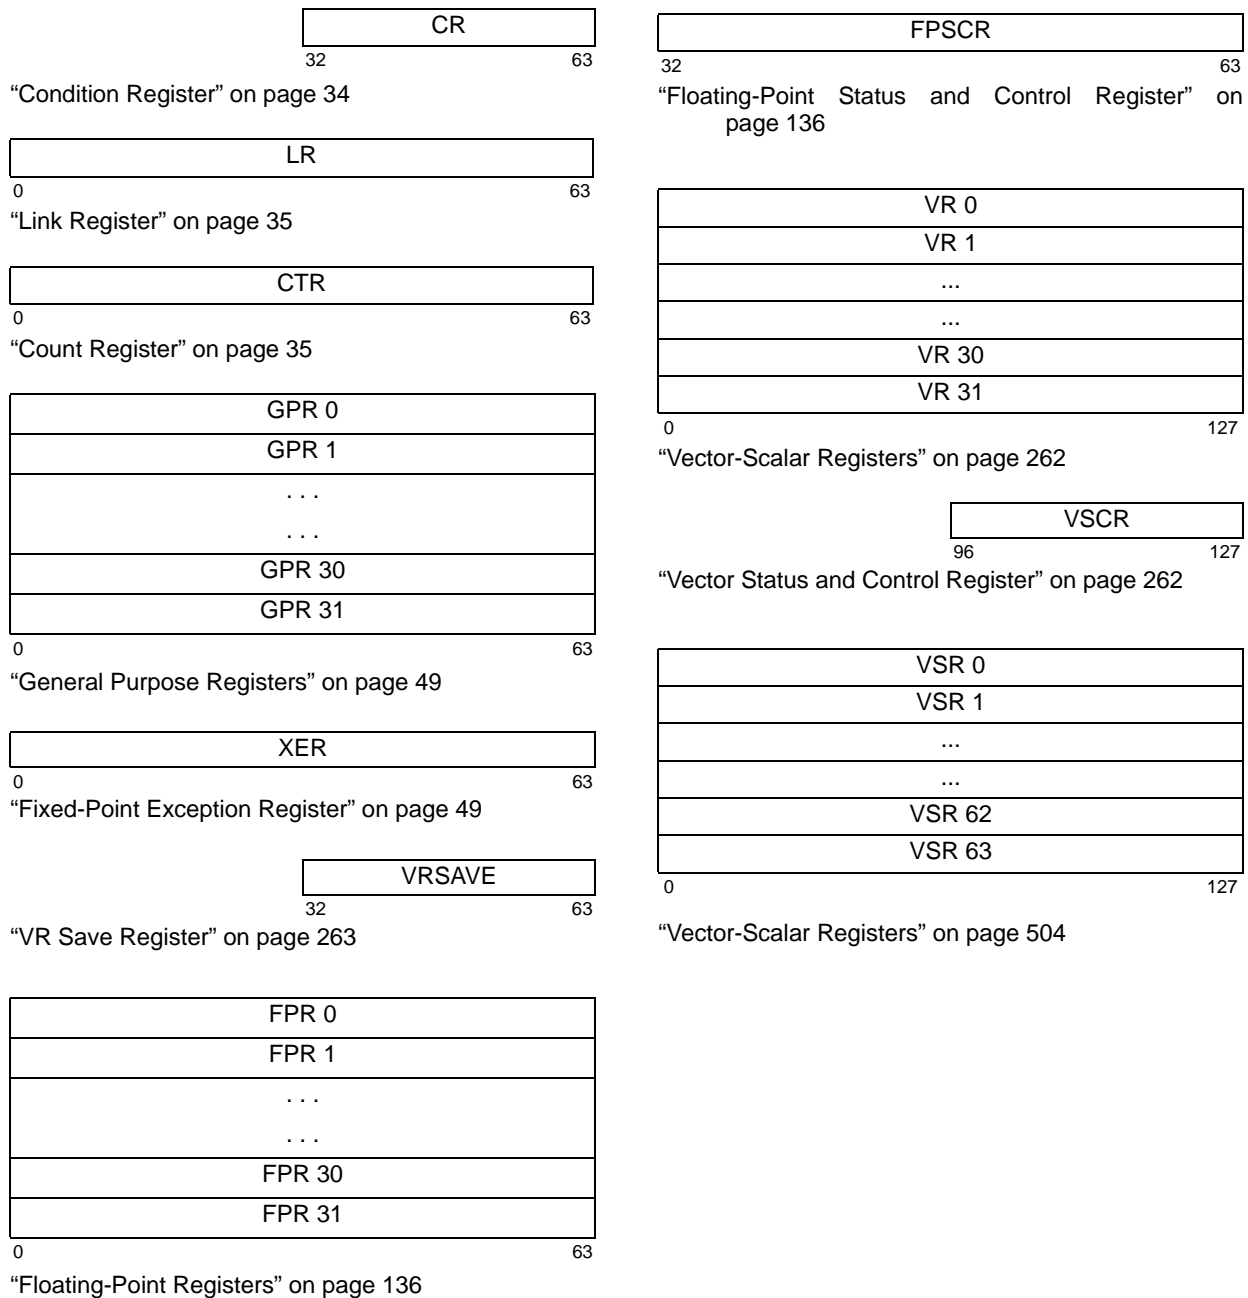

Figure 1. Logical processing model

**Figure 2. Registers that are defined in Book I**

## 1.5 Computation modes

Processors provide two execution modes, 64-bit mode and 32-bit mode. In both of these modes, instructions that set a 64-bit register affect all 64 bits. The computational mode controls how the effective address is interpreted, how Condition Register bits and XER bits are set, how the Link Register is set by *Branch* instructions

in which LK=1, and how the Count Register is tested by *Branch Conditional* instructions. Nearly all instructions are available in both modes (the only exceptions are a few instructions that are defined in Book III). In both modes, effective address computations use all 64 bits of the relevant registers (General Purpose Registers,

Link Register, Count Register, etc.) and produce a 64-bit result. However, in 32-bit mode the high-order 32 bits of the computed effective address are ignored for the purpose of addressing storage; see Section 1.10.3 for additional details.

#### Programming Note

Although instructions that set a 64-bit register affect all 64 bits in both 32-bit and 64-bit modes, operating systems often do not preserve the upper 32-bits of all registers across context switches done in 32-bit mode. For this reason, application programs operating in 32-bit mode should not assume that the upper 32 bits of the GPRs are preserved from instruction to instruction unless the operating system is known to preserve these bits.

## 1.6 Instruction Formats

Instructions are encoded in either four or eight bytes and are word-aligned. When referring specifically to only one of these two types of instructions, the term “word instruction” is used to refer to instructions that are encoded in four bytes, and the term “prefixed instruction” is used to refer to instructions that are encoded in eight bytes using a prefix.

Bits 0:5 always specify the primary opcode (PO, below). Many instructions also have an extended opcode (XO, below). Some instructions also have a third, expanded opcode (EO, below). The remaining bits of the instruction contain one or more fields as shown below for the different instruction formats.

Since all instructions are word-aligned, whenever instruction addresses are presented to the processor (as in *Branch* instructions) the low-order two bits are ignored. Similarly, whenever the processor develops an instruction address the low-order two bits are zero.

Prefixed instructions consist of a four-byte prefix followed by a four-byte suffix. As such, the address of a prefixed instruction is the address of its prefix. For some prefixed instructions, the four-byte suffix is a defined word instruction, and the prefix modifies or extends the word instruction’s behavior. For other prefixed instructions, while the suffix may or may not correspond to (i.e., have the same 32-bit binary value as) a defined word instruction, the prefix causes the suffix to be decoded using a different opcode space from that used by defined word instructions.

Prefixed instructions do not cross 64-byte instruction address boundaries. When a prefixed instruction crosses a 64-byte boundary, the system alignment error handler is invoked.

#### Programming Note

The instruction address boundary error can only occur with prefixed instructions. Word instructions are word-aligned (four-byte), and thus cannot cross 64-byte boundaries.

The format diagrams given below show horizontally all valid combinations of instruction fields. See Section 1.6.3, “Instruction Prefix Formats” for definitions of instruction fields defined in the prefix.

### Split Field Notation

In some cases an instruction field occupies more than one contiguous sequence of bits, or occupies one contiguous sequence of bits that are used in permuted order. Such a field is called a *split field*. In the format diagrams given below and in the individual instruction layouts, the name of a split field is shown in small letters, once for each of the contiguous sequences. In the RTL description of an instruction having a split field, and in certain other places where individual bits of a split field are identified, the name of the field in small letters represents the concatenation of the sequences from left to right. In all other places, the name of the field is capitalized and represents the concatenation of the sequences in some order, which need not be left to right, as described for each affected instruction.

## 1.6.2 Word Instruction Fields

### AA (30)

Absolute Address.

- 0 The immediate field represents an address relative to the current instruction address. For I-form branches the effective address of the branch target is the sum of the LI field sign-extended to 64 bits and the address of the branch instruction. For B-form branches the effective address of the branch target is the sum of the BD field sign-extended to 64 bits and the address of the branch instruction.
- 1 The immediate field represents an absolute address. For I-form branches the effective address of the branch target is the LI field sign-extended to 64 bits. For B-form branches the effective address of the branch target is the BD field sign-extended to 64 bits.

Formats: B, I

### AX,A (29,11:15)

Fields that are concatenated to specify a VSR to be used as a source.

Formats: XX3, XX4

### BA (11:15)

Field used to specify a bit in the CR to be used as a source.

Formats: XL

### BB (16:20)

Field used to specify a bit in the CR to be used as a source.

Formats: XL

### BC (21:25)

Field used to specify a bit in the CR to be used as a source.

Formats: A

### BD (16:29)

Immediate field used to specify a 14-bit signed two's complement branch displacement which is concatenated on the right with 0b00 and sign-extended to 64 bits.

Formats: B

### BF (6:8)

Field used to specify one of the CR fields or one of the FPSCR fields to be used as a target.

Formats: D, X, XL, XX2, XX3, Z22

### BFA (11:13)

Field used to specify one of the CR fields or one of the FPSCR fields to be used as a source.

Formats: X, XL

### BH (19:20)

Field used to specify a hint in the *Branch Conditional to Link Register* and *Branch Conditional to Count Register* instructions. The encoding is described in Section 2.4, "Branch Instructions".

Formats: XL

### BHRBE (11:20)

Field used to identify the BHRB entry to be used as a source by the *Move From Branch History Rolling Buffer* instruction.

Formats: X

### BI (11:15)

Field used to specify a bit in the CR to be tested by a *Branch Conditional* instruction.

Formats: B, XL

### BO (6:10)

Field used to specify options for the *Branch Conditional* instructions. The encoding is described in Section 2.4, "Branch Instructions".

Formats: B, XL, X, XL

### BT (6:10)

Field used to specify a bit in the CR or in the FPSCR to be used as a target.

Formats: XL

### BX,B (30,16:20)

Fields that are concatenated to specify a VSR to be used as a source.

Formats: XX2, XX3, XX4

### CT (7:10)

Field used in X-form instructions to specify a cache target (see Section 4.3.2 of Book II).

Formats: X

**CX,C (28,21:25)**

Fields that are concatenated to specify a VSR to be used as a source.

Formats: XX4

**D (16:31)**

Immediate field used to specify a 16-bit signed two's complement integer which is sign-extended to 64 bits.

Formats: D

**d0,d1,d2 (16:25,11:15,31)**

Immediate fields that are concatenated to specify a 16-bit signed two's complement integer which is sign-extended to 64 bits.

Formats: DX

**dc,dm,dx (25,29,11:15)**

Immediate fields that are concatenated to specify Data Class Mask.

Formats: XX2

**DCM (16:21)**

Immediate field used to specify Data Class Mask.

Formats: Z22

**DCMX (9:15)**

Immediate field used to specify Data Class Mask.

Formats: X, XX2

**DGM (16:21)**

Immediate field used as the Data Group Mask.

Formats: Z22

**DM (22:23)**

Immediate field used by *xxpermdi* instruction as doubleword permute control.

Formats: XX3

**DRM (18:20)**

Immediate operand field used to specify new decimal floating-point rounding mode.

Formats: X

**DQ (16:27)**

Immediate field used to specify a 12-bit signed two's complement integer which is concatenated on the right with 0b0000 and sign-extended to 64 bits.

Formats: DQ

**DS (16:29)**

Immediate field used to specify a 14-bit signed two's complement integer which is concatenated on the right with 0b00 and sign-extended to 64 bits.

Formats: DS

**DX,D (31,6:10)**

Immediate fields that are concatenated to specify a 6-bit unsigned integer which is concatenated on the right with 0b000 and concatenated on the left with 0b111\_1111 and sign extended to 64 bits. This 64-bit value is used as a byte offset by the *Hash* instructions.

Formats: X

**EH (31)**

Field used to specify a hint in the *Load And Reserve* instructions. The meaning is described in Section 4.6.2, "Load And Reserve and Store Conditional Instructions", in Book II.

Formats: X

**EO (11:12)**

Expanded opcode field

Formats: X

**EO (11:15)**

Expanded opcode field

Formats: VX, X, XX2

**EX (31)**

Field used to specify Inexact form of round to quad-precision integer.

Formats: X

**FC (16:20)**

Field used to specify the function code in *Load/Store Atomic* instructions.

Formats: X

**FLM (7:14)**

Field mask used to identify the FPSCR fields that are to be updated by the *mtfsf* instruction.

Formats: XFL

**FRA (11:15)**

Field used to specify a FPR to be used as a source.

Formats: A, X, Z22, Z23

**FRAp (11:15)**

Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

Formats: X, Z22, Z23

**FRB (16:20)**

Field used to specify an FPR to be used as a source.

Formats: A, X, XFL, Z23

**FRBp (16:20)**

Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

Formats: X, Z23

**FRC (21:25)**

Field used to specify an FPR to be used as a source.

Formats: A

**FRS (6:10)**

Field used to specify an FPR to be used as a source.

Formats: D, X

**FRSp (6:10)**

Field used to specify an even/odd pair of FPRs to be concatenated and used as a source.

Formats: DS, X

**FRT (6:10)**

Field used to specify an FPR to be used as a target.

Formats: A, D, X, Z22, Z23

**FRTp (6:10)**

Field used to specify an even/odd pair of FPRs to be concatenated and used as a target.

Formats: DS, X, Z22, Z23

**FXM (12:19)**

Field mask used to identify the CR fields that are to be written by the *mtcrf* and *mtocrf* instructions, or read by the *mfocrf* instruction.

Formats: XFX

**IB (16:20)**

Immediate field used to specify a 5-bit signed integer.

Formats: MDS

**IH (8:10)**

Field used to specify a hint in the *SLB Invalidate All* instruction. The meaning is described in Section 6.9.3.2, “SLB Management Instructions”, in Book III.

Formats: X

**IMM8 (13:20)**

Immediate field used to specify an 8-bit integer.

Formats: X

**IS (6:10)**

Immediate field used to specify a 5-bit signed integer.

Formats: MDS

**L (6)**

Field used to specify whether the *mtfsf* instruction updates the entire FPSCR.

Formats: XFL

**L (8:10)**

Field used by the *Data Cache Block Flush* instruction (see Section 4.3.2 of Book II) and also by the *Synchronize* instruction (see Section 4.6.3 of Book II).

Formats: X

**L (10)**

Field used to specify whether a fixed-point Compare instruction is to compare 64-bit numbers or 32-bit numbers.

Field used by the *Compare Range Byte* instruction to indicate whether to compare against 1 or 2 ranges of bytes.

Field used by the *Paste* instruction to indicate whether to zero the metadata.

Formats: D, X

**L (15)**

Field used by the *Move To Machine State Register* instruction (see Book III).

Field used by the SLB Invalidate All Global instruction to specify whether the invalidation is for a process or for a partition (see Section 6.9.3.2 of Book III).

Field used by the *SLB Move From Entry VSID* and *SLB Move From Entry ESID* instructions for implementation-specific purposes.

Formats: X

**L (14:15)**

Field used by the *Deliver A Random Number* instruction (see Section 3.3.9, “Fixed-Point Arithmetic Instructions”) to choose the random number format.

Formats: X

**LEV (20:26)**

Field used by the *System Call* instructions.

Formats: SC

**LI (6:29)**

Immediate field used to specify a 24-bit signed two’s complement integer which is concatenated on the right with 0b00 and sign-extended to 64 bits.

Formats: I

**LK (31)**

LINK bit.

0 Do not set the Link Register.

1 Set the Link Register. The address of the instruction following the *Branch* instruction is placed into the Link Register.

Formats: B, I, XL

**MB (21:25)**

Field used in M-form instructions to specify the first 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 107.

Formats: M

**mb (21:26)**

Field used in MD-form and MDS-form instructions to specify the first 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 107.

Formats: MD, MDS

**me (21:26)**

Field used in MD-form and MDS-form instructions to specify the last 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 107.

Formats: MD, MDS

**ME (26:30)**

Field used in M-form instructions to specify the last 1-bit of a 64-bit mask, as described in Section 3.3.14, “Fixed-Point Rotate and Shift Instructions” on page 107.

Formats: M

**NB (16:20)**

Field used to specify the number of bytes to move in an immediate *Move Assist* instruction.

Formats: X

**OE (21)**

Field used by XO-form instructions to enable setting OV and SO in the XER.

Formats: XO

**PL (14:15)**

Field used by the *wait* instruction to specify pause length.

Formats: X

**PO (0:5)**

Primary opcode.

Formats: all

**PRS (14)**

Field used to specify whether to invalidate process- or partition-scoped entries for *tlbie[]*.

Formats: X

**PS (22)**

Field used to specify preferred sign for BCD operations.

Formats: VX

**PT (28:31)**

Immediate field used to specify a 4-bit unsigned value.

Formats: DQ

**R (15)**

Immediate field that specifies whether the RMC is specifying the primary or secondary encoding

Field used to specify whether to invalidate Radix Tree or HPT entries for *tlbie[]*.

Formats: X, Z23

**RA (11:15)**

Field used to specify a GPR to be used as a source or as a target.

Formats: A, D, DQ, DQE, DS, M, MD, MDS, TX, VA, VX, X, XO, XS

**RB (16:20)**

Field used to specify a GPR to be used as a source.

Formats: A, M, MDS, VA, X, XO

**Rc (21)**

RECORD bit.

0 Do not alter the Condition Register.

1 Set Condition Register Field 6 as described in Section 2.3.1, “Condition Register” on page 34.

Formats: VC, XX3

**RC (21:25)**

Field used to specify a GPR to be used as a source.

Formats: VA

**Rc (31)**

RECORD bit.

0 Do not alter the Condition Register.

1 Set Condition Register Field 0 or Field 1 as described in Section 2.3.1, “Condition Register” on page 34.

Formats: A, M, MD, MDS, X, XFL, XO, XS, Z22, Z23

**RIC (12:13)**

Field used to specify what types of entries to invalidate for *tlbie[]*.

Formats: X

**RM (19:20)**

Immediate operand field used to specify new binary floating-point rounding mode.

Formats: X

**RMC (21:22)**

Immediate field used for DFP rounding mode control.

Formats: Z23

**RO (31)**

Round to Odd override

Formats: X

**RS (6:10)**

Field used to specify a GPR to be used as a source.

Formats: D, DS, M, MD, MDS, X, XFX, XS

**RSp (6:10)**

Field used to specify an even/odd pair of GPRs to be concatenated and used as a source.

Formats: DS, X

**RT (6:10)**

Field used to specify a GPR to be used as a target.

Formats: A, D, DQE, DS, DX, VA, VX, X, XFX, XO, XX2

**RTp (6:10)**

Field used to specify an even/odd pair of GPRs to be concatenated and used as a target.

Formats: DQ, X

**S (11)**

Immediate field that specifies signed versus unsigned conversion.

Formats: X

**S (20)**

Immediate field that specifies whether or not the *rfebb* instruction re-enables event-based branches.

Formats: XL

**SC (14:15)**

Field used by the *Synchronize* instruction to specify the kind(s) of stores that are ordered.

Formats: X

**SH (16:20)**

Field used to specify a shift amount.

Formats: M, X

**SH (16:21)**

Field used to specify a shift amount.

Formats: Z22

**sh (30,16:20)**

Fields that are concatenated to specify a shift amount.

Formats: MD, XS

**SHB (22:25)**

Field used to specify a shift amount in bytes.

Formats: VA

**SHW (22:23)**

Field used to specify a shift amount in words.

Formats: XX3

**SI (16:20)**

Immediate field used to specify a 5-bit signed integer.

Formats: X

**SI (16:31)**

Immediate field used to specify a 16-bit signed integer.

Formats: D

**SIM (11:15)**

Immediate field used to specify a 5-bit signed integer.

Formats: VX

**SP (11:12)**

Immediate field that specifies signed versus unsigned conversion.

Formats: X

**SPR (11:20)**

Field used to specify a Special Purpose Register for the *mtspr* and *mfspr* instructions.

Formats: X

**SR (12:15)**

Field used by the *Segment Register Manipulation* instructions (see Book III).

Formats: X

**SX,S (28,6:10)**

Fields SX and S are concatenated to specify a VSR to be used as a source.

Formats: DQ

**SX,S (31,6:10)**

Fields SX and S are concatenated to specify a VSR to be used as a source.

Formats: X

**TBR (11:20)**

Field used by the *Move From Time Base* instruction (see Section 5.1 of Book II).

Formats: X

**TE (11:15)**

Immediate field that specifies a DFP exponent.

Formats: Z23

**TH (6:10)**

Field used by the data stream variant of the *dcbt* and *dcbstf* instructions (see Section 4.3.2 of Book II).

Formats: X

**TO (6:10)**

Field used to specify the conditions on which to trap. The encoding is described in Section 3.3.10.1, “Character-Type Compare Instructions” on page 94.

Formats: TX, X

**TX,T (28,6:10)**

Fields that are concatenated to specify a VSR to be used as either a target.

Formats: DQ

**TX,T (31,6:10)**

Fields that are concatenated to specify a VSR to be used as either a target or a source.

Formats: X, XX2, XX3, XX4

**U (16:19)**

Immediate field used as the data to be placed into a field in the FPSCR.

Formats: X

**UI (16:20)**

Immediate field used to specify a 5-bit unsigned integer.

Formats: TX

**UI (16:31)**

Immediate field used to specify a 16-bit unsigned integer.

Formats: D

**UIM (11:15)**

Immediate field used to specify a 5-bit unsigned integer.

Formats: VX, X

**UIM (12:15)**

Immediate field used to specify a 4-bit unsigned integer.

## 1.6.3 Instruction Prefix Formats

Prefixed instructions consist of a 4-byte prefix followed by a 4-byte suffix. The prefix formats are specified below. The suffix formats share the same formats as word instructions, as specified in Section 1.6.1 on page 12.

Bits 0:5 of all prefixes are assigned the primary opcode value 0b000001. 0b000001 is not available for use as a primary opcode for either word instructions or suffixes of prefixed instructions.

Prefix bits 6:7 are used to identify one of four prefix format types. When bit 6 is set to 0 (prefix types 00 and 01), the suffix is not a defined word instruction (i.e., requires the prefix to identify the alternate opcode space the suffix is assigned to as well as additional or extended operand and/or control fields); when bit 6 is set to 1 (prefix types 10 and 11), the prefix is modifying the behavior of a defined word instruction in the suffix.

### 1.6.3.1 Type 00 Prefix – Eight-Byte Load/Store Instructions

1	0	ST	//	R	//	Sub-Type Specific	31
0	6	8	9	11	12	14	

The Type 00 prefix format provides a one-bit subtype (ST) field to specify the subformat employed by the prefix. The subformats are defined as follows.

#### ST=0: Eight-Byte Load/Store Form (8LS)

1	0	0	//	R	//	IE	31
0	6	8	9	11	12	14	

ST=1: Reserved

### 1.6.3.2 Type 01 Prefix – Eight-Byte Register-to-Register Instructions

1	1	ST	Sub-type Specific				31
0	6	8	12				

The Type 01 prefix format provides a four-bit subtype (ST) field to specify the subformat employed by the prefix. The subformats are defined as follows.

#### ST=0b0000: Eight-Byte Register-to-Register Form (8RR)

1	1	0	//	///			31
0	6	8	12	14			

1	1	0	//	///			UIM	31
0	6	8	12	14	29			

1	1	0	//	///			IMM	31
0	6	8	12	14	24			

1	1	0	//	//	imm0		31
0	6	8	12	14	16		

ST=0b0001-0b1111: Reserved

### 1.6.3.3 Type 10 - Modified Load/Store Instructions

1	2	ST	//	R	//	Sub-Type Specific	31
0	6	8	9	11	12	14	

The Type 10 prefix format provides a one-bit subtype (ST) field to specify the subformat employed by the prefix. The subformats are defined as follows.

#### ST=0: Modified Load/Store Form (MLS)

1	2	0	//	R	//	IE	31
0	6	8	9	11	12	14	

ST=1: Reserved

### 1.6.3.4 Type 11 - Modified Register-to-Register Instructions

1	3	ST	Sub-type Specific				31
0	6	8	12				

The Type 11 prefix format provides a four-bit subtype (ST) field to specify the subformat employed by the prefix. The subformats are defined as follows.

#### ST=0b0000: Modified Register to Register Form (MRR)

1	3	0	//	0			31
0	6	8	12	14			

- ***pnop*** (See Section 3.3.20, “Prefixed No-Operation Instruction” on page 133)

**ST=0b0001-0b1000:** Reserved

**ST=0b1001: Modified Masked Immediate Register to Register Form (MMIRR)**

1	3	9	//	//	//		XMSK	YMSK
0	6	8	12	14	15	16	24	28 31

1	3	9	//	//	//		XMSK	YMSK	//
0	6	8	12	14	15	16	24	28	30 31

1	3	9	//	//	//	PMSK	XMSK	YMSK
0	6	8	12	14	15	16	24	28 31

1	3	9	//	//	//	PMSK	//	XMSK	YMSK
0	6	8	12	14	15	16	20	24	28 31

1	3	9	//	//	//	PMSK	//	XMSK	YMSK
0	6	8	12	14	15	16	18	24	28 31

**ST=0b1010-0b1111:** Reserved

## 1.6.4 Instruction Prefix Fields

### IE (14:31)

18-bit immediate field that is concatenated with the D field in the suffix to extend the displacement value at the high-order end. This field is reserved when this prefix precedes instructions of other formats.

Alternate field names: d0, si0, imm18

Formats: 8LS, MLS

### imm0 (16:31)

16-bit immediate field that is concatenated with the 16-bit immediate field in the suffix to create a 32-bit value.

Formats: 8RR

### IMM (24:31)

8-bit immediate field used as control operand.

Formats: 8RR

### PMSK (16:23)

Immediate field used to specify product mask for *VSX Vector GER* instructions.

Formats: MMIRR

### PMSK (16:19)

Immediate field used to specify product mask for *VSX Vector GER* instructions.

Formats: MMIRR

### PMSK (16:17)

Immediate field used to specify product mask for *VSX Vector GER* instructions.

Formats: MMIRR

### R (11)

Field used to specify whether the effective address of the storage operand is computed relative to the address of the instruction (CIA).

0b0 Effective address is not computed relative to CIA

0b1 Effective address is computed relative to CIA

Formats: 8LS, MLS

### UIM (29:31)

3-bit immediate field used as control operand.

Formats: 8RR

### XMSK (24:27)

Field used to specify ACC row mask for *VSX Vector GER* instructions.

Formats: MMIRR

### YMSK (28:31)

Field used to specify ACC column mask for *VSX Vector GER* instructions.

Formats: MMIRR

### YMSK (28:29)

Field used to specify ACC column mask for *VSX Vector GER* instructions.

Formats: MMIRR

## 1.7 Classes of Instructions

An instruction falls into exactly one of the following three classes:

Defined  
Illegal  
Reserved

The class is determined by examining the opcode, and the extended opcode if any. If the opcode, or combination of opcode and extended opcode, is not that of a defined instruction or a reserved instruction, the instruction is illegal.

### 1.7.1 Defined Instruction Class

This class of instructions contains all the instructions defined in this document.

A defined instruction can have preferred and/or invalid forms, as described in Section 1.8.1, "Preferred Instruction Forms" and Section 1.8.2, "Invalid Instruction Forms".

## 1.7.2 Illegal Instruction Class

This class of instructions contains the set of instructions described in Appendix B of Book Appendices. Illegal instructions are available for future extensions of the Power ISA ; that is, some future version of the Power ISA may define any of these instructions to perform new functions.

Any attempt to execute an illegal instruction will cause the system illegal instruction error handler to be invoked and will have no other effect.

An instruction consisting entirely of binary 0s is guaranteed always to be an illegal instruction. This increases the probability that an attempt to execute data or uninitialized storage will result in the invocation of the system illegal instruction error handler.

## 1.7.3 Reserved Instruction Class

This class of instructions contains the set of instructions described in Appendix C of Book Appendices.

Reserved instructions are allocated to specific purposes that are outside the scope of the Power ISA.

Any attempt to execute a reserved instruction will:

- perform the actions described by the implementation if the instruction is implemented; or
- cause the system illegal instruction error handler to be invoked if the instruction is not implemented.

## 1.8 Forms of Defined Instructions

### 1.8.1 Preferred Instruction Forms

Some of the defined instructions have preferred forms. For such an instruction, the preferred form will execute in an efficient manner, but any other form may take significantly longer to execute than the preferred form.

Instructions having preferred forms are:

- the *Condition Register Logical* instructions
- the *Load Quadword* instruction
- the *Move Assist* instructions
- the *Or Immediate* instruction (preferred form of no-op)
- the *Move To Condition Register Fields* instruction

### 1.8.2 Invalid Instruction Forms

Some of the defined instructions can be coded in a form that is invalid. An instruction form is invalid if one or more fields of the instruction, excluding the opcode field(s), are coded incorrectly in a manner that can be deduced by examining only the instruction encoding.

In general, any attempt to execute an invalid form of an instruction will either cause the system illegal instruction error handler to be invoked or yield boundedly undefined results. Exceptions to this rule are stated in the instruction descriptions.

Some instruction forms are invalid because the instruction contains a reserved value in a defined field (see Section 1.3.3 on page 5). Instruction forms that are invalid for any other reason are identified in the instruction descriptions.

References to instructions elsewhere in this document assume the instruction form is not invalid, unless otherwise stated or obvious from context.

#### Assembler Note

Assemblers should report uses of invalid instruction forms as errors.

## 1.8.3 Reserved-no-op Instructions

Reserved-no-op instructions include the following extended opcodes under primary opcode 31: 530, 562, 594 and 626.

Reserved-no-op instructions are provided in the architecture to anticipate the eventual adoption of performance hint instructions to the architecture. For these instructions, which cause no visible change to architected state, employing a reserved-no-op opcode will allow software to use this new capability on new implementations that support it while remaining compatible with existing implementations that may not support the new function.

When a reserved-no-op instruction is executed, no operation is performed.

Reserved-no-op instructions are not assigned instruction names or mnemonics. There are no individual descriptions of reserved-no-op instructions in this document.

## 1.9 Exceptions

There are two kinds of exception, those caused directly by the execution of an instruction and those caused by an asynchronous event. In either case, the exception may cause one of several components of the system software to be invoked.

The exceptions that can be caused directly by the execution of an instruction include the following:

- an attempt to execute an illegal instruction, or an attempt by an application program to execute a “privileged” instruction (see Book III) (system illegal instruction error handler or system privileged instruction error handler)

- the execution of a defined instruction using an invalid form (system illegal instruction error handler or system privileged instruction error handler)
- an attempt to execute an instruction that is not provided by the implementation (system illegal instruction error handler)
- an attempt to execute a prefixed instruction that crosses a 64-byte address boundary. (system alignment error handler)
- an attempt to access a storage location that is unavailable (system instruction storage error handler or system data storage error handler)
- an attempt to access storage with an effective address alignment that is invalid for the instruction (system alignment error handler)
- the execution of a *System Call* or *System Call Vectored* instruction (system service program)
- the execution of a *Trap* instruction that traps (system trap handler)
- the execution of a floating-point instruction that causes a floating-point enabled exception to exist (system floating-point enabled exception error handler)

The exceptions that can be caused by an asynchronous event are described in Book III.

The invocation of the system error handler is precise, except that if one of the imprecise modes for invoking the system floating-point enabled exception error handler is in effect (see page 145), then the invocation of the system floating-point enabled exception error handler may also be imprecise. When the system error handler is invoked imprecisely, the excepting instruction does not appear to complete before the next instruction starts (because one of the effects of the excepting instruction, namely the invocation of the system error handler, has not yet occurred).

Additional information about exception handling can be found in Book III.

## 1.10 Storage Addressing

A program references storage using the effective address computed by the processor when it executes a *Storage Access* or *Branch* instruction (or certain other instructions described in Book II and Book III), or when it fetches the next sequential instruction.

Bytes in storage are numbered consecutively starting with 0. Each number is the address of the corresponding byte.

The byte ordering (Big-Endian or Little-Endian) for a storage access is specified by the operating system. This byte ordering is also referred to as the Endian mode and it applies to both data accesses and instruc-

tion fetches. The Endian mode is specified by the LE mode bit (see Section 4.2.1 of Book III), which applies to all of storage.

### 1.10.1 Storage Operands

A storage operand may be a byte, a halfword, a word, a doubleword, a quadword, an octword, or, for the *Load/Store Multiple*, *Move Assist*, and *Load/Store VSX Vector with Length [Left-justified]* instructions, a sequence of bytes (*Move Assist* and *Load/Store VSX Vector with Length [Left-justified]*) or words (*Load/Store Multiple*). The address of a storage operand is the address of its first byte (i.e., of its lowest-numbered byte). An instruction for which the storage operand is a byte is said to cause a byte access, and similarly for halfword, word, doubleword, quadword, and octword.

The length of the storage operand is the number of bytes (of the storage operand) that the instruction would access in the absence of invocations of the system error handler. The length is generally implied by the name of the instruction (equivalently, by the opcode, and extended opcode if any). For example, the length of the storage operand of a *Load Word and Zero*, *Load Floating-Point Single*, and *Load Vector Element Word* instruction is four bytes (one word), the length of a *Store Quadword*, *Store Floating-Point Double Pair*, and *Store VSX Vector Word\*4* instruction is 16 bytes (one quadword), and the length of a *Load VSX Vector Paired* instruction is 32 bytes (one octword). The only exceptions are the *Load/Store Multiple*, *Move Assist*, and *Load/Store VSX Vector with Length [Left-justified]* instructions, for which the length of the storage operand is implied by the identity of the specified source or target register (*Load/Store Multiple*), or by an immediate field in the instruction or the contents of a field in the XER (*Move Assist*), or by the contents of a byte in a GPR (*Load/Store VSX Vector with Length [Left-justified]*), as well as by the name of the instruction. For example, the length of the storage operand of a *Load Multiple Word* instruction for which the specified target register is GPR 20 is 48 bytes  $((32-20) \times 4)$ , and the length of the storage operand of a *Load String Word Immediate* instruction for which the immediate field contains the number 20 is 20 bytes.

For most *Load* and *Store* instructions, the storage operand is said to be aligned if the address of the storage operand is an integral multiple of the storage operand length; otherwise it is said to be unaligned. See the following table. The only *Load* and *Store* instructions to which this general rule does not apply are the *Load/Store Multiple* and *Move Assist* instructions, and *Load/Store VSX Vector with Length [Left-justified]* instructions for which the specified length is not an integral power of 2. The storage operand of *Load/Store Multiple Word* is said to be aligned if the address of the storage operand is an integral multiple of four; otherwise the storage operand is said to be unaligned. (The storage operand of a *Move Assist* instruction, or of a *Load/*

*Store VSX Vector with Length [Left-justified]* instruction for which the specified length is not an integral power of 2, is neither said to be aligned nor said to be unaligned. Its alignment properties are described, when necessary, using terms such as “word-aligned”, which are defined below.)

Operand	Length	Addr <sub>58:63</sub> if aligned
Byte	8 bits	xxxxxx
Halfword	2 bytes	xxxxx0
Word	4 bytes	xxxx00
Doubleword	8 bytes	xxx000
Quadword	16 bytes	xx0000
Octword	32 bytes	x00000

**Note:** An “x” in an address bit position indicates that the bit can be 0 or 1 independent of the contents of other bits in the address.

The concept of alignment is also applied more generally, to any datum in storage.

- A datum having length that is an integral power of 2 is said to be aligned if its address is an integral multiple of its length.
- A datum of any length is said to be halfword-aligned (or aligned at a halfword boundary) if its address is an integral multiple of 2, word-aligned (or aligned at a word boundary) if its address is an integral multiple of 4, etc. (All data in storage is byte-aligned.)

The concept of alignment can also be applied to data in registers, with the “address” of the datum interpreted as the byte number of the datum in the register. E.g., a word element (4 bytes) in a Vector Register is said to be aligned if its byte number is an integral multiple of 4.

#### Programming Note

The technical literature sometimes uses the term “naturally aligned” to mean “aligned.”

Versions of the architecture that precede Version 2.07 also used “naturally aligned” as defined above. The term was dropped from the architecture in Version 2.07 because it seemed to mean different things to different readers and is not needed.

Some instructions require their storage operands to have certain alignments. In addition, alignment may affect performance. In general, the best performance is obtained when storage operands are aligned.

When a datum of length  $N$  bytes starting at effective address  $EA$  is copied between storage and a register that is  $R$  bytes long (i.e., the register contains bytes numbered from 0, most significant, through  $R-1$ , least significant), the bytes of the datum are placed into the register or into storage in a manner that depends on the byte ordering for the storage access as shown in

Figure 28, unless otherwise specified in the instruction description.

Big-Endian Byte Ordering	
Load	Store
do $i = 0$ to $N-1$ : $RT_{(R-N)+i} \leftarrow \text{MEM}(EA+i, 1)$	do $i = 0$ to $N-1$ : $\text{MEM}(EA+i, 1) \leftarrow (RS)_{(R-N)+i}$
Little-Endian Byte Ordering	
Load	Store
do $i = 0$ to $N-1$ : $RT_{(R-1)-i} \leftarrow \text{MEM}(EA+i, 1)$	do $i = 0$ to $N-1$ : $\text{MEM}(EA+i, 1) \leftarrow (RS)_{(R-1)-i}$
<b>Notes:</b>	
1. In this table, subscripts refer to bytes in a register.	

**Figure 28. Storage data and byte ordering**

Figure 29 shows an example of a C language structure `s` containing an assortment of scalars and one character string. The value assumed to be in each structure element is shown in hex in the C comments; these values are used below to show how the bytes making up each structure element are mapped into storage. It is assumed that structure `s` is compiled for 32-bit mode or for a 32-bit implementation. (This affects the length of the pointer to `c`.)

C structure mapping rules permit the use of padding (skipped bytes) in order to align the scalars on desirable boundaries. Figures 30 and 31 show each scalar as aligned. This alignment introduces padding of four bytes between `a` and `b`, one byte between `d` and `e`, and two bytes between `e` and `f`. The same amount of padding is present for both Big-Endian and Little-Endian mappings.

The Big-Endian mapping of structure `s` is shown in Figure 30. Addresses are shown in hex at the left of each doubleword, and in small figures below each byte. The contents of each byte, as indicated in the C example in Figure 29, are shown in hex (as characters for the elements of the string).

The Little-Endian mapping of structure `s` is shown in Figure 31. Doublewords are shown laid out from right to left, which is the common way of showing storage maps for processors that implement only Little-Endian byte ordering.

```

struct {
  int a; /* 0x1112_1314 word */
  double b; /* 0x2122_2324_2526_2728 doubleword */
  char * c; /* 0x3132_3334 word */
  char d[7]; /* 'A', 'B', 'C', 'D', 'E', 'F', 'G' array of bytes */
  short e; /* 0x5152 halfword */
  int f; /* 0x6162_6364 word */
} s;
    
```

**Figure 31. Little-Endian mapping of structure 's'**

## 1.10.2 Instruction Fetches

Instructions are encoded in either four or eight bytes and are word-aligned. For purposes of byte ordering, prefixed instructions are treated as if they are two independent four-byte instructions, with the prefix preceding the suffix in storage regardless of the Endian mode.

When an instruction starting at effective address EA is fetched from storage, the relative order of the bytes within each word of the instruction image depends on the byte ordering for the storage access as shown in Figure 32.

Big-Endian Byte Ordering
for $i=0$ to 3: $inst_i \leftarrow MEM(EA+i, 1)$
Little-Endian Byte Ordering
for $i=0$ to 3: $inst_{3-i} \leftarrow MEM(EA+i, 1)$
Notes
1. In this table, subscripts refer to bytes within the instruction.

**Figure 32. Instructions and byte ordering**

Figure 33 shows an example of a small assembly language program **p**. In the program, prefixed instruction 1 is doubleword-aligned and prefixed instruction 2 is word-aligned.

```

loop:  cplwi      r5, 0
      beq       done
      lwzux    r4, r5, r6
      add      r7, r7, r4
      <prefixed instruction 1>
      subi    r5, r5, 4
      <prefixed instruction 2>
      b       loop

done:  stw      r7, total

```

**Figure 33. Assembly language program ‘p’**

The Big-Endian mapping of program **p** is shown in Figure 34 (assuming the program starts at address 0).

00	loop: cplwi r5, 0	beq done
	00 01 02 03	04 05 06 07
08	lwzux r4, r5, r6	add r7, r7, r7
	08 09 0A 0B	0C 0D 0E 0F

**Figure 35. Little-Endian mapping of program ‘p’**

## Programming Note

The terms *Big-Endian* and *Little-Endian* come from Part I, Chapter 4, of Jonathan Swift's *Gulliver's Travels*. Here is the complete passage, from the edition printed in 1734 by George Faulkner in Dublin.

... our Histories of six Thousand Moons make no Mention of any other Regions, than the two great Empires of *Lilliput* and *Blefuscu*. Which two mighty Powers have, as I was going to tell you, been engaged in a most obstinate War for six and thirty Moons past. It began upon the following Occasion. It is allowed on all Hands, that the primitive Way of breaking Eggs before we eat them, was upon the larger End: But his present Majesty's Grand-father, while he was a Boy, going to eat an Egg, and breaking it according to the ancient Practice, happened to cut one of his Fingers. Whereupon the Emperor his Father, published an Edict, commanding all his Subjects, upon great Penalties, to break the smaller End of their Eggs. The People so highly resented this Law, that our Histories tell us, there have been six Rebellions raised on that Account; wherein one Emperor lost his Life, and another his Crown. These civil Commotions were constantly fomented by the Monarchs of *Blefuscu*; and when they were quelled, the Exiles always fled for Refuge to that Empire. It is computed that eleven Thousand Persons have, at several Times, suffered Death, rather than submit to break their Eggs at the smaller End. Many hundred large Volumes have been published upon this Controversy: But the Books of the *Big-Endians* have been long

forbidden, and the whole Party rendered incapable by Law of holding Employments. During the Course of these Troubles, the Emperors of *Blefuscu* did frequently expostulate by their Ambassadors, accusing us of making a Schism in Religion, by offending against a fundamental Doctrine of our great Prophet *Lustrog*, in the fifty-fourth Chapter of the *Brundrecal*, (which is their *Alcoran*.) This, however, is thought to be a mere Strain upon the text: For the Words are these; *That all true Believers shall break their Eggs at the convenient End*: and which is the convenient End, seems, in my humble Opinion, to be left to every Man's Conscience, or at least in the Power of the chief Magistrate to determine. Now the *Big-Endian* Exiles have found so much Credit in the Emperor of *Blefuscu*'s Court; and so much private Assistance and Encouragement from their Party here at home, that a bloody War has been carried on between the two Empires for six and thirty Moons with various Success; during which Time we have lost Forty Capital Ships, and a much greater Number of smaller Vessels, together with thirty thousand of our best Seamen and Soldiers; and the Damage received by the Enemy is reckoned to be somewhat greater than ours. However, they have now equipped a numerous Fleet, and are just preparing to make a Descent upon us: and his Imperial Majesty, placing great Confidence in your Valour and Strength, hath commanded me to lay this Account of his Affairs before you.

### 1.10.3 Effective Address Calculation

An effective address is computed by the processor when executing a *Storage Access* or *Branch* instruction (or certain other instructions described in Book II and Book III) when fetching the next sequential instruction, or when invoking a system error handler. The following provides an overview of this process. More detail is provided in the individual instruction descriptions.

Effective address calculations, for both data and instruction accesses, use 64-bit two's complement addition. All 64 bits of each address component participate in the calculation regardless of mode (32-bit or 64-bit). In this computation one operand is an address (which is by definition an unsigned number) and the second is a signed offset. Carries out of the most significant bit are ignored.

In 64-bit mode, the entire 64-bit result comprises the 64-bit effective address. The effective address arithmetic wraps around from the maximum address,  $2^{64} - 1$ , to address 0, except that if the current instruction is a word instruction at effective address  $2^{64}-4$  or a prefixed instruction at effective address  $2^{64}-8$ , the effective address of the next sequential instruction is undefined, and if the current instruction is a prefixed instruction at effective address  $2^{64}-4$ , the effective address of the suffix is undefined.

In 32-bit mode, the low-order 32 bits of the 64-bit result, preceded by 32 0 bits, comprise the 64-bit effective address for the purpose of addressing storage, except that if the current instruction is a word instruction at effective address  $2^{32}-4$  or a prefixed instruction at effective address  $2^{32}-8$ , the 64-bit effective address of the next sequential instruction is undefined, and if the current instruction is a prefixed instruction at effective address  $2^{32}-4$ , the effective address of the suffix is undefined. Thus, as used to address storage, the effective address arithmetic appears to wrap around from

the maximum address  $2^{32}-1$ , to address 0, except when the resulting 64-bit effective address is undefined as just described. When an effective address is placed into a register by an instruction or event, the value placed into the register is as follows.

- Register RA when set by *Load with Update* and *Store with Update* instructions: the entire 64-bit result.
- All other cases (e.g., the Link Register when set by *Branch* instructions having LK=1, Special Purpose Registers when set to an effective address by invocation of a system error handler): the low-order 32 bits of the 64-bit result preceded by 32 0 bits, except that if the intended effective address is that of the NIA of either a word instruction at effective address  $2^{32}-4$ , or a prefixed instruction at effective address  $2^{32}-8$ , the value placed into the register is undefined.

RA is a field in the instruction which specifies an address component in the computation of an effective address. A zero in the RA field indicates the absence of the corresponding address component. A value of zero is substituted for the absent component of the effective address computation. This substitution is shown in the instruction descriptions as (RA|0).

Effective addresses are computed as follows. In the descriptions below, it should be understood that “the contents of a GPR” refers to the entire 64-bit contents, independent of mode, but that in 32-bit mode only bits 32:63 of the 64-bit result of the computation are used to address storage.

- With X-form instructions, in computing the effective address of a data element, the contents of the GPR designated by RB (or the value zero for *ldat*, *lswi*, *lwat*, *lxvl*, *lxvll*, *stdat*, *stswi*, *stwat*, *stxvl*, and *stxvll*) are added to the contents of the GPR designated by RA or to zero if RA=0 or RA is not used in forming the EA.

With X-form instructions that are preceded by an MLS-form or MMLS-form prefix with the R bit set to 1 (see Section 1.6.2 of Book I), in computing the effective address of the data element, the contents of the GPR designated by RB are added to the CIA and RA is not used in forming the EA.

- With D-form instructions, the 16-bit D field is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.

With prefixed instructions having a D-form suffix and an MLS-form or 8LS-form prefix, the 16-bit D field is concatenated on the left with the 18-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address compo-

nent. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

With prefixed instructions having a D-form suffix and an MMLS-form or 8MLS-form prefix, the 16-bit D field is concatenated on the left with the 12-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

- With DS-form instructions, the 14-bit DS field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.

With prefixed instructions having a DS-form suffix and an MLS-form or 8LS-form prefix, the 14-bit D field is concatenated on the right with 0b00 and is concatenated on the left with the 18-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

With prefixed instructions having a DS-form suffix and an MMLS-form or 8MLS-form prefix, the 14-bit D field is concatenated on the right with 0b00 and is concatenated on the left with the 12-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

- With DQ-form instructions, the 12-bit DQ field is concatenated on the right with 0b0000 and sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0.

With prefixed instructions having a DQ-form suffix and an MLS-form or 8LS-form prefix, the 12-bit DQ field is concatenated on the right with 0b0000 and is concatenated on the left with the 18-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing

the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

With prefixed instructions having a DQ-form suffix and an MMLS-form or 8MLS-form prefix, the 12-bit DQ field is concatenated on the right with 0b0000 and is concatenated on the left with the 12-bit IE field in the prefix, and the concatenation is sign-extended to form a 64-bit address component. In computing the effective address of a data element, this address component is added to the contents of the GPR designated by RA or to zero if RA=0 if the R bit in the prefix is set to 0, or is added to the CIA if the R bit in the prefix is set to 1.

- With I-form Branch instructions, the 24-bit LI field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. If AA=0, this address component is added to the address of the Branch instruction to form the effective address of the target instruction. If AA=1, this address component is the effective address of the target instruction.
- With B-form Branch instructions, the 14-bit BD field is concatenated on the right with 0b00 and sign-extended to form a 64-bit address component. If AA=0, this address component is added to the address of the Branch instruction to form the effective address of the target instruction. If AA=1, this address component is the effective address of the target instruction.
- With XL-form Branch instructions, bits 0:61 of the Link Register or the Count Register are concatenated on the right with 0b00 to form the effective address of the target instruction.
- With sequential instruction fetching, if the current instruction is a word instruction, the value 4 is added to the address of the current instruction to form the effective address of the next instruction, and if the current instruction is a prefixed instruction, the value 8 is added to the address of the current instruction to form the effective address of the next instruction, except that if the current instruction is at the maximum instruction effective address for the mode (for a word instruction,  $2^{64} - 4$  in 64-bit mode and  $2^{32} - 4$  in 32-bit mode; for a prefixed instruction,  $2^{64} - 8$  in 64-bit mode and  $2^{32} - 8$  in 32-bit mode) the effective address of the next sequential instruction is undefined.

If the size of the operand of a *Storage Access* instruction is more than one byte, the effective address for each byte after the first is computed by adding 1 to the effective address of the preceding byte.

## Chapter 2. Branch Facility

### 2.1 Branch Facility Overview

This chapter describes the registers and instructions that make up the Branch Facility.

### 2.2 Instruction Execution Order

In general, instructions appear to execute sequentially, in the order in which they appear in storage. The exceptions to this rule are listed below.

- *Branch* instructions for which the branch is taken cause execution to continue at the target address specified by the Branch instruction.
- *Trap* instructions for which the trap conditions are satisfied, and *System Call* and *System Call Vectored* instructions, cause the appropriate system handler to be invoked.
- Event-based exceptions can cause the event-based branch handler to be invoked, as described in Chapter 6 of Book II.
- Exceptions can cause the system error handler to be invoked, as described in Section 1.9, “Exceptions” on page 25.
- Returning from a system service program, system trap handler, or system error handler causes execution to continue at a specified address.

The model of program execution in which the processor appears to execute one instruction at a time, completing each instruction before beginning to execute the next instruction is called the “sequential execution model”. In general, the processor obeys the sequential execution model. For the instructions and facilities defined in this Book, the only exceptions to this rule are the following.

- A floating-point exception occurs when the processor is running in one of the Imprecise floating-point exception modes (see Section 4.4). The instruction that causes the exception need not complete before the next instruction begins execution, with respect to setting exception bits and (if the exception is enabled) invoking the system error handler.
- A *Store* instruction modifies one or more bytes in an area of storage that contains instructions that will subsequently be executed. Before an instruc-

tion in that area of storage is executed, software synchronization is required to ensure that the instructions executed are consistent with the results produced by the *Store* instruction.

#### Programming Note

This software synchronization will generally be provided by system library programs (see Section 1.8 of Book II). Application programs should call the appropriate system library program before attempting to execute modified instructions.

## 2.3 Branch Facility Registers

### 2.3.1 Condition Register

The Condition Register (CR) is a 32-bit register which reflects the result of certain operations, and provides a mechanism for testing (and branching).

**Figure 36. Condition Register**

The bits in the Condition Register are grouped into eight 4-bit fields, named CR Field 0 (CR0), ..., CR Field 7 (CR7), which are set in one of the following ways.

- Specified fields of the CR can be set by a move to the CR from a GPR (*mcrf*, *mtocrf*).
- A specified field of the CR can be set by a move to the CR from another CR field (*mcrf*), from OV, CA, OV32, and CA32 (*mcrxr*), or from the FPSCR (*mcrfs*).
- CR Field 0 can be set as the implicit result of a fixed-point instruction.
- CR Field 1 can be set as the implicit result of a floating-point instruction.
- CR Field 1 can be set as the implicit result of a decimal floating-point instruction.
- CR Field 6 can be set as the implicit result of a vector instruction.
- A specified CR field can be set as the result of a *Compare* instruction.

Instructions are provided to perform logical operations on individual CR bits and to test individual CR bits.

For all fixed-point instructions in which  $Rc=1$ , and for *addic.*, *andi.*, and *andis.*, the first three bits of CR Field 0 (bits 32:34 of the Condition Register) are set by signed comparison of the result to zero, and the fourth bit of CR Field 0 (bit 35 of the Condition Register) is copied from the SO field of the XER. “Result” here refers to the entire 64-bit value placed into the target register in 64-bit mode, and to bits 32:63 of the 64-bit value placed into the target register in 32-bit mode.

```

if (64-bit mode)
  then M ← 0
  else M ← 32
if (target_register)M:63 < 0 then c ← 0b100
else if (target_register)M:63 > 0 then c ← 0b010
else c ← 0b001
CR0 ← c || XERSO

```

If any portion of the result is undefined, then the value placed into the first three bits of CR Field 0 is undefined.

The bits of CR Field 0 are interpreted as follows.

Bit	Description
0	<b>Negative</b> (LT) The result is negative.
1	<b>Positive</b> (GT) The result is positive.
2	<b>Zero</b> (EQ) The result is zero.
3	<b>Summary Overflow</b> (SO) This is a copy of the contents of XER <sub>SO</sub> at the completion of the instruction.

The *paste* instruction (see Section 4.4, “Copy-Paste Facility”, in Book II) and the *stbcx.*, *stbcx.*, *stwcx.*, *stdcx.*, and *stqcx.* instructions (see Section 4.6.2, “Load And Reserve and Store Conditional Instructions”, in Book II) also set CR Field 0.

For all floating-point instructions in which  $Rc=1$ , CR Field 1 (bits 36:39 of the Condition Register) is set to the Floating-Point exception status, copied from bits 32:35 of the Floating-Point Status and Control Register. This occurs regardless of whether any exceptions are enabled, and regardless of whether the writing of the result is suppressed (see Section 4.4, “Floating-Point Exceptions” on page 144). These bits are interpreted as follows.

Bit	Description
32	<b>Floating-Point Exception Summary</b> (FX) This is a copy of the contents of FPSCR <sub>FX</sub> at the completion of the instruction.
33	<b>Floating-Point Enabled Exception Summary</b> (FEX) This is a copy of the contents of FPSCR <sub>FEX</sub> at the completion of the instruction.
34	<b>Floating-Point Invalid Operation Exception Summary</b> (VX) This is a copy of the contents of FPSCR <sub>VX</sub> at the completion of the instruction.
35	<b>Floating-Point Overflow Exception</b> (OX) This is a copy of the contents of FPSCR <sub>OX</sub> at the completion of the instruction.

For *Compare* instructions, a specified CR field is set to reflect the result of the comparison. The bits of the specified CR field are interpreted as follows. A complete description of how the bits are set is given in the instruction descriptions in Section 3.3.10, “Fixed-Point Compare Instructions” on page 92, and Section 4.6.8, “Floating-Point Compare Instructions” on page 183.

Bit	Description
0	<b>Less Than, Floating-Point Less Than</b> (LT, FL)

- For fixed-point Compare instructions, (RA) < SI or (RB) (signed comparison) or (RA) <<sup>u</sup> UI or (RB) (unsigned comparison). For floating-point Compare instructions, (FRA) < (FRB).
- 1 **Greater Than, Floating-Point Greater Than** (GT, FG)  
For fixed-point Compare instructions, (RA) > SI or (RB) (signed comparison) or (RA) ><sup>u</sup> UI or (RB) (unsigned comparison). For floating-point Compare instructions, (FRA) > (FRB).
- 2 **Equal, Floating-Point Equal** (EQ, FE)  
For fixed-point Compare instructions, (RA) = SI, UI, or (RB). For floating-point Compare instructions, (FRA) = (FRB).
- 3 **Summary Overflow, Floating-Point Unordered** (SO, FU)  
For fixed-point *Compare* instructions, this is a copy of the contents of XER<sub>SO</sub> at the completion of the instruction. For floating-point *Compare* instructions, one or both of (FRA) and (FRB) is a NaN.

The *Vector Integer Compare* instructions (see Section 6.9.3, “Vector Integer Compare Instructions”) compare two Vector Registers element by element, interpreting the elements as unsigned or signed integers depending on the instruction, and set the corresponding element of the target Vector Register to all 1s if the relation being tested is true and 0s if the relation being tested is false.

If Rc=1, CR Field 6 is set to reflect the result of the comparison, as follows

Bit	Description
0	The relation is true for all element pairs (i.e., VRT is set to all 1s).
1	0
2	The relation is false for all element pairs (i.e., VRT is set to all 0s).
3	0

The *Vector Floating-Point Compare* instructions compare two Vector Registers word element by word element, interpreting the elements as single-precision floating-point numbers. With the exception of the *Vector Compare Bounds Floating-Point* instruction, they set the target Vector Register, and CR Field 6 if Rc=1, in the same manner as do the *Vector Integer Compare* instructions.

Bit	Description
0	The relation is true for all element pairs (i.e., VRT is set to all 1s).
1	0

- 2 The relation is false for all element pairs (i.e., VRT is set to all 0s).
- 3 0

The *Vector Compare Bounds Floating-Point* instruction on page 434 sets CR Field 6 if Rc=1, to indicate whether the elements in VRA are within the bounds specified by the corresponding element in VRB, as explained in the instruction description. A single-precision floating-point value  $x$  is said to be “within the bounds” specified by a single-precision floating-point value  $y$  if  $-y \leq x \leq y$ .

Bit	Description
0	0
1	0
2	Set to indicate whether all four elements in VRA are within the bounds specified by the corresponding element in VRB, otherwise set to 0.
3	0

### 2.3.2 Link Register

The Link Register (LR) is a 64-bit register. It can be used to provide the branch target address for the *Branch Conditional to Link Register* instruction, and it holds the return address after Branch instructions for which LK=1 and after *System Call Vectored* instructions.

Figure 37. Link Register

### 2.3.3 Count Register

The Count Register (CTR) is a 64-bit register. It can be used to hold a loop count that can be decremented during execution of Branch instructions that contain an appropriately coded BO field. If the value in the Count Register is 0 before being decremented, it is -1 afterward. The Count Register can also be used to provide the branch target address for the *Branch Conditional to Count Register* instruction. The Count Register is modified by the *System Call Vectored* instruction.

Figure 38. Count Register

### 2.3.4 Target Address Register

The Target Address Register (TAR) is a 64-bit register. It can be used to provide bits 0:61 of the branch target

address for the *Branch Conditional to Branch Target Address Register* instruction. Bits 62:63 are ignored by the hardware but can be set and reset by software.

**Figure 39. Target Address Register**

**Programming Note**

The TAR is reserved for system software.

## 2.4 Branch Instructions

The sequence of instruction execution can be changed by the *Branch* instructions. Because all instructions are on word boundaries, bits 62 and 63 of the generated branch target address are ignored by the processor in performing the branch.

The *Branch* instructions compute the effective address (EA) of the target in one of the following five ways, as described in Section 1.10.3, “Effective Address Calculation” on page 30.

1. Adding a displacement to the address of the *Branch* instruction (*Branch* or *Branch Conditional* with AA=0).
2. Specifying an absolute address (*Branch* or *Branch Conditional* with AA=1).
3. Using the address contained in the Link Register (*Branch Conditional to Link Register*).
4. Using the address contained in the Count Register (*Branch Conditional to Count Register*).
5. Using the address contained in the Target Address Register (*Branch Conditional to Target Address Register*).

In all five cases, in 32-bit mode the final step in the address computation is setting the high-order 32 bits of the target address to 0.

For the first two methods, the target addresses can be computed sufficiently ahead of the *Branch* instruction that instructions can be prefetched along the target path. For the third through fifth methods, prefetching instructions along the target path is also possible provided the Link Register or the Count Register is loaded sufficiently ahead of the *Branch* instruction.

Branching can be conditional or unconditional, and the return address can optionally be provided. If the return address is to be provided (LK=1), the effective address of the instruction following the *Branch* instruction is placed into the Link Register after the branch target address has been computed; this is done regardless of whether the branch is taken.

For *Branch Conditional* instructions, the BO field specifies the conditions under which the branch is taken, as shown in Figure 40. In the figure, M=0 in 64-bit mode and M=32 in 32-bit mode.

BO	Description
0000z	Decrement the CTR, then branch if the decremented $CTR_{M:63} \neq 0$ and $CR_{BI}=0$
0001z	Decrement the CTR, then branch if the decremented $CTR_{M:63}=0$ and $CR_{BI}=0$
001at	Branch if $CR_{BI}=0$
0100z	Decrement the CTR, then branch if the decremented $CTR_{M:63} \neq 0$ and $CR_{BI}=1$
0101z	Decrement the CTR, then branch if the decremented $CTR_{M:63}=0$ and $CR_{BI}=1$
011at	Branch if $CR_{BI}=1$
1a00t	Decrement the CTR, then branch if the decremented $CTR_{M:63} \neq 0$
1a01t	Decrement the CTR, then branch if the decremented $CTR_{M:63}=0$
1z1zz	Branch always
Notes:	
1. “z” denotes a bit that is ignored.	
2. The “a” and “t” bits are used as described below.	

**Figure 40. BO field encodings**

The “a” and “t” bits of the BO field can be used by software to provide a hint about whether the branch is likely to be taken or is likely not to be taken, as shown in Figure 41.

at	Hint
00	No hint is given
01	Reserved
10	The branch is very likely not to be taken
11	The branch is very likely to be taken

**Figure 41. “at” bit encodings**

### Programming Note

Many implementations have dynamic mechanisms for predicting whether a branch will be taken. Because the dynamic prediction is likely to be very accurate, and is likely to be overridden by any hint provided by the “at” bits, the “at” bits should be set to 0b00 unless the static prediction implied by at=0b10 or at=0b11 is highly likely to be correct.

For *Branch Conditional to Link Register*, *Branch Conditional to Count Register*, and *Branch Conditional to Target Address Register* instructions, the BH field provides

a hint about the use of the instruction, as shown in Figure 42.

BH	Hint
00	<p><b><i>bclr</i></b>[<i>l</i>]: The instruction is a subroutine return</p> <p><b><i>bcctr</i></b>[<i>l</i>] and <b><i>bctar</i></b>[<i>l</i>]: The instruction is not a subroutine return; the target address is likely to be the same as the target address used the preceding time the branch was taken</p>
01	<p><b><i>bclr</i></b>[<i>l</i>]: The instruction is not a subroutine return; the target address is likely to be the same as the target address used the preceding time the branch was taken</p> <p><b><i>bcctr</i></b>[<i>l</i>] and <b><i>bctar</i></b>[<i>l</i>]: Reserved</p>
10	Reserved
11	<b><i>bclr</i></b> [ <i>l</i> ], <b><i>bcctr</i></b> [ <i>l</i> ], and <b><i>bctar</i></b> [ <i>l</i> ]: The target address is not predictable

**Figure 42. BH field encodings**

**Programming Note**

The hint provided by the BH field is independent of the hint provided by the “at” bits (e.g., the BH field provides no indication of whether the branch is likely to be taken).

## Extended mnemonics for branches

Many extended mnemonics are provided so that *Branch Conditional* instructions can be coded with portions of the BO and BI fields as part of the mnemonic rather than as part of a numeric operand. Some of these are shown as examples with the Branch instructions. See Appendix C for additional extended mnemonics.

**Programming Note**

The hints provided by the “at” bits and by the BH field do not affect the results of executing the instruction.

The “z” bits should be set to 0, because they may be assigned a meaning in some future version of the architecture.

## Programming Note

Many implementations have dynamic mechanisms for predicting the target addresses of *bclr[l]* and *bcctr[l]* instructions. These mechanisms may cache return addresses (i.e., Link Register values set by *Branch* instructions for which LK=1 and for which the branch was taken, other than the special form shown in the first example below) and recently used branch target addresses. To obtain the best performance across the widest range of implementations, the programmer should obey the following rules.

- Use *Branch* instructions for which LK=1 only as subroutine calls (including function calls, etc.), or in the special form shown in the first example below.
- Pair each subroutine call (i.e., each *Branch* instruction for which LK=1 and the branch is taken, other than the special form shown in the first example below) with a *bclr* instruction that returns from the subroutine and has BH=0b00.
- Do not use *bclr* as a subroutine call. (Some implementations access the return address cache at most once per instruction; such implementations are likely to treat *bclr* as a subroutine return, and not as a subroutine call.)
- For *bclr[l]* and *bcctr[l]*, use the appropriate value in the BH field.

The following are examples of programming conventions that obey these rules. In the examples, BH is assumed to contain 0b00 unless otherwise stated. In addition, the “at” bits are assumed to be coded appropriately.

Let A, B, and Glue be specific programs.

- Obtaining the address of the next instruction:  
Use the following form of *Branch and Link*.  
`bcl 20,31,$+4`
- Loop counts:  
Keep them in the Count Register, and use a *bc* instruction (LK=0) to decrement the count and to branch back to the beginning of the loop if the decremented count is nonzero.
- Computed goto's, case statements, etc.:  
Use the Count Register to hold the address to

branch to, and use a *bcctr* instruction (LK=0, and BH=0b11 if appropriate) to branch to the selected address.

- Direct subroutine linkage:  
Here A calls B and B returns to A. The two branches should be as follows.
  - A calls B: use a *bl* or *bcl* instruction (LK=1).
  - B returns to A: use a *bclr* instruction (LK=0) (the return address is in, or can be restored to, the Link Register).
- Indirect subroutine linkage:  
Here A calls Glue, Glue calls B, and B returns to A rather than to Glue. (Such a calling sequence is common in linkage code used when the subroutine that the programmer wants to call, here B, is in a different module from the caller; the Binder inserts “glue” code to mediate the branch.) The three branches should be as follows.
  - A calls Glue: use a *bl* or *bcl* instruction (LK=1).
  - Glue calls B: place the address of B into the Count Register, and use a *bcctr* instruction (LK=0).
  - B returns to A: use a *bclr* instruction (LK=0) (the return address is in, or can be restored to, the Link Register).
- Function call:  
Here A calls a function, the identity of which may vary from one instance of the call to another, instead of calling a specific program B. This case should be handled using the conventions of the preceding two bullets, depending on whether the call is direct or indirect, with the following differences.
  - If the call is direct, place the address of the function into the Count Register, and use a *bcctr* instruction (LK=1) instead of a *bl* or *bcl* instruction.
  - For the *bcctr[l]* instruction that branches to the function, use BH=0b11 if appropriate.

**Compatibility Note**

The bits corresponding to the current “a” and “t” bits, and to the current “z” bits except in the “branch always” BO encoding, had different meanings in versions of the architecture that precede Version 2.00.

- The bit corresponding to the “t” bit was called the “y” bit. The “y” bit indicated whether to use the architected default prediction (y=0) or to use the complement of the default prediction (y=1). The default prediction was defined as follows.
  - If the instruction is **bc[l][a]** with a negative value in the displacement field, the branch is taken. (This is the only case in which the prediction corresponding to the “y” bit differs from the prediction corresponding to the “t” bit.)
  - In all other cases (**bc[l][a]** with a nonnegative value in the displacement field, **bclr[l]**, or **bcctr[l]**), the branch is not taken.
- The BO encodings that test both the Count Register and the Condition Register had a “y” bit in place of the current “z” bit. The meaning of the “y” bit was as described in the preceding item.
- The “a” bit was a “z” bit.

Because these bits have always been defined either to be ignored or to be treated as hints, a given program will produce the same result on any implementation regardless of the values of the bits. Also, because even the “y” bit is ignored, in practice, by most processors that comply with versions of the architecture that precede Version 2.00, the performance of a given program on those processors will not be affected by the values of the bits.

**Branch I-form**

b	target_addr	(AA=0 LK=0)
ba	target_addr	(AA=1 LK=0)
bl	target_addr	(AA=0 LK=1)
bla	target_addr	(AA=1 LK=1)

18	LI	AA	LK
0	6	30	31

```

if AA then NIA ←iea EXTS(LI || 0b00)
else      NIA ←iea CIA + EXTS(LI || 0b00)
if LK then LR ←iea CIA + 4

```

*target\_addr* specifies the branch target address.

If AA=0 then the branch target address is the sum of LI || 0b00 sign-extended and the address of this instruction, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If AA=1 then the branch target address is the value LI || 0b00 sign-extended, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the Branch instruction is placed into the Link Register.

**Special Registers Altered:**

LR (if LK=1)

**Branch Conditional B-form**

bc	BO, BI, target_addr	(AA=0 LK=0)
bca	BO, BI, target_addr	(AA=1 LK=0)
bcl	BO, BI, target_addr	(AA=0 LK=1)
bcla	BO, BI, target_addr	(AA=1 LK=1)

16	BO	BI	BD	AA	LK
0	6	11	16	30	31

```

if (64-bit mode)
  then M ← 0
  else M ← 32
if -BO2 then CTR ← CTR - 1
ctr_ok ← BO2 | ((CTRM:63 ≠ 0) ⊕ BO3)
cond_ok ← BO0 | (CRBI+32 ≡ BO1)
if ctr_ok & cond_ok then
  if AA then NIA ←iea EXTS(BD || 0b00)
  else      NIA ←iea CIA + EXTS(BD || 0b00)
if LK then LR ←iea CIA + 4

```

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 40. *target\_addr* specifies the branch target address.

If AA=0 then the branch target address is the sum of BD || 0b00 sign-extended and the address of this instruction, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If AA=1 then the branch target address is the value BD || 0b00 sign-extended, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

**Special Registers Altered:**

CTR (if BO<sub>2</sub>=0)  
LR (if LK=1)

**Extended Mnemonics:**

Examples of extended mnemonics for *Branch Conditional*:

Extended mnemonic:	Equivalent to:
blt target	bc 12, 0, target
bne cr2, target	bc 4, 10, target
bdnz target	bc 16, 0, target

### Branch Conditional to Link Register XL-form

bclr BO,BI,BH (LK=0)  
 bclrl BO,BI,BH (LK=1)

19	BO	BI	///	BH	16	LK
0	6	11	16	19	21	31

```

if (64-bit mode)
  then M ← 0
  else M ← 32
if ¬BO2 then CTR ← CTR - 1
ctr_ok ← BO2 | ((CTRM:63 ≠ 0) ⊕ BO3)
cond_ok ← BO0 | (CRBI+32 ≡ BO1)
if ctr_ok & cond_ok then NIA ←iea LR0:61 || 0b00
if LK then LR ←iea CIA + 4
  
```

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 40. The BH field is used as described in Figure 42. The branch target address is LR<sub>0:61</sub> || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

#### Special Registers Altered:

CTR (if BO<sub>2</sub>=0)  
 LR (if LK=1)

#### Extended Mnemonics:

Examples of extended mnemonics for *Branch Conditional to Link Register*:

Extended mnemonic:	Equivalent to:
bclr 4,6	bclr 4,6,0
bltlr	bclr 12,0,0
bnelr cr2	bclr 4,10,0
bdnzlr	bclr 16,0,0

#### Programming Note

**bclr**, **bclrl**, **bcctr**, and **bcctrl** each serve as both a basic and an extended mnemonic. The Assembler will recognize a **bclr**, **bclrl**, **bcctr**, or **bcctrl** mnemonic with three operands as the basic form, and a **bclr**, **bclrl**, **bcctr**, or **bcctrl** mnemonic with two operands as the extended form. In the extended form the BH operand is omitted and assumed to be 0b00.

### Branch Conditional to Count Register XL-form

bcctr BO,BI,BH (LK=0)  
 bcctrl BO,BI,BH (LK=1)

19	BO	BI	///	BH	528	LK
0	6	11	16	19	21	31

```

cond_ok ← BO0 | (CRBI+32 ≡ BO1)
if cond_ok then NIA ←iea CTR0:61 || 0b00
if LK then LR ←iea CIA + 4
  
```

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 40. The BH field is used as described in Figure 42. The branch target address is CTR<sub>0:61</sub> || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

If the “decrement and test CTR” option is specified (BO<sub>2</sub>=0), the instruction form is invalid.

#### Special Registers Altered:

LR (if LK=1)

#### Extended Mnemonics:

Examples of extended mnemonics for *Branch Conditional to Count Register*:

Extended mnemonic:	Equivalent to:
bcctr 4,6	bcctr 4,6,0
bltctr	bcctr 12,0,0
bnectr cr2	bcctr 4,10,0

### Branch Conditional to Branch Target Address Register XL-form

bctar BO,BI,BH (LK=0)  
 bctarl BO,BI,BH (LK=1)

19	BO	BI	///	BH	560	LK
0	6	11	16	19 21		31

```

if (64-bit mode)
  then M ← 0
  else M ← 32
if ¬BO2 then CTR ← CTR - 1
ctr_ok ← BO2 | ((CTRM:63 ≠ 0) ⊕ BO3)
cond_ok ← BO0 | (CRBI+32 ≡ BO1)
if ctr_ok & cond_ok then NIA ←iea TAR0:61 || 0b00
if LK then LR ←iea CIA + 4

```

BI+32 specifies the Condition Register bit to be tested. The BO field is used to resolve the branch as described in Figure 40. The BH field is used as described in Figure 42. The branch target address is TAR<sub>0:61</sub> || 0b00, with the high-order 32 bits of the branch target address set to 0 in 32-bit mode.

If LK=1 then the effective address of the instruction following the *Branch* instruction is placed into the Link Register.

#### Special Registers Altered:

CTR (if BO<sub>2</sub>=0)  
 LR (if LK=1)

#### Programming Note

In some systems, the system software will restrict usage of the *bctar[]* instruction to only selected programs. If an attempt is made to execute the instruction when it is not available, the system error handler will be invoked. See Book III for additional information.

## 2.5 Condition Register Instructions

### 2.5.1 Condition Register Logical Instructions

The *Condition Register Logical* instructions have preferred forms; see Section 1.8.1. In the preferred forms, the BT and BB fields satisfy the following rule.

- The bit specified by BT is in the same Condition Register field as the bit specified by BB.

### Extended mnemonics for Condition Register logical operations

A set of extended mnemonics is provided that allow additional Condition Register logical operations, beyond those provided by the basic *Condition Register Logical* instructions, to be coded easily. Some of these are shown as examples with the *Condition Register Logical* instructions. See Appendix C for additional extended mnemonics.

#### Condition Register AND XL-form

crand BT,BA,BB

19	BT	BA	BB	257	/
0	6	11	16	21	31

$$CR_{BT+32} \leftarrow CR_{BA+32} \& CR_{BB+32}$$

The bit in the Condition Register specified by BA+32 is ANDed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

#### Special Registers Altered:

$$CR_{BT+32}$$

#### Condition Register OR XL-form

cror BT,BA,BB

19	BT	BA	BB	449	/
0	6	11	16	21	31

$$CR_{BT+32} \leftarrow CR_{BA+32} \mid CR_{BB+32}$$

The bit in the Condition Register specified by BA+32 is ORed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

#### Special Registers Altered:

$$CR_{BT+32}$$

#### Extended Mnemonics:

Example of extended mnemonics for *Condition Register OR*:

**Extended mnemonic:** crmove Bx,By  
**Equivalent to:** cror Bx,By,By

#### Condition Register NAND XL-form

crnand BT,BA,BB

19	BT	BA	BB	225	/
0	6	11	16	21	31

$$CR_{BT+32} \leftarrow \neg(CR_{BA+32} \& CR_{BB+32})$$

The bit in the Condition Register specified by BA+32 is ANDed with the bit in the Condition Register specified by BB+32, and the complemented result is placed into the bit in the Condition Register specified by BT+32.

#### Special Registers Altered:

$$CR_{BT+32}$$

#### Condition Register XOR XL-form

crxor BT,BA,BB

19	BT	BA	BB	193	/
0	6	11	16	21	31

$$CR_{BT+32} \leftarrow CR_{BA+32} \oplus CR_{BB+32}$$

The bit in the Condition Register specified by BA+32 is XORed with the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

#### Special Registers Altered:

$$CR_{BT+32}$$

#### Extended Mnemonics:

Example of extended mnemonics for *Condition Register XOR*:

**Extended mnemonic:** crclr Bx  
**Equivalent to:** crxor Bx,Bx,Bx

**Condition Register NOR XL-form**

crnor BT,BA,BB

0	19	BT	BA	BB	33	/
	6	11	16	21		31

$$CR_{BT+32} \leftarrow \neg(CR_{BA+32} \mid CR_{BB+32})$$

The bit in the Condition Register specified by BA+32 is ORed with the bit in the Condition Register specified by BB+32, and the complemented result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**CR<sub>BT+32</sub>**Extended Mnemonics:**

Example of extended mnemonics for *Condition Register NOR*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
crnot Bx, By	crnor Bx, By, By

**Condition Register AND with Complement XL-form**

crandc BT,BA,BB

0	19	BT	BA	BB	129	/
	6	11	16	21		31

$$CR_{BT+32} \leftarrow CR_{BA+32} \& \neg CR_{BB+32}$$

The bit in the Condition Register specified by BA+32 is ANDed with the complement of the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**CR<sub>BT+32</sub>**Condition Register Equivalent XL-form**

creqv BT,BA,BB

0	19	BT	BA	BB	289	/
	6	11	16	21		31

$$CR_{BT+32} \leftarrow CR_{BA+32} \equiv CR_{BB+32}$$

The bit in the Condition Register specified by BA+32 is XORed with the bit in the Condition Register specified by BB+32, and the complemented result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**CR<sub>BT+32</sub>**Extended Mnemonics:**

Example of extended mnemonics for *Condition Register Equivalent*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
crset Bx	creqv Bx, Bx, Bx

**Condition Register OR with Complement XL-form**

crorc BT,BA,BB

0	19	BT	BA	BB	417	/
	6	11	16	21		31

$$CR_{BT+32} \leftarrow CR_{BA+32} \mid \neg CR_{BB+32}$$

The bit in the Condition Register specified by BA+32 is ORed with the complement of the bit in the Condition Register specified by BB+32, and the result is placed into the bit in the Condition Register specified by BT+32.

**Special Registers Altered:**CR<sub>BT+32</sub>

## 2.5.2 Condition Register Field Instruction

### *Move Condition Register Field XL-form*

mcrf                    BF,BFA

19	BF	//	BFA	//	///	0	/
0	6	9	11	14	16	21	31

$CR_{4 \times BF + 32: 4 \times BF + 35} \leftarrow CR_{4 \times BFA + 32: 4 \times BFA + 35}$

The contents of Condition Register field BFA are copied to Condition Register field BF.

#### **Special Registers Altered:**

CR field BF

## 2.6 System Call Instructions

These instructions provide the means by which a program can call upon the system to perform a service.

### System Call SC-form

sc		LEV						
0	17	6	11	16	20	27	30	31
	///	///	///	LEV	///	1	/	

### System Call Vectored SC-form

scv		LEV						
0	17	6	11	16	20	27	30	31
	///	///	///	LEV	///	0	1	

These instructions call the system to perform a service. A complete description of these instructions can be found in Section 4.3.1 of Book III.

The first form of the instruction (**sc**) provides a single system call. The second form of the instruction (**scv**) provides the capability for 128 unique system calls.

The use of the LEV field is described in Book III. In the first form of the instruction the LEV values greater than 1 are reserved, and bits 0:5 of the LEV field (instruction bits 20:25) are treated as a reserved field.

When control is returned to the program that executed the *System Call* or *System Call Vectored* instruction, the contents of the registers will depend on the register conventions used by the program providing the system service.

These instructions are context synchronizing (see Book III).

#### Special Registers Altered:

Dependent on the system service

#### Programming Note

**sc** serves as both a basic and an extended mnemonic. The Assembler will recognize an **sc** mnemonic with one operand as the basic form, and an **sc** mnemonic with no operand as the extended form. In the extended form the LEV operand is omitted and assumed to be 0.

In application programs the value of the LEV operand for **sc** should be 0.

#### Programming Note

Since the **scv** instruction modifies the Count Register, programs should treat the contents of the Count Register as undefined after executing this instruction. See Section 4.3 of Book III.

## Chapter 3. Fixed-Point Facility

### 3.1 Fixed-Point Facility Overview

This chapter describes the registers and instructions that make up the Fixed-Point Facility.

### 3.2 Fixed-Point Facility Registers

#### 3.2.1 General Purpose Registers

All manipulation of information is done in registers internal to the Fixed-Point Facility. The principal storage internal to the Fixed-Point Facility is a set of 32 General Purpose Registers (GPRs). See Figure 43.

**Figure 43. General Purpose Registers**

Each GPR is a 64-bit register.

#### 3.2.2 Fixed-Point Exception Register

The Fixed-Point Exception Register (XER) is a 64-bit register.

**Figure 44. Fixed-Point Exception Register**

The bit definitions for the Fixed-Point Exception Register are shown below. Here M=0 in 64-bit mode and M=32 in 32-bit mode.

The bits are set based on the operation of an instruction considered as a whole, not on intermediate results (e.g., the *Subtract From Carrying* instruction, the result of which is specified as the sum of three values, sets bits in the Fixed-Point Exception Register based on the entire operation, not on an intermediate sum).

Bit(s)	Description
--------	-------------

0:31	Reserved
------	----------

32	<b>Summary Overflow (SO)</b>
----	------------------------------

The Summary Overflow bit is set to 1 whenever an instruction (except *mtspr* and *addex*) sets the Overflow bit. Once set, the SO bit remains set until it is cleared by an *mtspr* instruction (specifying the XER). It is not altered by *Compare* instructions, by *addex*, or by other instructions (except *mtspr* to the XER) that cannot overflow. Executing an *mtspr* instruction to the XER, supplying the values 0 for SO and 1 for OV, causes SO to be set to 0 and OV to be set to 1.

33	<b>Overflow (OV)</b>
----	----------------------

The Overflow bit is set to indicate that an overflow has occurred during execution of an instruction. The Overflow bit can also be used as an independent Carry bit by using the *addex* with operand CY=0 instruction and avoiding other instructions that modify the Overflow bit (e.g., any XO-form instruction with OE=1).

XO-form *Add*, *Subtract From*, and *Negate* instructions having OE=1 set it to 1 if the carry out of bit M is not equal to the carry out of bit M+1, and set it to 0 otherwise.

XO-form *Multiply Low* and *Divide* instructions having OE=1 set it to 1 if the result cannot be represented in 64 bits (*mulld*, *divd*, *divde*, *divdu*, *divdeu*) or in 32 bits (*mullw*, *divw*, *divwe*, *divwu*, *divweu*), and set it to 0 otherwise.

**addex** with operand CY=0 sets OV to 1 if there is a carry out of bit M, and sets it to 0 otherwise.

The OV bit is not altered by *Compare* instructions, or by other instructions (except *mtspr* to the XER) that cannot overflow.

34 **Carry (CA)**

The Carry bit is set as follows, during execution of certain instructions. *Add Carrying*, *Subtract From Carrying*, *Add Extended*, and *Subtract From Extended* types of instructions set it to 1 if there is a carry out of bit M, and set it to 0 otherwise. *Shift Right Algebraic* instructions set it to 1 if any 1-bits have been shifted out of a negative operand, and set it to 0 otherwise. The CA bit is not altered by *Compare* instructions, or by other instructions (except *Shift Right Algebraic*, *mtspr* to the XER) that cannot carry.

35:43 Reserved

44 **Overflow32 (OV32)**

OV32 is set whenever OV is implicitly set, and is set to the same value that OV is defined to be set to in 32-bit mode.

45 **Carry32 (CA32)**

CA32 is set whenever CA is implicitly set, and is set to the same value that CA is defined to be set to in 32-bit mode.

46:56 Reserved

Bits 48:55 are implemented, and can be read and written by software as if the bits contained a defined field.

57:63 This field specifies the number of bytes to be transferred by a *Load String Indexed* or *Store String Indexed* instruction.

**Programming Note**

Bits 48:55 of the XER correspond to bits 16:23 of the XER in the POWER Architecture. In the POWER Architecture bits 16:23 of the XER contain the comparison byte for the *lscbx* instruction. Power ISA lacks the *lscbx* instruction, but some application programs that run on processors that implement Power ISA may still use *lscbx*, and privileged software may emulate the instruction. XER<sub>48:55</sub> may be assigned a meaning in a future version of the architecture, when POWER compatibility for *lscbx* is no longer needed, so these bits should not be used for purposes other than the *lscbx* comparison byte.

### 3.2.3 VR Save Register

The VR Save Register (VRSARE) is a 32-bit register that can be used as a software use SPR; see Section 6.3.3.

## 3.3 Fixed-Point Facility Instructions

### 3.3.1 Fixed-Point Storage Access Instructions

The *Storage Access* instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3 on page 30.

#### Programming Note

The *la* extended mnemonic permits computing an effective address as a *Load* or *Store* instruction would, but loads the address itself into a GPR rather than loading the value that is in storage at that address.

#### Programming Note

The DS field in DS-form *Storage Access* instructions is a word offset, not a byte offset like the D field in D-form *Storage Access* instructions. However, for programming convenience, Assemblers should support the specification of byte offsets for both forms of instruction.

#### 3.3.1.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (*Store* only), or if the program attempts to access storage that is unavailable.

### 3.3.2 Fixed-Point Load Instructions

The byte, halfword, word, or doubleword in storage addressed by EA is loaded into register RT.

Many of the *Load* instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if  $RA \neq 0$  and  $RA \neq RT$ , the effective address is placed into register RA and the storage element (byte, halfword, word, or doubleword) addressed by EA is loaded into RT.

#### Programming Note

In some implementations, the *Load Algebraic* and *Load with Update* instructions may have greater latency than other types of *Load* instructions. Moreover, *Load with Update* instructions may take longer to execute in some implementations than the corresponding pair of a non-update *Load* instruction and an *Add* instruction.

### Load Byte and Zero D-form

lbz RT,D(RA)

34	RT	RA	D
0	6	11	16
0			31

### Prefix Load Byte and Zero MLS:D-form

plbz RT,D(RA),R

Prefix:

1	2	0	//	R	//	d0
0	6	8	9	11	12	14
0						31

Suffix:

34	RT	RA	d1
0	6	11	16
0			31

if "lbz" then  
 EA ← (RA|0) + EXTS64(D)  
 if "plbz" & R=0 then  
 EA ← (RA|0) + EXTS64(d0||d1)  
 if "plbz" & R=1 then  
 EA ← CIA + EXTS64(d0||d1)

RT ← EXTZ(MEM(EA, 1))

For **lbz**, let the effective address (EA) be the sum (RA|0) + EXTS64(D).

For **plbz** with R=0, let EA be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0||d1, sign-extended to 64 bits.

For **plbz** with R=1, let EA be the sum of the address of the instruction and the value d0||d1, sign-extended to 64 bits.

The byte in storage addressed by EA is loaded into RT<sub>56:63</sub>. RT<sub>0:55</sub> are set to 0.

For **plbz**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

**Special Registers Altered:**  
None

### Extended Mnemonics:

Extended mnemonics for *Prefix Load Byte and Zero*:

<b>Extended mnemonic:</b>		<b>Equivalent to:</b>	
pl bz	Rx, val ue(Ry)	pl bz	Rx, val ue(Ry), 0
pl bz	Rx, val ue	pl bz	Rx, val ue(0), 1

### Load Byte and Zero Indexed X-form

lbzx RT,RA,RB

31	RT	RA	RB	87	/
0	6	11	16	21	31

if RA = 0 then b ← 0  
 else b ← (RA)  
 EA ← b + (RB)  
 RT ← <sup>56</sup>0 || MEM(EA, 1)

Let the effective address (EA) be the sum (RA|0) + (RB). The byte in storage addressed by EA is loaded into RT<sub>56:63</sub>. RT<sub>0:55</sub> are set to 0.

**Special Registers Altered:**  
None

### Load Byte and Zero with Update D-form

lbzu RT,D(RA)

35	RT	RA	D
0	6	11	16
0			31

EA ← (RA) + EXTS(D)  
 RT ← <sup>56</sup>0 || MEM(EA, 1)  
 RA ← EA

Let the effective address (EA) be the sum (RA) + D. The byte in storage addressed by EA is loaded into RT<sub>56:63</sub>. RT<sub>0:55</sub> are set to 0.

EA is placed into register RA.

If RA=0 or RA=RT, the instruction form is invalid.

**Special Registers Altered:**  
None

### Load Byte and Zero with Update Indexed X-form

lbzux RT,RA,RB

31	RT	RA	RB	119	/
0	6	11	16	21	31

EA ← (RA) + (RB)  
 RT ← <sup>56</sup>0 || MEM(EA, 1)  
 RA ← EA

Let the effective address (EA) be the sum (RA) + (RB). The byte in storage addressed by EA is loaded into RT<sub>56:63</sub>. RT<sub>0:55</sub> are set to 0.

EA is placed into register RA.

If RA=0 or RA=RT, the instruction form is invalid.

**Special Registers Altered:**  
None

**Load Halfword and Zero D-form**

lhz RT,D(RA)

40	RT	RA	D

### 3.3.3 Fixed-Point Store Instructions

The contents of register RS are stored into the byte, halfword, word, or doubleword in storage addressed by EA.

Many of the *Store* instructions have an “update” form, in which register RA is updated with the effective address. For these forms, the following rules apply.

- If  $RA \neq 0$ , the effective address is placed into register RA.
  - If  $RS = RA$ , the contents of register RS are copied to the target storage element and then EA is placed into RA (RS).
-

**Store Byte D-form**

stb RS,D(RA)

38	RS	RA	D
0	6	11	16
			31

**Prefixed Store Byte MLS:D-form**

pstb RS,D(RA),R

Prefix:

1	2	0	//	R	//	d0
0	6	8	9	11	12	14

### 3.3.4 Fixed Point Load and Store Quadword Instructions

For **lq**, the quadword in storage addressed by EA is loaded into an even-odd pair of GPRs as follows. In Big-Endian mode, the even-numbered GPR is loaded with the doubleword from storage addressed by EA and the odd-numbered GPR is loaded with the doubleword addressed by EA+8. In Little-Endian mode, the even-numbered GPR is loaded with the byte-reversed doubleword from storage addressed by EA+8 and the odd-numbered GPR is loaded with the byte-reversed doubleword addressed by EA.

On the other hand, for **plq**, the quadword in storage addressed by EA is loaded into an even-odd pair of GPRs as follows. Independent of endian mode, the even-numbered GPR is loaded with the doubleword from storage addressed by EA and the odd-numbered GPR is loaded with the doubleword addressed by EA+8.

In the preferred form of the *Load Quadword* instruction  $RA \neq RTP+1$ .

For **stq**, the contents of an even-odd pair of GPRs is stored into the quadword in storage addressed by EA as follows. In Big-Endian mode, the even-numbered GPR is stored into the doubleword in storage addressed by EA and the odd-numbered GPR is stored into the doubleword addressed by EA+8. In Little-Endian mode, the even-numbered GPR is stored byte-reversed into the doubleword in storage addressed by EA+8 and the odd-numbered GPR is stored byte-reversed into the doubleword addressed by EA.

On the other hand, for **pstq**, the contents of an even-odd pair of GPRs is stored into the quadword in storage addressed by EA as follows. Independent of endian mode, the even-numbered GPR is stored into the doubleword in storage addressed by EA and the odd-numbered GPR is stored into the doubleword addressed by EA+8.

#### Programming Note

The **lq** and **stq** instructions exist primarily to permit software to access quadwords in storage "atomically"; see Section 1.4 of Book II. Because GPRs are 64 bits long, the Fixed-Point Facility on many designs is optimized for storage accesses of at most eight bytes. On such designs, the quadword atomicity required for **lq** and **stq** makes these instructions complex to implement, with the result that the instructions may perform less well on these designs than the corresponding two *Load Doubleword* or *Store Doubleword* instructions.

The complexity of providing quadword atomicity may be especially great for storage that is Write Through Required or Caching Inhibited (see Section 1.6 of Book II). This is why **lq** and **stq** are permitted to cause the data storage error handler to be invoked if the specified storage location is in either of these kinds of storage (see Section 3.3.1.1).

**Load Quadword DQ-form**

lq                      RTp,DQ(RA)

56	RTp	RA	DQ	///
0	6	11	16	28 31

**Prefixed Load Quadword 8LS:D-form**

plq                      RTp,D(RA),R

Prefix:

1	0	0	//	R	//	d0
0	6	8	9	11	12	14 31

Suffix::

56	RTp	RA	d1
0	6	11	16 31

```

if "lq" then
    EA ← (RA|0) + EXTS64(DQ||0b0000)
if "plq" & R=0 then
    EA ← (RA|0) + EXTS64(d0||d1)
if "plq" & R=1 then
    EA ← CIA + EXTS64(d0||d1)
if Big-Endian byte ordering then
    RTp||RTp+1 ← MEM(EA, 16)
if "lq" and Little-Endian byte ordering then
    RTp||RTp+1 ← MEM(EA, 16)
if "plq" and Little-Endian byte ordering then
    RTp+1||RTp ← MEM(EA, 16)

```

For **lq**, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value DQ||0b0000, sign-extended to 64 bits.

For **plq** with R=0, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0||d1, sign-extended to 64 bits.

For **plq** with R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0||d1, sign-extended to 64 bits.

For Big-Endian byte ordering, the quadword in storage addressed by EA is loaded into RTp||RTp+1.

For **lq** and Little-Endian byte ordering, the quadword in storage addressed by EA is byte-reversed and loaded into RTp||RTp+1.

For **plq** and Little-Endian byte ordering, the quadword in storage addressed by EA is byte-reversed and loaded into RTp+1||RTp.

If RTp is odd or RTp=RA, the instruction form is invalid. If RTp=RA, an attempt to execute this instruction will invoke

the system illegal instruction error handler. (The RTp=RA case includes the case of RTp=RA=0.)

The quadword in storage addressed by EA is loaded into an even-odd pair of GPRs as follows. In Big-Endian mode, the even-numbered GPR is loaded with the doubleword from storage addressed by EA and the odd-numbered GPR is loaded with the doubleword addressed by EA+8. In Little-Endian mode, the even-numbered GPR is loaded with the byte-reversed doubleword from storage addressed by EA+8 and the odd-numbered GPR is loaded with the byte-reversed doubleword addressed by EA.

For **plq**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

**Programming Note**

In versions of the architecture prior to v2.07, this instruction was privileged.

**Special Registers Altered:**

None

**Extended Mnemonics:**

Extended mnemonics for *Prefixed Load Quadword*:

<i>Extended mnemonic:</i>		<i>Equivalent to:</i>	
plq	Rx, val ue(Ry)	plq	Rx, val ue(Ry), 0

62	RSp	RA	DS	2
0	6	11	16	30 31

**Prefixed Store Quadword 8LS:D-form**

pstq                    RSp,D(RA),R

Prefix:

1	0	0	//	R	//	d0
0	6	8	9	11	12	14

Suffix::

60	RSp	RA	d1
0	6	11	16

```

if "stq" then
    EA ← (RA|0) + EXTS64(DS||0b00)
if "pstq" & R=0 then
    EA ← (RA|0) + EXTS64(d0||d1)
if "pstq" & R=1 then
    EA ← CIA + EXTS64(d0||d1)
if Big-Endian byte ordering then
    MEM(EA, 16) ← (RSp) || (RSp+1)
if "stq" and Little-Endian byte ordering then
    MEM(EA, 16) ← (RSp) || (RSp+1)
if "pstq" and Little-Endian byte ordering then
    MEM(EA, 16) ← (RSp+1) || (RSp)

```

For **stq**, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value DS||0b00, sign-extended to 64 bits.

For **pstq** with R=0, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0||d1, sign-extended to 64 bits.

For **pstq** with R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0||d1, sign-extended to 64 bits.

For Big-Endian byte ordering, the content of register pair RSp || RSp+1 is stored into the quadword in storage addressed by EA.

For **stq** and Little-Endian byte ordering, the content of register pair RSp || RSp+1 is byte-reversed and stored into the quadword in storage addressed by EA.

For **pstq** and Little-Endian byte ordering, the content of register pair RSp+1 || RSp is byte-reversed and stored into the quadword in storage addressed by EA.

If RSp is odd, the instruction form is invalid.

The contents of an even-odd pair of GPRs is stored into the quadword in storage addressed by EA as follows. In Big-Endian mode, the even-numbered GPR is stored into the doubleword in storage addressed by EA and the odd-numbered GPR is stored into the doubleword addressed by EA+8. In Little-Endian mode, the even-numbered GPR is stored byte-reversed into the doubleword in storage addressed by EA+8 and the odd-numbered GPR is stored byte-reversed into the doubleword addressed by EA.

For **pstq**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

**Programming Note**

In versions of the architecture prior to V. 2.07, this instruction was privileged.

### 3.3.6 Fixed-Point Load and Store Multiple Instructions

#### Load Multiple Word D-form

lmw                      RT,D(RA)

46	RT	RA	D
0	6	11	16

```

if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + EXTS(D)
r ← RT
do while r ≤ 31
  GPR(r) ← 320 || MEM(EA, 4)
  r ← r + 1
  EA ← EA + 4

```

Let  $n = (32-RT)$ . Let the effective address (EA) be the sum  $(RA|0) + D$ .

$n$  consecutive words starting at EA are loaded into the low-order 32 bits of GPRs RT through 31. The high-order 32 bits of these GPRs are set to zero.

If RA is in the range of registers to be loaded, including the case in which RA=0, the instruction form is invalid.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode, the system alignment error handler is invoked.

#### Special Registers Altered:

None

#### Store Multiple Word D-form

stmw                     RS,D(RA)

47	RS	RA	D
0	6	11	16

```

if RA = 0 then b ← 0
else            b ← (RA)
EA ← b + EXTS(D)
r ← RS
do while r ≤ 31
  MEM(EA, 4) ← GPR(r)32:63
  r ← r + 1
  EA ← EA + 4

```

Let  $n = (32-RS)$ . Let the effective address (EA) be the sum  $(RA|0) + D$ .

$n$  consecutive words starting at EA are stored from the low-order 32 bits of GPRs RS through 31.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode, the system alignment error handler is invoked.

#### Special Registers Altered:

None

### 3.3.7 Fixed-Point Move Assist Instructions [Phased Out]

The *Move Assist* instructions allow movement of an arbitrary sequence of bytes from storage to registers or from registers to storage without concern for alignment. These instructions can be used for a short move between arbitrary storage locations or to initiate a long move between unaligned storage fields.

The *Move Assist* instructions have preferred forms; see Section 1.8.1, “Preferred Instruction Forms” on

page 25. In the preferred forms, register usage satisfies the following rules.

- RS = 4 or 5
- RT = 4 or 5
- last register loaded/stored  $\leq 12$

For some implementations, using GPR 4 for RS and RT may result in slightly faster execution than using GPR 5.

---

**Load String Word Immediate X-form**

lswi RT,RA,NB

31	RT	RA	NB	597	/
0	6	11	16	21	31

```

if RA = 0 then EA ← 0
else EA ← (RA)
if NB = 0 then n ← 32
else n ← NB
r ← RT - 1
i ← 32
do while n > 0
  if i = 32 then
    r ← r + 1 (mod 32)
    GPR(r) ← 0
  GPR(r)i:i+7 ← MEM(EA, 1)
  i ← i + 8
  if i = 64 then i ← 32
  EA ← EA + 1
  n ← n - 1

```

Let the effective address (EA) be (RA|0). Let  $n = NB$  if  $NB \neq 0$ ,  $n = 32$  if  $NB=0$ ;  $n$  is the number of bytes to load. Let  $nr = \text{CEIL}(n/4)$ ;  $nr$  is the number of registers to receive data.

$n$  consecutive bytes starting at EA are loaded into GPRs RT through  $RT+nr-1$ . Data are loaded into the low-order four bytes of each GPR; the high-order four bytes are set to 0.

Bytes are loaded left to right in each register. The sequence of registers wraps around to GPR 0 if required. If the low-order four bytes of register  $RT+nr-1$  are only partially filled, the unfilled low-order byte(s) of that register are set to 0.

If RA is in the range of registers to be loaded, including the case in which  $RA=0$ , the instruction form is invalid.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode, the system alignment error handler is invoked.

**Special Registers Altered:**

None

**Load String Word Indexed X-form**

lswx RT,RA,RB

31	RT	RA	RB	533	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
n ← XER57:63
r ← RT - 1
i ← 32
RT ← undefi ned
do while n > 0
  if i = 32 then
    r ← r + 1 (mod 32)
    GPR(r) ← 0
  GPR(r)i:i+7 ← MEM(EA, 1)
  i ← i + 8
  if i = 64 then i ← 32
  EA ← EA + 1
  n ← n - 1

```

Let the effective address (EA) be the sum  $(RA|0) + (RB)$ . Let  $n = XER_{57:63}$ ;  $n$  is the number of bytes to load. Let  $nr = \text{CEIL}(n/4)$ ;  $nr$  is the number of registers to receive data.

If  $n > 0$ ,  $n$  consecutive bytes starting at EA are loaded into GPRs RT through  $RT+nr-1$ . Data are loaded into the low-order four bytes of each GPR; the high-order four bytes are set to 0.

Bytes are loaded left to right in each register. The sequence of registers wraps around to GPR 0 if required. If the low-order four bytes of register  $RT+nr-1$  are only partially filled, the unfilled low-order byte(s) of that register are set to 0.

If  $n=0$ , the contents of register RT are undefined.

If RA or RB is in the range of registers to be loaded, including the case in which  $RA=0$ , the instruction is treated as if the instruction form were invalid. If  $RT=RA$  or  $RT=RB$ , the instruction form is invalid.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode and  $n > 0$ , the system alignment error handler is invoked.

  n ← n - 1

```

Let the effective address (EA) be  $(RA|0)$ . Let  $n = NB$  if  $NB \neq 0$ ,  $n = 32$  if  $NB=0$ ;  $n$  is the number of bytes to store. Let  $nr = \text{CEIL}(n/4)$ ;  $nr$  is the number of registers to supply data.

$n$  consecutive bytes starting at EA are stored from GPRs RS through  $RS+nr-1$ . Data are stored from the low-order four bytes of each GPR.

Bytes are stored left to right from each register. The sequence of registers wraps around to GPR 0 if required.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode, the system alignment error handler is invoked.

**Special Registers Altered:**

None

**Store String Word Indexed X-form**

stswx RS,RA,RB

31	RS	RA	RB	661	/
0	6	11	16	21	31

```

if RA = 0 then b ← 0
else b ← (RA)
EA ← b + (RB)
n ← XER57:63
r ← RS - 1
i ← 32
do while n > 0
  if i = 32 then r ← r + 1 (mod 32)
  MEM(EA, 1) ← GPR(r)i:i+7
  i ← i + 8
  if i = 64 then i ← 32
  EA ← EA + 1
  n ← n - 1

```

Let the effective address (EA) be the sum  $(RA|0) + (RB)$ . Let  $n = XER_{57:63}$ ;  $n$  is the number of bytes to store. Let  $nr = \text{CEIL}(n/4)$ ;  $nr$  is the number of registers to supply data.

If  $n>0$ ,  $n$  consecutive bytes starting at EA are stored from GPRs RS through  $RS+nr-1$ . Data are stored from the low-order four bytes of each GPR.

Bytes are stored left to right from each register. The sequence of registers wraps around to GPR 0 if required.

If  $n=0$ , no bytes are stored.

This instruction is not supported in Little-Endian mode. If it is executed in Little-Endian mode and  $n>0$ , the system alignment error handler is invoked.

**Special Registers Altered:**

None

### 3.3.8 Other Fixed-Point Instructions

The remainder of the fixed-point instructions use the contents of the General Purpose Registers (GPRs) as source operands, and place results into GPRs, into the Fixed-Point Exception Register (XER), and into Condition Register fields. In addition, the *Trap* instructions test the contents of a GPR or XER bit, invoking the system trap handler if the result of the specified test is true.

These instructions treat the source operands as signed integers unless the instruction is explicitly identified as performing an unsigned operation.

The X-form and XO-form instructions with  $Rc=1$ , and the D-form instructions *addic.*, *andi.*, and *andis.*, set the first three bits of CR Field 0 to characterize the result placed into the target register. In 64-bit mode,

these bits are set by signed comparison of the result to zero. In 32-bit mode, these bits are set by signed comparison of the low-order 32 bits of the result to zero.

Unless otherwise noted and when appropriate, when CR Field 0 and the XER are set they reflect the value placed into the target register.

#### Programming Note

Instructions with the OE bit set or that set CA and CA32 may execute slowly or may prevent the execution of subsequent instructions until the instruction has completed.

### 3.3.9 Fixed-Point Arithmetic Instructions

The XO-form *Arithmetic* instructions with Rc=1, and the D-form *Arithmetic* instruction ***addic.***, set the first three bits of CR Field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions”.

***addic.***, ***addic.***, ***subfc.***, ***addc.***, ***subfc.***, ***adde.***, ***subfe.***, ***addme.***, ***subfme.***, ***addze.***, and ***subfze.*** always set CA, to reflect the carry out of bit 0 in 64-bit mode and out of bit 32 in 32-bit mode. These instructions also always set CA32 to reflect the carry out of bit 32. The XO-form *Arithmetic* instructions set SO, OV, and OV32 when OE=1 to reflect overflow of the result. Except for the *Multiply Low* and *Divide* instructions, the setting of SO and OV is mode-dependent, and reflects overflow of the 64-bit result in 64-bit mode and overflow of the low-order 32-bit result in 32-bit mode, while OV32 reflects overflow of the low-order 32-bit result independent of the mode. For XO-form *Multiply Low* and *Divide* instructions, the setting of SO, OV, and OV32 is mode-independent, and reflects overflow of the 64-bit result for ***mulld.***, ***divd.***, ***divde.***, ***divdu.*** and ***divdeu.***, and overflow of the low-order 32-bit result for ***mullw.***, ***divw.***, ***divwe.***, ***divwu.***, and ***divweu.***

#### Programming Note

Notice that CR Field 0 may not reflect the “true” (infinitely precise) result if overflow occurs.

#### Extended mnemonics for addition and subtraction

Several extended mnemonics are provided that use the *Add Immediate* and *Add Immediate Shifted* instructions to load an immediate value or an address into a target register. Some of these are shown as examples with the two instructions.

The Power ISA supplies *Subtract From* instructions, which subtract the second operand from the third. A set of extended mnemonics is provided that use the more “normal” order, in which the third operand is subtracted from the second, with the third operand being either an immediate field or a register. Some of these are shown as examples with the appropriate *Add* and *Subtract From* instructions.

See Appendix C for additional extended mnemonics.

### Add Immediate D-form

addi RT,RA,SI

### Prefixed Add Immediate MLS:D-form

paddi RT,RA,SI,R

Prefix:

Suffix::

if "addi" then  
 RT ← (RA|0) + EXTS64(SI)  
 if "paddi" & R=0 then  
 RT ← (RA|0) + EXTS64(si 0||si 1)  
 if "paddi" & R=1 then  
 RT ← CIA + EXTS64(si 0||si 1)

For **addi**, let the sum of the contents of register RA, or the value 0 if RA=0, and the value SI, sign-extended to 64 bits, is placed into register RT.

For **paddi** with R=0, the sum of the contents of register RA, or the value 0 if RA=0, and the value si 0||si 1, sign-extended to 64 bits, is placed into register RT.

For **paddi** with R=1, the sum of the address of the instruction and the value si 0||si 1, sign-extended to 64 bits, is placed into register RT.

For **paddi**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

#### Special Registers Altered:

None

#### Extended Mnemonics:

Examples of extended mnemonics for *Add Immediate*:

<i>Extended mnemonic:</i>	<i>Equivalent to:</i>
l i Rx, val ue	addi Rx, 0, val ue
l a Rx, di sp(Ry)	addi Rx, Ry, di sp
subi Rx, Ry, val ue	addi Rx, Ry, -val ue

Examples of extended mnemonics for *Prefixed Add Immediate*:

<i>Extended mnemonic:</i>	<i>Equivalent to:</i>
paddi Rx, Ry, val ue	paddi Rx, Ry, val ue, 0
pl i Rx, val ue	paddi Rx, 0, val ue, 0
pl a Rx, val ue(Ry)	paddi Rx, Ry, val ue, 0
pl a Rx, val ue	paddi Rx, 0, val ue, 1
psubi Rx, Ry, val ue	paddi Rx, Ry, -val ue, 0

#### Programming Note

**addi**, **addis**, **add**, and **subf** are the preferred instructions for addition and subtraction, because they set few status bits.

Notice that **addi** and **addis** use the value 0, not the contents of GPR 0, if RA=0.

### Add Immediate Shifted D-form

addis RT,RA,SI

if RA = 0 then RT ← EXTS(SI || <sup>16</sup>0)  
 else RT ← (RA) + EXTS(SI || <sup>16</sup>0)

The sum (RA|0) + (SI || 0x0000) is placed into register RT.

#### Special Registers Altered:

None

#### Extended Mnemonics:

Examples of extended mnemonics for *Add Immediate Shifted*:

<i>Extended mnemonic:</i>	<i>Equivalent to:</i>
l i s Rx, val ue	addi s Rx, 0, val ue
subi s Rx, di sp(Ry)	addi s Rx, Ry, -val ue

### Add PC Immediate Shifted DX-form

addpcis RT,D

D ← d0||d1||d2  
 RT ← NIA + EXTS(D || <sup>16</sup>0)

The sum of NIA + (D || 0x0000) is placed into register RT.

#### Special Registers Altered:

None

#### Extended Mnemonics:

Examples of extended mnemonics for *Add PC Immediate Shifted*:

<i>Extended mnemonic:</i>	<i>Equivalent to:</i>
l ni a Rx	addpcis Rx, 0
subpcis Rx, val ue	addpcis Rx, -val ue

 subfzeo. RT,RA (OE=1 Rc=1)

0	31	RT	RA	///	OE	200	Rc
		6	11	16	21	22	31

$$RT \leftarrow \neg(RA) + CA$$

The sum  $\neg(RA) + CA$  is placed into register RT.

**Special Registers Altered:**

CA CA32  
 CRO (if Rc=1)  
 SO OV OV32 (if OE=1)

**Programming Note**

The setting of CA and CA32 by the *Add* and *Subtract From* instructions, including the Extended versions thereof, is mode-dependent. If a sequence of these instructions is used to perform extended-precision addition or subtraction, the same mode should be used throughout the sequence.

### Add Extended using alternate carry bit Z23-form

addex RT,RA,RB,CY

0	31	RT	RA	RB	CY	170	/
	6	11	16	21	23		31

if CY=0 then  $RT \leftarrow (RA) + (RB) + OV$

For CY=0, the sum  $(RA) + (RB) + OV$  is placed into register RT.

For CY=0, OV is set to 1 if there is a carry out of bit 0 of the sum in 64-bit mode or there is a carry out of bit 32 of the sum in 32-bit mode, and set to 0 otherwise. OV32 is set to 1 if there is a carry out of bit 32 bit of the sum.

CY=1, CY=2, and CY=3 are reserved.

#### Special Registers Altered:

OV OV32 (if CY=0)

#### Programming Note

An *addc*-equivalent instruction using OV is not provided. An equivalent capability can be emulated by first initializing OV to 0, then using *addex*. OV can be initialized to 0 using *subfo*, subtracting any operand from itself.

### Negate XO-form

neg RT,RA (OE=0 Rc=0)  
 neg. RT,RA (OE=0 Rc=1)  
 nego RT,RA (OE=1 Rc=0)  
 nego. RT,RA (OE=1 Rc=1)

0	31	RT	RA	///	OE	104	Rc
	6	11	16	21	22		31

$RT \leftarrow \neg(RA) + 1$

The sum  $\neg(RA) + 1$  is placed into register RT.

If the processor is in 64-bit mode and register RA contains the most negative 64-bit number (0x8000\_0000\_0000\_0000), the result is the most negative number and, if OE=1, OV is set to 1. If  $(RA)_{32:63}$  contain the most negative 32-bit number (0x8000\_0000) and OE=1, OV32 is set to 1.

Similarly, if the processor is in 32-bit mode and  $(RA)_{32:63}$  contain the most negative 32-bit number (0x8000\_0000), the low-order 32 bits of the result contain the most negative 32-bit number and, if OE=1, OV and OV32 are set to 1.

#### Special Registers Altered:

CRO (if Rc=1)  
 SO OV OV32 (if OE=1)

**Multiply Low Immediate D-form**

mulli RT,RA,SI

7	RT	RA	SI
0	6	11	16
			31

$$\text{prod}_{0:127} \leftarrow (\text{RA}) \times \text{EXTS}(\text{SI})$$

$$\text{RT} \leftarrow \text{prod}_{64:127}$$

The 64-bit first operand is (RA). The 64-bit second operand is the sign-extended value of the SI field. The low-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as signed integers.

**Special Registers Altered:**

None

**Multiply Low Word XO-form**

mullw	RT,RA,RB	(OE=0 Rc=0)
mullw.	RT,RA,RB	(OE=0 Rc=1)
mullwo	RT,RA,RB	(OE=1 Rc=0)
mullwo.	RT,RA,RB	(OE=1 Rc=1)

31	RT	RA	RB	OE	235	Rc
0	6	11	16	21	22	31

$$\text{RT} \leftarrow (\text{RA})_{32:63} \times (\text{RB})_{32:63}$$

The 32-bit operands are the low-order 32 bits of RA and of RB. The 64-bit product of the operands is placed into register RT.

If OE=1 then OV and OV32 are set to 1 if the product cannot be represented in 32 bits.

Both operands and the product are interpreted as signed integers.

**Special Registers Altered:**

CRO	(if Rc=1)
SO OV OV32	(if OE=1)

**Programming Note**

For *mulli* and *mullw*, the low-order 32 bits of the product are the correct 32-bit product for 32-bit mode.

For *mulli* and *mullw*, the low-order 64 bits of the product are independent of whether the operands are regarded as signed or unsigned 64-bit integers. For *mullw* and *mullwo*, the low-order 32 bits of the product are independent of whether the operands are regarded as signed or unsigned 32-bit integers.

**Multiply High Word XO-form**

mulhw	RT,RA,RB	(Rc=0)
mulhw.	RT,RA,RB	(Rc=1)

31	RT	RA	RB	/	75	Rc
0	6	11	16	21	22	31

$$\text{prod}_{0:63} \leftarrow (\text{RA})_{32:63} \times (\text{RB})_{32:63}$$

$$\text{RT}_{32:63} \leftarrow \text{prod}_{0:31}$$

$$\text{RT}_{0:31} \leftarrow \text{undefined}$$

The 32-bit operands are the low-order 32 bits of RA and of RB. The high-order 32 bits of the 64-bit product of the operands are placed into RT<sub>32:63</sub>. The contents of RT<sub>0:31</sub> are undefined.

Both operands and the product are interpreted as signed integers.

**Special Registers Altered:**

CRO (bits 0:2 undefined in 64-bit mode) (if Rc=1)

**Multiply High Word Unsigned XO-form**

mulhwu	RT,RA,RB	(Rc=0)
mulhwu.	RT,RA,RB	(Rc=1)

31	RT	RA	RB	/	11	Rc
0	6	11	16	21	22	31

$$\text{prod}_{0:63} \leftarrow (\text{RA})_{32:63} \times (\text{RB})_{32:63}$$

$$\text{RT}_{32:63} \leftarrow \text{prod}_{0:31}$$

$$\text{RT}_{0:31} \leftarrow \text{undefined}$$

The 32-bit operands are the low-order 32 bits of RA and of RB. The high-order 32 bits of the 64-bit product of the operands are placed into RT<sub>32:63</sub>. The contents of RT<sub>0:31</sub> are undefined.

Both operands and the product are interpreted as unsigned integers, except that if Rc=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero.

**Special Registers Altered:**

CRO (bits 0:2 undefined in 64-bit mode) (if Rc=1)

**Divide Word XO-form**

divw	RT,RA,RB	(OE=0 Rc=0)
divw.	RT,RA,RB	(OE=0 Rc=1)
divwo	RT,RA,RB	(OE=1 Rc=0)
divwo.	RT,RA,RB	(OE=1 Rc=1)

0	31	RT	RA	RB	OE	491	Rc
		6	11	16	21 22		31

$di\ vi\ dend_{0:31} \leftarrow (RA)_{32:63}$   
 $di\ vi\ sor_{0:31} \leftarrow (RB)_{32:63}$   
 $RT_{32:63} \leftarrow di\ vi\ dend \div di\ vi\ sor$   
 $RT_{0:31} \leftarrow \text{undefi ned}$

The 32-bit dividend is  $(RA)_{32:63}$ . The 32-bit divisor is  $(RB)_{32:63}$ . The 32-bit quotient is placed into  $RT_{32:63}$ . The contents of  $RT_{0:31}$  are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

$$dividend = (quotient \times divisor) + r$$

where  $0 \leq r < |di\ vi\ sor|$  if the dividend is nonnegative, and  $-|di\ vi\ sor| < r \leq 0$  if the dividend is negative.

If an attempt is made to perform any of the divisions

$0x8000\_0000 \div -1$   
 $\langle \text{anythi ng} \rangle \div 0$

then the contents of register RT are undefined as are (if  $Rc=1$ ) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if  $OE=1$  then OV and OV32 are set to 1.

**Special Registers Altered:**

CRO (bits 0:2 undefined in 64-bit mode) (if  $Rc=1$ )  
 SO OV OV32 (if  $OE=1$ )

**Programming Note**

The 32-bit signed remainder of dividing  $(RA)_{32:63}$  by  $(RB)_{32:63}$  can be computed as follows, except in the case that  $(RA)_{32:63} = -2^{31}$  and  $(RB)_{32:63} = -1$ .

```

divw RT,RA,RB # RT = quotient
mullw RT,RT,RB # RT = quotient×divisor
subf RT,RT,RA # RT = remainder
    
```

**Divide Word Unsigned XO-form**

divwu	RT,RA,RB	(OE=0 Rc=0)
divwu.	RT,RA,RB	(OE=0 Rc=1)
divwuo	RT,RA,RB	(OE=1 Rc=0)

 $di\ vi\ sor_{0:31} \leftarrow (RB)_{32:63}$   
 $RT_{32:63} \leftarrow di\ vi\ dend \div di\ vi\ sor$   
 $RT_{0:31} \leftarrow \text{undefi ned}$

The 32 bit dividend is  $(RA)_{32:63}$ . The 32-bit divisor is  $(RB)_{32:63}$ . The 32-bit quotient is placed into  $RT_{32:63}$ . The contents of  $RT_{0:31}$  are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if  $Rc=1$  the first three bits of CR Field 0 are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies

$$dividend = (quotient \times divisor) + r$$

where  $0 \leq r < di\ vi\ sor$ .

If an attempt is made to perform the division

$\langle \text{anythi ng} \rangle \div 0$

then the contents of register RT are undefined as are (if  $Rc=1$ ) the contents of the LT, GT, and EQ bits of CR Field 0. In this case, if  $OE=1$  then OV and OV32 are set to 1.

**Special Registers Altered:**

CRO (bits 0:2 undefined in 64-bit mode) (if  $Rc=1$ )  
 SO OV OV32 (if  $OE=1$ )

**Programming Note**

The 32-bit unsigned remainder of dividing  $(RA)_{32:63}$  by  $(RB)_{32:63}$  can be computed as follows.

```

divwu RT,RA,RB # RT = quotient
mullw RT,RT,RB # RT = quotient×divisor
subf RT,RT,RA # RT = remainder
    
```

**Divide Word Extended XO-form**

divwe	RT,RA,RB	(OE=0 Rc=0)
divwe.	RT,RA,RB	(OE=0 Rc=1)
divweo	RT,RA,RB	(OE=1 Rc=0)
divweo.	RT,RA,RB	(OE=1 Rc=1)

31	RT	RA	RB	OE	427	Rc
0	6	11	16	21,22		31

$di\ vi\ dend_{0:63} \leftarrow (RA)_{32:63} \parallel 32^0$   
 $di\ vi\ sor_{0:31} \leftarrow (RB)_{32:63}$   
 $RT_{32:63} \leftarrow di\ vi\ dend \div di\ vi\ sor$   
 $RT_{0:31} \leftarrow \text{undefined}$

The 64-bit dividend is  $(RA)_{32:63} \parallel 32^0$ . The 32-bit divisor is  $(RB)_{32:63}$ . If the quotient can be represented in 32 bits, it is placed into  $RT_{32:63}$ . The contents of  $RT_{0:31}$  are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as signed integers. The quotient is the unique signed integer that satisfies

$$dividend = (quotient \times divisor) + r$$

where  $0 \leq r < |di\ vi\ sor|$  if the dividend is nonnegative, and  $-|di\ vi\ sor| < r \leq 0$  if the dividend is negative.

If the quotient cannot be represented in 32 bits, or if an attempt is made to perform the division

$\langle \text{anything} \rangle \div 0$

then the contents of register RT are undefined as are (if  $Rc=1$ ) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if  $OE=1$  then OV and OV32 are set to 1.

**Special Registers Altered:**

CR0 (bits 0:2 undefined in 64-bit mode) (if  $Rc=1$ )  
 SO OV OV32 (if  $OE=1$ )

**Divide Word Extended Unsigned XO-form**

divweu	RT,RA,RB	(OE=0 Rc=0)
divweu.	RT,RA,RB	(OE=0 Rc=1)

$di\ vi\ dend_{0:63} \leftarrow (RA)_{32:63} \parallel 32^0$   
 $di\ vi\ sor_{0:31} \leftarrow (RB)_{32:63}$   
 $RT_{32:63} \leftarrow di\ vi\ dend \div di\ vi\ sor$   
 $RT_{0:31} \leftarrow \text{undefined}$

The 64-bit dividend is  $(RA)_{32:63} \parallel 32^0$ . The 32-bit divisor is  $(RB)_{32:63}$ . If the quotient can be represented in 32 bits, it is placed into  $RT_{32:63}$ . The contents of  $RT_{0:31}$  are undefined. The remainder is not supplied as a result.

Both operands and the quotient are interpreted as unsigned integers, except that if  $Rc=1$  the first three bits of CR Field 0 are set by signed comparison of the result to zero. The quotient is the unique unsigned integer that satisfies

$$dividend = (quotient \times divisor) + r$$

where  $0 \leq r < di\ vi\ sor$ .

If  $(RA) \geq (RB)$ , or if an attempt is made to perform the division

$\langle \text{anything} \rangle \div 0$

then the contents of register RT are undefined as are (if  $Rc=1$ ) the contents of the LT, GT, and EQ bits of CR Field 0. In these cases, if  $OE=1$  then OV and OV32 are set to 1.

**Special Registers Altered:**

CR0 (bits 0:2 undefined in 64-bit mode) (if  $Rc=1$ )  
 SO OV OV32 (if  $OE=1$ )

## Programming Note

Unsigned long division of a 64-bit dividend contained in two 32-bit registers by a 32-bit divisor can be computed as follows. The algorithm is shown first, followed by Assembler code that implements the algorithm. The dividend is  $Dh \parallel Dl$ , the divisor is  $Dv$ , and the quotient and remainder are  $Q$  and  $R$  respectively, where these variables and all intermediate variables represent unsigned 32-bit integers. It is assumed that  $Dv > Dh$ , and that assigning a value to an intermediate variable assigns the low-order 32 bits of the value and ignores any higher-order bits of the value. (In both the algorithm and the Assembler code, “r1” and “r2” refer to “remainder 1” and “remainder 2”, rather than to GPRs 1 and 2.)

Algorithm:

3.  $q1 \leftarrow \text{divweu } Dh, Dv$
4.  $r1 \leftarrow -(q1 \times Dv)$  # remainder of step 1  
     divide operation  
     (see Note 1)
5.  $q2 \leftarrow \text{divwu } Dl, Dv$
6.  $r2 \leftarrow Dl - (q2 \times Dv)$  # remainder of step 2  
     divide operation
7.  $Q \leftarrow q1 + q2$
8.  $R \leftarrow r1 + r2$
9. if  $(R < r2) \mid (R \geq Dv)$  then # (see Note 2)  
      $Q \leftarrow Q + 1$  # increment quotient  
      $R \leftarrow R - Dv$  # decrement remainder

Assembler Code:

```
# Dh in r4, Dl in r5
# Dv in r6
divweu r3,r4,r6 # q1
divwu  r7,r5,r6 # q2
mullw  r8,r3,r6 # -r1 = q1 * Dv
mullw  r0,r7,r6 # q2 * Dv
subf   r10,r0,r5 # r2 = Dl - (q2 * Dv)
add    r3,r3,r7  # Q = q1 + q2
subf   r4,r8,r10 # R = r1 + r2
cmplw  r4,r10    # R < r2 ?
blt    *+12     # must adjust Q and R if yes
cmplw  r4,r6     # R ≥ Dv ?
blt    *+12     # must adjust Q and R if yes
addi   r3,r3,1  # Q = Q + 1
subf   r4,r6,r4 # R = R - Dv
# Quotient in r3
# Remainder in r4
```

Notes:

1. The remainder is  $Dh \parallel^{320} - (q1 \times Dv)$ . Because the remainder must be less than  $Dv$  and  $Dv < 2^{32}$ , the remainder is representable in 32 bits. Because the low-order 32 bits of  $Dh \parallel^{320}$  are 0s, the remainder is therefore equal to the low-order 32 bits of  $-(q1 \times Dv)$ . Thus assigning  $-(q1 \times Dv)$  to  $r1$  yields the correct remainder.
2.  $R$  is less than  $r2$  (and also less than  $r1$ ) if and only if the addition at step 6 carried out of 32 bits — i.e., if and only if the correct sum could not be represented in 32 bits — in which case the correct sum is necessarily greater than  $Dv$ .
3. For additional information see the book *Hacker's Delight*, by Henry S. Warren, Jr., as potentially amended at the web site <http://www.hackersdelight.org>.

**Modulo Signed Word X-form**

modsw RT,RA,RB

0	31	RT	RA	RB	779	/
		6	11	16	21	31

where  $0 \leq remain\ der < di\ vi\ sor$ .

If an attempt is made to perform any of the divisions

$\langle anythi\ ng \rangle \% 0$

then the contents of register RT are undefined.

**Special Registers Altered:**

None

### Deliver A Random Number X-form

darn RT,L

RT ← random(L)

A random number is placed into register RT in a format selected by L as shown in the following table. The value 0xFFFFFFFF\_FFFFFFFF indicates an error condition. For L=0, the random number range is 0:0xFFFFFFFF. For L=1 and L=2, the random number range is 0:0xFFFFFFFF\_FFFFFFFE.

L	Format
0	<sup>32</sup> 0    CRN <sub>0:31</sub>
1	CRN <sub>0:63</sub>
2	RRN <sub>0:63</sub>
3	reserved

Format above is for non-error conditions.  
 0xFFFFFFFF\_FFFFFFFF for error conditions.  
 CRN = conditioned random number  
 RRN = raw random number  
 A raw random number is unconditioned noise source output. A conditioned random number has been processed by hardware to reduce bias.

#### Special Registers Altered:

none

#### Programming Note

The random number generator provided by this instruction is NIST SP800-90B and SP800-90C compliant to the extent possible given the completeness of the standards at the time the hardware is designed. The random number generator provides a minimum of 0.5 bits of entropy per bit.

#### Programming Note

32-bit software running in an environment that does not preserve the high-order 32 bits of GPRs across invocations of the system error handler, signal handlers, event-based branch handlers, etc. may use the L=0 variant of **darn** and interpret the value 0xFFFFFFFF to indicate an error condition. The fact that the error condition includes the valid value 0x00000000\_FFFFFFFF together with the true error value 0xFFFFFFFF\_FFFFFFFF is not a problem.

#### Programming Note

When the error value is obtained, software is expected to repeat the operation. If a non-error value has not been obtained after several attempts, a software random number generation method should be used. The recommended number of attempts may be implementation specific. In the absence of other guidance, ten attempts should be adequate.

### 3.3.9.1 64-bit Fixed-Point Arithmetic Instructions

#### *Multiply Low Doubleword XO-form*

mulld	RT,RA,RB	(OE=0 Rc=0)
mulld.	RT,RA,RB	(OE=0 Rc=1)
mulldo	RT,RA,RB	(OE=1 Rc=0)
mulldo.	RT,RA,RB	(OE=1 Rc=1)

$$\text{prod}_{0:127} \leftarrow (RA) \times (RB)$$

$$RT \leftarrow \text{prod}_{64:127}$$

The 64-bit operands are (RA) and (RB). The low-order 64 bits of the 128-bit product of the operands are placed into register RT.

If OE=1 then OV and OV32 are set to 1 if the product cannot be represented in 64 bits.

Both operands and the product are interpreted as signed integers.

#### **Special Registers Altered:**

CRO	(if Rc=1)
S0 OV OV32	(if OE=1)

#### **Programming Note**

The XO-form *Multiply* instructions may execute faster on some implementations if RB contains the operand having the smaller absolute value.

#### *Multiply High Doubleword XO-form*

mulhd	RT,RA,RB	(Rc=0)
mulhd.	RT,RA,RB	(Rc=1)

$$\text{prod}_{0:127} \leftarrow (RA) \times (RB)$$

$$RT \leftarrow \text{prod}_{0:63}$$

The 64-bit operands are (RA) and (RB). The high-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as signed integers.

#### **Special Registers Altered:**

CRO	(if Rc=1)
-----	-----------

#### *Multiply High Doubleword Unsigned XO-form*

mulhdu	RT,RA,RB	(Rc=0)
mulhdu.	RT,RA,RB	(Rc=1)

$$\text{prod}_{0:127} \leftarrow (RA) \times (RB)$$

$$RT \leftarrow \text{prod}_{0:63}$$

The 64-bit operands are (RA) and (RB). The high-order 64 bits of the 128-bit product of the operands are placed into register RT.

Both operands and the product are interpreted as unsigned integers, except that if Rc=1 the first three bits of CR Field 0 are set by signed comparison of the result to zero.

#### **Special Registers Altered:**

CRO	(if Rc=1)
-----	-----------

**Multiply-Add High Doubleword VA-form**

maddhd RT,RA,RC

### 3.3.10 Fixed-Point Compare Instructions

The fixed-point *Compare* instructions compare the contents of register RA with (1) the sign-extended value of the SI field, (2) the zero-extended value of the UI field, or (3) the contents of register RB. The comparison is signed for *cmpi* and *cmp*, and unsigned for *cmpli* and *cmpl*.

The L field controls whether the operands are treated as 64-bit or 32-bit quantities, as follows:

L	Operand length
0	32-bit operands
1	64-bit operands

When the operands are treated as 32-bit signed quantities, bit 32 of the register (RA or RB) is the sign bit.

The *Compare* instructions set one bit in the leftmost three bits of the designated CR field to 1, and the other two to 0. XER<sub>SO</sub> is copied to bit 3 of the designated CR field.

The CR field is set as follows

Bit	Name	Description
0	LT	(RA) < SI or (RB) (signed comparison) (RA) < <sup>u</sup> UI or (RB) (unsigned comparison)
1	GT	(RA) > SI or (RB) (signed comparison) (RA) > <sup>u</sup> UI or (RB) (unsigned comparison)
2	EQ	(RA) = SI, UI, or (RB)
3	SO	Summary Overflow from the XER

#### Extended mnemonics for compares

A set of extended mnemonics is provided so that compares can be coded with the operand length as part of the mnemonic rather than as a numeric operand. Some of these are shown as examples with the *Compare* instructions. See Appendix C for additional extended mnemonics.

**Compare Immediate D-form**

cmpl w	cr3, Rx, Ry	cmpl	3, 0, Rx, Ry

### 3.3.10.1 Character-Type Compare Instructions

#### Compare Ranged Byte X-form

cmprb BF,L,RA,RB

src1 ← EXTZ((RA)<sub>56:63</sub>)

src21hi ← EXTZ((RB)<sub>32:39</sub>)

src21lo ← EXTZ((RB)<sub>40:47</sub>)

src22hi ← EXTZ((RB)<sub>48:55</sub>)

src22lo ← EXTZ((RB)<sub>56:63</sub>)

if L=0 then

in\_range ← (src22lo ≤ src1) & (src1 ≤ src22hi)

else

in\_range ← ((src21lo ≤ src1) & (src1 ≤ src21hi)) |  
((src22lo ≤ src1) & (src1 ≤ src22hi))

CR<sub>4×BF+32:4×BF+35</sub> ← 0b0 || in\_range || 0b00

Let src1 be the unsigned integer value in bits 56:63 of register RA.

Let src21hi be the unsigned integer value in bits 32:39 of register RB.

Let src21lo be the unsigned integer value in bits 40:47 of register RB.

Let src22hi be the unsigned integer value in bits 48:55 of register RB.

Let src22lo be the unsigned integer value in bits 56:63 of register RB.

Let x be considered “in range” of y:z if the value x is greater than or equal to the value y and the value x is less than or equal to the value z.

When L=0, the value in\_range is set to 1 if src1 is in range of src22lo:src22hi. Otherwise, the value in\_range is set to 0.

When L=1, the value in\_range is set to 1 if either src1 is in range of src21lo:src21hi, or src1 is in range of src22lo:src22hi. Otherwise, the value in\_range is set to 0.

CR field BF is set to the value 0b0 concatenated with in\_range concatenated with 0b00.

#### Special Registers Altered:

CR field BF

#### Programming Note

**cmprb** is useful for implementing character typing functions such as `isalpha()`, `isdigit()`, `isupper()`, and `islower()` that are implemented using one or two range compares of the character.

A single-range compare can be implemented with an **addi** to load the upper and lower bounds in the range, such as `isdigit()`.

```
addi  rRNG, 0, 0x3930    ; loads ASCII values for '9'
                                ; and '0' into rRNG
cmprb crTGT, 0, rCHAR, rRNG ; perform range compare
                                ; sets CR field TGT to
                                ; indicate in range
```

A combination of **addi-addis** can be used to set up 2 ranges, such as for `isalpha()`.

```
addi  rRNG, 0, 0x7A61    ; loads ASCII values for 'z'
                                ; and 'a' into rRNG
addis rRNG, rRNG, 0x5A41 ; appends ASCII values for 'Z'
                                ; and 'A' into rRNG
cmprb crTGT, 1, rCHAR, rRNG ; perform range compare on
                                ; character in rCHAR,
                                ; setting CR field TGT to
                                ; indicate in range
```

**Compare Equal Byte X-form**

cmpeqb            BF,RA,RB

31	BF	//	RA	RB	224	/
0	6	9	11	16	21	31

```
src1 ← GPR[RA].bit[56:63]
```

```
match ← (src1 = (RB)00:07) |
         (src1 = (RB)08:15) |
         (src1 = (RB)16:23) |
         (src1 = (RB)24:31) |
         (src1 = (RB)32:39) |
         (src1 = (RB)40:47) |
         (src1 = (RB)48:55) |
         (src1 = (RB)56:63)
```

```
CR4×BF+32:4×BF+35 ← 0b0 || match || 0b00
```

CR field BF is set to indicate if the contents of bits 56:63 of register RA are equal to the contents of any of the 8 bytes in register RB.

Results are undefined in 32-bit mode.

**Special Registers Altered:**

CR field BF

**Programming Note**

**cmpeqb** is useful for implementing character typing functions such as `isspace()` that are implemented by comparing the character to 1 or more values.

A function such as `isspace()` can be implemented by loading the 6 byte codes corresponding to characters considered as whitespace (HT, LF, VT, FF, CR, and SP) and using the **cmpeqb** to compare the subject character to those 6 values to determine if any match occurs.

```
ldx    rSPC, WS_CHARS    ; rSPC = 0x0909_090A_0B0C_0D20
                        ; load rSPC with all 6 ASCII
                        ; values corresponding to
                        ; white spaces
cmpeqb 2, cr1, rCHAR, rSPC ; perform match compare on
                        ; character in rCHAR with
                        ; byte values in rSPC
```

In this case, the byte code for HT (0x09) was replicated to fill the all 8 bytes to avoid a potential miscompare.

### 3.3.11 Fixed-Point Trap Instructions

The *Trap* instructions are provided to test for a specified set of conditions. If any of the conditions tested by a *Trap* instruction are met, the system trap handler is invoked. If none of the tested conditions are met, instruction execution continues normally.

The contents of register RA are compared with either the sign-extended value of the SI field or the contents of register RB, depending on the *Trap* instruction. For *tdi* and *td*, the entire contents of RA (and RB) participate in the comparison; for *twi* and *tw*, only the contents of the low-order 32 bits of RA (and RB) participate in the comparison.

This comparison results in five conditions which are ANDed with TO. If the result is not 0 the system trap handler is invoked. These conditions are as follows.

TO Bit	ANDed with Condition
--------	----------------------

0	Less Than, using signed comparison
1	Greater Than, using signed comparison
2	Equal
3	Less Than, using unsigned comparison
4	Greater Than, using unsigned comparison

#### Extended mnemonics for traps

A set of extended mnemonics is provided so that traps can be coded with the condition as part of the mnemonic rather than as a numeric operand. Some of these are shown as examples with the Trap instructions. See Appendix C for additional extended mnemonics.

**Trap Word Immediate D-form**

twi TO,RA,SI

3	TO	RA	SI
0	6	11	16 31

```

a ← EXTS((RA)32:63)
if (a < EXTS(SI)) & TO0 then TRAP
if (a > EXTS(SI)) & TO1 then TRAP
if (a = EXTS(SI)) & TO2 then TRAP
if (a <u EXTS(SI)) & TO3 then TRAP
if (a >u EXTS(SI)) & TO4 then TRAP

```

The contents of RA<sub>32:63</sub> are compared with the sign-extended value of the SI field. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III). **Special Registers Altered:**

None

**Extended Mnemonics:**

Examples of extended mnemonics for *Trap Word Immediate*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
twgti Rx, val ue	tw 8, Rx, val ue
twl ei Rx, val ue	tw 6, Rx, val ue

**Trap Word X-form**

tw TO,RA,RB

31	TO	RA	RB	4	/
0	6	11	16	21	31

```

a ← EXTS((RA)32:63)
b ← EXTS((RB)32:63)
if (a < b) & TO0 then TRAP
if (a > b) & TO1 then TRAP
if (a = b) & TO2 then TRAP
if (a <u b) & TO3 then TRAP
if (a >u b) & TO4 then TRAP

```

The contents of RA<sub>32:63</sub> are compared with the contents of RB<sub>32:63</sub>. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III). **Special Registers Altered:**

None

**Extended Mnemonics:**

Examples of extended mnemonics for *Trap Word*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
tw eq Rx, Ry	tw 4, Rx, Ry
tw l ge Rx, Ry	tw 5, Rx, Ry
trap	tw 31, 0, 0

### 3.3.11.1 64-bit Fixed-Point Trap Instructions

#### Trap Doubleword Immediate D-form

tdi TO,RA,SI

2	TO	RA	SI
0	6	11	16
			31

```

a ← (RA)
b ← EXTS(SI)
if (a < b) & TO0 then TRAP
if (a > b) & TO1 then TRAP
if (a = b) & TO2 then TRAP
if (a <u b) & TO3 then TRAP
if (a >u b) & TO4 then TRAP

```

The contents of register RA are compared with the sign-extended value of the SI field. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

**Special Registers Altered:**  
None

#### Extended Mnemonics:

Examples of extended mnemonics for *Trap Doubleword Immediate*:

Extended mnemonic:		Equivalent to:	
tdl ti	Rx, val ue	tdi	16, Rx, val ue
tdnei	Rx, val ue	tdi	24, Rx, val ue

#### Trap Doubleword X-form

td TO,RA,RB

31	TO	RA	RB	68	/
0	6	11	16	21	31

```

a ← (RA)
b ← (RB)
if (a < b) & TO0 then TRAP
if (a > b) & TO1 then TRAP
if (a = b) & TO2 then TRAP
if (a <u b) & TO3 then TRAP
if (a >u b) & TO4 then TRAP

```

The contents of register RA are compared with the contents of register RB. If any bit in the TO field is set to 1 and its corresponding condition is met by the result of the comparison, the system trap handler is invoked.

If the trap conditions are met, this instruction is context synchronizing (see Book III).

**Special Registers Altered:**  
None

#### Extended Mnemonics:

Examples of extended mnemonics for *Trap Doubleword*:

Extended mnemonic:		Equivalent to:	
tdge	Rx, Ry	td	12, Rx, Ry
tdl nl	Rx, Ry	td	5, Rx, Ry

### 3.3.12 Fixed-Point Select

#### Integer Select A-form

isel RT,RA,RB,BC

31	RT	RA	RB	BC	15	/
0	6	11	16	21	26	31

```

if RA=0 then a ← 0 else a ← (RA)
if CRBC+32=1 then
  RT ← a
else
  RT ← (RB)

```

If the contents of bit BC+32 of the Condition Register are equal to 1, then the contents of register RA (or 0) are placed into register RT. Otherwise, the contents of register RB are placed into register RT.

**Special Registers Altered:**  
None

#### Extended Mnemonics:

Examples of extended mnemonics for *Integer Select*:

Extended mnemonic:		Equivalent to:	
isel l t	Rx, Ry, Rz	isel	Rx, Ry, Rz, 0
isel gt	Rx, Ry, Rz	isel	Rx, Ry, Rz, 1
isel eq	Rx, Ry, Rz	isel	Rx, Ry, Rz, 2

### 3.3.13 Fixed-Point Logical Instructions

The *Logical* instructions perform bit-parallel operations on 64-bit operands.

The X-form Logical instructions with  $Rc=1$ , and the D-form *Logical* instructions *andi.* and *andis.*, set the first three bits of CR Field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions” on page 74. The Logical instructions do not change the S0, OV, OV32, CA, and CA32 bits in the XER.

#### Extended mnemonics for logical operations

Extended mnemonics are provided that generate two different types of “no-ops” (instructions that do nothing). The first type is the preferred form, which is optimized to minimize its use of the processor’s execution resources. This form is based on the *OR Immediate* instruction. The second type is the executed form, which is intended to consume the same amount of the processor’s execution resources as if it were not a

no-op. This form is based on the *XOR Immediate* instruction. (There are also no-ops that have other uses, such as affecting program priority, for which extended mnemonics have not been defined.)

Extended mnemonics are provided that use the *OR* and *NOR* instructions to copy the contents of one register to another, with and without complementing. These are shown as examples with the two instructions.

See Appendix C, “Assembler Extended Mnemonics” on page 1021 for additional extended mnemonics.

#### Programming Note

Warning: Some forms of no-op may have side effects such as affecting program priority. Programmers should use the preferred no-op unless the side effects of some other form of no-op are intended.

#### AND Immediate D-form

*andi.* RA,RS,UI

28	RS	RA	UI
0	6	11	16
			31

$$RA \leftarrow (RS) \& (^{48}0 \parallel UI)$$

The contents of register RS are ANDed with  $^{48}0 \parallel UI$  and the result is placed into register RA.

#### Special Registers Altered:

CRO

#### AND Immediate Shifted D-form

*andis.* RA,RS,UI

29	RS	RA	UI
0	6	11	16
			31

$$RA \leftarrow (RS) \& (^{32}0 \parallel UI \parallel ^{16}0)$$

The contents of register RS are ANDed with  $^{32}0 \parallel UI \parallel ^{16}0$  and the result is placed into register RA.

#### Special Registers Altered:

CRO

#### OR Immediate D-form

*ori* RA,RS,UI

24	RS	RA	UI
0	6	11	16
			31

$$RA \leftarrow (RS) \mid (^{48}0 \parallel UI)$$

The contents of register RS are ORed with  $^{48}0 \parallel UI$  and the result is placed into register RA.

The preferred “no-op” (an instruction that does nothing) is:

*ori* 0,0,0

Some other forms of *ori Rx,Rx,0* provide special functions; see Section 9.2.1 of Book III.

#### Special Registers Altered:

None

#### Extended Mnemonics:

Example of extended mnemonics for *OR Immediate*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
<i>no-op</i>	<i>ori</i> 0,0,0

**OR Immediate Shifted D-form**

oris RA,RS,UI

$$RA \leftarrow (RS) \mid (^{32}0 \mid \mid UI \mid \mid ^{16}0)$$

The contents of register RS are ORed with  $^{32}0 \mid \mid UI \mid \mid ^{16}0$  and the result is placed into register RA.

**Special Registers Altered:**  
None

**XOR Immediate D-form**

xori RA,RS,UI

$$RA \leftarrow (RS) \text{ XOR } (^{48}0 \mid \mid UI)$$

The contents of register RS are XORed with  $^{48}0 \mid \mid UI$  and the result is placed into register RA.

The executed form of a “no-op” (an instruction that does nothing, but consumes execution resources nevertheless) is:

```
xori 0,0,0
```

**Special Registers Altered:**  
None

**Extended Mnemonics:**

Example of extended mnemonics for *XOR Immediate*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
xnop	xori 0,0,0

**Programming Note**

The executed form of no-op should be used only when the intent is to alter the timing of a program.

**XOR Immediate Shifted D-form**

xoris RA,RS,UI

$$RA \leftarrow (RS) \text{ XOR } (^{32}0 \mid \mid UI \mid \mid ^{16}0)$$

The contents of register RS are XORed with  $^{32}0 \mid \mid UI \mid \mid ^{16}0$  and the result is placed into register RA.

**Special Registers Altered:**  
None

**AND X-form**

and RA,RS,RB (Rc=0)  
and. RA,RS,RB (Rc=1)

$$RA \leftarrow (RS) \& (RB)$$

The contents of register RS are ANDed with the contents of register RB and the result is placed into register RA.

Some forms of *and* Rx, Rx, Rx provide special functions; see Section 11.3 of Book III.

**Special Registers Altered:**  
CRO (if Rc=1)

**XOR X-form**

xor RA,RS,RB (Rc=0)  
xor. RA,RS,RB (Rc=1)

$$RA \leftarrow (RS) \oplus (RB)$$

The contents of register RS are XORed with the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**  
CRO (if Rc=1)

**NAND X-form**

nand RA,RS,RB (Rc=0)  
nand. RA,RS,RB (Rc=1)

$$RA \leftarrow \neg((RS) \& (RB))$$

The contents of register RS are ANDed with the contents of register RB and the complemented result is placed into register RA.

**Special Registers Altered:**  
CRO (if Rc=1)

**Programming Note**

*nand* or *nor* with RS=RB can be used to obtain the one’s complement.

**OR X-form**

or RA,RS,RB (Rc=0)  
 or. RA,RS,RB (Rc=1)

31	RS	RA	RB	444	Rc
0	6	11	16	21	31

$$RA \leftarrow (RS) \mid (RB)$$

The contents of register RS are ORed with the contents of register RB and the result is placed into register RA.

Some forms of *or Rx,Rx,Rx* provide special functions; see Section 3.2 of Book II and Section 4.3.3 of Book II.

**Special Registers Altered:**

CRO (if Rc=1)

**Extended Mnemonics:**

Example of extended mnemonics for *OR*:

**Extended mnemonic:** *mir Rx, Ry*      **Equivalent to:** *or Rx, Ry, Ry*

**OR with Complement X-form**

orc RA,RS,RB (Rc=0)  
 orc. RA,RS,RB (Rc=1)

31	RS	RA	RB	412	Rc
0	6	11	16	21	31

$$RA \leftarrow (RS) \mid \neg(RB)$$

The contents of register RS are ORed with the complement of the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**

CRO (if Rc=1)

**NOR X-form**

nor RA,RS,RB (Rc=0)  
 nor. RA,RS,RB (Rc=1)

31	RS	RA	RB	124	Rc
0	6	11	16	21	31

$$RA \leftarrow \neg((RS) \mid (RB))$$

The contents of register RS are ORed with the contents of register RB and the complemented result is placed into register RA.

**Special Registers Altered:**

CRO (if Rc=1)

**Extended Mnemonics:**

Example of extended mnemonics for *NOR*:

**Extended mnemonic:** *not Rx, Ry*      **Equivalent to:** *nor Rx, Ry, Ry*

**Equivalent X-form**

eqv RA,RS,RB (Rc=0)  
 eqv. RA,RS,RB (Rc=1)

31	RS	RA	RB	284	Rc
0	6	11	16	21	31

$$RA \leftarrow (RS) \equiv (RB)$$

The contents of register RS are XORed with the contents of register RB and the complemented result is placed into register RA.

**Special Registers Altered:**

CRO (if Rc=1)

**AND with Complement X-form**

andc RA,RS,RB (Rc=0)  
 andc. RA,RS,RB (Rc=1)

31	RS	RA	RB	60	Rc
0	6	11	16	21	31

$$RA \leftarrow (RS) \& \neg(RB)$$

The contents of register RS are ANDed with the complement of the contents of register RB and the result is placed into register RA.

**Special Registers Altered:**

CRO (if Rc=1)

**Extend Sign Byte X-form**

extsb RA,RS (Rc=0)  
extsb. RA,RS (Rc=1)

31	RS	RA	///	954	Rc
0	6	11	16	21	31

$s \leftarrow (RS)_{56}$   
 $RA_{56:63} \leftarrow (RS)_{56:63}$   
 $RA_{0:55} \leftarrow {}^{56}s$

$(RS)_{56:63}$  are placed into  $RA_{56:63}$ .  $RA_{0:55}$  are filled with a copy of  $(RS)_{56}$ .

**Special Registers Altered:**

CRO (if Rc=1)

**Extend Sign Halfword X-form**

extsh RA,RS (Rc=0)  
extsh. RA,RS (Rc=1)

31	RS	RA	///	922	Rc
0	6	11	16	21	31

$s \leftarrow (RS)_{48}$   
 $RA_{48:63} \leftarrow (RS)_{48:63}$   
 $RA_{0:47} \leftarrow {}^{48}s$

$(RS)_{48:63}$  are placed into  $RA_{48:63}$ .  $RA_{0:47}$  are filled with a copy of  $(RS)_{48}$ .

**Special Registers Altered:**

CRO (if Rc=1)

**Compare Bytes X-form**

cmpb RA,RS,RB

31	RS	RA	RB	508	Rc
0	6	11	16	21	31

do  $n = 0$  to 7  
 if  $RS_{8xn:8xn+7} = (RB)_{8xn:8xn+7}$  then  
 $RA_{8xn:8xn+7} \leftarrow {}^{8}1$   
 else  
 $RA_{8xn:8xn+7} \leftarrow {}^{8}0$

Each byte of the contents of register RS is compared to each corresponding byte of the contents in register RB. If they are equal, the corresponding byte in RA is set to 0xFF. Otherwise the corresponding byte in RA is set to 0x00.

**Special Registers Altered:**

None

**Count Leading Zeros Word X-form**

cntlzw RA,RS (Rc=0)  
cntlzw. RA,RS (Rc=1)

31	RS	RA	///	26	Rc
0	6	11	16	21	31

$n \leftarrow 32$

do while  $n < 64$   
 if  $(RS)_n = 1$  then leave  
 $n \leftarrow n + 1$

$RA \leftarrow n - 32$

A count of the number of consecutive zero bits starting at bit 32 of register RS is placed into register RA. This number ranges from 0 to 32, inclusive.

If Rc is equal to 1, CR field 0 is set to reflect the result.

**Special Registers Altered:**

CRO (if Rc=1)

**Programming Note**

For both *Count Leading Zeros* instructions, if Rc=1 then LT is set to 0 in CR Field 0.

**Count Trailing Zeros Word X-form**

cnttzw RA,RS (Rc=0)  
cnttzw. RA,RS (Rc=1)

31	RS	RA	///	538	Rc
0	6	11	16	21	31

$n \leftarrow 0$

do while  $n < 32$   
 if  $(RS)_{63-n} = 0b1$  then leave  
 $n \leftarrow n + 1$

$RA \leftarrow \text{EXTZ64}(n)$

A count of the number of consecutive zero bits starting at bit 63 of the rightmost word of register RS is placed into register RA. This number ranges from 0 to 32, inclusive.

If Rc is equal to 1, CR field 0 is set to reflect the result.

**Special Registers Altered:**

CRO (if Rc=1)

**Population Count Bytes X-form**

popcntb RA, RS

  n ← n + 1
RA ← EXTZ64(n)
```

A count of the number of consecutive zero bits starting at bit 63 of register RS is placed into register RA. This number ranges from 0 to 64, inclusive.

If Rc is equal to 1, CR field 0 is set to reflect the result.

#### Special Registers Altered:

CRO (if Rc=1)

**Count Leading Zeros Doubleword under bit Mask X-form**

cntlzdmd            RA,RS,RB

31	RS	RA	RB	59	/
0	6	11	16	21	31

```

count ← 0
do i = 0 to 63
  if((RB)i=1) then do
    if((RS)i=1) then break
    count ← count + 1
  end
end
RA ← EXTZ64(count)

```

Let  $n$  be the number of bits in register RB having the value 1.

Extract and pack together the contents of the bits in register RS corresponding to a mask specified in register RB, creating an  $n$ -bit value.

Count the number of contiguous leftmost 0 bits in the  $n$ -bit extracted value and place the result into register RA.

**Special Registers Altered:**  
None

**Count Trailing Zeros Doubleword under bit Mask X-form**

cnttzdm            RA,RS,RB

31	RS	RA	RB	571	/
0	6	11	16	21	31

```

count ← 0
do i = 0 to 63
  if((RB)63-i=1) then do
    if((RS)63-i=1) then break
    count ← count + 1
  end
end
RA ← EXTZ64(count)

```

Let  $n$  be the number of bits in register RB having the value 1.

Extract and pack together the contents of bits in register RS corresponding to a mask specified in register RB, creating an  $n$ -bit value.

Count the number of contiguous rightmost 0 bits in the  $n$ -bit extracted value and place the result into register RA.

**Special Registers Altered:**  
None

**Bit Permute Doubleword X-form**

bpermd            RA,RS,RB

31	RS	RA	RB	252	/
0	6	11	16	21	31

```

do i = 0 to 7
  index ← (RS)8*i:8*i+7
  if index < 64
    then permi ← (RB)index
    else permi ← 0
RA ← 560 || perm0:7

```

Eight permuted bits are produced. For each permuted bit  $i$  where  $i$  ranges from 0 to 7 and for each byte  $i$  of RS, do the following.

If byte  $i$  of RS is less than 64, permuted bit  $i$  is set to the bit of RB specified by byte  $i$  of RS; otherwise permuted bit  $i$  is set to 0.

The permuted bits are placed in the least-significant byte of RA, and the remaining bits are filled with 0s.

**Special Registers Altered:**  
None

**Programming Note**

The fact that the permuted bit is 0 if the corresponding index value exceeds 63 permits the permuted bits to be selected from a 128-bit quantity, using a single index register. For example, assume that the 128-bit quantity  $Q$ , from which the permuted bits are to be selected, is in registers  $r2$  (high-order 64 bits of  $Q$ ) and  $r3$  (low-order 64 bits of  $Q$ ), that the index values are in register  $r1$ , with each byte of  $r1$  containing a value in the range 0:127, and that each byte of register  $r4$  contains the value 64. The following code sequence selects eight permuted bits from  $Q$  and places them into the low-order byte of  $r6$ .

```

bpermd   r6,r1,r2   # select from high-
              order half of Q
xor      r0,r1,r4   # adjust index values
bpermd   r5,r0,r3   # select from low-
              order half of Q
or       r6,r6,r5   # merge the two
              selections

```

**Centrifuge Doubleword X-form**

cfugd RA,RS,RB

31	RS	RA	RB	220	/
0	6	11	16	21	31

```

ptr0 ← 0
ptr1 ← 0
do i = 0 to 63
  if((RB)i=0) then do
    resultptr0 ← (RS)i
    ptr0 ← ptr0 + 1
  end
  if((RB)63-i=1) then do
    result63-ptr1 ← (RS)63-i
    ptr1 ← ptr1 + 1
  end
end
RA ← result

```

The bits in GPR[RS] whose corresponding bits in the mask in GPR[RB] equal 1 are placed in the rightmost bits in GPR[RA] maintaining their relative original order. The other bits in GPR[RS] are placed in the leftmost bits in GPR[RA] maintaining their relative original order.

**Special Registers Altered:**

None

**Parallel Bits Extract Doubleword X-form**

pextd RA,RS,RB

31	RS	RA	RB	188	/
0	6	11	16	21	31

```

result ← 0
mask ← (RB)
m ← 0
k ← 0
do while(m < 64)
  if((RB)63-m == 1) then do
    result63-k ← (RS)63-m
    k ← k + 1
  end
  m ← m + 1
end
RA ← result

```

Let mask be the contents of register RB.

The contents of the bits in register RS corresponding to bits in mask containing a 1 are packed into an n-bit value. The extracted value is placed into register RA.

**Special Registers Altered:**

None

**Parallel Bits Deposit Doubleword X-form**

pdepd RA,RS,RB

31	RS	RA	RB	156	/
0	6	11	16	21	31

```

result ← 0
mask ← (RB)
m ← 0
k ← 0
do while(m < 64)
  if(mask63-m == 1) then do
    result63-k ← (RS)63-k
    k ← k + 1
  end
  m ← m + 1
end
RA ← result

```

Let mask be the contents of register RB.

Let n be the number of bits in mask having the value 1.

The contents of the rightmost n bits of register RS are placed into register RA under control of mask as follows.

- The contents of bit 63 of register RS are placed into the bit in register RA corresponding to the rightmost bit in mask that contains a 1,
- the contents of bit 62 of register RS are placed into the bit in register RA corresponding to the second rightmost bit in mask that contains a 1, and so forth until
- the contents of bit 64-n of register RS are placed into the bit in register RA corresponding to the leftmost bit in mask that contains a 1.

The contents of bits in register RA corresponding to bits in mask that contain a 0 are set to 0.

**Special Registers Altered:**

None

### 3.3.14 Fixed-Point Rotate and Shift Instructions

The Fixed-Point Facility performs rotation operations on data from a GPR and returns the result, or a portion of the result, to a GPR.

The rotation operations rotate a 64-bit quantity left by a specified number of bit positions. Bits that exit from position 0 enter at position 63.

Two types of rotation operation are supported.

For the first type, denoted  $\text{rotate}_{64}$  or  $\text{ROTL}_{64}$ , the value rotated is the given 64-bit value. The  $\text{rotate}_{64}$  operation is used to rotate a given 64-bit quantity.

For the second type, denoted  $\text{rotate}_{32}$  or  $\text{ROTL}_{32}$ , the value rotated consists of two copies of bits 32:63 of the given 64-bit value, one copy in bits 0:31 and the other in bits 32:63. The  $\text{rotate}_{32}$  operation is used to rotate a given 32-bit quantity.

The *Rotate* and *Shift* instructions employ a mask generator. The mask is 64 bits long, and consists of 1-bits from a start bit, *mstart*, through and including a stop bit, *mstop*, and 0-bits elsewhere. The values of *mstart* and *mstop* range from 0 to 63. If *mstart* > *mstop*, the 1-bits wrap around from position 63 to position 0. Thus the mask is formed as follows:

```

if mstart ≤ mstop then
  maskmstart:mstop = ones
  maskall other bits = zeros
else
  maskmstart:63 = ones
  mask0:mstop = ones
  maskall other bits = zeros

```

There is no way to specify an all-zero mask.

For instructions that use the  $\text{rotate}_{32}$  operation, the mask start and stop positions are always in the low-order 32 bits of the mask.

The use of the mask is described in following sections.

The *Rotate* and *Shift* instructions with  $Rc=1$  set the first three bits of CR field 0 as described in Section 3.3.8, “Other Fixed-Point Instructions” on page 74. *Rotate* and *Shift* instructions do not change the *OV*, *OV32*, and *S0* bits. *Rotate* and *Shift* instructions, except algebraic right shifts, do not change the *CA* and *CA32* bits.

#### Extended mnemonics for rotates and shifts

The *Rotate* and *Shift* instructions, while powerful, can be complicated to code (they have up to five operands). A set of extended mnemonics is provided that allow simpler coding of often-used functions such as clearing the leftmost or rightmost bits of a register, left justifying or right justifying an arbitrary field, and performing simple rotates and shifts. Some of these are shown as examples with the *Rotate* instructions. See Appendix C, “Assembler Extended Mnemonics” on page 1021 for additional extended mnemonics.

#### 3.3.14.1 Fixed-Point Rotate Instructions

These instructions rotate the contents of a register. The result of the rotation is

- inserted into the target register under control of a mask (if a mask bit is 1 the associated bit of the rotated data is placed into the target register, and if the mask bit is 0 the associated bit in the target register remains unchanged); or
- ANDed with a mask before being placed into the target register.

The *Rotate Left* instructions allow right-rotation of the contents of a register to be performed (in concept) by a left-rotation of 64-*n*, where *n* is the number of bits by which to rotate right. They allow right-rotation of the contents of the low-order 32 bits of a register to be performed (in concept) by a left-rotation of 32-*n*, where *n* is the number of bits by which to rotate right.

#### *Rotate Left Word Immediate then AND with Mask M-form*

`rlwinm` RA,RS,SH,MB,ME (Rc=0)  
`rlwinm.` RA,RS,SH,MB,ME (Rc=1)

21	RS	RA	SH	MB	ME	Rd
0	6	11	16	21	26	31

```

n ← SH
r ← ROTL32((RS)32:63, n)
m ← MASK(MB+32, ME+32)
RA ← r & m

```

The contents of register *RS* are rotated<sub>32</sub> left *SH* bits. A mask is generated having 1-bits from bit *MB*+32 through bit *ME*+32 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register *RA*.

#### Special Registers Altered:

CRO (if Rc=1)

**Extended Mnemonics:**

Examples of extended mnemonics for *Rotate Left Word Immediate then AND with Mask*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
extlwi Rx, Ry, n, b	rlwim Rx, Ry, b, 0, n-1
srwi Rx, Ry, n	rlwim Rx, Ry, 32-n, n, 31
clrrwi Rx, Ry, n	rlwim Rx, Ry, 0, 0, 31-n

**Programming Note**

Let RSL represent the low-order 32 bits of register RS, with the bits numbered from 0 through 31.

*rlwim* can be used to extract an n-bit field that starts at bit position b in RSL, right-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting SH=b+n, MB=32-n, and ME=31. It can be used to extract an n-bit field that starts at bit position b in RSL, left-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting SH=b, MB = 0, and ME=n-1. It can be used to rotate the contents of the low-order 32 bits of a register left (right) by n bits, by setting SH=n (32-n), MB=0, and ME=31. It can be used to shift the contents of the low-order 32 bits of a register right by n bits, by setting SH=32-n, MB=n, and ME=31. It can be used to clear the high-order b bits of the low-order 32 bits of the contents of a register and then shift the result left by n bits, by setting SH=n, MB=b-n, and ME=31-n. It can be used to clear the low-order n bits of the low-order 32 bits of a register, by setting SH=0, MB=0, and ME=31-n.

For all the uses given above, the high-order 32 bits of register RA are cleared.

Extended mnemonics are provided for all of these uses; see Appendix C, “Assembler Extended Mnemonics” on page 1021.

**Rotate Left Word then AND with Mask M-form**

rlwnm	RA,RS,RS,MB,ME	(RC=0)
rlwnm.	RA,RS,RS,MB,ME	(RC=1)

23	RS	RA	RB	MB	ME	Rc
0	6	11	16	21	26	31

n ← (RB)<sub>59:63</sub>  
 r ← ROTL<sub>32</sub>((RS)<sub>32:63</sub>, n)  
 m ← MASK(MB+32, ME+32)  
 RA ← r & m

The contents of register RS are rotated<sub>32</sub> left the number of bits specified by (RB)<sub>59:63</sub>. A mask is generated having 1-bits from bit MB+32 through bit ME+32 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

**Special Registers Altered:**

CRO (if RC=1)

**Extended Mnemonics:**

Example of extended mnemonics for *Rotate Left Word then AND with Mask*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
rotlw Rx, Ry, Rz	rlwnm Rx, Ry, Rz, 0, 31

**Programming Note**

Let RSL represent the low-order 32 bits of register RS, with the bits numbered from 0 through 31.

*rlwnm* can be used to extract an n-bit field that starts at variable bit position b in RSL, right-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting RB<sub>59:63</sub>=b+n, MB=32-n, and ME=31. It can be used to extract an n-bit field that starts at variable bit position b in RSL, left-justified into the low-order 32 bits of register RA (clearing the remaining 32-n bits of the low-order 32 bits of RA), by setting RB<sub>59:63</sub>=b, MB = 0, and ME=n-1. It can be used to rotate the contents of the low-order 32 bits of a register left (right) by variable n bits, by setting RB<sub>59:63</sub>=n (32-n), MB=0, and ME=31.

For all the uses given above, the high-order 32 bits of register RA are cleared.

Extended mnemonics are provided for some of these uses; see Appendix C, “Assembler Extended Mnemonics” on page 1021.

**Rotate Left Word Immediate then Mask Insert M-form**

rlwimi	RA,RS,SH,MB,ME	(RC=0)
rlwimi.	RA,RS,SH,MB,ME	(RC=1)

20	RS	RA	SH	MB	ME	Rc
0	6	11	16	21	26	31

n ← SH  
 r ← ROTL<sub>32</sub>((RS)<sub>32:63</sub>, n)  
 m ← MASK(MB+32, ME+32)  
 RA ← r & m | (RA) & ~m

The contents of register RS are rotated<sub>32</sub> left SH bits. A mask is generated having 1-bits from bit MB+32 through bit ME+32 and 0-bits elsewhere. The rotated data are inserted into register RA under control of the generated mask.

**Special Registers Altered:**

CRO (if RC=1)

**Extended Mnemonics:**

Example of extended mnemonics for *Rotate Left Word Immediate then Mask Insert*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
inslwi Rx, Ry, n, b	rlwimi Rx, Ry, 32-b, b, b+n-1

**Programming Note**

Let RAL represent the low-order 32 bits of register RA, with the bits numbered from 0 through 31.

*rlwimi* can be used to insert an  $n$ -bit field that is left-justified in the low-order 32 bits of register RS, into RAL starting at bit position  $b$ , by setting  $SH=32-b$ ,  $MB=b$ , and  $ME=(b+n)-1$ . It can be used to insert an  $n$ -bit field that is right-justified in the low-order 32 bits of register RS, into RAL starting at bit position  $b$ , by setting  $SH=32-(b+n)$ ,  $MB=b$ , and  $ME=(b+n)-1$ .

Extended mnemonics are provided for both of these uses; see Appendix C, “Assembler Extended Mnemonics” on page 1021.

## 3.3.14.1.1 64-bit Fixed-Point Rotate Instructions

**Rotate Left Doubleword Immediate then Clear Left MD-form**

`rldicl` RA,RS,SH,MB (Rc=0)  
`rldicl.` RA,RS,SH,MB (Rc=1)

0	30	RS	RA	sh	mb	0	sh	Rc
		6	11	16	21	27	30	31

$n \leftarrow sh_5 \parallel sh_0:4$   
 $r \leftarrow ROTL_{64}((RS), n)$   
 $b \leftarrow mb_5 \parallel mb_0:4$   
 $m \leftarrow MASK(b, 63)$   
 $RA \leftarrow r \& m$

The contents of register RS are rotated<sub>64</sub> left SH bits. A mask is generated having 1-bits from bit MB through bit 63 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

**Special Registers Altered:**

CRO (if Rc=1)

**Extended Mnemonics:**

Examples of extended mnemonics for *Rotate Left Doubleword Immediate then Clear Left*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
<code>extrdi</code> Rx, Ry, n, b	<code>rldicl</code> Rx, Ry, b+n, 64-n
<code>srdi</code> Rx, Ry, n	<code>rldicl</code> Rx, Ry, 64-n, n
<code>clrldi</code> Rx, Ry, n	<code>rldicl</code> Rx, Ry, 0, n

**Programming Note**

***rldicl*** can be used to extract an n-bit field that starts at bit position b in register RS, right-justified into register RA (clearing the remaining 64-n bits of RA), by setting SH=b+n and MB=64-n. It can be used to rotate the contents of a register left (right) by n bits, by setting SH=n (64-n) and MB=0. It can be used to shift the contents of a register right by n bits, by setting SH=64-n and MB=n. It can be used to clear the high-order n bits of a register, by setting SH=0 and MB=n.

Extended mnemonics are provided for all of these uses; see Appendix C, “Assembler Extended Mnemonics” on page 1021.

**Rotate Left Doubleword Immediate then Clear Right MD-form**

`rldicr` RA,RS,SH,ME (Rc=0)  
`rldicr.` RA,RS,SH,ME (Rc=1)

0	30	RS	RA	sh	me	1	sh	Rc
		6	11	16	21	27	30	31

$n \leftarrow sh_5 \parallel sh_0:4$   
 $r \leftarrow ROTL_{64}((RS), n)$   
 $e \leftarrow me_5 \parallel me_0:4$   
 $m \leftarrow MASK(0, e)$   
 $RA \leftarrow r \& m$

The contents of register RS are rotated<sub>64</sub> left SH bits. A mask is generated having 1-bits from bit 0 through bit ME and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

**Special Registers Altered:**

CRO (if Rc=1)

**Extended Mnemonics:**

Examples of extended mnemonics for *Rotate Left Doubleword Immediate then Clear Right*:

<b>Extended mnemonic:</b>	<b>Equivalent to:</b>
<code>extldi</code> Rx, Ry, n, b	<code>rldicr</code> Rx, Ry, b, n-1
<code>sl di</code> Rx, Ry, n	<code>rldicr</code> Rx, Ry, n, 63-n
<code>clr rdi</code> Rx, Ry, n	<code>rldicr</code> Rx, Ry, 0, 63-n

**Programming Note**

***rldicr*** can be used to extract an n-bit field that starts at bit position b in register RS, left-justified into register RA (clearing the remaining 64-n bits of RA), by setting SH=b and ME=n-1. It can be used to rotate the contents of a register left (right) by n bits, by setting SH=n (64-n) and ME=63. It can be used to shift the contents of a register left by n bits, by setting SH=n and ME=63-n. It can be used to clear the low-order n bits of a register, by setting SH=0 and ME=63-n.

Extended mnemonics are provided for all of these uses (some devolve to ***rldicl***); see Appendix C, “Assembler Extended Mnemonics” on page 1021.

***Rotate Left Doubleword Immediate then Clear MD-form***

rldic RA,RS,SH,MB (RC=0)  
 rldic. RA,RS,SH,MB (RC=1)

30	RS	RA	sh	mb	2	sh	Rc
0	6	11	16	21	27	30	31

```
n ← sh5 || sh0:4
r ← ROTL64((RS), n)
b ← mb5 || mb0:4
m ← MASK(b, ~n)
RA ← r & m
```

The contents of register RS are rotated<sub>64</sub> left SH bits. A mask is generated having 1-bits from bit MB through bit 63-SH and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

**Special Registers Altered:**

CRO (if RC=1)

**Extended Mnemonics:**

Example of extended mnemonics for *Rotate Left Doubleword Immediate then Clear*:

**Extended mnemonic:** *clrslidi Rx, Ry, b, n*  
**Equivalent to:** *rldic Rx, Ry, n, b-n*

**Programming Note**

*rldic* can be used to clear the high-order  $b$  bits of the contents of a register and then shift the result left by  $n$  bits, by setting  $SH=n$  and  $MB=b-n$ . It can be used to clear the high-order  $n$  bits of a register, by setting  $SH=0$  and  $MB=n$ .

Extended mnemonics are provided for both of these uses (the second devolves to *rldic*); see Appendix C, “Assembler Extended Mnemonics” on page 1021.

***Rotate Left Doubleword then Clear Left MDS-form***

rldcl RA,RS,RB,MB (RC=0)  
 rldcl. RA,RS,RB,MB (RC=1)

30	RS	RA	RB	mb	8	Rc
0	6	11	16	21	27	31

```
n ← (RB)58:63
r ← ROTL64((RS), n)
b ← mb5 || mb0:4
m ← MASK(b, 63)
RA ← r & m
```

The contents of register RS are rotated<sub>64</sub> left the number of bits specified by  $(RB)_{58:63}$ . A mask is generated having 1-bits from bit MB through bit 63 and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

**Special Registers Altered:**

CRO (if RC=1)

**Extended Mnemonics:**

Example of extended mnemonics for *Rotate Left Doubleword then Clear Left*:

**Extended mnemonic:** *rotld Rx, Ry, Rz*  
**Equivalent to:** *rldcl Rx, Ry, Rz, 0*

**Programming Note**

*rldcl* can be used to extract an  $n$ -bit field that starts at variable bit position  $b$  in register RS, right-justified into register RA (clearing the remaining  $64-n$  bits of RA), by setting  $RB_{58:63}=b+n$  and  $MB=64-n$ . It can be used to rotate the contents of a register left (right) by variable  $n$  bits, by setting  $RB_{58:63}=n$  ( $64-n$ ) and  $MB=0$ .

Extended mnemonics are provided for some of these uses; see Appendix C, “Assembler Extended Mnemonics” on page 1021.

**Rotate Left Doubleword then Clear Right MDS-form**

`rldcr` RA,RS,RB,ME (Rc=0)  
`rldcr.` RA,RS,RB,ME (Rc=1)

30	RS	RA	RB	me	9	Rc
0	6	11	16	21	27	31

$n \leftarrow (RB)_{58:63}$   
 $r \leftarrow ROTL_{64}((RS), n)$   
 $e \leftarrow me_5 \parallel me_{0:4}$   
 $m \leftarrow MASK(0, e)$   
 $RA \leftarrow r \& m$

The contents of register RS are rotated<sub>64</sub> left the number of bits specified by (RB)<sub>58:63</sub>. A mask is generated having 1-bits from bit 0 through bit ME and 0-bits elsewhere. The rotated data are ANDed with the generated mask and the result is placed into register RA.

**Special Registers Altered:**

CRO (if Rc=1)

**Programming Note**

***rldcr*** can be used to extract an n-bit field that starts at variable bit position b in register RS, left-justified into register RA (clearing the remaining 64-n bits of RA), by setting RB<sub>58:63</sub>=b and ME=n-1. It can be used to rotate the contents of a register left (right) by variable n bits, by setting RB<sub>58:63</sub>=n (64-n) and ME=63.

Extended mnemonics are provided for some of these uses (some devolve to ***rldcl***); see Appendix C, “Assembler Extended Mnemonics” on page 1021.

**Rotate Left Doubleword Immediate then Mask Insert MD-form**

`rldimi` RA,RS,SH,MB (Rc=0)  
`rldimi.` RA,RS,SH,MB (Rc=1)

30	RS	RA	sh	mb	3	sh	Rc
0	6	11	16	21	27	30	31

$n \leftarrow sh_5 \parallel sh_{0:4}$   
 $r \leftarrow ROTL_{64}((RS), n)$   
 $b \leftarrow mb_5 \parallel mb_{0:4}$   
 $m \leftarrow MASK(b, -n)$   
 $RA \leftarrow r \& m \mid (RA) \& -m$

The contents of register RS are rotated<sub>64</sub> left SH bits. A mask is generated having 1-bits from bit MB through bit 63-SH and 0-bits elsewhere. The rotated data are inserted into register RA under control of the generated mask.

**Special Registers Altered:**

CRO (if Rc=1)

**Extended Mnemonics:**

Example of extended mnemonics for *Rotate Left Doubleword Immediate then Mask Insert*:

**Extended mnemonic:** `insrdi Rx, Ry, n, b`  
**Equivalent to:** `rldimi Rx, Ry, 64-(b+n), b`

**Programming Note**

***rldimi*** can be used to insert an n-bit field that is right-justified in register RS, into register RA starting at bit position b, by setting SH=64-(b+n) and MB=b.

An extended mnemonic is provided for this use; see Appendix C, “Assembler Extended Mnemonics” on page 1021.

**Shift Right Algebraic Word Immediate X-form**

srawi RA,RS,SH (Rc=0)  
 srawi. RA,RS,SH (Rc=1)

31	RS	RA	SH	824	Rc
0	6	11	16	21	31

```

n ← SH
r ← ROTL32((RS)32:63, 64-n)
m ← MASK(n+32, 63)
s ← (RS)32
RA ← r&m | (64s) & ~m
carry ← s & ((r & ~m)32:63 ≠ 0)
CA ← carry
CA32 ← carry

```

The contents of the low-order 32 bits of register RS are shifted right SH bits. Bits shifted out of position 63 are lost. Bit 32 of RS is replicated to fill the vacated positions on the left. The 32-bit result is placed into RA<sub>32:63</sub>. Bit 32 of RS is replicated to fill RA<sub>0:31</sub>. CA and CA32 are set to 1 if the low-order 32 bits of (RS) contain a negative number and any 1-bits are shifted out of position 63; otherwise CA and CA32 are set to 0. A shift amount of zero causes RA to receive EXTS((RS)<sub>32:63</sub>), and CA and CA32 to be set to 0.

**Special Registers Altered:**

CA CA32  
 CRO (if Rc=1)

**Shift Right Algebraic Word X-form**

sraw RA,RS,RB (Rc=0)  
 sraw. RA,RS,RB (Rc=1)

CRO (if Rc=1)

### 3.3.15 Binary Coded Decimal (BCD) Assist Instructions

The *Binary Coded Decimal Assist* instructions operate on Binary Coded Decimal operands (*cbcdtd* and

*addg6s*) and Decimal Floating-Point operands (*cdt-bcd*) See Chapter 5. for additional information.

#### Convert Declets To Binary Coded Decimal X-form

cdtbcd RA, RS

31	RS	RA	///	282	/
0	6	11	16	21	31

```
do i = 0 to 1
  n ← i x 32
  RAn+0: n+7 ← 0
  RAn+8: n+19 ← DPD_TO_BCD((RS)n+12: n+21)
  RAn+20: n+31 ← DPD_TO_BCD((RS)n+22: n+31)
```

The low-order 20 bits of each word of register RS contain two declets which are converted to six, 4-bit BCD fields; each set of six, 4-bit BCD fields is placed into the low-order 24 bits of the corresponding word in RA. The high-order 8 bits in each word of RA are set to 0.

**Special Registers Altered:**  
None

#### Convert Binary Coded Decimal To Declets X-form

cbcdtd RA, RS

31	RS	RA	///	314	/
0	6	11	16	21	31

```
do i = 0 to 1
  n ← i x 32
  RAn+0: n+11 ← 0
  RAn+12: n+21 ← BCD_TO_DPD((RS)n+8: n+19)
  RAn+22: n+31 ← BCD_TO_DPD((RS)n+20: n+31)
```

The low-order 24 bits of each word of register RS contain six, 4-bit BCD fields which are converted to two declets; each set of two declets is placed into the low-order 20 bits of the corresponding word in RA. The high-order 12 bits in each word of RA are set to 0.

If a 4-bit BCD field has a value greater than 9 the results are undefined.

**Special Registers Altered:**  
None

**Add and Generate Sixes XO-form**

addg6s            RT,RA,RB

31	RT	RA	RB	/	74	/
0	6	11	16	21	22	31

```

do i = 0 to 15
    dci ← carry_out(RA4xi:63 + RB4xi:63)
c ← 4(dc0) || 4(dc1) || ... || 4(dc15)
RT ← (¬c) & 0x6666_6666_6666_6666

```

The contents of register RA are added to the contents of register RB. Sixteen carry bits are produced, one for each carry out of decimal position n (bit position 4xn).

A doubleword is composed from the 16 carry bits, and placed into RT. The doubleword consists of a decimal six (0b0110) in every decimal digit position for which the corresponding carry bit is 0, and a zero (0b0000) in every position for which the corresponding carry bit is 1.

**Special Registers Altered:**

None

**Programming Note**

**addg6s** can be used to add or subtract two BCD operands. In these examples it is assumed that r0 contains 0x666...666. (BCD data formats are described in Section 5.3.)

Addition of the unsigned BCD operand in register RA to the unsigned BCD operand in register RB can be accomplished as follows.

```

add      r1, RA, r0
add      r2, r1, RB
addg6s   RT, r1, RB
subf     RT, RT, r2 # RT = RA +BCD RB

```

Subtraction of the unsigned BCD operand in register RA from the unsigned BCD operand in register RB can be accomplished as follows. (In this example it is assumed that RB is not register 0.)

```

addi     r1, RB, 1
nor      r2, RA, RA # one's complement of RA
add      r3, r1, r2
addg6s   RT, r1, r2
subf     RT, RT, r3 # RT = RB -BCD RA

```

Additional instructions are needed to handle signed BCD operands, and BCD operands that occupy more than one register (e.g., unsigned BCD operands that have more than 16 decimal digits).

### 3.3.16 Byte-Reverse Instructions

#### *Byte-Reverse Halfword X-form*

brh RA,RS

31	RS	RA	///	219	/
0	6	11	16	21	31

$$RA \leftarrow (RS)_{8:15} \parallel (RS)_{0:7} \parallel$$

$$(RS)_{24:31} \parallel (RS)_{16:23} \parallel$$

$$(RS)_{40:47} \parallel (RS)_{32:39} \parallel$$

$$(RS)_{56:63} \parallel (RS)_{48:55}$$

The contents of bits 0:15 of register RS are placed into bits 0:15 of register RA in byte-reversed order.

The contents of bits 16:31 of register RS are placed into bits 16:31 of register RA in byte-reversed order.

The contents of bits 32:47 of register RS are placed into bits 32:47 of register RA in byte-reversed order.

The contents of bits 48:63 of register RS are placed into bits 48:63 of register RA in byte-reversed order.

#### **Special Registers Altered:**

None

#### *Byte-Reverse Word X-form*

brw RA,RS

31	RS	RA	///	155	/
0	6	11	16	21	31

$$RA \leftarrow (RS)_{24:31} \parallel (RS)_{16:23} \parallel$$

$$(RS)_{8:15} \parallel (RS)_{0:7} \parallel$$

$$(RS)_{56:63} \parallel (RS)_{48:55} \parallel$$

$$(RS)_{40:47} \parallel (RS)_{32:39}$$

The contents of bits 0:31 of register RS are placed into bits 0:31 of register RA in byte-reversed order.

The contents of bits 32:63 of register RS are placed into bits 32:63 of register RA in byte-reversed order.

#### **Special Registers Altered:**

None

#### *Byte-Reverse Doubleword X-form*

brd RA,RS

31	RS	RA	///	187	/
0	6	11	16	21	31

$$RA \leftarrow (RS)_{56:63} \parallel (RS)_{48:55} \parallel$$

$$(RS)_{40:47} \parallel (RS)_{32:39} \parallel$$

$$(RS)_{24:31} \parallel (RS)_{16:23} \parallel$$

$$(RS)_{8:15} \parallel (RS)_{0:7}$$

The contents of register RS are placed into register RA in byte-reversed order.

#### **Special Registers Altered:**

None

### 3.3.17 Fixed-Point Hash Instructions

The *Hash* instructions compute a doubleword hash value using a predefined hash function on two doublewords from two GPRs and a doubleword key provided by an SPR having higher privilege than the privilege of the instruction. The *Hash Store [Privileged]* instructions store the computed doubleword hash value to a doubleword storage location defined by one of the input GPRs and an immediate field of the instruction. The *Hash Check [Privileged]* instructions read the doubleword from the storage location specified in the same fashion with a GPR and an immediate field, compare the computed hash value with the value read, and invoke the system trap handler if the values do not match. The hash function used for these instructions is described in the following subsection. The privileged forms of these instructions are described in Section 5.4.2 of Book III.

#### Programming Note

The opcodes used by the *Hash* instructions were used for reserved-no-ops in versions of the architecture that precede Version 3.1B (and are subsequent to V. 2.04). Therefore programs that will run on processors that comply with any of these preceding versions can use the *Hash* instructions, and will obtain the benefits of the hash store and check functions when the programs run on processors that comply with V. 3.1B or a subsequent version.

#### 3.3.17.1 Hash Function Description

##### SIMON\_LIKE\_32\_64(x, key, lane)

Let  $x$  be a word and  $key$  be a doubleword.  $lane$  is an unsigned integer.  $result$  is a word.  $c$  is a halfword constant.  $Z0$  is a doubleword constant.  $Z$  and  $temp$  are halfwords.  $k[i]$ ,  $eff\_k[i]$ ,  $xleft[i]$ ,

$xright[i]$ ,  $fxleft[i]$  are all halfwords for all values of  $i = 0$  through 32.

```

c ← 0xFFFC
Z0 ← 0xFA25_61CD_F44A_C398 // = 0x3E89_5873_7D12_B0E6<<2
Z ← 0x0000
k[0] ← key.hword[0]
k[1] ← key.hword[1]
k[2] ← key.hword[2]
k[3] ← key.hword[3]
xleft[0] ← x.hword[1]
xright[0] ← x.hword[0]
for i = 0 to 27
  Z.bit[15] ← Z0.bit[i]
  temp ← (k[i + 3] >>> 3) ⊕ k[i + 1]
  k[i + 4] ← c ⊕ Z ⊕ k[i] ⊕ temp ⊕ (temp >>> 1)
end
for i = 0 to 7
  eff_k[4*i] ← k[4*i + ((0 + lane) mod 4)]
  eff_k[4*i+1] ← k[4*i + ((1 + lane) mod 4)]
  eff_k[4*i+2] ← k[4*i + ((2 + lane) mod 4)]
  eff_k[4*i+3] ← k[4*i + ((3 + lane) mod 4)]
end
for i = 0 to 31
  fxleft[i] ← ((xleft[i] <<< 1) & (xleft[i] <<< 8)) ⊕ (xleft[i] <<< 2)
  xleft[i + 1] ← xright[i] ⊕ fxleft[i] ⊕ eff_k[i]
  xright[i + 1] ← xleft[i]
end
result.hword[1] ← xleft[32]
result.hword[0] ← xright[32]
return(result)

```

##### HashDigest(x, y, key)

Let  $x, y$ , and  $key$  be doublewords.  $stage0$  and  $stage1$  are quadwords.  $stage2left$ ,  $stage2right$ , and  $result$  are doublewords.

```

for i = 0 to 7
  stage0.byte[2*i] ← y.byte[7 - i]
  stage0.byte[2*i + 1] ← x.byte[i]
end
for i = 0 to 3
  stage1.word[i] ← SIMON_LIKE_32_64(stage0.word[i], key, i)
end
stage2left.word[0] ← stage1.word[0]
stage2left.word[1] ← stage1.word[1]
stage2right.word[0] ← stage1.word[2]
stage2right.word[1] ← stage1.word[3]
result ← stage2left ⊕ stage2right

```

#### Programming Note

The hash function is similar to the SIMON cipher hash function with block size 32 bits and key size 64 bits described in the academic paper “The SIMON and SPECK lightweight block ciphers” In Proceedings of the 52nd Annual Design Automation Conference authored by Ray Beaulieu, Douglas Shors, Jason Smith, Stefan Treatman-Clark, Bryan Weeks, and Louis Wingers, with some differences regarding key schedule and digest computation.

### 3.3.17.2 Fixed-Point Hash Instructions

#### Hash Store

*X-form*

hashst RB,offset(RA)

0	31	D	RA	RB	722	DX
	6		11	16	21	31

```
DW ← 32×DX + D
d ← EXTS ( 0b111_1111 || DW || 0b000 )
EA ← (RA) + d
temp ← HashDigest((RA),(RB),HASHKEYR)
MEM(EA, 8) ← temp
```

Let DW be the value  $32 \times DX + D$ . The offset is  $(0b111\_1111 \parallel DW \parallel 0b000)$  sign extended to 64 bits. Let the effective address (EA) be the sum  $(RA) + \text{offset}$ . The doubleword hash value computed from the contents of RA, RB, and the privileged SPR HASHKEYR, as specified by the HashDigest function described in Section 3.3.17.1 of Book I, is stored into the doubleword in storage addressed by EA.

EA must be a multiple of 8. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

If RA=0, the instruction form is invalid.

#### Special Registers Altered:

None

#### Hash Check

*X-form*

hashchk RB,offset(RA)

0	31	D	RA	RB	754	DX
	6		11	16	21	31

```
DW ← 32×DX + D
d ← EXTS ( 0b111_1111 || DW || 0b000 )
EA ← (RA) + d
temp ← HashDigest((RA),(RB),HASHKEYR)
templ ← MEM(EA, 8)
if (temp ≠ templ) then TRAP
```

Let DW be the value  $32 \times DX + D$ . The offset is  $(0b111\_1111 \parallel DW \parallel 0b000)$  sign extended to 64 bits. Let the effective address (EA) be the sum  $(RA) + \text{offset}$ . The doubleword in storage addressed by EA is read and compared with the doubleword hash value computed from the contents of RA, RB, and the privileged SPR HASHKEYR, as specified by the HashDigest function described in Section 3.3.17.1 of Book I. If the values are unequal, the system trap handler is invoked.

This instruction is treated as a *Load*; see Section 4.3 of Book II.

If the values are unequal, this instruction is context synchronizing (see Book III).

EA must be a multiple of 8. If it is not, either the system alignment error handler is invoked or the results are boundedly undefined.

If RA=0, the instruction form is invalid.

#### Special Registers Altered:

None

#### Programming Note

If RA=0 the instruction form is invalid because otherwise, for architecture consistency, the EA computation would use  $(RA|0)$  instead of  $(RA)$ , and if RA=0 neither alternative --  $(RA)$  or 0 -- would make sense as the first argument of the HashDigest function.

- If the contents of GPR 0 were used as the first argument, the contents of GPR 0 would have to remain constant between the *hashst* and the *hashchk* (or be saved and restored between the two instructions), which is not normally the case when GPR 0 is used as RA in EA specification.
- If 0 were used as the first argument, security would be reduced because the first argument would be a constant.

(In normal use of the two instructions the hash value will be stored in the stack frame, and GPR 0 is never used as the stack frame pointer, so nothing is lost in practice by preventing GPR 0 from being used as RA.)

**Programming Note**

A primary use of the *Hash* instructions is to enable programs to protect against corruption of the saved value of the Link Register in the program stack and thereby to provide Return Oriented Programming (ROP) protection. The *hashst* and *hashchk* instructions can serve this purpose for application programs, while the *hashstp* and *hashchkp* instructions can do so for privileged programs (see Section 5.4.2 of Book III.).

On being called the callee would store a hash of the Link Register contents and the stack pointer in the following fashion:

```
mflr  r0          # move LR to GPR 0
std   r0,offset1(r1) # save LR in stack
hashst r0,offset2(r1) # save hash in stack
```

Before return the callee would restore the Link Register and recompute the hash of the Link Register contents and the stack pointer and compare the result with the hash value previously stored in the stack in the following fashion:

```
ld     r0,offset1(r1) # restore LR value
hashchk r0,offset2(r1) # recompute hash
                        # and check
                        # vs memory contents at
                        # (r1) + offset2
                        # trap if they mismatch
mtlcr  r0          # restore LR
blr    # return
```

Note that the EA specified by the *Hash* instructions — (RA) + EXTS(0b111\_1111 || DW || 0b000) — can be expressed as (RA) - (64-DW)×8. Therefore the Hash instructions can only access one of the 64 doublewords preceding the address provided by RA (from (RA) - 8 to (RA) - 512). Assuming RA is the stack pointer, as in the program fragments above, the stack needs to have spare storage in that range for this usage pattern.

Also note that in the above program pattern if the *Hash* instructions are treated as no-ops during program execution then the program still executes correctly albeit without the additional check on corruption of the Link Register value stored in the stack. This property permits dynamic runtime disablement of this check by setting the NPHIE (Non-Privileged Hash Instruction Enable) and PHIE (Privileged Hash Instruction Enable) bits to 0 in the DEXCR and HDEXCR. (See Section 9.3 of Book III.)

**Programming Note**

As part of creating a process, operating systems should generate a new key value using either a hardware random number generator (e.g. the *darn* instruction) or a software pseudo-random number generator and assign it to the HASHKEYR SPR. Thereafter the value should be maintained as part of the process context.

The hypervisor should have analogous behavior with regards to the HASHKEYR SPR and partition context.

The two SPRs are described in Section 5.3.8 of Book III.

### 3.3.18 Move To/From Vector-Scalar Register Instructions

#### Move From VSR Doubleword X-form

mfvsrd RA, XS

if SX=0 & MSR.FP=0 then FP\_Unavailable()  
if SX=1 & MSR.VEC=0 then Vector\_Unavailable()

GPR[RA] ← VSR[32×SX+S].dword[0]

Let XS be the value 32×SX + S.

The contents of doubleword element 0 of VSR[XS] are placed into GPR[RA].

For SX=0, **mfvsrd** is treated as a *Floating-Point* instruction in terms of resource availability.

For SX=1, **mfvsrd** is treated as a *Vector* instruction in terms of resource availability.

#### Extended Mnemonics:

Extended mnemonics for *Move From VSR Doubleword*:

<b>Extended mnemonic:</b>		<b>Equivalent to:</b>	
mffprd	RA, FRS	mfvsrd	RA, FRS
mfvrd	RA, VRS	mfvsrd	RA, VRS+32

#### Special Registers Altered

None

src

tgt

#### Move From VSR Lower Doubleword X-form

mfvsrld RA, XS

if SX=0 & MSR.VSX=0 then VSX\_Unavailable()  
if SX=1 & MSR.VEC=0 then Vector\_Unavailable()

GPR[RA] ← VSR[32×SX+S].dword[1]

Let XS be the value 32×SX + S.

The contents of doubleword 1 of VSR[XS] are placed into GPR[RA].

For SX=0, **mfvsrld** is treated as a *VSX* instruction in terms of resource availability.

For SX=1, **mfvsrld** is treated as a *Vector* instruction in terms of resource availability.

#### Special Registers Altered:

None

#### Data Layout for mfvsrld

src

tgt

### Move From VSR Word and Zero X-form

mfvsrwz RA, XS

if SX=0 & MSR.FP=0 then FP\_Unavailable()  
 if SX=1 & MSR.VEC=0 then Vector\_Unavailable()

GPR[RA] ← EXTZ64(VSR[32×SX+S].word[1])

Let XS be the value 32×SX + S.

The contents of word element 1 of VSR[XS] are placed into bits 32:63 of GPR[RA]. The contents of bits 0:31 of GPR[RA] are set to 0.

For SX=0, **mfvsrwz** is treated as a *Floating-Point* instruction in terms of resource availability.

For SX=1, **mfvsrwz** is treated as a *Vector* instruction in terms of resource availability.

#### Extended Mnemonics:

Extended mnemonics for *Move To VSR Word and Zero*:

<i>Extended mnemonic:</i>		<i>Equivalent to:</i>	
mffprwz	RA, FRS	mfvsrwz	RA, FRS
mfvrwz	RA, VRS	mfvsrwz	RA, VRS+32

#### Special Registers Altered

None

#### Data Layout for mfvsrwz

### Move To VSR Doubleword X-form

mtvsrd XT, RA

if TX=0 & MSR.FP=0 then FP\_Unavailable()  
 if TX=1 & MSR.VEC=0 then Vector\_Unavailable()

VSR[32×TX+T].dword[0] ← GPR[RA]  
 VSR[32×TX+T].dword[1] ← 0xUUUU\_UUUU\_UUUU\_UUUU

Let XT be the value 32×TX + T.

The contents of GPR[RA] are placed into doubleword element 0 of VSR[XT].

The contents of doubleword element 1 of VSR[XT] are undefined.

For TX=0, **mtvsrd** is treated as a *Floating-Point* instruction in terms of resource availability.

For TX=1, **mtvsrd** is treated as a *Vector* instruction in terms of resource availability.

#### Extended Mnemonics:

Extended mnemonics for *Move To VSR Doubleword*:

<i>Extended mnemonic:</i>		<i>Equivalent to:</i>

### 3.3.19 Move To/From System Register Instructions

The *Move To Condition Register Fields* instruction has a preferred form; see Section 1.8.1, “Preferred Instruction Forms” on page 25. In the preferred form, the FXM field satisfies the following rule.

- Exactly one bit of the FXM field is set to 1.

#### Extended mnemonics

Extended mnemonics are provided for the *mtspr* and *mfspr* instructions so that they can be coded with the

SPR name as part of the mnemonic rather than as a numeric operand. An extended mnemonic is provided for the *mtcrf* instruction for compatibility with old software (written for a version of the architecture that precedes Version 2.00) that uses it to set the entire Condition Register. Some of these extended mnemonics are shown as examples with the relevant instructions. See Appendix C, “Assembler Extended Mnemonics” on page 1021 for additional extended mnemonics.

#### Move To Special Purpose Register XFX-form

mtspr SPR,RS

0	31	RS	spr	467	/	31
	6		11			21

```

n ← spr5:9 || spr0:4
switch (n)
  case(13): see Book III
  case(808, 809, 810, 811):
  default:
    if length(SPR(n)) = 64 then
      SPR(n) ← (RS)
    else
      SPR(n) ← (RS)32:63

```

The SPR field denotes a Special Purpose Register, encoded as shown in the table below. If the SPR field contains a value from 808 through 811, the instruction specifies a reserved SPR, and is treated as a no-op; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”. Otherwise, unless the SPR field contains 13 (denoting the AMR), the contents of register RS are placed into the designated Special Purpose Register. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RS are placed into the SPR.

The AMR (Authority Mask Register) is used for “storage protection.” This use, and operation of *mtspr* for the AMR, are described in Book III.

decimal	SPR <sup>1</sup>		Register Name
	spr <sub>5:9</sub>	spr <sub>0:4</sub>	
1	00000	00001	XER
3	00000	00011	DSCR
8	00000	01000	LR
9	00000	01001	CTR
13	00000	01101	AMR
256	01000	00000	VRSERVE
769	11000	00001	MMCR2
770	11000	00010	MMCR1

- Note that the order of the two 5-bit halves of the SPR number is reversed.
- Accesses to these registers are no-ops; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”

decimal	SPR <sup>1</sup>		Register Name
	spr <sub>5:9</sub>	spr <sub>0:4</sub>	
771	11000	00011	PMC1
772	11000	00100	PMC2
773	11000	00101	PMC3
774	11000	00110	PMC4
775	11000	00111	PMC5
776	11000	01000	PMC6
779	11000	01011	MMCR0
800	11001	00000	BESCRS
801	11001	00001	BESCRSU
802	11001	00010	BESCRRL
803	11001	00011	BESCRRU
804	11001	00100	EBBHR
805	11001	00101	EBBRL
806	11001	00110	BESCR
808	11001	01000	reserved <sup>2</sup>
809	11001	01001	reserved <sup>2</sup>
810	11001	01010	reserved <sup>2</sup>
811	11001	01011	reserved <sup>2</sup>
815	11001	01111	TAR <sup>2</sup>
896	11100	00000	PPR
898	11100	00010	PPR32

- Note that the order of the two 5-bit halves of the SPR number is reversed.
- Accesses to these registers are no-ops; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”

If execution of this instruction is attempted specifying an SPR number that is not shown above, one of the following occurs.

- If spr<sub>0</sub> = 0, the illegal instruction error handler is invoked.
- If spr<sub>0</sub> = 1, the system privileged instruction error handler is invoked.

A complete description of this instruction can be found in Book III.

#### Special Registers Altered:

See above

#### Extended Mnemonics:

Examples of extended mnemonics for *Move To Special Purpose Register*.

<b>Extended mnemonic:</b>		<b>Equivalent to:</b>	
<i>mtxer</i>	Rx	<i>mtspr</i>	1, Rx
<i>mtlr</i>	Rx	<i>mtspr</i>	8, Rx
<i>mtctr</i>	Rx	<i>mtspr</i>	9, Rx
<i>mtppr</i>	Rx	<i>mtspr</i>	896, Rx
<i>mtppr32</i>	Rx	<i>mtspr</i>	898, Rx

**Programming Note**

The AMR is part of the “context” of the program (see Book III). Therefore modification of the AMR requires “synchronization” by software. For this reason, most operating systems provide a system library program that application programs can use to modify the AMR.

**Compiler and Assembler Note**

For the *mtspr* and *mfspr* instructions, the SPR number coded in Assembler language does not appear directly as a 10-bit binary number in the instruction. The number coded is split into two 5-bit halves that are reversed in the instruction, with the high-order 5 bits appearing in bits 16:20 of the instruction and the low-order 5 bits in bits 11:15.

### Move From Special Purpose Register XFX-form

mf spr                      RT, SPR

31	RT	spr	339	/
0	6	11	21	31

```

n ← spr5:9 || spr0:4
switch (n)
  case(808, 809, 810, 811):
    default:
      if length(SPR(n)) = 64 then
        RT ← SPR(n)
      else
        RT ← 320 || SPR(n)

```

The SPR field denotes a Special Purpose Register, encoded as shown in the table below. If the SPR field contains a value from 808 through 811, the instruction specifies a reserved SPR, and is treated as a no-op; see Section 1.3.3, “Reserved Fields, Reserved Values, and Reserved SPRs”. Otherwise, the contents of the designated Special Purpose Register are placed into register RT. For Special Purpose Registers that are 32 bits long, the low-order 32 bits of RT receive the contents of the Special Purpose Register and the high-order 32 bits of RT are set to zero.

decimal	SPR <sup>1</sup>		Register Name
	spr <sub>5:9</sub>	spr <sub>0:4</sub>	
1	00000	00001	XER
3	00000	00011	DSCR

Examples of extended mnemonics for Move From Special Purpose Register:

Extended mnemonic:		Equivalent to:	
mf xer	Rx	mf spr	Rx, 1
mf l r	Rx	mf spr	Rx, 8
mf ctr	Rx	mf spr	Rx, 9

#### Note

See the Notes that appear with *mtspr*.

**Move to CR from XER Extended X-form**

mcrxrx BF

31	BF	//	///	///	576	/
0	6	9	11	16	21	31

$$CR_{4 \times BF+32: 4 \times BF+35} \leftarrow XER_{OV\ 0V32\ CA\ CA32}$$

The contents of the OV, OV32, CA, and CA32 are copied to Condition Register field BF.

**Special Registers Altered:**

CR field BF

**Move To One Condition Register Field XFX-form**

mtocrf FXM,RS

31	RS	1	FXM	/	144	/
0	6	11	12	20	21	31

```

count ← 0
do i = 0 to 7
  if FXMi = 1 then
    n ← i
    count ← count + 1
if count = 1 then
  CR4×n+32: 4×n+35 ← (RS)4×n+32: 4×n+35
else
  CR ← undefi ned

```

If exactly one bit of the FXM field is set to 1, let  $n$  be the position of that bit in the field ( $0 \leq n \leq 7$ ). The contents of bits  $4 \times n + 32 : 4 \times n + 35$  of register RS are placed into CR field  $n$  (CR bits  $4 \times n + 32 : 4 \times n + 35$ ). Otherwise, the contents of the Condition Register are undefined.

**Special Registers Altered:**

CR field selected by FXM

**Move To Condition Register Fields XFX-form**

mtcrf FXM,RS

31	RS	0	FXM	/	144	/
0	6	11	12	20	21	31

$$\text{mask} \leftarrow {}^4(\text{FXM}_0) \mid \mid {}^4(\text{FXM}_1) \mid \mid \dots \mid {}^4(\text{FXM}_7)$$

$$CR \leftarrow ((RS)_{32:63} \& \text{mask}) \mid (CR \& \neg \text{mask})$$

The contents of bits 32:63 of register RS are placed into the Condition Register under control of the field mask specified by FXM. The field mask identifies the 4-bit fields affected. Let  $i$  be an integer in the range 0-7. If  $\text{FXM}_i = 1$  then CR field  $i$  (CR bits  $4 \times i + 32 : 4 \times i + 35$ ) is set to the contents of the corresponding field of the low-order 32 bits of RS.

**Special Registers Altered:**

CR fields selected by mask

**Extended Mnemonics:**

Example of extended mnemonics for *Move To Condition Register Fields*:

**Extended mnemonic:**

mtcr Rx

**Equivalent to:**

mtcrf 0xFF, Rx

**Move From One Condition Register Field XFX-form**

mfocrf RT,FXM

31	RT	1	FXM	/	19	/
0	6	11	12	20	21	31

```

RT ← undefined
count ← 0
do i = 0 to 7
  if FXMi = 1 then
    n ← i
    count ← count + 1
if count = 1 then
  RT ← 640
  RT4xn+32:4xn+35 ← CR4xn+32:4xn+35

```

If exactly one bit of the FXM field is set to 1, let  $n$  be the position of that bit in the field ( $0 \leq n \leq 7$ ). The contents of CR field  $n$  (CR bits  $4*n+32:4*n+35$ ) are placed into bits  $4xn+32:4xn+35$  of register RT, and the contents of the remaining bits of register RT are undefined. Otherwise, the contents of register RT are undefined.

If exactly one bit of the FXM field is set to 1, the contents of the remaining bits of register RT are set to 0's instead of being undefined as specified above.

**Special Registers Altered:**

None

**Programming Note**

**Warning:** *mfocrf* is not backward compatible with processors that comply with versions of the architecture that precede Version 2.08. Such processors may not set to 0 the bits of register RT that do not correspond to the specified CR field. If programs that depend on this clearing behavior are run on such processors, the programs may get incorrect results.

The POWER4, POWER5, POWER7 and POWER8 processors set to 0's all bytes of register RT other than the byte that contains the specified CR field. In the byte that contains the CR field, bits other than those containing the CR field may or may not be set to 0s.

**Move From Condition Register XFX-form**

mfocrf RT

31	RT	0	///	/	19	/
0	6	11	12	20	21	31

RT ← <sup>32</sup>0 || CR

The contents of the Condition Register are placed into RT<sub>32:63</sub>. RT<sub>0:31</sub> are set to 0.

**Special Registers Altered:**

None

**Set Boolean X-form**

setb RT,BFA

31	RT	BFA	//	///	128	/
0	6	11	14	16	21	31

if  $CR_{4 \times BFA+32}=1$  then  
 $RT \leftarrow 0xFFFF\_FFFF\_FFFF\_FFFF$

else if  $CR_{4 \times BFA+33}=1$  then  
 $RT \leftarrow 0x0000\_0000\_0000\_0001$

else  
 $RT \leftarrow 0x0000\_0000\_0000\_0000$

If the contents of bit 0 of CR field BFA are equal to 0b1, the contents of register RT are set to 0xFFFF\_FFFF\_FFFF\_FFFF.

Otherwise, if the contents of bit 1 of CR field BFA are equal to 0b1, the contents of register RT are set to 0x0000\_0000\_0000\_0001.

Otherwise, the contents of register RT are set to 0x0000\_0000\_0000\_0000.

**Special Registers Altered:**  
None

**Set Boolean Condition X-form**

setbc RT,BI

31	RT	BI	///	384	/
0	6	11	16	21	31

$$RT = (CR_{BI}=1) ? 1 : 0$$

If bit BI of the CR contains a 1, register RT is set to 1. Otherwise, register RT is set to 0.

**Special Registers Altered:**  
None

**Set Boolean Condition Reverse X-form**

setbcr RT,BI

31	RT	BI	///	416	/
0	6	11	16	21	31

$$RT = (CR_{BI}=1) ? 0 : 1$$

If bit BI of the CR contains a 1, register RT is set to 0. Otherwise, register RT is set to 1.

**Special Registers Altered:**  
None

**Set Negative Boolean Condition X-form**

setnbc RT,BI

31	RT	BI	///	448	/
0	6	11	16	21	31

$$RT = (CR_{BI}=1) ? -1 : 0$$

If bit BI of the CR contains a 1, register RT is set to -1. Otherwise, register RT is set to 0.

**Special Registers Altered:**  
None

**Set Negative Boolean Condition Reverse X-form**

setnbcr RT,BI

31	RT	BI	///	480	/
0	6	11	16	21	31

$$RT = (CR_{BI}=1) ? 0 : -1$$

If bit BI of the CR contains a 1, register RT is set to 0. Otherwise, register RT is set to -1.

**Special Registers Altered:**  
None

### 3.3.20 Prefixed No-Operation Instruction

#### ***Prefixed Nop MRR: \*-form***

`pnop`

Prefix:

1	3	0	///	0
0	6	8	12	14
				31

Suffix::

any value <sup>1</sup>	
0	31

1. Value must not correspond to a *Branch* instruction, an *rfebb* instruction, a context synchronizing instruction other than *isync*, or a "Service Processor Attention" instruction

No operation is performed.

#### **Special Registers Altered:**

None

#### **Programming Note**

The *pnop* instruction behaves as a *b \$+8* instruction regardless of its suffix. However, it does not cause any side effects such as modification of the Come From Address Register. (see Section 10.2 of Book III).

#### **Programming Note**

If the value in the suffix of a *pnop* instruction corresponds to a *Branch* instruction, an *rfebb* instruction, a context synchronizing instruction other than *isync*, or a "Service Processor Attention" instruction, the instruction form is invalid. The behavior associated with invalid form instructions is described in Section 1.8.2 on page 25. *rfebb* and *isync* are defined in Book II: Power ISA Virtual Environment Architecture. Context synchronization and other context synchronizing instructions are defined in Book III: Power ISA Operating Environment Architecture. *Service Processor Attention* is a reserved instruction; see Appendix C, "Reserved Instructions" on page 1369.)

This restriction eases hardware implementation complexity.

#### **Engineering Note**

Because the list of word instructions that must not be used as the suffix of *pnop* may change in the future, hardware should treat these invalid instruction forms of *pnop* either as a no-op or as an illegal instruction. This treatment enhances software compatibility. The choice may vary according to which of the word instructions is used as the suffix.

## Chapter 4. Floating-Point Facility

### 4.1 Floating-Point Facility Overview

This chapter describes the registers and instructions that make up the Floating-Point Facility.

The processor (augmented by appropriate software support, where required) implements a floating-point system compliant with the ANSI/IEEE Standard 754-1985, “IEEE Standard for Binary Floating-Point Arithmetic” (hereafter referred to as “the IEEE standard”). That standard defines certain required “operations” (addition, subtraction, etc.). Herein, the term “floating-point operation” is used to refer to one of these required operations and to additional operations defined (e.g., those performed by *Multiply-Add* or *Reciprocal Estimate* instructions). A Non-IEEE mode is also provided. This mode, which may produce results not in strict compliance with the IEEE standard, allows shorter latency.

Instructions are provided to perform arithmetic, rounding, conversion, comparison, and other operations in floating-point registers; to move floating-point data between storage and these registers; and to manipulate the Floating-Point Status and Control Register explicitly.

These instructions are divided into two categories.

- computational instructions

The computational instructions are those that perform addition, subtraction, multiplication, division, extracting the square root, rounding, conversion, comparison, and combinations of these operations. These instructions provide the floating-point operations. They place status information into the Floating-Point Status and Control Register. They are the instructions described in Sections 4.6.6 through 4.6.8.

- non-computational instructions

The non-computational instructions are those that perform loads and stores, move the contents of a floating-point register to another floating-point register possibly altering the sign, manipulate the Floating-Point Status and Control Register explic-

itly, and select the value from one of two floating-point registers based on the value in a third floating-point register. The operations performed by these instructions are not considered floating-point operations. With the exception of the instructions that manipulate the Floating-Point Status and Control Register explicitly, they do not alter the Floating-Point Status and Control Register. They are the instructions described in Sections 4.6.2 through 4.6.5, and 4.6.10.

A floating-point number consists of a signed exponent and a signed significand. The quantity expressed by this number is the product of the significand and the number  $2^{\text{exponent}}$ . Encodings are provided in the data format to represent finite numeric values,  $\pm$ Infinity, and values that are “Not a Number” (NaN). Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. Their encoding permits a variable diagnostic information field. They may be used to indicate such things as uninitialized variables and can be produced by certain invalid operations.

There is one class of exceptional events that occur during instruction execution that is unique to the Floating-Point Facility: the Floating-Point Exception. Floating-point exceptions are signaled with bits set in the Floating-Point Status and Control Register (FPSCR). They can cause the system floating-point enabled exception error handler to be invoked, precisely or imprecisely, if the proper control bits are set.

### Floating-Point Exceptions

The following floating-point exceptions are detected by the processor:

- Invalid Operation Exception (VX)  
 SNaN (VXSNAN)  
 Infinity–Infinity (VXI S1)  
 Infinity÷Infinity (VXI D1)  
 Zero÷Zero (VXZDZ)  
 Infinity×Zero (VXI MZ)  
 Invalid Compare (VXVC)  
 Software-Defined Condition (VXSOFI)  
 Invalid Square Root (VXSQRT)

Invalid Integer Convert	(VXCVI)
• Zero Divide Exception	(ZX)
• Overflow Exception	(OX)
• Underflow Exception	(UX)
• Inexact Exception	(XX)

Each floating-point exception, and each category of Invalid Operation Exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. See Section 4.2.2, “Floating-Point Status and Control Register” on page 136 for a description of these exception and enable bits, and Section 4.4, “Floating-Point Exceptions” on page 144 for a detailed discussion of floating-point exceptions, including the effects of the enable bits.

## 4.2 Floating-Point Facility Registers

### 4.2.1 Floating-Point Registers

Implementations of this architecture provide 32 floating-point registers (FPRs). The floating-point instruction formats provide 5-bit fields for specifying the FPRs to be used in the execution of the instruction. The FPRs are numbered 0-31. See Figure 45 on page 136.

Each FPR contains 64 bits that support the floating-point double format. Every instruction that interprets the contents of an FPR as a floating-point value uses the floating-point double format for this interpretation.

The computational instructions, and the *Move* and *Select* instructions, operate on data located in FPRs and, with the exception of the *Compare* instructions, place the result value into an FPR and optionally (when Rc=1) place status information into the Condition Register.

*Load Double* and *Store Double* instructions are provided that transfer 64 bits of data between storage and the FPRs with no conversion. *Load Single* instructions are provided to transfer and convert floating-point values in floating-point single format from storage to the same value in floating-point double format in the FPRs. *Store Single* instructions are provided to transfer and convert floating-point values in floating-point double format from the FPRs to the same value in floating-point single format in storage.

Instructions are provided that manipulate the Floating-Point Status and Control Register and the Condition Register explicitly. Some of these instructions copy data from an FPR to the Floating-Point Status and Control Register or vice versa.

The computational instructions and the *Select* instruction accept values from the FPRs in double format. For single-precision arithmetic instructions, all input values must be representable in single format; if they are not,

the result placed into the target FPR, and the setting of status bits in the FPSCR and in the Condition Register (if Rc=1), are undefined.

Figure 45. Floating-Point Registers

### 4.2.2 Floating-Point Status and Control Register

The Floating-Point Status and Control Register (FPSCR) controls the handling of floating-point exceptions and records status resulting from the floating-point operations. Bits 32:55 are status bits. Bits 56:63 are control bits.

The exception bits in the FPSCR (bits 35:44, 53:55) are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an *mcrfs*, *mtfsfi*, *mtfsf*, or *mtfsb0* instruction. The exception summary bits in the FPSCR (FX, FEX, and VX, which are bits 32:34) are not considered to be “exception bits”, and only FX is sticky.

FEX and VX are simply the ORs of other FPSCR bits. Therefore these two bits are not listed among the FPSCR bits affected by the various instructions.

Figure 46. Floating-Point Status and Control Register

The bit definitions for the FPSCR are as follows.

Bit(s)	Description
0:28	Reserved
29:31	<b>Decimal Rounding Mode (DRN)</b> See Section 5.2.1, “DFP Usage of Floating-Point Registers” on page 192.
32	<b>Floating-Point Exception Summary (FX)</b> Every floating-point instruction, except <i>mtfsfi</i> and <i>mtfsf</i> , implicitly sets FX to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. <i>mcrfs</i> , <i>mtfsfi</i> , <i>mtfsf</i> , <i>mtfsb0</i> , and <i>mtfsb1</i> can alter FX explicitly.

**Programming Note**

FX is defined not to be altered implicitly by *mtfsfi* and *mtfsf* because permitting these instructions to alter FX implicitly could cause a paradox. An example is an *mtfsfi* or *mtfsf* instruction that supplies 0 for FX and 1 for 0X, and is executed when 0X=0. See also the Programming Notes with the definition of these two instructions.

33 **Floating-Point Enabled Exception Summary (FEX)**

This bit is the OR of all the floating-point exception bits masked by their respective enable bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter FEX explicitly.

34 **Floating-Point Invalid Operation Exception Summary (VX)**

This bit is the OR of all the Invalid Operation exception bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter VX explicitly.

35 **Floating-Point Overflow Exception (OX)**

See Section 4.4.3, “Overflow Exception” on page 147.

36 **Floating-Point Underflow Exception (UX)**

See Section 4.4.4, “Underflow Exception” on page 148.

37 **Floating-Point Zero Divide Exception (ZX)**

See Section 4.4.2, “Zero Divide Exception” on page 146.

38 **Floating-Point Inexact Exception (XX)**

See Section 4.4.5, “Inexact Exception” on page 148.

XX is a sticky version of FI (see below). Thus the following rules completely describe how XX is set by a given instruction.

- If the instruction affects FI, the new value of XX is obtained by ORing the old value of XX with the new value of FI.
- If the instruction does not affect FI, the value of XX is unchanged.

39 **Floating-Point Invalid Operation Exception (SNaN) (VXSNaN)**

See Section 4.4.1, “Invalid Operation Exception” on page 146.

40 **Floating-Point Invalid Operation Exception ( $\infty - \infty$ ) (VXI SI)**

See Section 4.4.1.

41 **Floating-Point Invalid Operation Exception ( $\infty \div \infty$ ) (VXI DI)**

See Section 4.4.1.

42 **Floating-Point Invalid Operation Exception ( $0 \div 0$ ) (VXZDZ)**

See Section 4.4.1.

43 **Floating-Point Invalid Operation Exception ( $\infty \times 0$ ) (VXI MZ)**

See Section 4.4.1.

44 **Floating-Point Invalid Operation Exception (Invalid Compare) (VXVC)**

See Section 4.4.1.

45 **Floating-Point Fraction Rounded (FR)**

The last *Arithmetic* or *Rounding and Conversion* instruction incremented the fraction during rounding. See Section 4.3.6, “Rounding” on page 143. This bit is not sticky.

46 **Floating-Point Fraction Inexact (FI)**

The last *Arithmetic* or *Rounding and Conversion* instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 4.3.6. This bit is not sticky.

See the definition of XX, above, regarding the relationship between FI and XX.

47:51 **Floating-Point Result Flags (FPRF)**

*Arithmetic*, rounding, and *Convert From Integer* instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined. Floating-point *Compare* instructions set this field based on the relative values of the operands being compared. For *Convert To Integer* instructions, the value placed into FPRF is undefined. Additional details are given below.

**Programming Note**

A single-precision operation that produces a denormalized result sets FPRF to indicate a denormalized number. When possible, single-precision denormalized numbers are represented in normalized double format in the target register.

47 **Floating-Point Result Class Descriptor (C)**

*Arithmetic*, rounding, and *Convert From Integer* instructions may set this bit with the FPCC bits, to indicate the class of the result as shown in Figure 47 on page 139.

- 48:51 **Floating-Point Condition Code (FPCC)**  
Floating-point *Compare* instructions set one of the FPCC bits to 1 and the other three FPCC bits to 0. Arithmetic, rounding, and *Convert From Integer* instructions may set the FPCC bits with the C bit, to indicate the class of the result as shown in Figure 47 on page 139. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.
- 48 **Floating-Point Less Than or Negative (FL or <)**
- 49 **Floating-Point Greater Than or Positive (FG or >)**
- 50 **Floating-Point Equal or Zero (FE or =)**
- 51 **Floating-Point Unordered or NaN (FU or ?)**
- 52 Reserved
- 53 **Floating-Point Invalid Operation Exception (Software-Defined Condition) (VXSOF)**  
This bit can be altered only by *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, or *mtfsb1*. See Section 4.4.1.
- Programming Note**

FPSCR<sub>VXSOF</sub> can be used by software to indicate the occurrence of an arbitrary, software-defined, condition that is to be treated as an Invalid Operation Exception. For example, the bit could be set by a program that computes a base 10 logarithm if the supplied input is negative.
- 54 **Floating-Point Invalid Operation Exception (Invalid Square Root) (VXSQRT)**  
See Section 4.4.1.
- 55 **Floating-Point Invalid Operation Exception (Invalid Integer Convert) (VXCVI)**  
See Section 4.4.1.
- 56 **Floating-Point Invalid Operation Exception Enable (VE)**  
See Section 4.4.1.
- 57 **Floating-Point Overflow Exception Enable (OE)**  
See Section 4.4.3, “Overflow Exception” on page 147.
- 58 **Floating-Point Underflow Exception Enable (UE)**  
See Section 4.4.4, “Underflow Exception” on page 148.
- 59 **Floating-Point Zero Divide Exception Enable (ZE)**  
See Section 4.4.2, “Zero Divide Exception” on page 146.
- 60 **Floating-Point Inexact Exception Enable (XE)**  
See Section 4.4.5, “Inexact Exception” on page 148.
- 61 **Floating-Point Non-IEEE Mode (NI)**  
Floating-point non-IEEE mode is optional. If floating-point non-IEEE mode is not implemented, this bit is treated as reserved, and the remainder of the definition of this bit does not apply.
- If floating-point non-IEEE mode is implemented, this bit has the following meaning.
- 0 The processor is not in floating-point non-IEEE mode (i.e., all floating-point operations conform to the IEEE standard).
- 1 The processor is in floating-point non-IEEE mode.
- When the processor is in floating-point non-IEEE mode, the remaining FPSCR bits may have meanings different from those given in this document, and floating-point operations need not conform to the IEEE standard. The effects of executing a given floating-point instruction with FPSCR<sub>NI</sub>=1, and any additional requirements for using non-IEEE mode, are implementation-dependent. The results of executing a given instruction in non-IEEE mode may vary between implementations, and between different executions on the same implementation.
- Programming Note**

When the processor is in floating-point non-IEEE mode, the results of floating-point operations may be approximate, and performance for these operations may be better, more predictable, or less data-dependent than when the processor is not in non-IEEE mode. For example, in non-IEEE mode an implementation may return 0 instead of a denormalized number, and may return a large number instead of an infinity.
- 62:63 **Floating-Point Rounding Control (RN)** See Section 4.3.6, “Rounding” on page 143.
- 00 Round to Nearest
- 01 Round toward Zero
- 10 Round toward +Infinity
- 11 Round toward -Infinity

Result Flags	Result Value Class
<b>C &lt; &gt; = ?</b>	
1 0 0 0 1	Quiet NaN
0 1 0 0 1	- Infinity
0 1 0 0 0	- Normalized Number
1 1 0 0 0	- Denormalized Number
1 0 0 1 0	- Zero
0 0 0 1 0	+ Zero
1 0 1 0 0	+ Denormalized Number
0 0 1 0 0	+ Normalized Number
0 0 1 0 1	+ Infinity

Figure 47. Floating-Point Result Flags

## 4.3 Floating-Point Data

### 4.3.1 Data Format

This architecture defines the representation of a floating-point value in two different binary fixed-length formats. The format may be a 32-bit single format for a single-precision value or a 64-bit double format for a double-precision value. The single format may be used for data in storage. The double format may be used for data in storage and for data in floating-point registers.

The lengths of the exponent and the fraction fields differ between these two formats. The structure of the single and double formats is shown below.

Figure 48. Floating-point single format

Figure 49. Floating-point double format

Values in floating-point format are composed of three fields:

S	sign bit
EXP	exponent+bias
FRACTION	fraction

Representation of numeric values in the floating-point formats consists of a sign bit (S), a biased exponent (EXP), and the fraction portion (FRACTION) of the significand. The significand consists of a leading implied bit concatenated on the right with the FRACTION. This leading implied bit is 1 for normalized numbers and 0 for denormalized numbers and is located in the unit bit position (i.e., the first bit to the left of the binary point). Values representable within the two floating-point for-

ats can be specified by the parameters listed in Figure 50.

	Format	
	Single	Double
Exponent Bias	+127	+1023
Maximum Exponent	+127	+1023
Minimum Exponent	-126	-1022
Widths (bits)		
Format	32	64
Sign	1	1
Exponent	8	11
Fraction	23	52
Significand	24	53

Figure 50. IEEE floating-point fields

The architecture requires that the FPRs of the Floating-Point Facility support the floating-point double format only.

### 4.3.2 Value Representation

This architecture defines numeric and non-numeric values representable within each of the two supported formats. The numeric values are approximations to the real numbers and include the normalized numbers, denormalized numbers, and zero values. The non-numeric values representable are the infinities and the Not a Numbers (NaNs). The infinities are adjoined to the real numbers, but are not numbers themselves, and the standard rules of arithmetic do not hold when they are used in an operation. They are related to the real numbers by order alone. It is possible however to define restricted operations among numbers and infinities as defined below. The relative location on the real number line for each of the defined entities is shown in Figure 51.

Figure 51. Approximation to real numbers

The NaNs are not related to the numeric values or infinities by order or value but are encodings used to convey diagnostic information such as the representation of uninitialized variables.

The following is a description of the different floating-point values defined in the architecture:

#### Binary floating-point numbers

Machine representable values used as approximations to real numbers. Three categories of numbers are supported: normalized numbers, denormalized numbers, and zero values.

**Normalized numbers** ( $\pm$  NOR)

These are values that have a biased exponent value in the range:

- 1 to 254 in single format
- 1 to 2046 in double format

They are values in which the implied unit bit is 1. Normalized numbers are interpreted as follows:

$$\text{NOR} = (-1)^s \times 2^E \times (1.\text{fraction})$$

where  $s$  is the sign,  $E$  is the unbiased exponent, and 1.fraction is the significand, which is composed of a leading unit bit (implied bit) and a fraction part.

The ranges covered by the magnitude ( $M$ ) of a normalized floating-point number are approximately equal to:

Single Format:

$$1.2 \times 10^{-38} \leq M \leq 3.4 \times 10^{38}$$

Double Format:

$$2.2 \times 10^{-308} \leq M \leq 1.8 \times 10^{308}$$

**Zero values** ( $\pm 0$ )

These are values that have a biased exponent value of zero and a fraction value of zero. Zeros can have a positive or negative sign. The sign of zero is ignored by comparison operations (i.e., comparison regards +0 as equal to -0).

**Denormalized numbers** ( $\pm$  DEN)

These are values that have a biased exponent value of zero and a nonzero fraction value. They are nonzero numbers smaller in magnitude than the representable normalized numbers. They are values in which the implied unit bit is 0. Denormalized numbers are interpreted as follows:

$$\text{DEN} = (-1)^s \times 2^{E_{\text{min}}} \times (0.\text{fraction})$$

where  $E_{\text{min}}$  is the minimum representable exponent value (-126 for single-precision, -1022 for double-precision).

**Infinities** ( $\pm \infty$ )

These are values that have the maximum biased exponent value:

- 255 in single format
- 2047 in double format

and a zero fraction value. They are used to approximate values greater in magnitude than the maximum normalized value.

Infinity arithmetic is defined as the limiting case of real arithmetic, with restricted operations defined among numbers and infinities. Infinities and the real numbers can be related by ordering in the affine sense:

$$-\infty < \text{every finite number} < +\infty$$

Arithmetic on infinities is always exact and does not signal any exception, except when an exception occurs

due to the invalid operations as described in Section 4.4.1, “Invalid Operation Exception” on page 146.

For comparison operations, +Infinity compares equal to +Infinity and -Infinity compares equal to -Infinity.

**Not a Numbers** (NaNs)

These are values that have the maximum biased exponent value and a nonzero fraction value. The sign bit is ignored (i.e., NaNs are neither positive nor negative). If the high-order bit of the fraction field is 0 then the NaN is a *Signaling NaN*; otherwise it is a *Quiet NaN*.

Signaling NaNs are used to signal exceptions when they appear as operands of computational instructions.

Quiet NaNs are used to represent the results of certain invalid operations, such as invalid arithmetic operations on infinities or on NaNs, when Invalid Operation Exception is disabled ( $VE=0$ ). Quiet NaNs propagate through all floating-point operations except ordered comparison, *Floating Round to Single-Precision*, and conversion to integer. Quiet NaNs do not signal exceptions, except for ordered comparison and conversion to integer operations. Specific encodings in QNaNs can thus be preserved through a sequence of floating-point operations, and used to convey diagnostic information to help identify results from invalid operations.

When a QNaN is the result of a floating-point operation because one of the operands is a NaN or because a QNaN was generated due to a disabled Invalid Operation Exception, then the following rule is applied to determine the NaN with the high-order fraction bit set to 1 that is to be stored as the result.

```

if (FRA) is a NaN
  then FRT ← (FRA)
  else if (FRB) is a NaN
    then if instruction is frsp
      then FRT ← (FRB)0:34 || 290
      else FRT ← (FRB)
    else if (FRC) is a NaN
      then FRT ← (FRC)
    else if generated QNaN
      then FRT ← generated QNaN
  
```

If the operand specified by FRA is a NaN, then that NaN is stored as the result. Otherwise, if the operand specified by FRB is a NaN (if the instruction specifies an FRB operand), then that NaN is stored as the result, with the low-order 29 bits of the result set to 0 if the instruction is *frsp*. Otherwise, if the operand specified by FRC is a NaN (if the instruction specifies an FRC operand), then that NaN is stored as the result. Otherwise, if a QNaN was generated due to a disabled Invalid Operation Exception, then that QNaN is stored as the result. If a QNaN is to be generated as a result, then the QNaN generated has a sign bit of 0, an exponent field of all 1s, and a high-order fraction bit of 1 with all other fraction bits 0. Any instruction that generates a QNaN as

the result of a disabled Invalid Operation Exception generates this QNaN (i.e., 0x7FF8\_0000\_0000\_0000).

A double-precision NaN is considered to be representable in single format if and only if the low-order 29 bits of the double-precision NaN's fraction are zero.

### 4.3.3 Sign of Result

The following rules govern the sign of the result of an arithmetic, rounding, or conversion operation, when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the operand having the larger absolute value. If both operands have the same sign, the sign of the result of an add operation is the same as the sign of the operands. The sign of the result of the subtract operation  $x-y$  is the same as the sign of the result of the add operation  $x+(-y)$ .

When the sum of two operands with opposite sign, or the difference of two operands with the same sign, is exactly zero, the sign of the result is positive in all rounding modes except Round toward  $-\infty$ , in which mode the sign is negative.

- The sign of the result of a multiply or divide operation is the Exclusive OR of the signs of the operands.
- The sign of the result of a *Square Root* or *Reciprocal Square Root Estimate* operation is always positive, except that the square root of  $-0$  is  $-0$  and the reciprocal square root of  $-0$  is  $-\infty$ .
- The sign of the result of a *Round to Single-Precision*, or *Convert From Integer*, or *Round to Integer* operation is the sign of the operand being converted.

For the *Multiply-Add* instructions, the rules given above are applied first to the multiply operation and then to the add or subtract operation (one of the inputs to the add or subtract operation is the result of the multiply operation).

### 4.3.4 Normalization and Denormalization

The intermediate result of an arithmetic or *frsp* instruction may require normalization and/or denormalization as described below. Normalization and denormalization do not affect the sign of the result.

When an arithmetic or rounding instruction produces an intermediate result which carries out of the significand, or in which the significand is nonzero but has a leading zero bit, it is not a normalized number and must be normalized before it is stored. For the carry-out case, the significand is shifted right one bit, with a one shifted into the leading significand bit, and the exponent is incre-

mented by one. For the leading-zero case, the significand is shifted left while decrementing its exponent by one for each bit shifted, until the leading significand bit becomes one. The Guard bit and the Round bit (see Section 4.5.1, "Execution Model for IEEE Operations" on page 149) participate in the shift with zeros shifted into the Round bit. The exponent is regarded as if its range were unlimited.

After normalization, or if normalization was not required, the intermediate result may have a nonzero significand and an exponent value that is less than the minimum value that can be represented in the format specified for the result. In this case, the intermediate result is said to be "Tiny" and the stored result is determined by the rules described in Section 4.4.4, "Underflow Exception". These rules may require denormalization.

A number is denormalized by shifting its significand right while incrementing its exponent by 1 for each bit shifted, until the exponent is equal to the format's minimum value. If any significant bits are lost in this shifting process then "Loss of Accuracy" has occurred (See Section 4.4.4, "Underflow Exception" on page 148) and Underflow Exception is signaled.

### 4.3.5 Data Handling and Precision

Most of the *Floating-Point Facility Architecture*, including all computational, *Move*, and *Select* instructions, use the floating-point double format to represent data in the FPRs. Single-precision and integer-valued operands may be manipulated using double-precision operations. Instructions are provided to coerce these values from a double format operand. Instructions are also provided for manipulations which do not require double-precision. In addition, instructions are provided to access a true single-precision representation in storage, and a fixed-point integer representation in GPRs.

#### 4.3.5.1 Single-Precision Operands

For single format data, a format conversion from single to double is performed when loading from storage into an FPR and a format conversion from double to single is performed when storing from an FPR to storage. No floating-point exceptions are caused by these instructions. An instruction is provided to explicitly convert a double format operand in an FPR to single-precision. Floating-point single-precision is enabled with four types of instruction.

##### 1. Load Floating-Point Single

This form of instruction accesses a single-precision operand in single format in storage, converts it to double format, and loads it into an FPR. No floating-point exceptions are caused by these instructions.

## 2. Round to Floating-Point Single-Precision

The Floating Round to Single-Precision instruction rounds a double-precision operand to single-precision, checking the exponent for single-precision range and handling any exceptions according to respective enable bits, and places that operand into an FPR in double format. For results produced by single-precision arithmetic instructions, single-precision loads, and other instances of the Floating Round to Single-Precision instruction, this operation does not alter the value.

## 3. Single-Precision Arithmetic Instructions

This form of instruction takes operands from the FPRs in double format, performs the operation as if it produced an intermediate result having infinite precision and unbounded exponent range, and then coerces this intermediate result to fit in single format. Status bits, in the FPSCR and optionally in the Condition Register, are set to reflect the single-precision result. The result is then converted to double format and placed into an FPR. The result lies in the range supported by the single format.

If any input value is not representable in single format and either OE=1 or UE=1, the result placed into the target FPR, and the setting of status bits in the FPSCR and in the Condition Register (if Rc=1), are undefined.

For *fres*[,] or *frsqrtes*[,] if the input value is finite and has an unbiased exponent greater than +127, the input value is interpreted as an Infinity.

## 4. Store Floating-Point Single

This form of instruction converts a double-precision operand to single format and stores that operand into storage. No floating-point exceptions are caused by these instructions. (The value being stored is effectively assumed to be the result of an instruction of one of the preceding three types.)

When the result of a *Load Floating-Point Single*, *Floating Round to Single-Precision*, or single-precision arithmetic instruction is stored in an FPR, the low-order 29 FRACTION bits are zero.

### Programming Note

The *Floating Round to Single-Precision* instruction is provided to allow value conversion from double-precision to single-precision with appropriate exception checking and rounding. This instruction should be used to convert double-precision floating-point values (produced by double-precision load and arithmetic instructions and by *fcfid*) to single-precision values prior to storing them into single format storage elements or using them as operands for single-precision arithmetic instructions. Values produced by single-precision load and arithmetic instructions are already single-precision values and can be stored directly into single format storage elements, or used directly as operands for single-precision arithmetic instructions, without preceding the store, or the arithmetic instruction, by a *Floating Round to Single-Precision* instruction.

### Programming Note

A single-precision value can be used in double-precision arithmetic operations. The reverse is true only if the double-precision value is representable in single format.

Some implementations may execute single-precision arithmetic instructions faster than double-precision arithmetic instructions. Therefore, if double-precision accuracy is not required, single-precision data and instructions should be used.

## 4.3.5.2 Integer-Valued Operands

Instructions are provided to round floating-point operands to integer values in floating-point format. To facilitate exchange of data between the floating-point and fixed-point facilities, instructions are provided to convert between floating-point double format and fixed-point integer format in an FPR. Computation on integer-valued operands may be performed using arithmetic instructions of the required precision. (The results may not be integer values.) The two groups of instructions provided specifically to support integer-valued operands are described below.

### 1. Floating Round to Integer

The *Floating Round to Integer* instructions round a double-precision operand to an integer value in floating-point double format. These instructions may cause Invalid Operation (VXSNAN) exceptions. See Sections 4.3.6 and 4.5.1 for more information about rounding.

### 2. Floating Convert To/From Integer

The *Floating Convert To Integer* instructions convert a double-precision operand to a 32-bit or 64-bit signed fixed-point integer format. Variants are provided both to perform rounding based on

the value of  $FPSCR_{RN}$  and to round toward zero. These instructions may cause Invalid Operation (VXSNAN, VXCVI) and Inexact exceptions. The *Floating Convert From Integer* instruction converts a 64-bit signed fixed-point integer to a double-precision floating-point integer. Because of the limitations of the source format, only an Inexact exception may be generated.

### 4.3.6 Rounding

The material in this section applies to operations that have numeric operands (i.e., operands that are not infinities or NaNs). Rounding the intermediate result of such an operation may cause an Overflow Exception, an Underflow Exception, or an Inexact Exception. The remainder of this section assumes that the operation causes no exceptions and that the result is numeric. See Section 4.3.2, “Value Representation” and Section 4.4, “Floating-Point Exceptions” for the cases not covered here.

The *Arithmetic* and *Rounding and Conversion* instructions round their intermediate results. With the exception of the *Estimate* instructions, these instructions produce an intermediate result that can be regarded as having infinite precision and unbounded exponent range. All but two groups of these instructions normalize or denormalize the intermediate result prior to rounding and then place the final result into the target FPR in double format. The *Floating Round to Integer* and *Floating Convert To Integer* instructions with biased exponents ranging from 1022 through 1074 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 1075. (Intermediate results with biased exponents 1075 or larger are already integers, and with biased exponents 1021 or less round to zero.) After rounding, the final result for *Floating Round to Integer* is normalized and put in double format, and for *Floating Convert To Integer* is converted to a signed fixed-point integer.

$FPSCR$  bits  $FR$  and  $FI$  generally indicate the results of rounding. Each of the instructions which rounds its intermediate result sets these bits. If the fraction is incremented during rounding then  $FR$  is set to 1, otherwise  $FR$  is set to 0. If the result is inexact then  $FI$  is set to 1, otherwise  $FI$  is set to zero. The *Round to Integer* instructions are exceptions to this rule, setting  $FR$  and  $FI$  to 0. The *Estimate* instructions set  $FR$  and  $FI$  to undefined values. The remaining floating-point instructions do not alter  $FR$  and  $FI$ .

Four user-selectable rounding modes are provided through the Floating-Point Rounding Control field in the  $FPSCR$ . See Section 4.2.2, “Floating-Point Status and Control Register”. These are encoded as follows.

RN	Rounding Mode
00	Round to Nearest
01	Round toward Zero
10	Round toward +Infinity
11	Round toward -Infinity

Let  $Z$  be the intermediate arithmetic result or the operand of a convert operation. If  $Z$  can be represented exactly in the target format, then the result in all rounding modes is  $Z$  as represented in the target format. If  $Z$  cannot be represented exactly in the target format, let  $Z1$  and  $Z2$  bound  $Z$  as the next larger and next smaller numbers representable in the target format. Then  $Z1$  or  $Z2$  can be used to approximate the result in the target format.

Figure 52 shows the relation of  $Z$ ,  $Z1$ , and  $Z2$  in this case. The following rules specify the rounding in the four modes. “LSB” means “least significant bit”.

Figure 52. Selection of  $Z1$  and  $Z2$

#### Round to Nearest

Choose the value that is closer to  $Z$  ( $Z1$  or  $Z2$ ). In case of a tie, choose the one that is even (least significant bit 0).

#### Round toward Zero

Choose the smaller in magnitude ( $Z1$  or  $Z2$ ).

#### Round toward +Infinity

Choose  $Z1$ .

#### Round toward -Infinity

Choose  $Z2$ .

See Section 4.5.1, “Execution Model for IEEE Operations” on page 149 for a detailed explanation of rounding.

## 4.4 Floating-Point Exceptions

This architecture defines the following floating-point exceptions:

- Invalid Operation Exception
  - SNaN
  - Infinity–Infinity
  - Infinity÷Infinity
  - Zero÷Zero
  - Infinity×Zero
  - Invalid Compare
  - Software-Defined Condition
  - Invalid Square Root
  - Invalid Integer Convert
- Zero Divide Exception
- Overflow Exception
- Underflow Exception
- Inexact Exception

These exceptions, other than Invalid Operation Exception due to Software-Defined Condition, may occur during execution of computational instructions. An Invalid Operation Exception due to Software-Defined Condition occurs when a *Move To FPSCR* instruction sets *VXS0FT* to 1.

Each floating-point exception, and each category of Invalid Operation Exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. The exception bit indicates occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see page 145), whether and how the system floating-point enabled exception error handler is invoked. (In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its inputs, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow Exception may depend on the setting of the enable bit.)

A single instruction, other than *mtfsfi* or *mtfsf*, may set more than one exception bit only in the following cases:

- Inexact Exception may be set with Overflow Exception.
- Inexact Exception may be set with Underflow Exception.
- Invalid Operation Exception (SNaN) is set with Invalid Operation Exception ( $\infty \times 0$ ) for *Multiply-Add* instructions for which the values being multiplied are infinity and zero and the value being added is an SNaN.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Compare) for *Compare Ordered* instructions.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Integer Convert) for *Convert To Integer* instructions.

When an exception occurs the writing of a result to the target register may be suppressed or a result may be delivered, depending on the exception.

The writing of a result to the target register is suppressed for the following kinds of exception, so that there is no possibility that one of the operands is lost:

- Enabled Invalid Operation
- Enabled Zero Divide

For the remaining kinds of exception, a result is generated and written to the destination specified by the instruction causing the exception. The result may be a different value for the enabled and disabled conditions for some of these exceptions. The kinds of exception that deliver a result are the following:

- Disabled Invalid Operation
- Disabled Zero Divide
- Disabled Overflow
- Disabled Underflow
- Disabled Inexact
- Enabled Overflow
- Enabled Underflow
- Enabled Inexact

Subsequent sections define each of the floating-point exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of “traps” and “trap handlers”. In this architecture, an FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the “trap enabled” case; the expectation is that the exception will be detected by software, which will revise the result. An FPSCR exception enable bit of 0 causes generation of the “default result” value specified for the “trap disabled” (or “no trap occurs” or “trap is not implemented”) case; the expectation is that the exception will not be detected by software, which will simply use the default result. The result to be delivered in each case for each exception is described in the sections below.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is desired for all exceptions, all FPSCR exception enable bits should be set to 0 and Ignore Exceptions Mode (see below) should be used. In this case the system floating-point enabled exception error handler is not invoked, even if floating-point exceptions occur: software can inspect the FPSCR exception bits if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to 1 and a mode other than Ignore Exceptions Mode must be used. In this case the system floating-point enabled exception error handler is invoked if an enabled float-

ing-point exception occurs. The system floating-point enabled exception error handler is also invoked if a *Move To FPSCR* instruction causes an exception bit and the corresponding enable bit both to be 1; the *Move To FPSCR* instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The location of these bits and the requirements for altering them are described in Book III. (The system floating-point enabled exception error handler is never invoked because of a disabled floating-point exception.) The effects of the four possible settings of these bits are as follows.

#### FE0 FE1 Description

0	0	<p><b>Ignore Exceptions Mode</b> Floating-point exceptions do not cause the system floating-point enabled exception error handler to be invoked.</p>
0	1	<p><b>Imprecise Nonrecoverable Mode</b> The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction may have been used by or may have affected subsequent instructions that are executed before the error handler is invoked.</p>
1	0	<p><b>Imprecise Recoverable Mode</b> The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. Sufficient information is provided to the error handler that it can identify the excepting instruction and the operands, and correct the result. No results produced by the excepting instruction have been used by or have affected subsequent instructions that are executed before the error handler is invoked.</p>
1	1	<p><b>Precise Mode</b> The system floating-point enabled exception error handler is invoked precisely at the instruction that caused the enabled exception.</p>

In all cases, the question of whether a floating-point result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions

before the instruction at which the system floating-point enabled exception error handler is invoked have completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. The instruction at which the system floating-point enabled exception error handler is invoked has completed if it is the excepting instruction and there is only one such instruction. Otherwise it has not begun execution (or may have been partially executed in some cases, as described in Book III).

#### Programming Note

In any of the three non-Precise modes, a *Floating-Point Status and Control Register* instruction can be used to force any exceptions, due to instructions initiated before the *Floating-Point Status and Control Register* instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In either of the Imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any invocations of the system floating-point enabled exception error handler, due to instructions initiated before the *Floating-Point Status and Control Register* instruction, to occur. (This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.)

The last sentence of the paragraph preceding this Programming Note can apply only in the Imprecise modes, or if the mode has just been changed from Ignore Exceptions Mode to some other mode. (It always applies in the latter case.)

In order to obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to 0.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to 1 for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to 1.
- Precise Mode may degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

## 4.4.1 Invalid Operation Exception

### 4.4.1.1 Definition

An Invalid Operation Exception occurs when an operand is invalid for the specified operation. The invalid operations are:

- Any floating-point operation on a Signaling NaN (SNaN)
- For add or subtract operations, magnitude subtraction of infinities ( $\infty - \infty$ )
- Division of infinity by infinity ( $\infty \div \infty$ )
- Division of zero by zero ( $0 \div 0$ )
- Multiplication of infinity by zero ( $\infty \times 0$ )
- Ordered comparison involving a NaN (Invalid Compare)
- Square root or reciprocal square root of a negative (and nonzero) number (Invalid Square Root)
- Integer convert involving a number too large in magnitude to be represented in the target format, or involving an infinity or a NaN (Invalid Integer Convert)

An Invalid Operation Exception also occurs when an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets VXSOFT to 1 (Software-Defined Condition).

### 4.4.1.2 Action

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

When Invalid Operation Exception is enabled ( $VE=1$ ) and an Invalid Operation Exception occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set
 

VXSNAN	(if SNaN)
VXI SI	(if $\infty - \infty$ )
VXI DI	(if $\infty \div \infty$ )
VXZDZ	(if $0 \div 0$ )
VXI MZ	(if $\infty \times 0$ )
VXVC	(if invalid compare)
VXSOFT	(if software-defined condition)
VXSQRT	(if invalid square root)
VXCVI	(if invalid integer convert)
2. If the operation is an arithmetic, *Floating Round to Single-Precision*, *Floating Round to Integer*, or convert to integer operation,
  - the target FPR is unchanged
  - FR FI are set to zero
  - FPRF is unchanged
3. If the operation is a compare,
  - FR FI C are unchanged
  - FPCC is set to reflect unordered
4. If an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets VXSOFT to 1,
  - The FPSCR is set as specified in the instruction description.

When Invalid Operation Exception is disabled ( $VE=0$ ) and an Invalid Operation Exception occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set
 

VXSNAN	(if SNaN)
VXI SI	(if $\infty - \infty$ )
VXI DI	(if $\infty \div \infty$ )
VXZDZ	(if $0 \div 0$ )
VXI MZ	(if $\infty \times 0$ )
VXVC	(if invalid compare)
VXSOFT	(if software-defined condition)
VXSQRT	(if invalid square root)
VXCVI	(if invalid integer convert)
2. If the operation is an arithmetic or *Floating Round to Single-Precision* operation,
  - the target FPR is set to a Quiet NaN
  - FR FI are set to zero
  - FPRF is set to indicate the class of the result (Quiet NaN)
3. If the operation is a convert to 64-bit integer operation,
  - the target FPR is set as follows:
    - FRT is set to the most positive 64-bit integer if the operand in FRB is a positive number or  $+\infty$ , and to the most negative 64-bit integer if the operand in FRB is a negative number,  $-\infty$ , or NaN
    - FR FI are set to zero
    - FPRF is undefined
4. If the operation is a convert to 32-bit integer operation,
  - the target FPR is set as follows:
    - $FRT_{0:31} \leftarrow$  undefined
    - $FRT_{32:63}$  are set to the most positive 32-bit integer if the operand in FRB is a positive number or  $+\infty$ , and to the most negative 32-bit integer if the operand in FRB is a negative number,  $-\infty$ , or NaN
    - FR FI are set to zero
    - FPRF is undefined
5. If the operation is a compare,
  - FR FI C are unchanged
  - FPCC is set to reflect unordered
6. If an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets VXSOFT to 1,
  - The FPSCR is set as specified in the instruction description.

## 4.4.2 Zero Divide Exception

### 4.4.2.1 Definition

A Zero Divide Exception occurs when a *Divide* instruction is executed with a zero divisor value and a finite nonzero dividend value. It also occurs when a *Reciprocal Estimate* instruction (*fre[s]* or *frsqrt[e[s]]*) is executed with an operand value of zero.

### 4.4.2.2 Action

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

When Zero Divide Exception is enabled ( $ZE=1$ ) and a Zero Divide Exception occurs, the following actions are taken:

1. Zero Divide Exception is set  
 $ZX \leftarrow 1$
2. The target FPR is unchanged
3. FR FI are set to zero
4. FPRF is unchanged

When Zero Divide Exception is disabled ( $ZE=0$ ) and a Zero Divide Exception occurs, the following actions are taken:

1. Zero Divide Exception is set  
 $ZX \leftarrow 1$
2. The target FPR is set to  $\pm$  Infinity, where the sign is determined by the XOR of the signs of the operands
3. FR FI are set to zero
4. FPRF is set to indicate the class and sign of the result ( $\pm$  Infinity)

1. Overflow Exception is set  
 $OX \leftarrow 1$
2. Inexact Exception is set  
 $XX \leftarrow 1$
3. The result is determined by the rounding mode (RN) and the sign of the intermediate result as follows:
  - Round to Nearest  
Store  $\pm$  Infinity, where the sign is the sign of the intermediate result
  - Round toward Zero  
Store the format's largest finite number with the sign of the intermediate result
  - Round toward + Infinity  
For negative overflow, store the format's most negative finite number; for positive overflow, store +Infinity
  - Round toward - Infinity  
For negative overflow, store -Infinity; for positive overflow, store the format's largest finite number
4. The result is placed into the target FPR
5. FR is undefined
6. FI is set to 1
7. FPRF is set to indicate the class and sign of the result ( $\pm$  Infinity or  $\pm$  Normal Number)

## 4.4.3 Overflow Exception

### 4.4.3.1 Definition

An Overflow Exception occurs when the magnitude of what would have been the rounded result if the exponent range were unbounded exceeds that of the largest finite number of the specified result precision.

### 4.4.3.2 Action

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

When Overflow Exception is enabled ( $OE=1$ ) and an Overflow Exception occurs, the following actions are taken:

1. Overflow Exception is set  
 $OX \leftarrow 1$
2. For double-precision arithmetic instructions, the exponent of the normalized intermediate result is adjusted by subtracting 1536
3. For single-precision arithmetic instructions and the *Floating Round to Single-Precision* instruction, the exponent of the normalized intermediate result is adjusted by subtracting 192
4. The adjusted rounded result is placed into the target FPR
5. FPRF is set to indicate the class and sign of the result ( $\pm$  Normal Number)

When Overflow Exception is disabled ( $OE=0$ ) and an Overflow Exception occurs, the following actions are taken:

## 4.4.4 Underflow Exception

### 4.4.4.1 Definition

Underflow Exception is defined separately for the enabled and disabled states:

- Enabled:  
Underflow occurs when the intermediate result is “Tiny”.
- Disabled:  
Underflow occurs when the intermediate result is “Tiny” and there is “Loss of Accuracy”.

A “Tiny” result is detected before rounding, when a non-zero intermediate result computed as though both the precision and the exponent range were unbounded would be less in magnitude than the smallest normalized number.

If the intermediate result is “Tiny” and Underflow Exception is disabled ( $UE=0$ ) then the intermediate result is denormalized (see Section 4.3.4, “Normalization and Denormalization” on page 141) and rounded (see Section 4.3.6, “Rounding” on page 143) before being placed into the target FPR.

“Loss of Accuracy” is detected when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

### 4.4.4.2 Action

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

When Underflow Exception is enabled ( $UE=1$ ) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set  
 $UX \leftarrow 1$
2. For double-precision arithmetic instructions, the exponent of the normalized intermediate result is adjusted by adding 1536
3. For single-precision arithmetic instructions and the *Floating Round to Single-Precision* instruction, the exponent of the normalized intermediate result is adjusted by adding 192
4. The adjusted rounded result is placed into the target FPR
5. FPRF is set to indicate the class and sign of the result ( $\pm$  Normalized Number)

### Programming Note

The FR and FI bits are provided to allow the system floating-point enabled exception error handler, when invoked because of an Underflow Exception, to simulate a “trap disabled” environment. That is, the FR and FI bits allow the system floating-point enabled exception error handler to unround the result, thus allowing the result to be denormalized.

When Underflow Exception is disabled ( $UE=0$ ) and an Underflow Exception occurs, the following actions are taken:

1. Underflow Exception is set  
 $UX \leftarrow 1$
2. The rounded result is placed into the target FPR
3. FPRF is set to indicate the class and sign of the result ( $\pm$  Normalized Number,  $\pm$  Denormalized Number, or  $\pm$  Zero)

## 4.4.5 Inexact Exception

### 4.4.5.1 Definition

An Inexact Exception occurs when one of two conditions occur during rounding:

1. The rounded result differs from the intermediate result assuming both the precision and the exponent range of the intermediate result to be unbounded. In this case the result is said to be inexact. (If the rounding causes an enabled Overflow Exception or an enabled Underflow Exception, an Inexact Exception also occurs only if the significands of the rounded result and the intermediate result differ.)
2. The rounded result overflows and Overflow Exception is disabled.

### 4.4.5.2 Action

The action to be taken does not depend on the setting of the Inexact Exception Enable bit of the FPSCR.

When an Inexact Exception occurs, the following actions are taken:

1. Inexact Exception is set  
 $XX \leftarrow 1$
2. The rounded or overflowed result is placed into the target FPR
3. FPRF is set to indicate the class and sign of the result

### Programming Note

In some implementations, enabling Inexact Exceptions may degrade performance more than does enabling other types of floating-point exception.

## 4.5 Floating-Point Execution Models

All implementations of this architecture must provide the equivalent of the following execution models to ensure that identical results are obtained.

Special rules are provided in the definition of the computational instructions for the infinities, denormalized numbers and NaNs. The material in the remainder of this section applies to instructions that have numeric operands and a numeric result (i.e., operands and result that are not infinities or NaNs), and that cause no exceptions. See Section 4.3.2 and Section 4.4 for the cases not covered here.

Although the double format specifies an 11-bit exponent, exponent arithmetic makes use of two additional bits to avoid potential transient overflow conditions. One extra bit is required when denormalized double-precision numbers are prenormalized. The second bit is required to permit the computation of the adjusted exponent value in the following cases when the corresponding exception enable bit is 1:

- Underflow during multiplication using a denormalized operand.
- Overflow during division using a denormalized divisor.

The IEEE standard includes 32-bit and 64-bit arithmetic. The standard requires that single-precision arithmetic be provided for single-precision operands. The standard permits double-precision floating-point operations to have either (or both) single-precision or double-precision operands, but states that single-precision floating-point operations should not accept double-precision operands. The Power ISA follows these guidelines; double-precision arithmetic instructions can have operands of either or both precisions, while single-precision arithmetic instructions require all operands to be single-precision. Double-precision arithmetic instructions and *fcfid* produce double-precision values, while single-precision arithmetic instructions produce single-precision values.

For arithmetic instructions, conversions from double-precision to single-precision must be done explicitly by software, while conversions from single-precision to double-precision are done implicitly.

### 4.5.1 Execution Model for IEEE Operations

The following description uses 64-bit arithmetic as an example. 32-bit arithmetic is similar except that the `FRACTION` is a 23-bit field, and the single-precision Guard, Round, and Sticky bits (described in this section) are logically adjacent to the 23-bit `FRACTION` field.

IEEE-conforming significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:55 comprise the significand of the intermediate result.

Figure 53. IEEE 64-bit execution model

The S bit is the sign bit.

The C bit is the carry bit, which captures the carry out of the significand.

The L bit is the leading unit bit of the significand, which receives the implicit bit from the operand.

The `FRACTION` is a 52-bit field that accepts the fraction of the operand.

The Guard (G), Round (R), and Sticky (X) bits are extensions to the low-order bits of the accumulator. The G and R bits are required for postnormalization of the result. The G, R, and X bits are required during rounding to determine if the intermediate result is equally near the two nearest representable values. The X bit serves as an extension to the G and R bits by representing the logical OR of all bits that may appear to the low-order side of the R bit, due either to shifting the accumulator right or to other generation of low-order result bits. The G and R bits participate in the left shifts with zeros being shifted into the R bit. Figure 54 shows the significance of the G, R, and X bits with respect to the intermediate result (IR), the representable number next lower in magnitude (NL), and the representable number next higher in magnitude (NH).

G R X	Interpretation
0 0 0	IR is exact
0 0 1	IR closer to NL
0 1 0	
0 1 1	IR midway between NL and NH
1 0 0	
1 0 1	
1 1 0	
1 1 1	IR closer to NH

Figure 54. Interpretation of G, R, and X bits

Figure 55 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers relative to the accumulator illustrated in Figure 53.

Format	Guard	Round	Sticky
Double	G bit	R bit	X bit
Single	24	25	OR of 26:52, G, R, X

Figure 55. Location of the Guard, Round, and Sticky bits in the IEEE execution model

The significand of the intermediate result is prepared for rounding by shifting its contents right, if required, until the least significant bit to be retained is in the low-order bit position of the fraction. Four user-selectable rounding modes are provided through RN as described in Section 4.3.6, “Rounding” on page 143. Using Z1 and Z2 as defined on page 143, the rules for rounding in each mode are as follows.

- **Round to Nearest**

- **Guard bit = 0**

- The result is truncated. (Result exact (GRX=000) or closest to next lower value in magnitude (GRX=001, 010, or 011))

- **Guard bit = 1**

- Depends on Round and Sticky bits:

- **Case a**

- If the Round or Sticky bit is 1 (inclusive), the result is incremented. (Result closest to next higher value in magnitude (GRX=101, 110, or 111))

- **Case b**

- If the Round and Sticky bits are 0 (result midway between closest representable values), then if the low-order bit of the result is 1 the result is incremented. Otherwise (the low-order bit of the result is 0) the result is truncated (this is the case of a tie rounded to even).

- **Round toward Zero**

- Choose the smaller in magnitude of Z1 or Z2. If the Guard, Round, or Sticky bit is nonzero, the result is inexact.

- **Round toward + Infinity**

- Choose Z1.

- **Round toward - Infinity**

- Choose Z2.

If rounding results in a carry into C, the significand is shifted right one position and the exponent is incremented by one. This yields an inexact result, and possibly also exponent overflow. If any of the Guard, Round, or Sticky bits is nonzero, then the result is also inexact. Fraction bits are stored to the target FPR. For *Floating Round to Integer*, *Floating Round to Single-Precision*, and single-precision arithmetic instructions, low-order zeros must be appended as appropriate to fill out the double-precision fraction.

## 4.5.2 Execution Model for Multiply-Add Type Instructions

The Power ISA provides a special form of instruction that performs up to three operations in one instruction (a multiplication, an addition, and a negation). With this added capability comes the special ability to produce a more exact intermediate result as input to the rounder. 32-bit arithmetic is similar except that the FRACTION field is smaller.

Multiply-add significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0:106 comprise the significand of the intermediate result.

**Figure 56. Multiply-add 64-bit execution model**

The first part of the operation is a multiplication. The multiplication has two 53-bit significands as inputs, which are assumed to be prenormalized, and produces a result conforming to the above model. If there is a carry out of the significand (into the C bit), then the significand is shifted right one position, shifting the L bit (leading unit bit) into the most significant bit of the FRACTION and shifting the C bit (carry out) into the L bit. All 106 bits (L bit, the FRACTION) of the product take part in the add operation. If the exponents of the two inputs to the adder are not equal, the significand of the operand with the smaller exponent is aligned (shifted) to the right by an amount that is added to that exponent to make it equal to the other input's exponent. Zeros are shifted into the left of the significand as it is aligned and bits shifted out of bit 105 of the significand are ORed into the X' bit. The add operation also produces a result conforming to the above model with the X' bit taking part in the add operation.

The result of the addition is then normalized, with all bits of the addition result, except the X' bit, participating in the shift. The normalized result serves as the intermediate result that is input to the rounder.

For rounding, the conceptual Guard, Round, and Sticky bits are defined in terms of accumulator bits. Figure 57 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers in the multiply-add execution model.

Format	Guard	Round	Sticky
Double	53	54	OR of 55:105, X'
Single	24	25	OR of 26:105, X'

**Figure 57. Location of the Guard, Round, and Sticky bits in the multiply-add execution model**

The rules for rounding the intermediate result are the same as those given in Section 4.5.1.

If the instruction is *Floating Negative Multiply-Add* or *Floating Negative Multiply-Subtract*, the final result is negated.

## 4.6 Floating-Point Facility Instructions

### 4.6.1 Floating-Point Storage Access Instructions

The *Storage Access* instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3, “Effective Address Calculation” on page 30.

#### Programming Note

The *la* extended mnemonic permits computing an effective address as a *Load* or *Store* instruction would, but loads the address itself into a GPR rather than loading the value that is in storage at that address. This extended mnemonic is described in Section C.10, “Miscellaneous Mnemonics” on page 1032.

#### 4.6.1.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (*Store* only), or if the program attempts to access storage that is unavailable.

## 4.6.2 Floating-Point Load Instructions

There are three basic forms of load instruction: single-precision, double-precision, and integer. The integer form is provided by the *Load Floating-Point as Integer Word Algebraic* instruction, described on page 157. Because the FPRs support only floating-point double format, single-precision *Load Floating-Point* instructions convert single-precision data to double format prior to loading the operand into the target FPR. The conversion and loading steps are as follows.

Let  $WORD_{0:31}$  be the floating-point single-precision operand accessed from storage.

### Normalized Operand

```

if  $WORD_{1:8} > 0$  and  $WORD_{1:8} < 255$  then
   $FRT_{0:1} \leftarrow WORD_{0:1}$ 
   $FRT_2 \leftarrow \neg WORD_1$ 
   $FRT_3 \leftarrow \neg WORD_1$ 
   $FRT_4 \leftarrow \neg WORD_1$ 
   $FRT_{5:63} \leftarrow WORD_{2:31} \parallel 2^9_0$ 

```

### Denormalized Operand

```

if  $WORD_{1:8} = 0$  and  $WORD_{9:31} \neq 0$  then
  sign  $\leftarrow WORD_0$ 
  exp  $\leftarrow -126$ 
   $frac_{0:52} \leftarrow 0b0 \parallel WORD_{9:31} \parallel 2^9_0$ 
  normalize the operand
  do while  $frac_0 = 0$ 
     $frac_{0:52} \leftarrow frac_{1:52} \parallel 0b0$ 
    exp  $\leftarrow exp - 1$ 
   $FRT_0 \leftarrow sign$ 
   $FRT_{1:11} \leftarrow exp + 1023$ 
   $FRT_{12:63} \leftarrow frac_{1:52}$ 

```

### Zero / Infinity / NaN

```

if  $WORD_{1:8} = 255$  or  $WORD_{1:31} = 0$  then
   $FRT_{0:1} \leftarrow WORD_{0:1}$ 
   $FRT_2 \leftarrow WORD_1$ 
   $FRT_3 \leftarrow WORD_1$ 
   $FRT_4 \leftarrow WORD_1$ 
   $FRT_{5:63} \leftarrow WORD_{2:31} \parallel 2^9_0$ 

```

For double-precision *Load Floating-Point* instructions and for the *Load Floating-Point as Integer Word Algebraic* instruction no conversion is required, as the data from storage are copied directly into the FPR.

Many of the *Load Floating-Point* instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if  $RA \neq 0$ , the effective address is placed into register RA and the storage element (word or doubleword) addressed by EA is loaded into FRT.

**Note:** Recall that RA and RB denote General Purpose Registers, while FRT denotes a Floating-Point Register.

**Load Floating-Point Single D-form**

lfs            FRT,D(RA)

48	FRT	RA	D
0	6	11	16
31			31

**Prefixed Load Floating-Point Single  
MLS:D-form**

plfs            FRT,D(RA),R

Prefix:

1	2	0	//	R	//	d0
0	6	8	9	11	12	14
31						31

Suffix::

48	FRT	RA	d1
0	6	11	16
31			31

```

if "lfs" then
    EA ← (RA|0) + EXTS64(D)
if "plfs" & R=0 then
    EA ← (RA|0) + EXTS64(d0||d1)
if "plfs" & R=1 then
    EA ← CIA + EXTS64(d0||d1)

```

```

FRT ← DOUBLE(MEM(EA, 4))

```

For **lfs**, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value D, sign-extended to 64 bits.

For **plfs** with R=0, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0||d1, sign-extended to 64 bits.

For **plfs** with R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0||d1, sign-extended to 64 bits.

The word in storage addressed by EA is interpreted as a floating-point single-precision operand. This word is converted to floating-point double format (see page 153) and placed into register FRT.

For **plfs**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

**Special Registers Altered:**

None

The word in storage addressed by EA is loaded into  $FRT_{32:63}$ .  $FRT_{0:31}$  are set to 0.

**Special Registers Altered:**

None

### 4.6.3 Floating-Point Store Instructions

There are three basic forms of store instruction: single-precision, double-precision, and integer. The integer form is provided by the *Store Floating-Point as Integer Word* instruction, described on page 162. Because the FPRs support only floating-point double format for floating-point data, single-precision *Store Floating-Point* instructions convert double-precision data to single format prior to storing the operand into storage. The conversion steps are as follows.

Let  $WORD_{0:31}$  be the word in storage written to.

#### **No Denormalization Required (includes Zero / Infinity / NaN)**

```
if  $FRS_{1:11} > 896$  or  $FRS_{1:63} = 0$  then
   $WORD_{0:1} \leftarrow FRS_{0:1}$ 
   $WORD_{2:31} \leftarrow FRS_{5:34}$ 
```

#### **Denormalization Required**

```
if  $874 \leq FRS_{1:11} \leq 896$  then
  sign  $\leftarrow FRS_0$ 
  exp  $\leftarrow FRS_{1:11} - 1023$ 
  frac $_{0:52} \leftarrow 0b1 \parallel FRS_{12:63}$ 
  denormalize operand
  do while exp < -126
    frac $_{0:52} \leftarrow 0b0 \parallel frac_{0:51}$ 
    exp  $\leftarrow exp + 1$ 
   $WORD_0 \leftarrow sign$ 
   $WORD_{1:8} \leftarrow 0x00$ 
   $WORD_{9:31} \leftarrow frac_{1:23}$ 
else WORD  $\leftarrow$  undefined
```

Notice that if the value to be stored by a single-precision *Store Floating-Point* instruction is larger in magnitude than the maximum number representable in single format, the first case above (No Denormalization Required) applies. The result stored in WORD is then a well-defined value, but is not numerically equal to the value in the source register (i.e., the result of a single-precision *Load Floating-Point* from WORD will not compare equal to the contents of the original source register).

For double-precision *Store Floating-Point* instructions and for the *Store Floating-Point as Integer Word* instruction no conversion is required, as the data from the FPR are copied directly into storage.

Many of the *Store Floating-Point* instructions have an “update” form, in which register RA is updated with the effective address. For these forms, if  $RA \neq 0$ , the effective address is placed into register RA.

**Note:** Recall that RA and RB denote General Purpose Registers, while FRS denotes a Floating-Point Register.

## 4.6.4 Floating-Point Load and Store Double Pair Instructions [Phased-Out]

For *lfdp[x]*, the doubleword-pair in storage addressed by EA is loaded into an even-odd pair of FPRs with the even-numbered FPR being loaded with the leftmost doubleword from storage and the odd-numbered FPR being loaded with the rightmost doubleword.

For *stfdp[x]*, the content of an even-odd pair of FPRs is stored into the doubleword-pair in storage addressed by EA, with the even-numbered FPR being stored into the leftmost doubleword in storage and the

odd-numbered FPR being stored into the rightmost doubleword.

### Programming Note

The instructions described in this section should not be used to access an operand in DFP Extended format when the processor is in Little-Endian mode.

### Load Floating-Point Double Pair DS-form

*lfdp*            FRTp,DS(RA)

57	FRTp	RA	DS	0
0	6	11	16	30 31

```

if RA = 0 then b ← 0

## 4.6.6 Floating-Point Arithmetic Instructions

### 4.6.6.1 Floating-Point Elementary Arithmetic Instructions

#### Floating Add A-form

fadd           FRT,FRA,FRB                                 (RC=0)  
 fadd.        FRT,FRA,FRB                                 (RC=1)

#### Floating Add Single A-form

fadds         FRT,FRA,FRB                                 (RC=0)  
 fadds.       FRT,FRA,FRB                                 (RC=1)

The floating-point operand in register FRA is added to the floating-point operand in register FRB.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN and placed into register FRT.

Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.

If a carry occurs, the sum’s significand is shifted right one bit position and the exponent is increased by one.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1 and Zero Divide Exceptions when ZE=1.

The results of executing this instruction may vary between implementations, and between different executions on the same implementation.

**Special Registers Altered:**

FPRF FR (undefined) FI (undefined)  
FX OX UX ZX XX (undefined)  
VXSNAN  
CR1 (if Rc=1)

**Programming Note**

For the *Floating-Point Estimate* instructions, some implementations might implement a precision higher than the minimum architected precision. Thus, a program may take advantage of the higher precision instructions to increase performance by decreasing the iterations needed for software emulation of floating-point instructions. However, there is no guarantee given about the precision which may vary (up or down) between implementations. Only programs targeted at a specific implementation (i.e., the program will not be migrated to another implementation) should take advantage of the higher precision of the instructions. All other programs should rely on the minimum architected precision, which will guarantee the program to run properly across different implementations.

### Floating Reciprocal Square Root Estimate A-form

### Floating Test for software Divide X-form

ftdiv BF,FRA,FRB

0	63	BF	//	FRA	FRB	128	/
	6	9	11	16	21	31	

Let  $e_a$  be the unbiased exponent of the double-precision floating-point operand in register FRA.

Let  $e_b$  be the unbiased exponent of the double-precision floating-point operand in register FRB.

$fe\_flag$  is set to 1 if any of the following conditions occurs.

- The double-precision floating-point operand in register FRA is a NaN or an Infinity.
- The double-precision floating-point operand in register FRB is a Zero, a NaN, or an Infinity.
- $e_b$  is less than or equal to -1022.
- $e_b$  is greater than or equal to 1021.
- The double-precision floating-point operand in register FRA is not a zero and the difference,  $e_a - e_b$ , is greater than or equal to 1023.
- The double-precision floating-point operand in register FRA is not a zero and the difference,  $e_a - e_b$ , is less than or equal to -1021.
- The double-precision floating-point operand in register FRA is not a zero and  $e_a$  is less than or equal to -970

Otherwise  $fe\_flag$  is set to 0.

$fg\_flag$  is set to 1 if either of the following conditions occurs.

- The double-precision floating-point operand in register FRA is an Infinity.
- The double-precision floating-point operand in register FRB is a Zero, an Infinity, or a denormalized value.

Otherwise  $fg\_flag$  is set to 0.

If the implementation guarantees a relative error of *fre[s][.]* of less than or equal to  $2^{-14}$ , then  $fl\_flag$  is set to 1. Otherwise  $fl\_flag$  is set to 0.

CR field BF is set to the value  $fl\_flag \parallel fg\_flag \parallel fe\_flag \parallel 0b0$ .

#### Special Registers Altered:

ftsqr      BF,FRB

0	63	BF	//	///	FRB	160	/
		6	9	11	16	21	31

Let  $e_b$  be the unbiased exponent of the double-precision floating-point operand in register FRB.

$fe\_flag$  is set to 1 if either of the following conditions occurs.

- The double-precision floating-point operand in register FRB is a zero, a NaN, or an infinity, or a negative value.
- $e_b$  is less than or equal to -970.

Otherwise  $fe\_flag$  is set to 0.

$fg\_flag$  is set to 1 if the following condition occurs.

- The double-precision floating-point operand in register FRB is a Zero, an Infinity, or a denormalized value.

Otherwise  $fg\_flag$  is set to 0.

If the implementation guarantees a relative error of ***frsqrts***[s][.] of less than or equal to  $2^{-14}$ , then  $fl\_flag$  is set to 1. Otherwise  $fl\_flag$  is set to 0.

CR field BF is set to the value  $fl\_flag \parallel fg\_flag \parallel fe\_flag \parallel 0b0$ .

#### **Special Registers Altered:**

CR field BF

#### **Programming Note**

***ftdiv*** and ***ftsqr*** are provided to accelerate software emulation of divide and square root operations, by performing the requisite special case checking. Software needs only a single branch, on FE=1 (in CR[BF]), to a special case handler. FG and FL may provide further acceleration opportunities.

### 4.6.6.2 Floating-Point Multiply-Add Instructions

These instructions combine a multiply and an add operation without an intermediate rounding operation. The fraction part of the intermediate product is 106 bits wide (L bit, FRACTION), and all 106 bits take part in the add/subtract portion of the instruction.

Status bits are set as follows.

- Overflow, Underflow, and Inexact Exception bits, the FR and FI bits, and the FPRF field are set

based on the final result of the operation, and not on the result of the multiplication.

- Invalid Operation Exception bits are set as if the multiplication and the addition were performed using two separate instructions (*fmul[s]*, followed by *fadd[s]* or *fsub[s]*). That is, multiplication of infinity by 0 or of anything by an SNaN, and/or addition of an SNaN, cause the corresponding exception bits to be set.

#### Floating Multiply-Add A-form

fmadd      FRT,FRA,FRC,FRB      (Rc=0)  
fmadd.     FRT,FRA,FRC,FRB      (Rc=1)

63	FRT	FRA	FRB	FRC	29	Rc

fmsubs.    FRT,FRA,FRC,FRB      (Rc=1)

59	FRT	FRA	FRB	FRC	28	Rc
0	6	11	16	21	26	31

The operation

$$FRT \leftarrow [(FRA) \times (FRC)] - (FRB)$$

is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is subtracted from this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN and placed into register FRT.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

#### Special Registers Altered:

FPRF FR FI  
FX OX UX XX

	6	11	16	21	26	31	31

The operation

$$FRT \leftarrow - ( [(FRA) \times (FRC)] + (FRB) )$$
 is performed.

The floating-point operand in register FRA is multiplied by the floating-point operand in register FRC. The floating-point operand in register FRB is added to this intermediate result.

If the most significant bit of the resultant significand is not 1, the result is normalized. The result is rounded to the target precision under control of RN, then negated and placed into register FRT.

This instruction produces the same result as would be obtained by using the *Floating Multiply-Add* instruction and then negating the result, with the following exceptions.

- QNaNs propagate with no effect on their “sign” bit.
- QNaNs that are generated as the result of a disabled Invalid Operation Exception have a “sign” bit of 0.
- SNaNs that are converted to QNaNs as the result of a disabled Invalid Operation Exception retain the “sign” bit of the SNaN.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

#### 4.6.7.2 Floating-Point Convert To/From Integer Instructions

*Floating Convert with round Double-Precision To Signed Doubleword format X-form*

fctid FRT,FRB (Rc=0)  
 fctid. FRT,FRB (Rc=1)

Let src be the double-precision floating-point value in FRB.

If src is a NaN, then the result is 0x8000\_0000\_0000\_0000, VXCVI is set to 1, and, if src is an SNaN, VXSNaN is set to 1.

Otherwise, src is rounded to a floating-point integer using the rounding mode specified by RN.

If the rounded value is greater than  $2^{63}-1$ , then the result is 0x7FFF\_FFFF\_FFFF\_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than  $-2^{63}$ , then the result is 0x8000\_0000\_0000\_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit signed-integer format, and XX is set to 1 if the result is inexact.

If an enabled Invalid Operation Exception does not occur, then the result is placed into FRT.

The conversion is described fully in Section A.2, “Floating-Point Convert to Integer Model” on page 1009.

Except for enabled Invalid Operation Exceptions, FPRF is undefined. FR is set if the result is incremented when rounded. FI is set if the result is inexact.

### 4.6.7.3 Floating Round to Integer Instructions

The *Floating Round to Integer* instructions provide direct support for rounding functions found in high level languages. For example, *frin*, *friz*, *frip*, and *frim* implement C++ `round()`, `trunc()`, `ceil()`, and `floor()`, respectively. Note that *frin* does not implement the IEEE

Round to Nearest function, which is often further described as “ties to even.” The rounding performed by these instructions is described fully in Section A.4, “Floating-Point Round to Integer Model” on page 1014.

#### Programming Note

These instructions set FR and FI to 0b00 regardless of whether the result is inexact or rounded because there is a desire to preserve the value of XX. Furthermore, it is believed that most programs do not need to know whether these rounding operations produce inexact or rounded results. If it is necessary to determine whether the result is inexact or rounded, software must compare the result with the original source operand.

**Floating Round to Integer Nearest X-form**

frin FRT,FRB (Rc=0)  
frin. FRT,FRB (Rc=1)

0	63	FRT	///	FRB	392	Rc
	6	11	16	21	31	

The floating-point operand in register FRB is rounded to an integral value as follows, with the result placed into register FRT. If the sign of the operand is positive, (FRB) + 0.5 is truncated to an integral value, otherwise (FRB) - 0.5 is truncated to an integral value.

FPRF is set to the class and sign of the result, except for Invalid Operation Exceptions when VE=1.

## 4.6.8 Floating-Point Compare Instructions

The floating-point *Compare* instructions compare the contents of two floating-point registers. Comparison ignores the sign of zero (i.e., regards +0 as equal to -0). The comparison can be ordered or unordered.

The comparison sets one bit in the designated CR field to 1 and the other three to 0. The FPCC is set in the same way.

The CR field and the FPCC are set as follows.

Bit	Name	Description
0	FL	(FRA) < (FRB)
1	FG	(FRA) > (FRB)
2	FE	(FRA) = (FRB)
3	FU	(FRA) ? (FRB) (unordered)

### Floating Compare Unordered X-form

fcmpu BF,FRA,FRB

0	63	BF	//	FRA	FRB	0	/	31
		6	9	11	16	21		

```

if (FRA) is a NaN or
   (FRB) is a NaN then c ← 0b0001
else if (FRA) < (FRB) then c ← 0b1000
else if (FRA) > (FRB) then c ← 0b0100
else
   c ← 0b0010
FPCC ← c
CR4×BF: 4×BF+3 ← c
if (FRA) is an SNaN or
   (FRB) is an SNaN then
   VXSNaN ← 1

```

The floating-point operand in register FRA is compared to the floating-point operand in register FRB. The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, then CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, then VXSNaN is set.

#### Special Registers Altered:

CR field BF  
FPCC  
FX  
VXSNaN

### Floating Compare Ordered X-form

fcmpo BF,FRA,FRB

0	63	BF	//	FRA	FRB	32	/	31
		6	9	11	16	21		

```

if (FRA) is a NaN or
   (FRB) is a NaN then c ← 0b0001
else if (FRA) < (FRB) then c ← 0b1000
else if (FRA) > (FRB) then c ← 0b0100
else
   c ← 0b0010
FPCC ← c
CR4×BF: 4×BF+3 ← c
if (FRA) is an SNaN or
   (FRB) is an SNaN then
   VXSNaN ← 1
   if VE = 0 then VXVC ← 1
else if (FRA) is a QNaN or
   (FRB) is a QNaN then VXVC ← 1

```

The floating-point operand in register FRA is compared to the floating-point operand in register FRB. The result of the compare is placed into CR field BF and the FPCC.

If either of the operands is a NaN, either quiet or signaling, then CR field BF and the FPCC are set to reflect unordered. If either of the operands is a Signaling NaN, then VXSNaN is set and, if Invalid Operation is disabled (VE=0), VXVC is set. If neither operand is a Signaling NaN but at least one operand is a Quiet NaN, then VXVC is set.

#### Special Registers Altered:

CR field BF  
FPCC  
FX  
VXSNaN VXVC

## 4.6.9 Floating-Point Select Instruction

### *Floating Select A-form*

*fsel* FRT,FRA,FRC,FRB (Rc=0)  
*fsel.* FRT,FRA,FRC,FRB (Rc=1)

63	FRT	FRA	FRB	FRC	23	Rc
0	6	11	16	21	26	31

if (FRA)  $\geq$  0.0 then FRT  $\leftarrow$  (FRC)  
 else FRT  $\leftarrow$  (FRB)

The floating-point operand in register FRA is compared to the value zero. If the operand is greater than or equal to zero, register FRT is set to the contents of register FRC. If the operand is less than zero or is a NaN, register FRT is set to the contents of register FRB. The comparison ignores the sign of zero (i.e., regards +0 as equal to -0).

#### Special Registers Altered:

CR1 (if Rc=1)

#### Programming Note

**Warning:** Care must be taken in using *fsel* if IEEE compatibility is required, or if the values being tested can be NaNs or infinities.

### fsel Usage Notes

This section gives examples of how the *Floating Select* instruction can be used to implement certain simple forms of if-then-else constructions, without branching.

The examples show program fragments in an imaginary, C-like, high-level programming language, and the corresponding program fragment using *fsel* and other Power ISA instructions. In the examples, a, b, x, y, and z are floating-point variables, which are assumed to be in FPRs fa, fb, fx, fy, and fz. FPR fs is assumed to be available for scratch space.

**Warning:** Care must be taken in using *fsel* if IEEE compatibility is required, or if the values being tested can be NaNs or infinities; see Section .

#### Comparison to Zero

High-level language:	Power ISA:	Notes
if a ≥ 0.0 then x ← y else x ← z	fsel fx, fa, fy, fz	(1)
if a > 0.0 then x ← y else x ← z	fneg fs, fa fsel fx, fs, fz, fy	(1, 2)
if a = 0.0 then x ← y else x ← z	fsel fx, fa, fy, fz fneg fs, fa fsel fx, fs, fx, fz	(1)

#### Notes:

The following Notes apply to the preceding examples and to the corresponding cases using the other three arithmetic relations (<, ≤, and ≠). They should also be considered when any other use of *fsel* is contemplated.

In these Notes, the “optimized program” is the Power ISA program shown, and the “unoptimized program” (not shown) is the corresponding Power ISA program that uses *fcmpu* and *Branch Conditional* instructions instead of *fsel*.

1. The unoptimized program affects the VXSNAN bit of the FPSCR, and therefore may cause the system error handler to be invoked if the corresponding exception is enabled, while the optimized program does not affect this bit. This property of the optimized program is incompatible with the IEEE standard.
2. The optimized program gives the incorrect result if a is a NaN.

#### Simple if-then-else Constructions

High-level language:	Power ISA:	Notes
if a ≥ b then x ← y else x ← z	fsub fs, fa, fb fsel fx, fs, fy, fz	(4, 5)
if a > b then x ← y else x ← z	fsub fs, fb, fa fsel fx, fs, fz, fy	(3, 4, 5)
if a = b then x ← y else x ← z	fsub fs, fa, fb fsel fx, fs, fy, fz fneg fs, fs fsel fx, fs, fx, fz	(4, 5)

3. The optimized program gives the incorrect result if a and/or b is a NaN (except that it may give the correct result in some cases for the minimum and maximum functions, depending on how those functions are defined to operate on NaNs).
4. The optimized program gives the incorrect result if a and b are infinities of the same sign. (Here it is assumed that Invalid Operation Exceptions are disabled, in which case the result of the subtraction is a NaN. The analysis is more complicated if Invalid Operation Exceptions are enabled, because in that case the target register of the subtraction is unchanged.)
5. The optimized program affects the OX, UX, XX, and VXSI bits of the FPSCR, and therefore may cause the system error handler to be invoked if the corresponding exceptions are enabled, while the unoptimized program does not affect these bits. This property of the optimized program is incompatible with the IEEE standard.

## 4.6.10 Floating-Point Status and Control Register Instructions

Except as described below for *mffsce*, *mffscdrn*[], *mffscrn*[], and *mffsl*, *Floating-Point Status and Control Register* instructions synchronize the effects of all floating-point instructions executed by a given processor. Executing a *Floating-Point Status and Control Register* instruction ensures that all floating-point instructions previously initiated by the given processor have completed before the *Floating-Point Status and Control Register* instruction is initiated, and that no subsequent floating-point instructions are initiated by the given processor until the *Floating-Point Status and Control Register* instruction has completed. In particular:

- All exceptions that will be caused by the previously initiated instructions are recorded in the FPSCR before the Floating-Point Status and Control Register instruction is initiated.
- All invocations of the system floating-point enabled exception error handler that will be caused by the previously initiated instructions have occurred before the Floating-Point Status and Control Register instruction is initiated.
- No subsequent floating-point instruction that depends on or alters the settings of any FPSCR bits is initiated until the Floating-Point Status and Control Register instruction has completed.

While not satisfying all of the conditions described above, *mffsce*, *mffscdrn*[], *mffscrn*[], and *mffsl* still obey the sequential execution model. Any FPSCR status bits read by *mffsce* or *mffsl* will reflect updates due to all preceding floating-point instructions. That is, all floating-point instructions following an *mffsce*, *mffscdrn*[], or *mffscrn*[] will execute based on any updates applied to any control bits in the FPSCR by the *mffsce*, *mffscdrn*[], or *mffscrn*[].

(Floating-point *Storage Access* instructions are not affected.)

The instruction descriptions in this section refer to “FPSCR fields,” where FPSCR field k is FPSCR bits 4\*k: 4\*k+3.

### **Move From FPSCR X-form**

mffs             FRT                             (RC=0)  
mffs.            FRT                             (RC=1)

0	63	FRT	0	///	583	Rc
		6	11	16	21	31

The contents of the FPSCR are placed into register FRT.

If RC=1, CR field 1 is set to the value FX||FEX||VX||0X.

### **Special Registers Altered:**

CR1   (if RC=1)

### **Move From FPSCR & Clear Enables X-form**

mffsce          FRT

0	63	FRT	1	///	583	/
		6	11	16	21	31

The contents of the FPSCR are placed into register FRT.

The contents of bits 56:60 (VE, OE, UE, ZE, XE) of the FPSCR are set to 0.

### **Special Registers Altered:**

VE (set to 0)   OE (set to 0)   UE (set to 0)  
ZE (set to 0)   XE (set to 0)

### **Move From FPSCR Control & Set DRN X-form**

mffscdrn        FRT,FRB

0	63	FRT	20	FRB	583	/
		6	11	16	21	31

Let *new\_DRN* be the contents of bits 29:31 of register FRB.

The contents of the control bits in the FPSCR, that is, bits 29:31 (DRN) and bits 56:63 (VE, OE, UE, ZE, XE, NI, RN), are placed into the corresponding bits in register FRT. All other bits in register FRT are set to 0.

*new\_DRN* is placed into bits 62:64 of the FPSCR (DRN).

### **Special Registers Altered:**

DRN

#### **Programming Note**

*mffscdrn* permits software to simultaneously read control bits in the FPSCR and set the DRN field without the higher latency typically associated with accessing the status bits.

### Move From FPSCR Control & Set DRN Immediate X-form

mffsdrni FRT,DRM

0	63	FRT	21	//	DRM	583	/
	6		11	16	18	21	31

The contents of the control bits in the FPSCR, that is, bits 29:31 (DRN) and bits 56:63 (VE, OE, UE, ZE, XE, NI, RN), are placed into the corresponding bits in register FRT. All other bits in register FRT are set to 0.

The contents of bits 29:31 of the FPSCR (DRN) are set to the value of DRM.

#### Special Registers Altered:

DRN

#### Programming Note

*mffsdrni* permits software to simultaneously read control bits in the FPSCR and set the DRN field without the higher latency typically associated with accessing the status bits.

### Move From FPSCR Control & Set RN X-form

mffscrn FRT,FRB

0	63	FRT	22	FRB	583	/
	6		11	16	21	31

Let *new\_RN* be the contents of bits 62:63 of register FRB.

The contents of the control bits in the FPSCR, that is, bits 29:31 (DRN) and bits 56:63 (VE, OE, UE, ZE, XE, NI, RN), are placed into the corresponding bits in register FRT. All other bits in register FRT are set to 0.

*new\_RN* is placed into bits 62:63 of the FPSCR (RN).

#### Special Registers Altered:

RN

#### Programming Note

*mffscrn* permits software to simultaneously read control bits in the FPSCR and set the RN field without the higher latency typically associated with accessing the status bits.

### Move From FPSCR Control & Set RN Immediate X-form

mffscrni FRT,RM

0	63	FRT	23	///	RM	583	/
	6		11	16	19	21	31

The contents of the control bits in the FPSCR, that is, bits 29:31 (DRN) and bits 56:63 (VE, OE, UE, ZE, XE, NI, RN), are placed into the corresponding bits in register FRT. All other bits in register FRT are set to 0.

The contents of bits 62:63 of the FPSCR (RN) are set to the value of RM.

#### Special Registers Altered:

RN

#### Programming Note

*mffscrni* permits software to simultaneously read control bits in the FPSCR and set the RN field without the higher latency typically associated with accessing the status bits.

### Move From FPSCR Lightweight X-form

mffsl FRT

0	63	FRT	24	///	583	/
	6		11	16	21	31

The contents of the control bits in the FPSCR, that is, bits 29:31 (DRN) and bits 56:63 (VE, OE, UE, ZE, XE, NI, RN), and the non-sticky status bits in the FPSCR, that is, bits 45:51 (FR, FI, C, FL, FG, FE, FU), are placed into the corresponding bits in register FRT. All other bits in register FRT are set to 0.

#### Special Registers Altered:

None

#### Programming Note

*mffsl* permits software to read the control and non-sticky status bits in the FPSCR without the higher latency typically associated with accessing the sticky status bits.

### Move to Condition Register from FPSCR X-form

mcrcfs BF,BFA

0	63	BF	//	BFA	//	///	64	/
		6	9	11	14	16	21	31

The contents of FPSCR<sub>32:63</sub> field BFA are copied to Condition Register field BF. All exception bits copied are set to 0 in the FPSCR. If the FX bit is copied, it is set to 0 in the FPSCR.

#### Special Registers Altered:

CR field BF  
 FX OX (if BFA=0)  
 UX ZX XX VXSNaN (if BFA=1)  
 VXI SI VXI DI VXZDZ VXI MZ (if BFA=2)  
 VXVC (if BFA=3)  
 VXSOFT VXSQRT VXCVI (if BFA=5)

### Move To FPSCR Field Immediate X-form

mtfsfi BF,U,W (RC=0)  
 mtfsfi. BF,U,W (RC=1)

0	63	BF	//	///	W	U	/	134	Rc
		6	9	11	15	16	20	21	31

The value of the U field is placed into FPSCR field  $BF+8*(1-W)$ .

FX is altered only if BF=0 and W=0.

#### Special Registers Altered:

FPSCR field  $BF + 8*(1-W)$   
 CR1 (if RC=1)

#### Programming Note

*mtfsfi* serves as both a basic and an extended mnemonic. The Assembler will recognize a *mtfsfi* mnemonic with three operands as the basic form, and a *mtfsfi* mnemonic with two operands as the extended form. In the extended form the W operand is omitted and assumed to be 0.

#### Programming Note

When FPSCR<sub>32:35</sub> is specified, bits 32 (FX) and 35 (OX) are set to the values of  $U_0$  and  $U_3$  (i.e., even if this instruction causes OX to change from 0 to 1, FX is set from  $U_0$  and not by the usual rule that FX is set to 1 when an exception bit changes from 0 to 1). Bits 33 and 34 (FEX and VX) are set according to the usual rule, given on page 137, and not from  $U_1:2$ .

### Move To FPSCR Fields XFL-form

mtfsf FLM,FRB,L,W (RC=0)  
 mtfsf. FLM,FRB,L,W (RC=1)

0	63	L	FLM	W	FRB	711	Rc
		6	7	15	16	21	31

The FPSCR is modified as specified by the FLM, L, and W fields.

L=0

The contents of register FRB are placed into the FPSCR under control of the W field and the field mask specified by FLM. W and the field mask identify the 4-bit fields affected. Let  $i$  be an integer in the range 0-7. If  $FLM_i=1$  then FPSCR field  $k$  is set to the contents of the corresponding field of register FRB, where  $k=i+8*(1-W)$ .

L=1

The contents of register FRB are placed into the FPSCR.

FX is not altered implicitly by this instruction.

#### Special Registers Altered:

FPSCR fields selected by mask, L, and W  
 CR1 (if RC=1)

#### Programming Note

*mtfsf* serves as both a basic and an extended mnemonic. The Assembler will recognize a *mtfsf* mnemonic with four operands as the basic form, and a *mtfsf* mnemonic with two operands as the extended form. In the extended form the W and L operands are omitted and both are assumed to be 0.

#### Programming Note

If L=1 or if L=0 and FPSCR<sub>32:35</sub> is specified, bits 32 (FX) and 35 (OX) are set to the values of  $(FRB)_{32}$  and  $(FRB)_{35}$  (i.e., even if this instruction causes OX to change from 0 to 1, FX is set from  $(FRB)_{32}$  and not by the usual rule that FX is set to 1 when an exception bit changes from 0 to 1). Bits 33 and 34 (FEX and VX) are set according to the usual rule, given on page 137, and not from  $(FRB)_{33:34}$ .

**Move To FPSCR Bit 0 X-form**

mtfsb0 BT (Rc=0)  
 mtfsb0. BT (Rc=1)

0	63	BT	///	///	70	Rc	31
	6		11	16	21		

Bit BT+32 of the FPSCR is set to 0.

**Special Registers Altered:**

FPSCR bit BT+32  
 CR1 (if Rc=1)

**Programming Note**  
 Bits 33 and 34 (FEX and VX) cannot be explicitly reset.

**Move To FPSCR Bit 1 X-form**

mtfsb1 BT (Rc=0)  
 mtfsb1. BT (Rc=1)

0	63	BT	///	///	38	Rc	31
	6		11	16	21		

Bit BT+32 of the FPSCR is set to 1.

**Special Registers Altered:**

FPSCR bits BT+32 and FX  
 CR1 (if Rc=1)

**Programming Note**  
 Bits 33 and 34 (FEX and VX) cannot be explicitly set.

## Chapter 5. Decimal Floating-Point

---

### 5.1 Decimal Floating-Point (DFP) Facility Overview

This chapter describes the behavior of the decimal floating-point facility, the supported data types, formats, and classes, and the usage of registers. Also included are the execution model, exceptions, and instructions supported by the decimal floating-point facility.

The decimal floating-point (DFP) facility shares the 32 floating-point registers (FPRs) and the Floating-Point Status and Control Register (FPSCR) with the floating-point (BFP) facility. However, the interpretation of data formats in the FPRs, and the meaning of some control and status bits in the FPSCR are different between the BFP and DFP facilities.

The DFP facility also shares the Condition Register (CR) with the fixed-Point facility, the BFP facility, and the vector facility.

The DFP facility supports three DFP data formats: DFP Short (single precision), DFP Long (double precision), and DFP Extended (quad precision). Most operations are performed on DFP Long or DFP Extended format directly. Support for DFP Short is limited to conversion to and from DFP Long. Some DFP instructions operate on other data types, including signed or unsigned binary fixed-point data, and signed or unsigned decimal data.

DFP instructions are provided to perform arithmetic, compare, test, quantum-adjustment, conversion, and format operations on operands held in FPRs or FPR pairs.

- Arithmetic instructions

These instructions perform addition, subtraction, multiplication, and division operations.

- Compare instructions

These instructions perform a comparison operation on the numerical value of two DFP operands.

- Test instructions

These instructions test the data class, the data group, the exponent, or the number of significant digits of a DFP operand.

- Quantum-adjustment instructions

These instructions convert a DFP number to a result in the form that has the designated exponent, which may be explicitly or implicitly specified.

- Conversion instructions

These instructions perform conversion between different data formats or data types.

- Format instructions

These instructions facilitate composing or decomposing a DFP operand.

These instructions are described in Section 5.6 “DFP Instruction Descriptions” on page 209.

The three DFP data formats allow finite numbers to be represented with different precision and ranges. Special codes are also provided to represent +Infinity, -Infinity, Quiet NaN (Not-a-Number), and Signaling NaN. Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. The encoding of NaNs provides a diagnostic information field. This diagnostic field may be used to indicate such things as the source of an uninitialized variable or the reason an invalid result was produced.

The DFP processor recognizes a set of DFP exceptions which are indicated via bits set in the FPSCR. Additionally, the DFP exception actions depend on the setting of the various exception enable bits in the FPSCR.

The following DFP exceptions are detected by the DFP processor. The exception status bits in the FPSCR are indicated in parentheses.

- Invalid Operation Exception (VX)
  - SNaN (VXSNAN)
  - $\infty - \infty$  (VXI S1)
  - $\infty \div \infty$  (VXI D1)
  - $0 \div 0$  (VXZDZ)
  - $\infty \times 0$  (VXI MZ)
  - Invalid Compare (VXVC)
  - Invalid conversion (VXCVI)
- Zero Divide Exception (ZX)
- Overflow Exception (OX)
- Underflow Exception (UX)
- Inexact Exception (XX)

Each DFP exception and each category of Invalid Operation Exception has an exception status bit in the FPSCR. In addition, each of the five DFP exceptions has a corresponding enable bit in the FPSCR. These enable bits enable or disable the invocation of the system floating-point enabled exception error handler, and may affect the setting of some exception status bits in the FPSCR.

The usage of these bits by the DFP facility differs from the usage by the BFP facility. Section 5.5.10 “DFP Exceptions” on page 201 provides a detailed discussion of DFP exceptions, including the effects of the enable bits.

## 5.2 DFP Register Handling

The following sections describe first how the floating-point registers are utilized by the DFP facility. The subsequent section covers the DFP usage of CR and FPSCR.

### 5.2.1 DFP Usage of Floating-Point Registers

The DFP facility shares the same 32 64-bit FPRs with the BFP facility. Like the FP instructions, DFP instructions also use 5-bit fields for designating the FPRs to hold the source or target operands.

When data in DFP Short format is held in a FPR, it occupies the rightmost 32 bits of the FPR. The *Load Floating-Point as Integer Word Algebraic* instruction is provided to load the rightmost 32 bits of a FPR with a single-word data from storage. The *Store Floating-Point as Integer Word* instruction is available to store the rightmost 32 bits of a FPR to a storage location.

Data in DFP Long format, 64-bit binary fixed-point values, or 64-bit BCD values is held in a FPR using all 64 bits. Data of 64 bits may be loaded from storage via any of the *Load Floating-Point Double* instructions and

stored via any of the *Store Floating-Point Double* instructions.

Data in DFP Extended format or 128-bit BCD values is held in an even-odd FPR pair using all 128 bits. Data of 128 bits must be loaded into the desired even-odd pair of floating-point registers using an appropriate sequence of the *Load Floating-Point Double* instructions and stored using an appropriate sequence of the *Store Floating-Point Double* instructions.

Data used as a source operand by any *Decimal Floating-Point* instruction that was produced, either directly or indirectly, by a *Load Floating-Point Single* instruction, a *Floating Round to Single-Precision* instruction, or a binary floating-point single-precision arithmetic instruction is boundedly undefined.

When an even-odd FPR pair is used to hold a 128-bit operand, the even-numbered FPR is used to hold the leftmost doubleword of the operand and the next higher-numbered FPR is used to hold the rightmost doubleword. A DFP instruction designating an odd-numbered FPR for a 128-bit operand is an invalid instruction form.

#### Programming Note

The *Floating-Point Move* instructions can be used to move operands between FPRs.

The bit definitions for the FPSCR are as follows.

Bit(s)	Description
0:28	Reserved
29:31	<b>DFP Rounding Control</b> (DRN) See Section 5.5.2, “Rounding Mode Specification” on page 199.
000	Round to Nearest, Ties to Even
001	Round toward Zero
010	Round toward +Infinity
011	Round toward -Infinity
100	Round to Nearest, Ties away from 0
101	Round to Nearest, Ties toward 0
110	Round to away from Zero
111	Round to Prepare for Shorter Precision

#### Programming Note

FPSCR<sub>28</sub> is reserved for extension of the DRN field, therefore DRN may be set using the *mtfsfi* instruction to set the rounding mode.

32 **Floating-Point Exception Summary** (FX)  
Every floating-point instruction, except *mtfsfi* and *mtfsf*, implicitly sets FX to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* can alter FX explicitly.

- 33 **Floating-Point Enabled Exception Summary (FEX)**  
This bit is the OR of all the floating-point exception bits masked by their respective enable bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter FEX explicitly.
- 34 **Floating-Point Invalid Operation Exception Summary (VX)**  
This bit is the OR of all the Invalid Operation exception bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter VX explicitly.
- 35 **Floating-Point Overflow Exception (OX)** See Section 5.5.10.3, “Overflow Exception” on page 205.
- 36 **Floating-Point Underflow Exception (UX)**  
See Section 5.5.10.4, “Underflow Exception” on page 205.
- 37 **Floating-Point Zero Divide Exception (ZX)**  
See Section 5.5.10.2, “Zero Divide Exception” on page 204.
- 38 **Floating-Point Inexact Exception (XX)**  
See Section 5.5.10.5, “Inexact Exception” on page 206.  
  
XX is a sticky version of FI (see below). Thus the following rules completely describe how XX is set by a given instruction.
- If the instruction affects FI, the new value of XX is obtained by ORing the old value of XX with the new value of FI.
  - If the instruction does not affect FI, the value of XX is unchanged.
- 39 **Floating-Point Invalid Operation Exception (SNaN) (VXSNAN)**  
See Section 5.5.10.1, “Invalid Operation Exception” on page 203.
- 40 **Floating-Point Invalid Operation Exception (Infinity - Infinity) (VXI SI)**  
See Section 5.5.10.1.
- 41 **Floating-Point Invalid Operation Exception (Infinity ÷ Infinity) (VXI DI)**  
See Section 5.5.10.1.
- 442 **Floating-Point Invalid Operation Exception (Zero ÷ Zero) (VXZDZ)**  
See Section 5.5.10.1.
- 43 **Floating-Point Invalid Operation Exception (Infinity × Zero) (VXI MZ)**  
See Section 5.5.10.1.
- 44 **Floating-Point Invalid Operation Exception (Invalid Compare) (VXVC)**  
See Section 5.5.10.1.
- 45 **Floating-Point Fraction Rounded (FR)**  
The last *Arithmetic* or *Rounding and Conversion* instruction incremented the fraction during rounding. See Section 5.5.1, “Rounding” on page 198. This bit is not sticky.
- 46 **Floating-Point Fraction Inexact (FI)**  
The last *Arithmetic* or *Rounding and Conversion* instruction either produced an inexact result during rounding or caused a disabled Overflow Exception. See Section 5.5.1. This bit is not sticky.  
  
See the definition of XX, above, regarding the relationship between FI and XX.
- 47:51 **Floating-Point Result Flags (FPRF)**  
This field is set as described below. For arithmetic, rounding, and conversion instructions, the field is set based on the result placed into the target register, except that if any portion of the result is undefined then the value placed into FPRF is undefined.
- 47 **Floating-Point Result Class Descriptor (C)**  
Arithmetic, rounding, and conversion instructions may set this bit with the FPCC bits, to indicate the class of the result as shown in Figure 58 on page 194.
- 48:51 **Floating-Point Condition Code (FPCC)**  
Floating-point *Compare* and *DFP Test* instructions set one of the FPCC bits to 1 and the other three FPCC bits to 0. Arithmetic, rounding, and conversion instructions may set the FPCC bits with the C bit, to indicate the class of the result as shown in Figure 58 on page 194. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.
- 48 **Floating-Point Less Than or Negative (FL or <)**
- 49 **Floating-Point Greater Than or Positive (FG or >)**
- 50 **Floating-Point Equal or Zero (FE or =)**
- 51 **Floating-Point Unordered or NaN (FU or ?)**
- 52 Reserved
- 53 **Floating-Point Invalid Operation Exception (Software Request) (VXSOFT)**  
This bit can be altered only by *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, or *mtfsb1*. See Section 5.5.10.1, “Invalid Operation Exception” on page 203.
- 54 Neither used nor changed by DFP.

**Programming Note**

Although the architecture does not provide a DFP square root instruction, if software simulates such an instruction, it should set bit 54 whenever the source operand of the square root function is invalid.

- 55 **Floating-Point Invalid Operation Exception (Invalid Conversion)** (YC)  
See Section 5.5.10.1.
- 56 **Floating-Point Invalid Operation Exception Enable** (FEX)  
See Section 5.5.10.1.
- 57 **Floating-Point Overflow Exception Enable** (FEX)  
See Section 5.5.10.3, “Overflow Exception” on page 205.
- 58 **Floating-Point Underflow Exception Enable** (FEX)  
See Section 5.5.10.4, “Underflow Exception” on page 205.
- 59 **Floating-Point Zero Divide Exception Enable** (FEX)  
See Section 5.5.10.2, “Zero Divide Exception” on page 204.
- 60 **Floating-Point Inexact Exception Enable** (FEX)  
See Section 5.5.10.5, “Inexact Exception” on page 206
- 61 Reserved (not used by FEX)
- 62:63 **Binary Floating-Point Rounding Control** (FEX)  
See Section 5.5.1, “Rounding” on page 198.
  - 00 Round to Nearest
  - 01 Round toward Zero
  - 10 Round toward +Infinity
  - 11 Round toward -Infinity

Result Flags	Result Value Class
<b>C &lt; &gt; = ?</b>	
0 0 0 0 1	Signaling NaN (DFP only)
1 0 0 0 1	Quiet NaN
0 1 0 0 1	- Infinity
0 1 0 0 0	- Normal Number
1 1 0 0 0	- Subnormal Number
1 0 0 1 0	- Zero
0 0 0 1 0	+ Zero
1 0 1 0 0	+ Subnormal Number
0 0 1 0 0	+ Normal Number
0 0 1 0 1	+ Infinity

**Figure 58. Floating-Point Result Flags**

### 5.3 DFP Support for Non-DFP Data Types

In addition to the DFP data types, the DFP processor provides limited support for the following non-DFP data types: signed or unsigned binary fixed-point data, and signed or unsigned decimal data.

In unsigned binary fixed-point data, all bits are used to express the absolute value of the number. For signed binary fixed-point data, the leftmost bit represents the sign, which is followed by the numeric field. Positive numbers are represented in true binary notation with the sign bit set to zero. When the value is zero, all bits are zeros, including the sign bit. Negative numbers are represented in two’s complement binary notation with a one in the sign-bit position.

For decimal data, each byte contains a pair of four-bit nibbles; each four-bit nibble contains a binary-coded-decimal (BCD) code. There are two kinds of BCD codes: digit code and sign code. For unsigned decimal data, all nibbles contain a digit code (D) as shown in Figure 59

**Figure 59. Format for Unsigned Decimal Data**

For signed decimal data, the rightmost nibble contains a sign code (S) and all other nibbles contain a digit code as shown in Figure 60.

**Figure 60. Format for Signed Decimal Data**

The decimal digits 0-9 have the binary encoding 0000-1001. The preferred plus-sign codes are 1100 and 1111. The preferred minus sign code is 1101. These are the sign codes generated for the results of the *Decode DPD To BCD* instruction. A selection is provided by this instruction to specify which of the two preferred plus sign codes is to be generated. Alternate sign codes are also recognized as valid in the sign position: 1010 and 1110 are alternate sign codes for plus, and 1011 is an alternate sign code for minus. Alternate sign codes are accepted for any source operand, but are not generated as a result by the instruction. When an invalid digit or sign code is detected by the *Encode BCD To DPD* instruction, an invalid-operation exception occurs. A

summary of digit and sign codes are provided in Figure 61.

Binary Code	Recognized As	
	Digit	Sign
0000	0	Invalid
0001	1	Invalid
0010	2	Invalid
0011	3	Invalid
0100	4	Invalid
0101	5	Invalid
0110	6	Invalid
0111	7	Invalid
1000	8	Invalid
1001	9	Invalid
1010	Invalid	Plus
1011	Invalid	Minus
1100	Invalid	Plus (preferred; option 1)
1101	Invalid	Minus (preferred)
1110	Invalid	Plus
1111	Invalid	Plus (preferred; option 2)

Figure 61. Summary of BCD Digit and Sign Codes

## 5.4 DFP Number Representation

A DFP finite number consists of three components: a sign bit, a signed exponent, and a significand. The signed exponent is a signed binary integer. The *significand* consists of a number of decimal digits, which are to the left of the implied decimal point. The rightmost digit of the significand is called the *units* digit. The numerical value of a DFP finite number is represented as  $(-1)^{sign} \times significand \times 10^{exponent}$  and the unit value of this number is  $(1 \times 10^{exponent})$ , which is called the *quantum*.

DFP finite numbers are not normalized. This allows leading zeros and trailing zeros to exist in the significand. This unnormalized DFP number representation allows some values to have redundant forms; each form represents the DFP number with a different combination of the significand value and the exponent value. For example,  $1000000 \times 10^5$  and  $10 \times 10^{10}$  are two different forms of the same numerical value. A *form* of this number representation carries information about both the numerical value and the quantum of a DFP finite number.

The *significant digits* of a DFP finite number are the digits in the significand beginning with the leftmost non-zero digit and ending with the units digit.

### 5.4.1 DFP Data Format

DFP numbers and NaNs may be represented in FPRs in any of the three data formats: DFP Short, DFP Long, or DFP Extended. The contents of each data format represent encoded information. Special codes are assigned to NaNs and infinities. Different formats support different sizes in both significand and exponent. Arithmetic, compare, test, quantum-adjustment, and format instructions are provided for DFP Long and DFP Extended formats only.

The *sign* is encoded as a one bit binary value. *Significand* is encoded as an unsigned decimal integer in two distinct parts. The leftmost digit (LMD) of the *significand* is encoded as part of the *combination* field; the remaining digits of the *significand* are encoded in the *trailing significand* field. The *exponent* is contained in the *combination* field in two parts. However, prior to encoding, the *exponent* is converted to an unsigned binary value called the *biased exponent* by adding a *bias* value which is a constant for each format. The two leftmost bits of the *biased exponent* are encoded with the leftmost digit of the significand in the leftmost bits of the combination field. The rest of the biased exponent occupies the remaining portion of the *combination* field.

#### 5.4.1.1 Fields Within the Data Format

The DFP data representation comprises three fields, as diagrammed below for each of the three formats:

Figure 62. DFP Short format

Figure 63. DFP Long format

Figure 64. DFP Extended format

The fields are defined as follows:

#### Sign bit (S)

The sign bit is in bit 0 of each format, and is zero for plus and one for minus.

#### Combination field (G)

As the name implies, this field provides a combination of the exponent and the left-most digit (LMD) of the significand, for finite numbers, or provides a special code

for denoting the value as either a Not-a-Number or an Infinity.

The first 5 bits of the combination field contain the encoding of NaN or infinity, or the two leftmost bits of the biased exponent and the leftmost digit (LMD) of the significand. The following tables show the encoding:

G <sub>0:4</sub>	Description
11111	NaN
11110	Infinity
All others	Finite Number (see Figure 66)

**Figure 65. Encoding of the G field for Special Symbols**

LMD	Leftmost 2-bits of biased exponent		
	00	01	10
0	00000	01000	10000
1	00001	01001	10001
2	00010	01010	10010
3	00011	01011	10011
4	00100	01100	10100
5	00101	01101	10101
6	00110	01110	10110
7	00111	01111	10111
8	11000	11010	11100
9	11001	11011	11101

**Figure 66. Encoding of bits 0:4 of the G field for Finite Numbers**

For DFP finite numbers, the rightmost N-5 bits of the N-bit combination field contain the remaining bits of the *biased exponent*. For NaNs, bit 5 of the combination field is used to distinguish a Quiet NaN from a Signaling NaN; the remaining bits in a source operand are ignored and they are set to zeros in a target operand by most operations. For infinities, the rightmost N-5 bits of the N-bit combination field of a source operand are ignored and they are set to zeros in a target operand by most operations.

#### **Trailing Significand field (T)**

For DFP finite numbers, this field contains the remaining *significand* digits. For NaNs, this field may be used to contain diagnostic information. For infinities, contents in this field of a source operand are ignored and they are set to zeros in a target operand by most operations. The trailing significand field is a multiple of 10-bit blocks. The multiple depends on the format. Each 10-bit block is called a *delet* and represents three decimal digits, using the *Densely Packed Decimal (DPD)* encoding defined in Appendix B.

### **5.4.1.2 Summary of DFP Data Formats**

The properties of the three DFP formats are summarized in the following table:

	Format		
	DFP Short	DFP Long	DFP Extended
Widths (bits):			
Format	32	64	128
Sign (S)	1	1	1
Combination (G)	11	13	17
Trailing Significand (T)	20	50	110
Exponent:			
Maximum biased	191	767	12, 287
Maximum ( $X_{max}$ )	90	369	6111
Minimum ( $X_{min}$ )	-101	-398	-6176
Bias	101	398	6176
Precision (p) (digits)	7	16	34
Magnitude:			
Maximum normal number ( $N_{max}$ )	$(10^7 - 1) \times 10^{90}$	$(10^{16} - 1) \times 10^{369}$	$(10^{34} - 1) \times 10^{6111}$
Minimum normal number ( $N_{min}$ )	$1 \times 10^{-95}$	$1 \times 10^{-383}$	$1 \times 10^{-6143}$
Minimum subnormal number ( $D_{min}$ )	$1 \times 10^{-101}$	$1 \times 10^{-398}$	$1 \times 10^{-6176}$

**Figure 67. Summary of DFP Formats**

### 5.4.1.3 Preferred DPD Encoding

Execution of DFP instructions decodes source operands from DFP data formats to an internal format for processing, and encodes the operation result before the final result is returned as the target operand.

As part of the decoding process, declets in the trailing significand field of source operands are decoded to their corresponding BCD digit codes using the DPD-to-BCD decoding algorithm. As part of the encoding process, BCD digit codes to be stored into the trailing significand field of the target operand are encoded into declets using the BCD-to-DPD encoding algorithm. Both the decoding and encoding algorithms are defined in Appendix B.

As explained in Appendix B, there are eight 3-digit decimal values that have redundant DPD codes and one preferred DPD code. All redundant DPD codes are recognized in source operands for the associated 3-digit decimal number. DFP operations will always generate the preferred DPD codes for the trailing significand field of the target operand.

## 5.4.2 Classes of DFP Data

There are six classes of DFP data, which include numerical and nonnumeric entities. The numerical entities include zero, subnormal number, normal number, and infinity data classes. The nonnumeric entities include quiet and signaling NaNs data classes. The value of a DFP finite number, including zero, subnormal number, and normal number, is a quantization of the real number based on the data format. The *Test Data Class* instruction may be used to determine the class of a DFP operand. In general, an operation that returns a DFP result sets the FPRF field to indicate the data class of the result.

The following tables show the value ranges for finite-number data classes, and the codes for NaNs and infinities.

Data Class	Sign	Magnitude
Zero	±	0*
Subnormal	±	$D_{min} \leq  X  < N_{min}$
Normal	±	$N_{min} \leq  Y  \leq N_{max}$
* The significand is zero and the exponent is any representable value		

**Figure 68. Value Ranges for Finite Number Data Classes**

Data Class	S	G	T
+Infinity	0	11110xxx . . . xxx	xxx . . . xxx
-Infinity	1	11110xxx . . . xxx	xxx . . . xxx
Quiet NaN	x	111110xx . . . xxx	xxx . . . xxx
Signaling NaN	x	111111xx . . . xxx	xxx . . . xxx
x Don't care			

**Figure 69. Encoding of NaN and Infinity Data Classes**

### Zeros

Zeros have a zero significand and any representable value in the exponent. A +0 is distinct from -0, and zeros with different exponents are distinct, except that comparison treats them as equal.

### Subnormal Numbers

Subnormal numbers have values that are smaller than  $N_{min}$  and greater than zero in magnitude.

### Normal Numbers

Normal numbers are nonzero finite numbers whose magnitude is between  $N_{min}$  and  $N_{max}$  inclusively.

### Infinities

Infinities are represented by 0b11110 in the leftmost 5 bits of the combination field. When an operation is defined to generate an infinity as the result, a default infinity is sometimes supplied. A default infinity has all remaining bits in the combination field and trailing significand field set to zeros.

When infinities are used as source operands, only the leftmost 5 bits of the combination field are interpreted (i.e., 0b11110 indicates the value is an infinity). The trailing significand field of infinities is usually ignored. For generated infinities, the leftmost 5 bits of the combination field are set to 0b11110 and all remaining combination bits are set to zero.

Infinities can participate in most arithmetic operations and give a consistent result. In comparisons, any +Infinity compares greater than any finite number, and any -Infinity compares less than any finite number. All +Infinity are compared equal and all -Infinity are compared equal.

### Signaling and Quiet NaNs

There are two types of Not-a-Numbers (NaNs), Signaling (SNaN) and Quiet (QNaN).

0b111110 in the leftmost 6 bits of the combination field indicates a Quiet NaN, whereas 0b111111 indicates a Signaling NaN.

A special QNaN is sometimes supplied as the *default QNaN* for a disabled invalid-operation exception; it has a plus sign, the leftmost 6 bits of the combination field set to 0b111110 and remaining bits in the combination field and the trailing significand field set to zero.

Normally, source QNaNs are *propagated* during operations so that they will remain visible at the end. When a

QNaN is propagated, the sign is preserved, the decimal value of the trailing significand field is preserved but reencoded using the preferred DPD codes, and the contents in the rightmost  $N-6$  bits of the combination field set to zero, where  $N$  is the width of the combination field for the format.

A source SNaN generally causes an invalid-operation exception. If the exception is disabled, the SNaN is converted to the corresponding QNaN and propagated. The primary encoding difference between an SNaN and a QNaN is that bit 5 of an SNaN is 1 and bit 5 of a QNaN is 0. When an SNaN is propagated as a QNaN, bit 5 is set to 0, and, just as with QNaN propagation, the sign is preserved, the decimal value of the trailing significand field is preserved but reencoded using the preferred DPD codes, and the contents in the rightmost  $N-6$  bits of the combination field set to zero, where  $N$  is the width of the combination field for the format. For some format-conversion instructions, a source SNaN does not cause an invalid-operation exception, and an SNaN is returned as the target operand.

For instructions with two source NaNs and a NaN is to be propagated as the result, do the following.

- If there is a QNaN in FRA and an SNaN in FRB, the SNaN in FRB is propagated.
- Otherwise, propagate the NaN in FRA.

## 5.5 DFP Execution Model

DFP operations are performed as if they first produce an intermediate result correct to infinite precision and with unbounded range. The intermediate result is then rounded to the destination's precision according to one of the eight DFP rounding modes. If the rounded result has only one form, it is delivered as the final result; if the rounded result has redundant forms, then an *ideal exponent* is used to select the form of the final result. The ideal exponent determines the form, not the value, of the final result. (See Section 5.5.3 "Formation of Final Result" on page 199.)

### 5.5.1 Rounding

Rounding takes a number regarded as infinitely precise and, if necessary, modifies it to fit the destination's precision. The destination's precision of an operation defines the set of permissible resultant values. For most operations, the destination's precision is the target-format precision and the permissible resultant values are those values representable in the target format. For some special operations, the destination precision is constrained by both the target format and some additional restrictions, and the permissible resultant values are a subset of the values representable in the target format.

Rounding sets FPSCR bits FR and FI. When an inexact exception occurs, FI is set to one; otherwise, FI is set to

zero. When an inexact exception occurs and if the rounded result is greater in magnitude than the intermediate result, then FR is set to one; otherwise, FR is set to zero. The exception is the *Round to FP Integer Without Inexact* instruction, which always sets FR and FI to zero. Rounding may cause an overflow exception or underflow exception; it may also cause an inexact exception.

Refer to Figure 70 below for rounding. Let  $Z$  be the intermediate result of a DFP operation.  $Z$  may or may not fit in the destination's precision. If  $Z$  is exactly one of the permissible representable resultant values, then the final result in all rounding modes is  $Z$ . Otherwise, either  $Z1$  or  $Z2$  is chosen to approximate the result, where  $Z1$  and  $Z2$  are the next larger and smaller permissible resultant values, respectively.

Figure 70. Rounding

#### **Round to Nearest, Ties to Even**

Choose the value that is closer to  $Z$  ( $Z1$  or  $Z2$ ). In case of a tie, choose the one whose units digit would have been even in the form with the largest common quantum of the two permissible resultant values. However, an infinitely precise result with magnitude at least  $(N_{\max} + 0.5Q(N_{\max}))$  is rounded to infinity with no change in sign; where  $Q(N_{\max})$  is the quantum of  $N_{\max}$ .

#### **Round toward 0**

Choose the smaller in magnitude ( $Z1$  or  $Z2$ ).

#### **Round toward $+\infty$**

Choose  $Z1$ .

#### **Round toward $-\infty$**

Choose  $Z2$ .

#### **Round to Nearest, Ties away from 0**

Choose the value that is closer to  $Z$  ( $Z1$  or  $Z2$ ). In case of a tie, choose the larger in magnitude ( $Z1$  or  $Z2$ ). However, an infinitely precise result with magnitude at least  $(N_{\max} + 0.5Q(N_{\max}))$  is rounded to infinity with no change in sign; where  $Q(N_{\max})$  is the quantum of  $N_{\max}$ .

#### **Round to Nearest, Ties toward 0**

Choose the value that is closer to  $Z$  ( $Z1$  or  $Z2$ ). In case of a tie, choose the smaller in magnitude ( $Z1$  or  $Z2$ ). However, an infinitely precise result with magnitude greater than  $(N_{\max} + 0.5Q(N_{\max}))$  is rounded to infinity

with no change in sign; where  $Q(N_{\max})$  is the quantum of  $N_{\max}$ .

#### Round away from 0

Choose the larger in magnitude (Z1 or Z2).

#### Round to prepare for shorter precision

Choose the smaller in magnitude (Z1 or Z2). If the selected value is inexact and the units digit of the selected value is either 0 or 5, then the digit is incremented by one and the incremented result is delivered. In all other cases, the selected value is delivered. When a value has redundant forms, the units digit is determined by using the form that has the smallest exponent.

## 5.5.2 Rounding Mode Specification

Unless otherwise specified in the instruction definition, the rounding mode used by an operation is specified in the DFP rounding control (DRN) field of the FPSCR. The eight DFP rounding modes are encoded in the DRN field as specified in the table below.

DRN	Rounding Mode
000	Round to Nearest, Ties to Even
001	Round toward 0
010	Round toward +Infinity
011	Round toward -Infinity
100	Round to Nearest, Ties away from 0
101	Round to Nearest, Ties toward 0
110	Round away from 0
111	Round to Prepare for Shorter Precision

**Figure 71. Encoding of DFP Rounding-Mode Control (DRN)**

For the quantum-adjustment, a 2-bit immediate field, called RMC (*Rounding Mode Control*), in the instruction specifies the rounding mode used. The RMC field may contain a primary encoding or a secondary encoding. For *Quantize*, *Quantize Immediate*, and *Reround*, the RMC field contains the primary encoding. For *Round to FP Integer* the field contains either encoding, depending on the setting of a RMC-encoding-selection bit. The following tables define the primary encoding and the secondary encoding.

Primary RMC	Rounding Mode
00	Round to nearest, ties to even
01	Round toward 0
10	Round to nearest, ties away from 0
11	Round according to DRN

**Figure 72. Primary Encoding of Rounding-Mode Control**

Secondary RMC	Rounding Mode
00	Round to $+\infty$
01	Round to $-\infty$
10	Round away from 0
11	Round to nearest, ties toward 0

**Figure 73. Secondary Encoding of Rounding-Mode Control**

## 5.5.3 Formation of Final Result

An ideal exponent is defined for each DFP instruction that returns a DFP data operand.

### 5.5.3.1 Use of Ideal Exponent

For all DFP operations,

- if the rounded intermediate result has only one form, then that form is delivered as the final result.
- if the rounded intermediate result has redundant forms and is exact, then the form with the exponent closest to the ideal exponent is delivered.
- if the rounded intermediate result has redundant forms and is inexact, then the form with the smallest exponent is delivered.

The following table specifies the ideal exponent for each instruction.

Operations	Ideal Exponent
Add	$\min(E(\text{FRA}), E(\text{FRB}))$
Subtract	$\min(E(\text{FRA}), E(\text{FRB}))$
Multiply	$E(\text{FRA}) + E(\text{FRB})$
Divide	$E(\text{FRA}) - E(\text{FRB})$
Quantize-Immediate	See Instruction Description
Quantize	$E(\text{FRA})$
Reround	See Instruction Description
Round to FP Integer	$\max(0, E(\text{FRA}))$
Convert to DFP Long	$E(\text{FRA})$
Convert to DFP Extended	$E(\text{FRA})$
Round to DFP Short	$E(\text{FRA})$
Round to DFP Long	$E(\text{FRA})$
Convert from Fixed	0
Encode BCD to DPD	0
Insert Biased Exponent	$E(\text{FRA})$
Notes:	
$E(x)$ - exponent of the DFP operand in register x.	

**Figure 74. Summary of Ideal Exponents**

## 5.5.4 Arithmetic Operations

Four arithmetic operations are provided: Add, Subtract, Multiply, and Divide.

### 5.5.4.1 Sign of Arithmetic Result

The following rules govern the sign of an arithmetic operation when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the source operand having the larger absolute value. If both source operands have the same sign, the sign of the result of an add operation is the same as the sign of the source operands. When the sum of two operands with opposite signs is exactly zero, the sign of the result is positive in all rounding modes except Round toward  $-\infty$ , in which case the sign is negative.
- The sign of the result of the subtract operation  $x - y$  is the same as the sign of the result of the add operation  $x + (-y)$ .
- The sign of the result of a multiply or divide operation is the exclusive-OR of the signs of the source operands.

## 5.5.5 Compare Operations

Two sets of instructions are provided for comparing numerical values: *Compare Ordered* and *Compare Unordered*. In the absence of NaNs, these instructions work the same. These instructions work differently when either of the followings is true:

1. At least one source operand of the instruction is an SNaN and the invalid-operation exception is disabled.
2. When there is no SNaN in any source operand, at least one source operand of the instruction is a QNaN

In case 1, *Compare Unordered* recognizes an invalid-operation exception and sets the VXSNaN flag, but *Compare Ordered* recognizes the exception and sets both the VXSNaN and VXVC flags. In case 2, *Compare Unordered* does not recognize an exception, but *Compare Ordered* recognizes an invalid-operation exception and sets the VXVC flag.

For finite numbers, comparisons are performed on values, that is, all redundant forms of a DFP number are treated equal.

Comparisons are always exact and cannot cause an inexact exception.

Comparison ignores the sign of zero, that is,  $+0$  equals  $-0$ .

Infinities with like sign compare equal, that is,  $+\infty$  equals  $+\infty$ , and  $-\infty$  equals  $-\infty$ .

A NaN compares as unordered with any other operand, whether a finite number, an infinity, or another NaN, including itself.

Execution of a compare instruction always completes, regardless of whether any DFP exception occurs or not, and whether the exception is enabled or not.

## 5.5.6 Test Operations

Four kinds of test operations are provided: *Test Data Class*, *Test Data Group*, *Test Exponent*, and *Test Significance*.

The *Test Data Class* instruction examines the contents of a source operand and determines if the operand is one of the specified data classes. The test result and the sign of the source operand are indicated in the FPCC field and CR field BF.

The *Test Data Group* instruction examines the contents of a source operand and determines if the operand is one of the specified data groups. The test result and the sign of the source operand are indicated in the FPCC field and CR field BF.

The *Test Exponent* instruction compares the exponent of the two source operands. The test operation ignores the sign and significand of operands. Infinities compare equal, and NaNs compare equal. The test result is indicated in the FPCC field and CR field BF.

The *Test Significance* instruction compares the number of significant digits of one source operand with the referenced number of significant digits in another source operand. The test result is indicated in the FPCC field and CR field BF.

Execution of a test instruction does not cause any DFP exception.

## 5.5.7 Quantum Adjustment Operations

Four kinds of quantum-adjustment operations are provided: *Quantize*, *Quantize Immediate*, *Reround*, and *Round To FP Integer*. Each of them has an immediate field which specifies whether the rounding mode in FPSCR or a different one is to be used.

The *Quantize* instruction is used to adjust a DFP number to the form that has the specified target exponent. The *Quantize Immediate* instruction is similar to the *Quantize* instruction, except that the target exponent is specified in a 5-bit immediate field as a signed binary integer and has a limited range.

The *Reround* instruction is used to simulate a DFP operation of a precision other than that of DFP Long or DFP Extended. For the *Reround* instruction to produce

a result which accurately reflects that which would have resulted from a DFP operation of the desired precision  $d$  in the range {1: 33} inclusively, the following conditions must be met:

- The precision of the preceding DFP operation must be at least one digit larger than  $d$ .
- The rounding mode used by the preceding DFP operation must be *round-to-prepare-for-shorter-precision*.

The *Round To FP Integer* instruction is used to round a DFP number to an integer value of the same format. The target exponent is implicitly specified, and is greater than or equal to zero.

## 5.5.8 Conversion Operations

There are two kinds of conversion operations: data-format conversion and data-type conversion.

### 5.5.8.1 Data-Format Conversion

The instructions *Convert To DFP Long* and *Convert To DFP Extended* convert DFP operands to wider formats; the instructions *Round To DFP Short* and *Round To DFP Long* convert DFP operands to narrower formats.

When converting a finite number to a wider format, the result is exact. When converting a finite number to a narrower format, the source operand is rounded to the target-format precision, which is specified by the instruction, not by the target register size.

When converting a finite number, the ideal exponent of the result is the source exponent.

Conversion of an infinity or NaN to a different format does not preserve the source combination field. Let  $N$  be the width of the target format's combination field.

- When the result is an infinity or a QNaN, the contents of the rightmost  $N-5$  bits of the  $N$ -bit target combination field are set to zero.
- When the result is an SNaN, bit 5 of the target format's combination field is set to one and the rightmost  $N-6$  bits of the  $N$ -bit target combination field are set to zero.

When converting a NaN to a wider format or when converting an infinity from DFP Short to DFP Long, digits in the source trailing significand field are reencoded using the preferred DPD codes with sufficient zeros appended on the left to form the target trailing significand field. When converting a NaN to a narrower format or when converting an infinity from DFP Long to DFP Short, the appropriate number of leftmost digits of the source trailing significand field are removed and the remaining digits of the field are reencoded using the preferred DPD codes to form the target trailing significand field.

When converting an infinity between DFP Long and DFP Extended, a default infinity with the same sign is produced.

When converting an SNaN between DFP Short and DFP Long, it is converted to an SNaN without causing an invalid-operation exception. When converting an SNaN between DFP Long and DFP Extended, the invalid-operation exception occurs; if the invalid-operation exception is disabled, the result is converted to the corresponding QNaN.

### 5.5.8.2 Data-Type Conversion

The instructions *Convert From Fixed* and *Convert To Fixed* are provided to convert a number between the DFP data type and the signed 64-bit binary-integer data type.

Conversion of a signed 64-bit binary integer to a DFP Extended number is always exact.

Conversion of a DFP number to a signed 64-bit binary integer results in an invalid-operation exception when the converted value does not fit into the target format, or when the source operand is an infinity or NaN. When the exception is disabled, the most positive integer is returned if the source operand is a positive number or  $+\infty$ , and the most negative integer is returned if the source operand is a negative number,  $-\infty$ , or NaN.

## 5.5.9 Format Operations

The format instructions are provided to facilitate composing or decomposing a DFP number, and consist of *Encode BCD To DPD*, *Decode DPD To BCD*, *Extract Biased Exponent*, *Insert Biased Exponent*, *Shift Significand Left Immediate*, and *Shift Significand Right Immediate*. A source operand of SNaN does not cause an invalid-operation exception, and an SNaN may be produced as the target operand.

### 5.5.10 DFP Exceptions

This architecture defines the following DFP exceptions:

- Invalid Operation Exception
  - SNaN
  - $\infty - \infty$
  - $\infty \div \infty$
  - $0 \div 0$
  - $\infty \times 0$
  - Invalid Compare
  - Invalid Conversion
- Zero Divide Exception
- Overflow Exception
- Underflow Exception
- Inexact Exception

These exceptions may occur during execution of a DFP instruction.

Each DFP exception, and each category of the Invalid Operation Exception, has an exception status bit in the FPSCR. In addition, each DFP exception has a corresponding enable bit in the FPSCR. The exception status bit indicates occurrence of the corresponding exception. If an exception occurs, the corresponding enable bit governs the result produced by the instruction and, in conjunction with the FE0 and FE1 bits (see the discussion of FE0 and FE1 below), whether and how the system floating-point enabled exception error handler is invoked. (In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its source operands, not on the setting of any control bits. The only deviation from this general rule is that the occurrence of an Underflow Exception may depend on the setting of the enable bit.)

A single instruction, other than *mtfsfi* or *mtfsf*, may set more than one exception bit only in the following cases:

- Inexact Exception may be set with Overflow Exception.
- Inexact Exception may be set with Underflow Exception.
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Compare) for *Compare Ordered* instructions
- Invalid Operation Exception (SNaN) may be set with Invalid Operation Exception (Invalid Conversion) for *Convert To Fixed* instructions.

When an exception occurs the instruction execution may be completed or partially completed, depending on the exception and the operation.

For all instructions, except for the Compare and Test instructions, the following exceptions cause the instruction execution to be partially completed. That is, setting of CR field 1 (when  $R_c=1$ ) and exception status flags is performed, but no result is stored into the target FPR or FPR pair. For Compare and Test instructions, instruction execution is always completed, regardless of whether any DFP exception occurs or not, and whether the exception is enabled or not.

- Enabled Invalid Operation
- Enabled Zero Divide

For the remaining kinds of exceptions, instruction execution is completed, a result, if specified by the instruction, is generated and stored into the target FPR or FPR pair, and appropriate status flags are set. The result may be a different value for the enabled and disabled conditions for some of these exceptions. The kinds of exceptions that deliver a result in target FPR are the following:

- Disabled Invalid Operation
- Disabled Zero Divide
- Disabled Overflow
- Disabled Underflow

- Disabled Inexact
- Enabled Overflow
- Enabled Underflow
- Enabled Inexact

Subsequent sections define each of the DFP exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of “traps” and “trap handlers”. In this architecture, a FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the “trap enabled” case: the expectation is that the exception will be detected by software, which will revise the result. A FPSCR exception enable bit of 0 causes generation of the “default result” value specified for the “trap disabled” (or “no trap occurs” or “trap is not implemented”) case: the expectation is that the exception will not be detected by software, which will simply use the default result. The result to be delivered in each case for each exception is described in the sections below.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is desired for all exceptions, all FPSCR exception enable bits should be set to zero and Ignore Exceptions Mode (see below) should be used. In this case the system floating-point enabled exception error handler is not invoked, even if DFP exceptions occur: software can inspect the FPSCR exception bits if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be set to one and a mode other than Ignore Exceptions Mode must be used. In this case the system floating-point enabled exception error handler is invoked if an enabled DFP exception occurs. The system floating-point enabled exception error handler is also invoked if a *Move To FPSCR* instruction causes an exception bit and the corresponding enable bit both to be 1; the *Move To FPSCR* instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled DFP exception occurs. The location of these bits and the requirements for altering them are described in Book III, *Power ISA Operating Environment Architecture*. (The system floating-point enabled exception error handler is never invoked

because of a disabled DFP exception.) The effects of the four possible settings of these bits are as follows.

FE0	FE1	Description
0	0	<b>Ignore Exceptions Mode</b> DFP exceptions do not cause the system floating-point enabled exception error handler to be invoked.
0	1	<b>Imprecise Nonrecoverable Mode</b> The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction may have been used by or may have affected subsequent instructions that are executed before the error handler is invoked.
1	0	<b>Imprecise Recoverable Mode</b> The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. Sufficient information is provided to the error handler that it can identify the excepting instruction and the operands, and correct the result. No results produced by the excepting instruction have been used by or have affected subsequent instructions that are executed before the error handler is invoked.
1	1	<b>Precise Mode</b> The system floating-point enabled exception error handler is invoked precisely at the instruction that caused the enabled exception.

In all cases, the question of whether a DFP result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in subsequent sections, and is not affected by the value of the FE0 and FE1 bits.

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler is invoked have completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. (Recall that, for the two Imprecise modes, the instruction at which the system floating-point enabled exception error handler is invoked need not be the instruction that caused the exception.) The instruction at which the system floating-point enabled exception error handler is invoked has not been executed unless it is the excepting instruction, in which case it has been executed if the

exception is not among those listed on page 201 as suppressed.

#### Programming Note

In the ignore and both imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any exceptions, due to instructions initiated before the *Floating-Point Status and Control Register* instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In either of the Imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any invocations of the system floating-point enabled exception error handler, due to instructions initiated before the *Floating-Point Status and Control Register* instruction, to occur. (This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.)

In order to obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to zero.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to one for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to one.
- Precise Mode may degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

### 5.5.10.1 Invalid Operation Exception

#### Definition

An Invalid Operation Exception occurs when an operand is invalid for the specified DFP operation. The invalid DFP operations are:

- Any DFP operation on a signaling NaN (SNaN), except for *Test*, *Round To DFP Short*, *Convert To DFP Long*, *Decode DPD To BCD*, *Extract Biased Exponent*, *Insert Biased Exponent*, *Shift Significand Left Immediate*, and *Shift Significand Right Immediate*

- For add or subtract operations, magnitude subtraction of infinities ( $+\infty$ ) + ( $-\infty$ )
- Division of infinity by infinity ( $\infty \div \infty$ )
- Division of zero by zero ( $0 \div 0$ )
- Multiplication of infinity by zero ( $\infty \times 0$ )
- Ordered comparison involving a NaN (Invalid Compare)
- The *Quantize* operation detects that the significand associated with the specified target exponent would have more significant digits than the target-format precision
- For the *Quantize* operation, when one source operand specifies an infinity and the other specifies a finite number
- The *Reround* operation detects that the target exponent associated with the specified target significance would be greater than  $X_{\max}$
- The *Encode BCD To DPD* operation detects an invalid BCD digit or sign code
- The *Convert To Fixed* operation involving a number too large in magnitude to be represented in the target format, or involving a NaN.

#### Programming Note

In addition, an Invalid Operation Exception occurs if software explicitly requests this by executing an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction that sets VXSOFT to 1 (Software Request). The purpose of VXSOFT is to allow software to cause an Invalid Operation Exception for a condition that is not necessarily associated with the execution of a DFP instruction. For example, it might be set by a program that computes a square root, if the source operand is negative.

## Action

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

When Invalid Operation Exception is enabled ( $VE=1$ ) and Invalid Operation occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set:
 

VXSNAN	(if SNaN)
VXI SI	(if $\infty - \infty$ )
VXI DI	(if $\infty \div \infty$ )
VXZDZ	(if $0 \div 0$ )
VXI MZ	(if $\infty \times 0$ )
VXVC	(if invalid comp)
VXCVI	(if invalid conversion)
2. If the operation is an arithmetic, quantum-adjustment, conversion, or format,
  - the target FPR is unchanged,
  - FR and FI are set to zero, and
  - FPRF is unchanged.
3. If the operation is a compare,
  - FR, FI, and C are unchanged, and
  - FPCC is set to reflect unordered.

When Invalid Operation Exception is disabled ( $VE=0$ ) and Invalid Operation occurs, the following actions are taken:

1. One or two Invalid Operation Exceptions are set:
 

VXSNAN	(if SNaN)
VXI SI	(if $\infty - \infty$ )
VXI DI	(if $\infty \div \infty$ )
VXZDZ	(if $0 \div 0$ )
VXI MZ	(if $\infty \times 0$ )
VXVC	(if invalid comp)
VXCVI	(if invalid conversion)
2. If the operation is an arithmetic, quantum-adjustment, *Round to DFP Long*, *Convert to DFP Extended*, or format
  - the target FPR is set to a Quiet NaN
  - FR and FI are set to zero
  - FPRF is set to indicate the class of the result (Quiet NaN)
3. If the operation is a *Convert To Fixed*
  - the target FPR is set as follows:
    - FRT is set to the most positive 64-bit binary integer if the operand in FRB is a positive or  $+\infty$ , and to the most negative 64-bit binary integer if the operand in FRB is a negative number,  $-\infty$ , or NaN.
    - FR and FI are set to zero
    - FPRF is unchanged
4. If the operation is a compare,
  - FR, FI, and C are unchanged
  - FPCC is set to reflect unordered

## 5.5.10.2 Zero Divide Exception

### Definition

A Zero Divide Exception occurs when a Divide instruction is executed with a zero divisor value and a finite nonzero dividend value.

### Action

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

When Zero Divide Exception is enabled ( $ZE=1$ ) and Zero Divide occurs, the following actions are taken:

1. Zero Divide Exception is set
  - $ZX \leftarrow 1$
2. The target FPR is unchanged
3. FR and FI are set to zero
4. FPRF is unchanged

When Zero Divide Exception is disabled ( $ZE=0$ ) and Zero Divide occurs, the following actions are taken:

1. Zero Divide Exception is set
  - $ZE \leftarrow 1$
2. The target FPR is set to  $\pm\infty$ , where the sign is determined by the XOR of the signs of the operands

3. FR and FI are set to zero
4. FPRF is set to indicate the class and sign of the result ( $\pm\infty$ )

### 5.5.10.3 Overflow Exception

#### Definition

An overflow exception occurs whenever the target format's largest finite number is exceeded in magnitude by what would have been the rounded result if the exponent range were unbounded.

#### Action

Except for *Reround*, the following describes the handling of the IEEE overflow exception condition. The *Reround* operation does not recognize an overflow exception condition.

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

When Overflow Exception is enabled ( $OE=1$ ) and overflow occurs, the following actions are taken:

1. Overflow Exception is set  
 $OX \leftarrow 1$
2. The infinitely precise result is divided by  $10^\alpha$ . That is, the exponent adjustment  $\alpha$  is subtracted from the exponent. This is called the *wrapped result*. The exponent adjustment for all operations, except for *Round To DFP Short* and *Round To DFP Long*, is 576 for DFP Long and 9216 for DFP Extended. For *Round To DFP Short* and *Round To DFP Long*, the exponent adjustment is 192 for the source format of DFP Long and 3072 for the source format of DFP Extended.
3. The wrapped result is rounded to the target-format precision. This is called the *wrapped rounded result*.
4. If the wrapped rounded result has only one form, it is the delivered result. If the wrapped rounded result has redundant forms and is exact, the result of the form that has the exponent closest to the wrapped ideal exponent is returned. If the wrapped rounded result has redundant forms and is inexact, the result of the form that has the smallest exponent is returned. The wrapped ideal exponent is the result of subtracting the exponent adjustment from the ideal exponent.
5. FPRF is set to indicate the class and sign of the result ( $\pm$  Normal Number)

When Overflow Exception is disabled ( $OE=0$ ) and overflow occurs, the following actions are taken:

1. Overflow Exception is set  
 $OX \leftarrow 1$
2. Inexact Exception is set  
 $XX \leftarrow 1$

3. The result is determined by the rounding mode and the sign of the intermediate result as follows.

Rounding Mode	Sign of intermediate result	
	Plus	Minus
Round to Nearest, Ties to Even	$+\infty$	$-\infty$
Round toward 0	$+N_{\max}$	$-N_{\max}$
Round toward $+\infty$	$+\infty$	$-N_{\max}$
Round toward $-\infty$	$+N_{\max}$	$-\infty$
Round to Nearest, Ties away from 0	$+\infty$	$-\infty$
Round to Nearest, Ties toward 0	$+\infty$	$-\infty$
Round away from 0	$+\infty$	$-\infty$
Round to prepare for shorter precision	$+N_{\max}$	$-N_{\max}$

**Figure 75. Overflow Results When Exception Is Disabled**

4. The result is placed into the target FPR
5. FR is set to one if the returned result is  $\pm\infty$ , and is set to zero if the returned result is  $\pm N_{\max}$
6. FI is set to one
7. FPRF is set to indicate the class and sign of the result ( $\pm\infty$  or  $\pm$  Normal number)

### 5.5.10.4 Underflow Exception

#### Definition

Except for *Reround*, the following describes the handling of the IEEE underflow exception condition. The *Reround* operation does not recognize an underflow exception condition.

The Underflow Exception is defined differently for the enabled and disabled states. However, a tininess condition is recognized in both states when a result computed as though both the precision and exponent range were unbounded would be nonzero and less than the target format's smallest normal number,  $N_{\min}$ , in magnitude.

Unless otherwise defined in the instruction description, an underflow exception occurs as follows:

- Enabled:  
When the tininess condition is recognized.
- Disabled:  
When the tininess condition is recognized and when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

## Action

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

When Underflow Exception is enabled (UE=1) and underflow occurs, the following actions are taken:

1. Underflow Exception is set  
 $UX \leftarrow 1$
2. The infinitely precise result is multiplied by  $10^\alpha$ . That is, the exponent adjustment  $\alpha$  is added to the exponent. This is called the *wrapped result*. The exponent adjustment for all operations, except for *Round To DFP Short* and *Round To DFP Long*, is 576 for DFP Long and 9216 for DFP Extended. For *Round To DFP Short* and *Round To DFP Long*, the exponent adjustment is 192 for the source format of DFP Long and 3072 for the source format of DFP Extended.
3. The wrapped result is rounded to the target-format precision. This is called the *wrapped rounded result*.
4. If the wrapped rounded result has only one form, it is the delivered result. If the wrapped rounded result has redundant forms and is exact, the result of the form that has the exponent closest to the wrapped ideal exponent is returned. If the wrapped rounded result has redundant forms and is inexact, the result of the form that has the smallest exponent is returned. The wrapped ideal exponent is the result of adding the exponent adjustment to the ideal exponent.
5. FPRF is set to indicate the class and sign of the result ( $\pm$  Normal number)

When Underflow Exception is disabled (UE=0) and underflow occurs, the following actions are taken:

1. Underflow Exception is set  
 $UX \leftarrow 1$
2. The infinitely precise result is rounded to the target-format precision.
3. The rounded result is returned. If this result has redundant forms, the result of the form that is closest to the ideal exponent is returned.
4. FPRF is set to indicate the class and sign of the result ( $\pm$  Normal number,  $\pm$  Subnormal Number, or  $\pm$  Zero)

### 5.5.10.5 Inexact Exception

#### Definition

Except for *Round to FP Integer Without Inexact*, the following describes the handling of the IEEE inexact exception condition. The *Round to FP Integer Without Inexact* does not recognize an inexact exception condition.

An Inexact Exception occurs when either of two conditions occur during rounding:

1. The delivered result differs from what would have been computed were both the precision and exponent range unbounded.
2. The rounded result overflows and Overflow Exception is disabled.

#### Action

The action to be taken does not depend on the setting of the Inexact Exception Enable bit of the FPSCR.

When Inexact Exception occurs, the following actions are taken:

1. Inexact Exception is set  
 $XX \leftarrow 1$
2. The rounded or overflowed result is placed into the target FPR
3. FPRF is set to indicate the class and sign of the result

#### Programming Note

In some implementations, enabling Inexact Exceptions may degrade performance more than does enabling other types of floating-point exception.

## 5.5.11 Summary of Normal Rounding And Range Actions

Figure 76 and Figure 77 summarize rounding and range actions, with the following exceptions:

- The *Reround* operation recognizes neither an underflow nor an overflow exception.
- The *Round to FP Integer Without Inexact* operation does not recognize the inexact operation exception.

Range of v	Case	Result (r) when Rounding Mode Is								
		RNE	RNTZ	RNAZ	RAFZ	RTMI	RFSP	RTPI	RTZ	
$v < -N_{max}$ , $q < -N_{max}$	Overflow	$-\infty^1$	$-\infty^1$	$-\infty^1$	$-\infty^1$	$-\infty^1$	$-\infty^1$	-Nmax	-Nmax	-Nmax
$v < -N_{max}$ , $q = -N_{max}$	Normal	-Nmax	-Nmax	-Nmax	—	—	-Nmax	-Nmax	-Nmax	-Nmax

Explanation:

- This situation cannot occur.
- 1 The normal result r is considered to have been incremented.
- \* The rounded value, in the extreme case, may be Nmin. In this case, the exception conditions are underflow, inexact, and incremented.
- b The value derived when the precise result v is rounded to the destination's precision, including both bounded precision and bounded exponent range.
- q The value derived when the precise result v is rounded to the destination's precision, but assuming an unbounded exponent range.
- r This is the returned value when neither overflow nor underflow is enabled.
- v Precise result before rounding, assuming unbounded precision and an unbounded exponent range. For data-format conversion operations, v is the source value.
- Dmin Smallest (in magnitude) representable subnormal number in the target format.
- EZD The result r of the exact-zero-difference case applies only to ADD and SUBTRACT with both source operands having opposite signs. (For ADD and SUBTRACT, when both source operands have the same sign, the sign of the zero result is the same sign as the sign of the source operands.)
- Nmax Largest (in magnitude) representable finite number in the target format.
- Nmin Smallest (in magnitude) representable normalized number in the target format.
- RAFZ Round away from 0.
- RFSP Round to Prepare for Shorter Precision.
- RNAZ Round to Nearest, Ties away from 0.
- RNE Round to Nearest, Ties to even.
- RNTZ Round to Nearest, Ties toward 0.
- RTPI Round toward  $+\infty$ .
- RTMI Round toward  $-\infty$ .
- RTZ Round toward 0.

Tiny	Yes	—	Yes	—	—	No	No <sup>1</sup>	Tw(q×β), UX←1, FI←0, FR←0, TU
Tiny	Yes	—	Yes	—	—	Yes	No	Tw(q×β), UX←1, FI←1, FR←0, XX←1, TU
Tiny	Yes	—	Yes	—	—	Yes	Yes	Tw(q×β), UX←1, FI←1, FR←1, XX←1, TU

Explanation:

- The results do not depend on this condition.
- 1 This condition is true by virtue of the state of some condition to the left of this column.
- \* Rounding sets only FI and FR. Setting of OX, XX, or UX is part of the exception actions. They are listed here for reference.
- β Wrap adjust, which depends on the type of operation and operand format. For all operations except *Round to DFP Short* and *Round to DFP Long*, the wrap adjust depends on the target format:  $\beta = 10^\alpha$ , where  $\alpha$  is 576 for DFP Long, and 9216 for DFP Extended. For *Round to DFP Short* and *Round to DFP Long*, the wrap adjust depends on the source format:  $\beta = 10^\kappa$  where  $\kappa$  is 192 for DFP Long and 3072 for DFP Extended.
- q The value derived when the precise result v is rounded to destination's precision, but assuming an unbounded exponent range.
- r The result as defined in Part 1 of this figure.
- v Precise result before rounding, assuming unbounded precision and unbounded exponent range.
- FI Floating-Point-Fraction-Inexact status flag, FI. This status flag is non-sticky.
- FR Floating-Point-Fraction-Rounded status flag, FR.
- OX Floating-Point Overflow Exception status flag, OX.
- TO The system floating-point enabled exception error handler is invoked for the overflow exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
- TU The system floating-point enabled exception error handler is invoked for the underflow exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
- TX The system floating-point enabled exception error handler is invoked for the inexact exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
- T(x) The value x is placed at the target operand location.
- Tw(x) The wrapped rounded result x is placed at the target operand location. For all operations except data format conversions, the wrapped rounded result is in the same format and length as normal results at the target location. For data format conversions, the wrapped rounded result is in the same format and length as the source, but rounded to the target-format precision.
- UX Floating-Point-Underflow-Exception status bit.
- XX Float-Point Inexact exception status bit. The flag is a sticky version of FI. When FI is set to a new value, the new value of XX is set to the result of ORing the old value of XX with the new value of FI.

Figure 77. Rounding and Range Actions (Part 2)

## 5.6 DFP Instruction Descriptions

The following sections describe the DFP instructions. When a 128-bit operand is used, it is held in a FPR pair and the instruction mnemonic uses a letter “q” to mean the quad-precision operation. Note that in the following descriptions,  $FRXp$  denotes a FPR pair and must address an even-odd pair. If the  $FRXp$  field specifies an odd-numbered register, then the instruction form is invalid. The notation  $FRX[p]$  means either a FPR,  $FRX$ , or a FPR pair,  $FRXp$ .

For DFP instructions, if a DFP operand is returned, the trailing significand field of the target operand is encoded using preferred DPD codes.

---

### 5.6.1 DFP Arithmetic Instructions

All DFP arithmetic instructions are X-form instructions. They all set the FI and FR status flags, and also set the FPRF field. Furthermore, they all have an ideal exponent assigned and employ the record bit (Rc).

The arithmetic instructions consist of Add, Divide, Multiply, and Subtract.

**DFP Add X-form**

dadd FRT,FRA,FRB (Rc=0)  
 dadd. FRT,FRA,FRB (Rc=1)

**DFP Add Quad X-form**

daddq FRTp,FRAp,FRBp (Rc=0)  
 daddq. FRTp,FRAp,FRBp (Rc=1)

The DFP operand in FRA[p] is added to the DFP operand in FRB[p].

The result is rounded to the target-format precision under control of DRN (bits 29:31 of the FPSCR). An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the smaller exponent of the two source operands.

Figure 78 summarizes the actions for Add. Figure 78 does not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

*dadd[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

- FPRF FR FI
- FX OX UX XX
- VXSNAN VXI SI
- CR1 (if Rc=1)

**DFP Subtract X-form**

dsub FRT,FRA,FRB (Rc=0)  
 dsub. FRT,FRA,FRB (Rc=1)

**DFP Subtract Quad X-form**

dsubq FRTp,FRAp,FRBp (Rc=0)  
 dsubq. FRTp,FRAp,FRBp (Rc=1)

The DFP operand in FRB[p] is subtracted from the DFP operand in FRA[p].

The result is rounded to the target-format precision under control of DRN (bits 29:31 of the FPSCR). An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the smaller exponent of the two source operands.

The execution of Subtract is identical to that of Add, except that the operand in FRB participates in the operation with its sign bit inverted. See Figure 78. The table does not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

*dsub[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

- FPRF FR FI
- FX OX UX XX
- VXSNAN VXI SI
- CR1 (if Rc=1)

Operand a in FRA[p] is	Actions for Add (a + b) when operand b in FRB[p] is

 dmulq. FRTp,FRAp,FRBp (Rc=1)

63	FRTp	FRAp	FRBp	34	Rd
0	6	11	16	21	31

The DFP operand in FRA[p] is multiplied by the DFP operand in FRB[p].

The result is rounded to the target-format precision under control of DRN (bits 29:31 of the FPSCR). An appropriate form of the rounded result is selected based on the ideal exponent and is placed in FRT[p]. The ideal exponent is the sum of the two exponents of the source operands.

Figure 79 summarizes the actions for Multiply. Figure 79 does not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

*dmul[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

Explanation:

a÷b The value a divided by b, rounded to the target-format precision and returned in the appropriate form. (See Section 5.5.11 on page 207.)

dI NF Default infinity.

dNaN Default quiet NaN.

Fn Finite nonzero number (includes both normal and subnormal numbers).

P(x) The QNaN of operand x is propagated and placed in FRT[p].

S(x) The value x is placed in FRT[p] with the sign set to the exclusive-OR of the source-operand signs.

T(x) The value x is placed in FRT[p].

U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].

VXI DI: Floating-Point Invalid Operation (Infinity ÷ Infinity) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203 for the exception actions.)

VXSNAN: Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203.)

VXZDZ: Floating-Point Invalid Operation (Zero ÷ Zero) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203.)

zt True zero (zero significand and most negative exponent).

Zx The Zero-Divide Exception occurs. The result is produced only when the exception is disabled (See Section 5.5.10.2 “Zero Divide Exception” on page 204.)

**Figure 80. Actions: Divide**

## 5.6.2 DFP Compare Instructions

The DFP compare instructions consist of the *Compare Ordered* and *Compare Unordered* instructions. The compare instructions do not provide the record bit.

The comparison sets the designated CR field to indicate the result. FPCC is set in the same way.

The codes in the CR field BF and FPCC are defined for the DFP compare operations as follows.

**Bit Name Description**

0	FL	$(FRA[p]) < (FRB[p])$
1	FG	$(FRA[p]) > (FRB[p])$
2	FE	$(FRA[p]) = (FRB[p])$
3	FU	$(FRA[p]) ? (FRB[p])$

## 5.6.3 DFP Test Instructions

The DFP test instructions consist of the *Test Data Class*, *Test Data Group*, *Test Exponent*, and *Test Significance* instructions, and they do not provide the record bit.

The test instructions set the designated CR field to indicate the result. The  $FPSCR_{FPCC}$  is set in the same way.

### DFP Test Data Class Z22-form

dtstdc BF,FRA,DCM

59	BF	//	FRA	DCM	194	/
0	6	9	11	16	22	31

### DFP Test Data Class Quad Z22-form

dtstdcq BF,FRAp,DCM

63	BF	//	FRAp	DCM	194	/
0	6	9	11	16	22	31

Let the DCM (Data Class Mask) field specify one or more of the 6 possible data classes, where each bit corresponds to a specific data class.

DCM Bit	Data Class
0	Zero
1	Subnormal
2	Normal
3	Infinity
4	Quiet NaN
5	Signaling NaN

CR field BF and FPCC are set to indicate the sign of the DFP operand in  $FRA[p]$  and whether the data class of the DFP operand in  $FRA[p]$  matches any of the data classes specified by DCM.

Field	Meaning
0000	Operand positive with no match
0010	Operand positive with match
1000	Operand negative with no match
1010	Operand negative with match

$dtstdc[q]$  are treated as *Floating-Point* instructions in terms of resource availability.

#### Special Registers Altered:

### DFP Test Data Group Z22-form

dtstdg BF,FRA,DGM

59	BF	//	FRA	DGM	226	/
0	6	9	11	16	22	31

### DFP Test Data Group Quad Z22-form

dtstdgq BF,FRAp,DGM

63	BF	//	FRAp	DGM	226	/
0	6	9	11	16	22	31

Let the DGM (Data Group Mask) field specify one or more of the 6 possible data groups, where each bit corresponds to a specific data group.

The term extreme exponent means either the maximum exponent,  $X_{max}$ , or the minimum exponent,  $X_{min}$ .

DGM Bit	Data Group
0	Zero with non-extreme exponent
1	Zero with extreme exponent
2	Subnormal or (Normal with extreme exponent)
3	Normal with non-extreme exponent and leftmost zero digit in significand
4	Normal with non-extreme exponent and leftmost nonzero digit in significand
5	Special symbol (Infinity, QNaN, or SNaN)

CR field BF and FPCC are set to indicate the sign of the DFP operand in  $FRA[p]$  and whether the data group of the DFP operand in  $FRA[p]$  matches any of the data groups specified by DGM.

Field	Meaning
0000	Operand positive with no match
0010	Operand positive with match
1000	Operand negative with no match
1010	Operand negative with match

$dtstdg[q]$  are treated as *Floating-Point* instructions in terms of resource availability.

#### Special Registers Altered:

## 5.6.4 DFP Quantum Adjustment Instructions

The *Quantum Adjustment* operations consist of the *Quantize*, *Quantize Immediate*, *Reround*, and *Round To FP Integer* operations.

The *Quantum Adjustment* instructions are Z23-form instructions and have an immediate RMC (Rounding-Mode-Control) field, which specifies the rounding mode used. For *Quantize*, *Quantize Immediate*, and *Reround*, the RMC field contains the primary encoding. For *Round to FP Integer*, the field contains either primary or secondary encoding, depending on the setting of a RMC-encoding-selection bit. See Section 5.5.2 “Rounding Mode Specification” on page 199 for the definition of RMC encoding.

All *Quantum Adjustment* instructions set the FI and FR status flags, and also set the FPRF field. The record bit is provided to each of these instructions. They return the target operand in a form with the ideal exponent.

### DFP Quantize Immediate Z23-form

dquai                    TE,FRT,FRB,RMC                    (Rc=0)  
dquai.                    TE,FRT,FRB,RMC                    (Rc=1)

	59	FRT	TE	FRB	RMC	67	Rd
0	6	11	16	21	23	31	

### DFP Quantize Immediate Quad Z23-form

dquaiq                    TE,FRTp,FRBp,RMC                    (Rc=0)  
dquaiq.                    TE,FRTp,FRBp,RMC                    (Rc=1)

	63	FRTp	TE	FRBp	RMC	67	Rd
0	6	11	16	21	23	31	

The DFP operand in FRB[p] is converted and rounded to the form with the exponent specified by TE based on the rounding mode specified in the RMC field. TE is a 5-bit signed binary integer. The result of that form is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the exponent specified by TE.

When the value of the operand in FRB[p] is greater than  $(10^p - 1) \times 10^{TE}$ , where p is the format precision, an invalid operation exception is recognized.

When the delivered result differs in value from the operand in FRB[p], an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

FPRF is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

**dquai[q].** are treated as *Floating-Point* instructions in terms of resource availability.

### Special Registers Altered:

FPRF FR FI  
FX XX  
VXSNAN VXCVI  
CR1

(if Rc=1)

**Programming Note**

*DFP Quantize Immediate* can be used to adjust values to a form having the specified exponent in the range -16 to 15. If the adjustment requires the significand to be shifted left, then:

- if the result would cause overflow from the most significant digit, the result is a default QNaN;
- otherwise the result is the adjusted value (left shifted with matching exponent).

If the adjustment requires the significand to be shifted right, the result is rounded based on the value of the RMC field.

*DFP Quantize Immediate* can round a value to a specific number of fractional digits. Consider the computation of sales tax. Values expressed in U.S. dollars have 2 fractional digits, and sales tax rates typically have 3 fractional digits. The product of value and rate will yield 5 fractional digits. For example:

$$39.95 * 0.075 = 2.99625$$

This result needs to be rounded to the penny to compute the correct tax of \$3.00.

The following sequence computes the sales tax assuming the pre-tax total is in FRA and the tax rate is in FRB. The *DFP Quantize Immediate* instruction rounds the product (FRA \* FRB) to 2 fractional digits (TE = -2) using Round to nearest, ties away from 0 (RMC = 2). The quantized and rounded result is placed in FRT.

```

**DFP Quantize Quad Z23-form**

dquaq                    FRTp,FRAp,FRBp,RMC                    (Rc=0)  
 dquaq.                   FRTp,FRAp,FRBp,RMC                    (Rc=1)

63	FRTp	FRAp	FRBp	RMC	3	Rd
0	6	11	16	21	23	31

The DFP operand in register FRB[p] is converted and rounded to the form with the same exponent as that of the DFP operand in FRA[p] based on the rounding mode specified by RMC. The result of that form is placed in FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the exponent specified in FRA[p].

When the value of the operand in FRB[p] is greater than  $(10^p-1) \times 10^{Ea}$ , where p is the format precision and Ea is the exponent of the operand in FRA[p], an invalid operation exception is recognized.

When the delivered result differs in value from the operand in FRB[p], an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

Figure 87 and Figure 88 summarize the actions. The tables do not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

*dqua[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Register Altered:**

- FPRF FR FI
- FX XX
- VXSNAN VXCVI
- CR1 (if Rc=1)

**Programming Note**

*DFP Quantize* can be used to adjust one DFP value (FRB[p]) to a form having the same exponent as a second DFP value (FRA[p]). If the adjustment requires the significand to be shifted left, then:

- if the result would cause overflow from the most significant digit, the result is a default QNaN.;
- otherwise the result is the adjusted value (left shifted with matching exponent).

If the adjustment requires the significand to be shifted right, the result is rounded based on the value of RMC. Figure 86 shows examples of these adjustments.

FRA	FRB	FRT when RMC=1	FRT when RMC=2
1 (1 x 10 <sup>0</sup> )	9. (9 x 10 <sup>0</sup> )	9 (9 x 10 <sup>0</sup> )	9 (9 x 10 <sup>0</sup> )

SNaN	VXSNAN: U(a)	VXSNAN: U(a)	VXSNAN: U(a)	VXSNAN: U(a)	VXSNAN: U(a)

Explanation:

- \* See next table.
- dI NF Default infinity
- dNaN Default quiet NaN
- Fn Finite nonzero numbers (includes both subnormal and normal numbers)
- P(x) The QNaN of operand x is propagated and placed in FRT[p]
- T(x) The value x is placed in FRT[p]
- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].
- VXCVI : Floating-Point Invalid Operation (Invalid Conversion) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203.)
- VXSNAN: Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203.)

Figure 87. Actions (part 1) Quantize

	Actions for Quantize when operand b in FRB[p] is		
		0	Fn
Te < Se	$V_b > (10^p - 1) \times 10^{Te}$	E(0)	VXCVI : T(dNaN)
	$V_b \leq (10^p - 1) \times 10^{Te}$	E(0)	L(b)
Te = Se		E(0)	W(b)
Te > Se		E(0)	QR(b)

Explanation:

- dNaN Default quiet NaN
- E(0) The value of zero with the exponent value Te is placed in FRT[p].
- L(x) The operand x is converted to the form with the exponent value Te.
- p The precision of the format.
- QR(x) The operand x is rounded to the result of the form with the exponent value Te based on the specified rounding mode. The result of that form is placed in FRT[p].
- Se The exponent of the operand in FRB[p].
- Te The target exponent; FRA[p] for **dqua[q]**, or TE, a 5-bit signed binary integer for **dquai[q]**.
- T(x) The value x is placed in FRT[p].
- Vb The value of the operand in FRB[p].
- W(x) The value and the form of operand x is placed in FRT[p].
- VXCVI : Floating-Point Invalid Operation (Invalid Conversion) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203.)

Figure 88. Actions (part2) Quantize

**DFP Reround Z23-form**

drnd                    FRT,FRA,FRB,RMC                    (Rc=0)  
 drnd.                   FRT,FRA,FRB,RMC                    (Rc=1)

59	FRT	FRA	FRB	RMC	35	Rd
0	6	11	16	21 23		31

**DFP Reround Quad Z23-form**

drndq                   FRTp,FRA,FRBp,RMC                    (Rc=0)  
 drndq.                 FRTp,FRA,FRBp,RMC                    (Rc=1)

63	FRTp	FRA	FRBp	RMC	35	Rd
0	6	11	16	21 23		31

Let  $k$  be the contents of bits 58:63 of FRA that specifies the reference significance.

When the DFP operand in FRB[ $p$ ] is a finite number, and if the reference significance is zero, or if the reference significance is nonzero and the number of significant digits of the source operand is less than or equal to the reference significance, then the value and the form of the source operand is placed in FRT[ $p$ ]. If the reference significance is nonzero and the number of significant digits of the source operand is greater than the reference significance, then the source operand is converted and rounded to the number of significant digits specified in the reference significance based on the rounding mode specified in the RMC field. The result of the form with the specified number of significant digits is placed in FRT[ $p$ ]. The sign of the result is the same as the sign of the operand in FRB[ $p$ ].

For this instruction, the number of significant digits of the value 0 is considered to be zero. The ideal exponent is the greater value of the exponent of the operand in FRB[ $p$ ] and the referenced exponent. The referenced exponent is the resultant exponent if the operand in FRB[ $p$ ] would have been converted and rounded to the number of significant digits specified in the reference significance based on the rounding mode specified by RMC.

If the exponent of the rounded result of the form that has the specified number of significant digits would be greater than  $X_{max}$ , an invalid operation exception (VXCVI) occurs. When the invalid-operation exception occurs, and if the exception is disabled, a default QNaN is returned. When an invalid-operation exception occurs, no inexact exception is recognized.

In the absence of an invalid-operation exception, if the result differs in value from the operand in FRB[ $p$ ], an inexact exception is recognized.

This operation causes neither an overflow nor an underflow exception.

Figure 90 summarizes the actions for *Reround*. The table does not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation exception, in which case the field remains unchanged.

*drnd[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF FR FI  
 FX XX  
 VXSNaN VXCVI  
 CR1

(if Rc=1)

**Programming Note**

*DFP Reround* can be used to adjust a DFP value (FRB[ $p$ ]) to have no more than a specified number (FRA[ $p$ ]58:63) of significant digits. The result (FRT[ $p$ ]) is right-justified leaving the specified number of digits and rounded as specified by RMC. If rounding increases the number of significant digits, the result is adjusted again (the significand is shifted right 1 digit and the exponent is incremented by 1). Figure 89 has example results from *DFP Reround* for 1, 2, and 10 significant digits.

**Programming Note**

*DFP Reround* is primarily used to round a DFP value to a specific number of digits before conversion to string format for printing or display. Another use for *DFP Reround* is to obtain the effective exponent of the most significant digit by specifying a reference significance of 1. The exponent can be extracted and used to compute the number of significant digits or to left-justify a value.

For example, the following sequence computes the number of significant digits and returns it as an integer. FRB is the DFP value for which we want the number of significant digits; f13 contains the reference significance value 0x0000000000000001; and r1 is the stack pointer, with free space for doublewords at offsets -8 and -16. These doublewords are used to transfer the biased exponents from the FPRs to GPRs for integer computation. R3 contains the result of  $E(\text{reround}(1, \text{FRA})) - E(\text{FRA}) + 1$ , where  $E(x)$  represents the biased exponent of  $x$ .

```

dxex  f0,FRB
stfd  f0,-16(r1)
drrnd f1,f13,FRB,1 # reround 1 digit toward 0
dxex  f1,f1
stfd  f1,-8(r1)
lfd   r11,-16(r1)
lfd   r3,-8(r1)
subf  r3,r11,r3
addi  r3,r3,1

```

Given the value 412.34 the result is  $E(4 \times 10^2) - E(41234 \times 10^{-2}) + 1 = (398+2) - (398-2) + 1 = 400 - 396 + 1 = 5$ . Additional code is required to detect and handle special values like Subnormal, Infinity, and NAN.

FRA <sub>58:63</sub> (binary)	FRB	FRT when RMC=1	FRT when RMC=2
1	0.41234 ( $41234 \times 10^{-5}$ )	0.4 ( $4 \times 10^{-1}$ )	0.4 ( $4 \times 10^{-1}$ )
1	4.1234 ( $41234 \times 10^{-4}$ )	4 ( $4 \times 10^0$ )	4 ( $4 \times 10^0$ )
1	41.234 ( $41234 \times 10^{-3}$ )	4 ( $4 \times 10^1$ )	4 ( $4 \times 10^1$ )

**Figure 89. DFP Reround examples**

**Programming Note**

*DFP Reround* combined with *DFP Quantize* can be used to left justify a value (as needed by the *frexp* function). FRB is the DFP value for which we want to left justify; f13 contains the reference significance value 0x0000000000000001; and r1 is the stack pointer, with free space for a doubleword at offset -8. This doubleword is used to transfer the biased exponents from the FPR to a GPR, for integer computation. The adjusted biased exponent (+ format precision - 1) is transferred back into an FPR so it can be inserted into the rerounded value. The adjusted rerounded value becomes the quantize reference value. The quantize instruction returns the left justified result in FRT.

```

drrnd  f1,f13,FRB,1 # reround 1 digit toward 0
dxex   f0,f1
stfd   f0,-8(r1)
lfd    r11,-8(r1)
addi   r11,r11,15 # biased exp + precision - 1
lfd    r11,-8(r1)
stfd   f0,-8(r1)
diex   f1,f0,f1 # adjust exponent
dqua   FRT,f1,f0,1 # quantize to adjusted
                    exponent

```

	Actions for Reround when operand b in FRB[p] is				
	0*	Fn	$\infty$	QNaN	SNaN
<b>k <math>\neq</math> 0, k &lt; m</b>	-	RR(b) or VXCVI: T(dNaN)	T(dI NF)	P(b)	VXSNAN: U(b)
<b>k <math>\neq</math> 0, k = m</b>	-	W(b)	T(dI NF)	P(b)	VXSNAN: U(b)
<b>k <math>\neq</math> 0 and k &gt; m, or k = 0</b>	W(b)	W(b)	T(dI NF)	P(b)	VXSNAN: U(b)

Explanation:

- \* The number of significant digits of the value 0 is considered to be zero for this instruction.
- Not applicable.
- dI NF Default infinity.
- Fn Finite nonzero numbers (includes both subnormal and normal numbers).
- k Reference significance, which specifies the number of significant digits in the target operand.
- m Number of significant digits in the operand in FRB[p].
- P(x) The QNaN of operand x is propagated and placed in FRT[p].
- RR(x) The value x is rounded to the form that has the specified number of significant digits. If  $RR(x) \leq (10^k - 1) \times 10^{x_{max}}$ , then RR(x) is returned; otherwise an invalid-operation exception is recognized.
- T(x) The value x is placed in FRT[p].
- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].
- VXCVI Floating-Point Invalid Operation (Invalid Conversion) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203.)
- VXSNAN: Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203.)
- W(x) The value and the form of x is placed in FRT[p].

**Figure 90. Actions: Reround**

**DFP Round To FP Integer With Inexact Z23-form**

drintx                 R,FRT,FRB,RMC                 (Rc=0)  
 drintx.               R,FRT,FRB,RMC                 (Rc=1)

59	FRT	///	R	FRB	RMC	99	Rc
0	6	11	15,16	21	23		31

**DFP Round To FP Integer With Inexact Quad Z23-form**

drintxq               R,FRTp,FRBp,RMC             (Rc=0)  
 drintxq.              R,FRTp,FRBp,RMC             (Rc=1)

63	FRTp	///	R	FRBp	RMC	99	Rc
0	6	11	15,16	21	23		31

The DFP operand in FRB[p] is rounded to a floating-point integer and placed into FRT[p]. The sign of the result is the same as the sign of the operand in FRB[p]. The ideal exponent is the larger value of zero and the exponent of the operand in FRB[p].

The rounding mode used is specified by RMC. When the RMC-encoding-selection (R) bit is zero, RMC field contains the primary encoding; when the bit is one, the field contains the secondary encoding.

In addition to coercion of the converted value to fit the target format, the special rounding used by *Round To FP Integer* also coerces the target exponent to the ideal exponent.

When the operand in FRB[p] is a finite number and the exponent is less than zero, the operand is rounded to the result with an exponent of zero. When the exponent is greater than or equal to zero, the result is set to the numerical value and the form of the operand in FRB[p].

When the result differs in value from the operand in FRB[p], an inexact exception is recognized. No underflow exception is recognized by this operation, regardless of the value of the operand in FRB[p].

Figure 91 summarizes the actions for *Round To FP Integer With Inexact*. The table does not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation, in which case the field remains unchanged.

**drintx[q][.]** are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF FR FI  
 FX XX  
 VXSNaN  
 CR1   (if Rc=1)

**Programming Note**

The *DFP Round To FP Integer With Inexact* and *DFP Round To FP Integer With Inexact Quad* instructions can be used to implement the decimal equivalent of the C99 rint function by specifying the primary RMC encoding for round according to DRN (R=0, RMC=11). The specification for rint requires the inexact exception be raised if detected.

Operand b in FRB is	Is n not precise (n ≠ b)	Inv.-Op. Exception Enabled	Inexact Exception Enabled	Is n Incremented ( n  >  b )	Actions*
$-\infty$	No <sup>1</sup>	-	-	-	T(-dI NF), FI←0, FR←0
F	No	-	-	-	W(n), FI←0, FR←0
F	Yes	-	No	No	W(n), FI←1, FR←0, XX←1
F	Yes	-	No	Yes	W(n), FI←1, FR←1, XX←1
F	Yes	-	Yes	No	W(n), FI←1, FR←0, XX←1, TX
F	Yes	-	Yes	Yes	W(n), FI←1, FR←1, XX←1, TX
$+\infty$	No <sup>1</sup>	-	-	-	T(+dI NF), FI←0, FR←0
QNaN	No <sup>1</sup>	-	-	-	P(b), FI←0, FR←0
SNaN	No <sup>1</sup>	No	-	-	U(b), FI←0, FR←0, VXSNAN←1
SNaN	No <sup>1</sup>	Yes	-	-	VXSNAN←1, TV

Explanation:

- \* Setting of XX and VXSNAN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR is part of the exception actions. (See the sections, “Inexact Exception” and “Invalid Operation Exception” for more details.)
- The actions do not depend on this condition.
- <sup>1</sup> This condition is true by virtue of the state of some condition to the left of this column.
- dI NF Default infinity.
- F All finite numbers, including zeros.
- FI Floating-Point Fraction Inexact status bit.
- FR Floating-Point Fraction Rounded status bit.
- n The value derived when the source operand, b, is rounded to an integer using the special rounding for *Round To FP Integer*.
- P(x) The QNaN of operand x is propagated and placed in FRT[p].
- T(x) The value x is placed in FRT[p].
- TV The system floating-point enabled exception error handler is invoked for the invalid operation exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
- TX The system floating-point enabled exception error handler is invoked for the inexact exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
- U(x) The SNaN of operand x is converted to the corresponding QNaN and placed in FRT[p].
- W(x) The value x in the form of zero exponent or the source exponent is placed in FRT[p].
- XX Floating-Point Inexact exception status bit.

**Figure 91. Actions: Round to FP Integer With Inexact**

***DFP Round To FP Integer Without Inexact Z23-form***

`drintrn`                `R,FRT,FRB,RMC`                (`Rc=0`)  
`drintrn.`                `R,FRT,FRB,RMC`                (`Rc=1`)

59	FRT	///	R	FRB	RMC	227	Rc
0	6	11	15 16	21	23	31	

***DFP Round To FP Integer Without Inexact Quad Z23-form***

`drintrq`                `R,FRTp,FRBp,RMC`                (`Rc=0`)  
`drintrq.`                `R,FRTp,FRBp,RMC`                (`Rc=1`)

63	FRTp	///	R	FRBp	RMC	227	Rc
0	6	11	15 16	21	23	31	

This operation is the same as the *Round To FP Integer With Inexact* operation, except that this operation does not recognize an inexact exception.

Figure 92 summarizes the actions for *Round To FP Integer Without Inexact*. The table does not include the setting of FPRF. FPRF is always set to the class and sign of the result, except for an enabled invalid-operation, in which case the field remains unchanged.

`drintr[q][.]` are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

- FPRF   `FR` (set to 0)   `FI` (set to 0)
- FX
- VXSNAN
- CR1 (if `Rc=1`)

**Programming Note**

The *DFP Round To FP Integer Without Inexact* and *DFP Round To FP Integer Without Inexact Quad* instructions can be used to implement decimal equivalents of several C99 rounding functions by specifying the appropriate `R` and `RMC` field values.

<b>Function</b>	<b>R</b>	<b>RMC</b>
<code>Ceil</code>	1	0b00
<code>Floor</code>	1	0b01
<code>Nearbyint0</code>	0	0b11
<code>Round</code>	0	0b10
<code>Trunc</code>	0	0b01

Note that `nearbyint` is similar to the `rint` function but without raising the inexact exception. Similarly `ceil`, `floor`, `round`, and `trunc` do not require the inexact exception.

Operand b in FRB is	Inv.-Op. Exception Enabled	Actions*
$-\infty$	-	T(-dI NF), FI $\leftarrow$ 0, FR $\leftarrow$ 0
F	-	W(n), FI $\leftarrow$ 0, FR $\leftarrow$ 0
$+\infty$	-	T(+dI NF), FI $\leftarrow$ 0, FR $\leftarrow$ 0
QNaN	-	P(b), FI $\leftarrow$ 0, FR $\leftarrow$ 0
SNaN	No	U(b), FI $\leftarrow$ 0, FR $\leftarrow$ 0, VXSNaN $\leftarrow$ 1
SNaN	Yes	VXSNaN $\leftarrow$ 1, TV
<p>Explanation:</p> <ul style="list-style-type: none"> <li>* Setting of VXSNaN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR bits is part of the exception actions. **Figure 92. Actions: Round to FP Integer Without Inexact**

## 5.6.5 DFP Conversion Instructions

The DFP conversion instructions consist of data-format conversion instructions and data-type conversion instructions. They are all X-form instructions and employ the record bit (Rc).

### 5.6.5.1 DFP Data-Format Conversion Instructions

The data-format conversion instructions consist of *Convert To DFP Long*, *Convert To DFP Extended*, *Round To DFP Short*, and *Round To DFP Long*. Figure 93 summarizes the actions for these instructions.

#### Programming Note

DFP does not provide operations on short operands, so they must be converted to long format, and then converted back to be stored. Preserving correct signaling NaN semantics requires that signaling NaNs be propagated from the source to the result without recognizing an exception during widening from short to long or narrowing from long to short. Because DFP does not provide equivalents to the FP *Load Floating-Point Single* and *Store Floating-Point Single* functions, the widening is performed by loading the DFP short value with a *Load Floating as Integer Word Indexed* followed by a *DFP Convert to DFP Long*, and narrowing is performed by a *DFP Round to DFP Short* followed by a *Store Floating-Point as Integer Word Indexed*. If the SNaN or infinity in DFP short format uses the preferred DPD encoding, then converting this operand to DFP long format and back to DFP short will result in the original bit pattern.

Instruction	Actions when operand b in FRB[p] is			
	F	$\infty$	QNaN	SNaN
Convert To DFP Long	$T(b)^1$	$P(b)^{2,4}$	$P(b)^{2,4}$	$P(b)^{3,4}$
Convert To DFP Extended	$T(b)^1$	$T(dI NF)$	$P(b)^{2,4}$	VXSNAN: $U(b)^{2,4}$
Round To DFP Short	$R(b)^1$	$P(b)^{2,5}$	$P(b)^{2,5}$	$P(b)^{3,5}$
Round To DFP Long	$R(b)^1$	$T(dI NF)$	$P(b)^{2,5}$	VXSNAN: $U(b)^{2,5}$

**Explanation:**

- The ideal exponent is the exponent of the source operand.
- Bits 5:N-1 of the N-bit combination field are set to zero.
- Bit 5 of the N-bit combination field is set to one. Bits 6:N-1 of the combination field are set to zero.
- The trailing significand field is padded on the left with zeros.
- Leftmost digits in the trailing significand field are removed.

dI NF Default infinity.  
 F All finite numbers, including zeros.  
 P(x) The special symbol in operand x is propagated into FRT[p].  
 R(x) The value x is rounded to the target-format precision; see Section 5.5.11  
 T(x) The value x is placed in FRT[p].  
 U(x) The SNaN of operand x is converted to the corresponding QNaN.  
 VXSNAN Floating-Point Invalid Operation (SNaN) exception occurs. The result is produced only when the exception is disabled. (See Section 5.5.10.1 “Invalid Operation Exception” on page 203.)

Figure 93. Actions: Data-Format Conversion Instructions

**DFP Convert To DFP Long X-form**

dctdp                    FRT,FRB                    (Rc=0)  
dctdp.                    FRT,FRB                    (Rc=1)

59	FRT	///	FRB	258	Rd
0	6	11	16	21	31

The DFP short operand in bits 32:63 of FRB is converted to DFP long format and the converted result is placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the source operand.

If the operand in FRB is an SNaN, it is converted to an SNaN in DFP long format and does not cause an invalid-operation exception.

*dctdp[.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF FR (undefined) FI (undefined)  
CR1 (if Rc=1)

**Programming Note**

Note that DFP short format is a storage-only format. Therefore, conversion of a short SNaN to long format will not cause an exception and the SNaN is preserved. Subsequent operation on that SNaN in long format will cause an exception.

**DFP Convert To DFP Extended X-form**

dctqpq                    FRTp,FRB                    (Rc=0)  
dctqpq.                    FRTp,FRB                    (Rc=1)

63	FRTp	///	FRB	258	Rd
0	6	11	16	21	31

The DFP long operand in the FRB is converted to DFP extended format and placed into FRTp. The sign of the result is the same as the sign of the operand in FRB. The ideal exponent is the exponent of the operand in FRB.

If the operand in FRB is an SNaN, an invalid-operation exception is recognized. If the exception is disabled, the SNaN is converted to the corresponding QNaN in DFP extended format.

*dctqpq[.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF FR (set to 0) FI (set to 0)  
FX  
VXSNaN  
CR1 (if Rc=1)

**DFP Round To DFP Short X-form**

drsp FRT,FRB (Rc=0)  
drsp. FRT,FRB (Rc=1)

The DFP long operand in FRB is converted and rounded to DFP short format. The DFP short value is extended on the left with zeros to form a 64-bit entity and placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the source operand.

If the operand in FRB is an SNaN, it is converted to an SNaN in DFP short format and does not cause an invalid-operation exception.

Normally, the result is in the format and length of the target. However, when an overflow or underflow exception occurs and if the exception is enabled, the operation is completed by producing a wrapped rounded result in the same format and length as the source but rounded to the target-format precision.

*drsp*[.] are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF FR FI  
FX OX UX XX  
CR1 (if Rc=1)

**Programming Note**

Note that DFP short format is a storage-only format. Therefore, conversion of a long SNaN to short format will not cause an exception. Converting a long format SNaN to short format is an implied move operation.

**DFP Round To DFP Long X-form**

drdpq FRTp,FRBp (Rc=0)  
drdpq. FRTp,FRBp (Rc=1)

The DFP extended operand in FRBp is converted and rounded to DFP long format. The result concatenated with 64 0s is placed in FRTp. The sign of the result is the same as the sign of the source operand. The ideal exponent is the exponent of the operand in FRBp.

If the operand in FRBp is an SNaN, an invalid-operation exception is recognized. If the exception is disabled, the SNaN is converted to the corresponding QNaN in DFP long format.

Normally, the result is in the format and length of the target. However, when an overflow or underflow exception occurs and if the exception is enabled, the operation is completed by producing a wrapped rounded result in the same format and length as the source but rounded to the target-format precision.

*drdpq*[.] are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF FR FI  
FX OX UX XX  
VXSNAN  
CR1 (if Rc=1)

**Programming Note**

Note that DFP Round to DFP Long, while producing a result in DFP long format, actually targets a register pair, writing 64 0s in FRTp+1.

### 5.6.5.2 DFP Data-Type Conversion Instructions

The DFP data-type conversion instructions are used to convert data type between DFP and fixed.

The data-type conversion instructions consist of *Convert From Fixed* and *Convert To Fixed*.

#### DFP Convert From Fixed X-form

dcffix                      FRT,FRB                      (Rc=0)  
dcffix.                      FRT,FRB                      (Rc=1)

The 64-bit signed binary integer in FRB is converted and rounded to a DFP Long value and placed into FRT. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

FPRF is set to the class and sign of the result.

*dcffix[.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF FR FI  
FX XX  
CR1    (if Rc=1)

#### DFP Convert From Fixed Quad X-form

dcffixq                      FRTp,FRB                      (Rc=0)  
dcffixq.                      FRTp,FRB                      (Rc=1)

The 64-bit signed binary integer in FRB is converted and rounded to a DFP Extended value and placed into FRTp. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

FPRF is set to the class and sign of the result.

*dcffixq[.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF FR (undefined) FI (undefined)  
CR1    (if Rc=1)

**DFP Convert From Fixed Quadword Quad X-form**

dcffixqq                    FRTp,VRB

63	FRTp	0	VRB	994	/
0	6	11	16	21	31

The 128-bit signed binary integer in VRB is converted and rounded to a DFP Extended value and placed into FRTp. The sign of the result is the same as the sign of the source operand. The ideal exponent is zero.

If the source operand is a zero, then a plus zero with a zero exponent is returned.

FPRF is set to the class and sign of the result.

*dcffixqq* is treated as a *Floating-Point* and a *Vector* instruction in terms of resource availability.

**Special Registers Altered:**

FPRF FR FI FX XX

**VSR Data Layout for dcffixqq**

**DFP Convert To Fixed X-form**

dctfix                      FRT,FRB                      (Rc=0)  
 dctfix.                     FRT,FRB                     (Rc=1)

**DFP Convert To Fixed Quad X-form**

dctfixq                     FRT,FRBp                    (Rc=0)  
 dctfixq.                    FRT,FRBp                    (Rc=1)

The DFP operand in FRB[p] is rounded to an integer value and is placed into FRT in the 64-bit signed binary integer format. The sign of the result is the same as the sign of the source operand, except when the source operand is a NaN or a zero.

Figure 94 summarizes the actions for *Convert To Fixed*.

*dctfix[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

FPRF (undefined) FR FI  
 FX XX  
 VXSNaN VXCVI  
 CR1 (if Rc=1)

**Programming Note**

It is recommended that software pre-round the operand to a floating-point integral using *drintx[q]* or *drintr[q]* if a rounding mode other than the current rounding mode specified by DRN is needed. Saving, modifying and restoring the FPSCR just to temporarily change the rounding mode is less efficient than just employing *drintx[p]* or *drint[p]* which override the current rounding mode using an immediate control field.

For example if the desired function rounding is Round to Nearest, Ties away from 0 but the default rounding (from DRN) is Round to Nearest, Ties to Even then following is preferred.

```
drintn    0, f1, f1, 2
dctfix   f1, f1
```

**DFP Convert To Fixed Quadword Quad X-form**

dctfixqq                    VRT,FRBp

The DFP operand in FRBp is rounded to an integer value and is placed into VRT in the 128-bit signed binary integer format. The sign of the result is the same as the sign of the source operand, except when the source operand is a NaN or a zero.

Figure 96 summarizes the actions for *Convert To Fixed*.

*dctfixqq* is treated as a Floating-Point and a Vector instruction in terms of resource availability.

**Special Registers Altered:**

FPRF (undefined) FR FI FX VXSNaN VXCVI XX

**VSR Data Layout for dctfixqq**

Operand b in FRB[p] is	q is	Is n not precise (n ≠ b)	Inv.-Op. Except. Enabled	Inexact Except. Enabled	Is n Incremented ( n  >  b )	Actions *

SNaN	-	-	Yes	-	-	VXCVI ← 1, VXSNaN ← 1, TV

Explanation:

- \* Setting of XX, VXCVI, and VXSNaN is part of the corresponding exception actions. Also, when an invalid-operation exception occurs, setting of FI and FR bits is part of the exception actions. (See the sections, “Inexact Exception” and “Invalid Operation Exception” for more details.)
- The actions do not depend on this condition.
- FI Floating-Point Fraction Inexact status bit.
- FR Floating-Point Fraction Rounded status bit.
- MN Maximum negative number representable by the 64-bit binary integer format
- MP Maximum positive number representable by the 64-bit binary integer format.
- n The value q converted to a fixed-point result.
- q The value derived when the source value b is rounded to an integer using the specified rounding mode
- T(x) The value x is placed in FRT[p].
- TV The system floating-point enabled exception error handler is invoked for the invalid-operation exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
- TX The system floating-point enabled exception error handler is invoked for the inexact exception if FE0 and FE1 are set to any mode other than the ignore-exception mode.
- VXCVI Floating-Point Invalid Operation (Invalid Conversion) exception status bit.
- VXSNaN Floating-Point Invalid Operation (SNaN) exception status bit.
- XX Floating-Point Inexact exception status bit.

Figure 94. Actions: Convert To Fixed

## 5.6.6 DFP Format Instructions

The DFP format instructions are used to compose or decompose a DFP operand. A source operand of SNaN does not cause an invalid-operation exception. All format instructions employ the record bit (Rc).

The format instructions consist of *Decode DPD To BCD*, *Encode BCD To DPD*, *Extract Biased Exponent*, *Insert Biased Exponent*, *Shift Significand Left Immediate*, and *Shift Significand Right Immediate*.

### DFP Decode DPD To BCD X-form

ddedpd SP,FRT,FRB (Rc=0)  
 ddedpd. SP,FRT,FRB (Rc=1)

### DFP Decode DPD To BCD Quad X-form

ddedpdq SP,FRTp,FRBp (Rc=0)  
 ddedpdq. SP,FRTp,FRBp (Rc=1)

A portion of the significand of the DFP operand in FRB[p] is converted to a signed or unsigned BCD number depending on the SP field. For infinity and NaN, the significand is considered to be the contents in the trailing significand field padded on the left by a zero digit.

#### SP<sub>0</sub> = 0 (unsigned conversion)

The rightmost 16 digits of the significand (32 digits for **ddedpdq**) is converted to an unsigned BCD number and the result is placed into FRT[p].

#### SP<sub>0</sub> = 1 (signed conversion)

The rightmost 15 digits of the significand (31 digits for **ddedpdq**) is converted to a signed BCD number with the same sign as the DFP operand, and the result is placed into FRT[p]. If the DFP operand is negative, the sign is encoded as 0b1101. If the DFP operand is positive, SP<sub>1</sub> indicates which preferred plus sign encoding is used. If SP<sub>1</sub> = 0, the plus sign is encoded as 0b1100 (the option-1 preferred sign code), otherwise the plus sign is encoded as 0b1111 (the option-2 preferred sign code).

**ddedpdq**[q][.] are treated as *Floating-Point* instructions in terms of resource availability.

#### Special Registers Altered:

CR1 (if Rc=1)

### DFP Encode BCD To DPD X-form

denbcd S,FRT,FRB (Rc=0)  
 denbcd. S,FRT,FRB (Rc=1)

### DFP Encode BCD To DPD Quad X-form

denbcdq S,FRTp,FRBp (Rc=0)  
 denbcdq. S,FRTp,FRBp (Rc=1)

The signed or unsigned BCD operand, depending on the S field, in FRB[p] is converted to a DFP number. The ideal exponent is zero.

#### S = 0 (unsigned BCD operand)

The unsigned BCD operand in FRB[p] is converted to a positive DFP number of the same magnitude and the result is placed into FRT[p].

#### S = 1 (signed BCD operand)

The signed BCD operand in FRB[p] is converted to the corresponding DFP number and the result is placed into FRT[p].

If an invalid BCD digit or sign code is detected in the source operand, an invalid-operation exception (VXCVI) occurs.

FPRF is set to the class and sign of the result, except for Invalid Operation Exception when VE=1.

**denbcd**[q][.] are treated as *Floating-Point* instructions in terms of resource availability.

#### Special Registers Altered:

FPRF FR (set to 0) FI (set to 0)  
 FX  
 VXCVI  
 CR1 (if Rc=1)

**DFP Extract Biased Exponent X-form**

dxex                    FRT,FRB                    (Rc=0)  
 dxex.                  FRT,FRB                    (Rc=1)

59	FRT	///	FRB	354	Rc
0	6	11	16	21	31

**DFP Extract Biased Exponent Quad X-form**

dxexq                  FRT,FRBp                  (Rc=0)  
 dxexq.                FRT,FRBp                  (Rc=1)

63	FRT	///	FRBp	354	Rc
0	6	11	16	21	31

The biased exponent of the operand in FRB[p] is extracted and placed into FRT in the 64-bit signed binary integer format. When the operand in FRB is an infinity, QNaN, or SNaN, a special code is returned.

Operand	Result
Finite Number	biased exponent value
Infinity	-1
QNaN	-2
SNaN	-3

*dxex[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

CR1 (if Rc=1)

**Programming Note**

The exponent bias value is 101 for DFP Short, 398 for DFP Long, and 6176 for DFP Extended.

**DFP Insert Biased Exponent X-form**

diex                    FRT,FRA,FRB              (Rc=0)  
 diex.                  FRT,FRA,FRB              (Rc=1)

59	FRT	FRA	FRB	866	Rc
0	6	11	16	21	31

**DFP Insert Biased Exponent Quad X-form**

diexq                  FRTp,FRA,FRBp            (Rc=0)  
 diexq.                FRTp,FRA,FRBp            (Rc=1)

63	FRTp	FRA	FRBp	866	Rc
0	6	11	16	21	31

Let *a* be the value of the 64-bit signed binary integer in FRA.

<i>a</i>	Result
$a > MBE^1$	QNaN
$0 \leq a \leq MBE$	Finite number with biased exponent <i>a</i>
$a = -1$	Infinity
$a = -2$	QNaN
$a = -3$	SNaN
$a < -3$	QNaN
<sup>1</sup>	Maximum biased exponent for the target format

When  $0 \leq a \leq MBE$ , *a* is the biased target exponent that is combined with the sign bit and the significand value of the DFP operand in FRB[p] to form the DFP result in FRT[p]. The ideal exponent is the specified target exponent.

When *a* specifies a special code ( $a < 0$  or  $a > MBE$ ), an infinity, QNaN, or SNaN is formed in FRT[p] with the trailing significand field containing the value from the trailing significand field of the source operand in FRB[p], and with an N-bit combination field set as follows.

- For an Infinity result,
  - the leftmost 5 bits are set to 0b11110, and
  - the rightmost N-5 bits are set to zero.
- For a QNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to zero, and
  - the rightmost N-5 bits are set to zero.
- For an SNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to one, and
  - the rightmost N-5 bits are set to zero.

*diex[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

CR1 (if Rc=1)

**Programming Note**

The exponent bias value is 101 for DFP Short, 398 for DFP Long, and 6176 for DFP Extended.

Operand a in FRA[p] specifies	Actions for Insert Biased Exponent when operand b in FRB[p] specifies			
	F	$\infty$	QNaN	SNaN
F	N, Rb	Z, Rb	Z, Rb	Z, Rb
$\infty$	I, Rb	I, Rb	I, Rb	I, Rb
QNaN	Q, Rb	Q, Rb	Q, Rb	Q, Rb
SNaN	S, Rb	S, Rb	S, Rb	S, Rb

Explanation:

F	All finite numbers, including zeros
I	The combination field in FRT[p] is set to indicate a default Infinity.
N	The combination field in FRT[p] is set to the specified biased exponent in FRA and the leftmost significand digit in FRB[p].
Q	The combination field in FRT[p] is set to indicate a default QNaN.
S	The combination field in FRT[p] is set to indicate a default SNaN.
Z	The combination field in FRT[p] is set to indicate the specific biased exponent in FRA and a leftmost coefficient digit of zero.
Rb	The contents of the trailing significand field in FRB[p] are reencoded using preferred DPD encodings and the reencoded result is placed in the same field in FRT[p]. The sign bit of FRB[p] is copied into the sign bit in FRT[p].

**Figure 95. Actions: Insert Biased Exponent**

**DFP Shift Significant Left Immediate Z22-form**

dscli                      FRT,FRA,SH                      (Rc=0)  
 dscli.                      FRT,FRA,SH                      (Rc=1)

59	FRT	FRA	SH	66	Rd
0	6	11	16	22	31

**DFP Shift Significant Left Immediate Quad Z22-form**

dscliq                      FRTp,FRAp,SH                      (Rc=0)  
 dscliq.                      FRTp,FRAp,SH                      (Rc=1)

63	FRTp	FRAp	SH	66	Rd
0	6	11	16	22	31

The significand of the DFP operand in FRA[p] is shifted left SH digits. For a NaN or infinity, all significand digits are in the trailing significand field. SH is a 6-bit unsigned binary integer. Digits shifted out of the leftmost digit are lost. Zeros are supplied to the vacated positions on the right. The result is placed into FRT[p]. The sign of the result is the same as the sign of the source operand in FRA[p].

If the source operand in FRA[p] is a finite number, the exponent of the result is the same as the exponent of the source operand.

For an Infinity, QNaN or SNaN result, the target format's N-bit combination field is set as follows.

- For an Infinity result,
  - the leftmost 5 bits are set to 0b11110, and
  - the rightmost N-5 bits are set to zero.
- For a QNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to zero, and
  - the rightmost N-6 bits are set to zero.
- For an SNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to one, and
  - the rightmost N-6 bits are set to zero.

*dscli[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

63	FRTp	FRAp	SH	98	Rd
0	6	11	16	22	31

The significand of the DFP operand in FRA[p] is shifted right SH digits. For a NaN or infinity, all significand digits are in the trailing significand field. SH is a 6-bit unsigned binary integer. Digits shifted out of the units digit are lost. Zeros are supplied to the vacated positions on the left. The result is placed into FRT[p]. The sign of the result is the same as the sign of the source operand in FRA[p].

If the source operand in FRA[p] is a finite number, the exponent of the result is the same as the exponent of the source operand.

For an Infinity, QNaN or SNaN result, the target format's N-bit combination field is set as follows.

- For an Infinity result,
  - the leftmost 5 bits are set to 0b11110, and
  - the rightmost N-5 bits are set to zero.
- For a QNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to zero, and
  - the rightmost N-6 bits are set to zero.
- For an SNaN result,
  - the leftmost 5 bits are set to 0b11111,
  - bit 5 is set to one, and
  - the rightmost N-6 bits are set to zero.

*dscri[q][.]* are treated as *Floating-Point* instructions in terms of resource availability.

**Special Registers Altered:**

CR1                      (if Rc=1)

## 5.6.7 DFP Instruction Summary

Mnemonic	Full Name	FORM	Operands	SNaN Vs G	Encoding	FPRF		FP Exception V Z O U X	FR/FI	IE	RC

Figure 96. Decimal Floating-Point Instructions Summary (Continued)

## Explanation:

- # FI and FR are set to zeros for these instructions.
- Not applicable.
- 1 A unique definition of the FPSCR<sub>FPC</sub> field is provided for the instruction.
- 2 These are the only instructions that may generate an SNaN and also set the FPSCR<sub>FPRF</sub> field. Since the BFP FPRF field does not include a code for SNaN, these instructions cause the need for redefining the FPRF field for DFP.
- DCM A 6-bit immediate operand specifying the data-class mask.
- DGM A 6-bit immediate operand specifying the data-group mask.
- G An SNaN can be generated as the target operand.
- IE An ideal exponent is defined for the instruction.
- FI Setting of the FPSCR<sub>FI</sub> flag.
- FR Setting of the FPSCR<sub>FR</sub> flag.
- N No.
- O An overflow exception may be recognized.
- Rc The record bit, Rc, is provided to record FPSCR<sub>32:35</sub> in CR field 1.
- RE The trailing significand field is reencoded using preferred DPD encodings. The preferred DPD encoding are also used for propagated NaNs, or converted NaNs and infinities.
- RMC A 2-bit immediate operand specifying the rounding-mode control.
- S An one-bit immediate operand specifying if the operation is signed or unsigned.

**Explanation:**

- SP A two-bit immediate operand: one bit specifies if the operation is signed or unsigned and, for signed operations, another bit specifies which preferred plus sign code is generated.
- U An underflow exception may be recognized.
- V An invalid-operation exception may be recognized.
- Vs An input operand of SNaN causes an invalid-operation exception.
- X An inexact exception may be recognized.
- Y Yes.
- U Undefined
- Z A zero-divide exception may be recognized.

## Chapter 6. Vector Facility

---

### 6.1 Vector Facility Overview

This chapter describes the registers and instructions that make up the Vector Facility.

### 6.2 Chapter Conventions

#### 6.2.1 Description of Instruction Operation

The following notation, in addition to that described in Section 1.3.2, is used in this chapter.

**x. bit[y: z]**  
Return the contents of bits y:z of x.

**x. nibble[y: z]**  
Return the contents of the 4-bit nibble elements y:z of x.

**x. byte[y: z]**  
Return the contents of 8-bit byte elements y:z of x.

**x. hword[y: z]**  
Return the contents of 16-bit halfword elements y:z of x.

**x. word[y: z]**  
Return the contents of 32-bit word element y:z of x.

**x. dword[y: z]**  
Return the contents of 64-bit doubleword elements y:z of x.

**x ? y : z**  
if the value of x is true, then the value of y, otherwise the value z.

**+**  
Addition.

**-**  
Subtraction.

**x**  
Multiplication.

**~**  
One's complement.

**=, <, <=, >, >=**  
Equal, less than, less than or equal, greater than, and greater than or equal comparison relations.

**x << y**

Result of shifting x left by y bits, filling vacated bits with zeros.

```

b ← LENGTH(x)
result ← x
do i = 0 to y-1
    result ← result.bit[1: b-1] || 0b0

```

**x >> y**

Result of shifting x right by y bits, filling vacated bits with copies of bit 0 of x.

```

b ← LENGTH(x)
result ← x
do i = 0 to y-1
    result ← result.bit[0] || result.bit[0: b-2]

```

**bcd\_ADD(x, y, z)**

Let x and y be 31-digit signed decimal values.

Performs a signed decimal addition of x and y.

If the unbounded result is equal to zero, eq\_flg is set to 1. Otherwise, eq\_flg is set to 0.

If the unbounded result is greater than zero, gt\_flg is set to 1. Otherwise, gt\_flg is set to 0.

If the unbounded result is less than zero, lt\_flg is set to 1. Otherwise, lt\_flg is set to 0.

If the magnitude of the unbounded result is greater than  $10^{31}-1$ , ox\_flg is set to 1. Otherwise, ox\_flg is set to 0.

If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1100 if z=0.

If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1111 if z=1.

If the unbounded result is less than zero, the sign code of the result is set to 0b1101.

The low-order 31 digits of the unbounded result magnitude concatenated with the sign code are returned.

If either operand is an invalid encoding of a signed decimal value, the result returned is undefined and inv\_flg is set to 1 and lt\_flg, gt\_flg and eq\_flg are set to 0. Otherwise, inv\_flg is set to 0.

**bcd\_CONVERT\_FROM\_SI 128(x, y)**

Let x be a signed integer quadword.  
Let y indicate the preferred sign code.

Return the signed integer value x in packed decimal format.

```

if x < 0 then do
    x ← -x + 1
    sign ← 0x000D
end
else
    sign ← (y=0) ? 0x000C : 0x000F

result ← 0
shcnt ← 4

do while (x > 0)
    digit ← x % 10
    result ← result | (digit << shcnt)
    x ← x ÷ 10
    shcnt ← shcnt + 4
end

return result | sign

```

**bcd\_INCREMENT(result)**

Increments the magnitude of the packed decimal value x by 1.

**bcd\_SUBTRACT(x, y, z)**

Let x and y be 31-digit signed decimal values.

Performs a signed decimal subtract of y from x.

If the unbounded result is equal to zero, eq\_flag is set to 1. Otherwise, eq\_flag is set to 0.  
If the unbounded result is greater than zero, gt\_flag is set to 1. Otherwise, gt\_flag is set to 0.  
If the unbounded result is less than zero, lt\_flag is set to 1. Otherwise, lt\_flag is set to 0.

If the magnitude of the unbounded result is greater than  $10^{31}-1$ , ox\_flag is set to 1. Otherwise, ox\_flag is set to 0.

If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1100 if z=0.  
If the unbounded result is greater than or equal to zero, the sign code of the result is set to 0b1111 if z=1.  
If the unbounded result is less than zero, the sign code of the result is set to 0b1101.

The low-order 31 digits of the unbounded result magnitude concatenated with the sign code are returned.

If either operand is an invalid encoding of a signed decimal value, the result returned is undefined and inv\_flag is set to 1 and lt\_flag, gt\_flag and eq\_flag are set to 0. Otherwise, inv\_flag is set to 0.

**bfp32\_ADD(x, y)**

x is a binary floating-point value represented in single-precision format.

y is a binary floating-point value represented in single-precision format.

If x is a QNaN, the result is x.

Otherwise, if x is an SNaN, the result is x converted to a QNaN.

Otherwise, if y is a QNaN, the result is y.

Otherwise, if y is an SNaN, the result is y converted to a QNaN.

Otherwise, if x and y are Infinities having opposite signs, the result is the single-precision standard QNaN.

Otherwise, if x is an Infinity, the result is x.

Otherwise, if y is an Infinity, the result is y.

Otherwise, the result is the sum, x added to y, rounded to the nearest single-precision value.

Return the result represented in single-precision format.

**bfp32\_CONVERT\_FROM\_SI 32(x, y)**

Let x be a 32-bit signed integer value.

```

sign      ← X.bit[0]
exp       ← 32 + 127
frac.bit[0] ← x.bit[0]
frac.bit[1:32] ← x.bit[0:31]

```

```

if frac=0 return 0x0000_0000 // Zero operand
if sign=1 then frac = ~frac + 1

```

```

do while (frac.bit[0]=0)
  frac ← frac << 1
  exp ← exp - 1
end

```

```

lsb ← frac.bit[23]
gbit ← frac.bit[24]
xbit ← frac.bit[25:32]!=0
inc ← (lsb & gbit) | (gbit & xbit)

```

```

frac.bit[0:23] ← frac.bit[0:23] + inc
if carry_out=1 then exp ← exp + 1

```

```

result.bit[0] ← sign
result.bit[1:8] ← exp - y
result.bit[9:31] ← frac.bit[1:23]

```

```

return result

```

**bfp32\_CONVERT\_FROM\_UI32(x, y)**

x is a 32-bit unsigned integer value.

```

exp ← 31 + 127
frac ← x.bit[0:31]

if frac=0 return 0x0000_0000 // Zero

do while frac0=0
    frac ← frac << 1
    exp ← exp - 1
end

lsb ← frac.bit[23]
gbit ← frac.bit[24]
xbit ← frac.bit[25:31]≠0
inc ← (lsb & gbit) | (gbit & xbit)

frac.bit[0:23] ← frac.bit[0:23] + inc
if carry_out=1 then exp ← exp + 1

result.bit[0] ← 0b0
result.bit[1:8] ← exp - y
result.bit[9:31] ← frac.bit[1:23]

return result

```

**bfp32\_LOG\_BASE2\_ESTIMATE(x)**

x is a floating-point value represented in single-precision format.

Returns a floating-point estimate of the base 2 logarithm of x, represented in single-precision format.

**bfp32\_MAXIMUM(x, y)**

x is a floating-point value represented in single-precision format.

y is a floating-point value represented in single-precision format.

Return the largest value of x and y, represented in single-precision format.

The maximum of +0.0 and -0.0 is +0.0.

The maximum of any value and a NaN is a QNaN.

**bfp32\_MINIMUM(x, y)**

x is a floating-point value represented in single-precision format.

y is a floating-point value represented in single-precision format.

Return the smallest value of x and y, represented in single-precision format.

The minimum of +0.0 and -0.0 is -0.0.

The minimum of any value and a NaN is a QNaN.

**bfp32\_MULTIPLY\_ADD(x, z, y)**

x is a binary floating-point value represented in single-precision format.  
y is a binary floating-point value represented in single-precision format.  
z is a binary floating-point value represented in single-precision format.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, the result is x converted to a QNaN.

Otherwise, if y is a QNaN, the result is y.

Otherwise, if y is an SNaN, the result is y converted to a QNaN.

Otherwise, if z is a QNaN, the result is z.

Otherwise, if z is an SNaN, the result is z converted to a QNaN.

Otherwise, if x is an Infinity and z is a Zero, the result is the single-precision standard QNaN.

Otherwise, if x is a Zero and z is an Infinity, the result is the single-precision standard QNaN.

Otherwise, if the product, x multiplied by z, and y are Infinities having opposite signs, the result is the single-precision standard QNaN.

Otherwise, the result is the sum of the product, x multiplied by z, added to y, rounded to the nearest single-precision value.

Return the result represented in single-precision format.

**bfp32\_NEGATIVE\_MULTIPLY\_SUBTRACT(x, z, y)**

x is a binary floating-point value represented in single-precision format.  
y is a binary floating-point value represented in single-precision format.  
z is a binary floating-point value represented in single-precision format.

If x is a QNaN, the result is x.

Otherwise, if x is an SNaN, the result is x converted to a QNaN.

Otherwise, if y is a QNaN, the result is y.

Otherwise, if y is an SNaN, the result is y converted to a QNaN.

Otherwise, if z is a QNaN, the result is z.

Otherwise, if z is an SNaN, the result is z converted to a QNaN.

Otherwise, if x is an Infinity and z is a Zero, the result is the single-precision standard QNaN.

Otherwise, if x is a Zero and z is an Infinity, the result is the single-precision standard QNaN.

Otherwise, if the product, x multiplied by z, and y are Infinities having the same signs, the result is the single-precision standard QNaN.

Otherwise, the result is the difference of the product, x multiplied by z, subtracted by y, then rounded to the nearest single-precision value, and then negated.

Return the result represented in single-precision format.

**bfp32\_POWER2\_ESTIMATE(x)**

x is a floating-point value represented in single-precision format.

Returns a floating-point estimate of 2 raised to the power of x, represented in single-precision format.

**bfp32\_RECIPROCAL\_ESTIMATE(x)**

x is a floating-point value represented in single-precision format.

Returns a floating-point estimate of the reciprocal of x, represented in single-precision format.

**bfp32\_RECIPROCAL\_SQRT\_ESTIMATE(x)**

x is a floating-point value represented in single-precision format.

Returns a floating-point estimate of the reciprocal of the square root of x, represented in single-precision format.

**bf32\_ROUND\_TO\_INTEGER\_CEIL(x)**

x is a floating-point value represented in single-precision format.

Returns the smallest floating-point integer that is greater than or equal to x, represented in single-precision format.

**bf32\_ROUND\_TO\_INTEGER\_FLOOR(x)**

x is a floating-point value represented in single-precision format.

Returns the largest floating-point integer that is less than or equal to x, represented in single-precision format.

**bf32\_ROUND\_TO\_INTEGER\_NEAR(x)**

x is a floating-point value represented in single-precision format.

Returns the floating-point integer that is nearest to x (in case of a tie, the even single-precision floating-point integer is used), represented in single-precision format.

**bf32\_ROUND\_TO\_INTEGER\_TRUNC(x)**

x is a floating-point value represented in single-precision format.

Returns the largest floating-point integer that is less than or equal to x if  $x > 0$ , or the smallest floating-point integer that is greater than or equal to x if  $x < 0$ , or represented in single-precision format.

**bf32\_ROUND\_TO\_NEAR(x)**

x is a floating-point value represented in the working floating-point format.

Returns the single-precision floating-point value that is nearest to x (in case of a tie, the single-precision floating-point value with the least-significant bit equal to 0 is used), represented in single-precision format.

**bf32\_SUBTRACT(x, y)**

x is a binary floating-point value represented in single-precision format.

y is a binary floating-point value represented in single-precision format.

If x is a QNaN, the result is x.

Otherwise, if x is an SNaN, the result is x converted to a QNaN.

Otherwise, if y is a QNaN, the result is y.

Otherwise, if y is an SNaN, the result is y converted to a QNaN.

Otherwise, if x and y are infinities having the same signs, the result is the single-precision standard QNaN.

Otherwise, if x is an infinity, the result is x.

Otherwise, if y is an infinity, the result is y.

Otherwise, the result is the difference, x subtracted by y, rounded to the nearest single-precision value.

Return the result represented in single-precision format.

**bool\_COMPARE\_GE\_BFP32(x, y)**

x is a floating-point value represented in the single-precision format.

y is a floating-point value represented in the single-precision format.

Returns the value 1 if x is greater than or equal to y. Otherwise, returns the value 0.

**bool\_COMPARE\_GT\_BFP32(x, y)**

x is a floating-point value represented in the single-precision format.

y is a floating-point value represented in the single-precision format.

Returns the value 1 if x is greater than y. Otherwise, returns the value 0.

**bool\_COMPARE\_EQ\_BFP32(x, y)**

x is a floating-point value represented in the single-precision format.  
y is a floating-point value represented in the single-precision format.

Returns the value 1 if x is equal to y. Otherwise, returns the value 0.

**bool\_COMPARE\_LE\_BFP32(x, y)**

x is a floating-point value represented in the single-precision format.  
y is a floating-point value represented in the single-precision format.

Returns the value 1 if x is less than or equal to y. Otherwise, returns the value 0.

**CHOP8(x)**

Returns rightmost 8 bits of x padded on the left with zeros if necessary.

**CHOP16(x)**

Returns rightmost 16 bits of x padded on the left with zeros if necessary.

**CHOP32(x)**

Returns rightmost 32 bits of x padded on the left with zeros if necessary.

**CHOP64(x)**

Returns rightmost 64 bits of x padded on the left with zeros if necessary.

**CHOP128(x)**

Returns rightmost 128 bits of x padded on the left with zeros if necessary.

**Clamp(x, y, z)**

x is interpreted as a signed integer. If the value of x is less than y, then the value y is returned, else if the value of x is greater than z, the value z is returned, else the value x is returned.

```

if x < y then
    result ← y
else if x > z then
    result ← z
else
    result ← x

```

**EXTS(x)**

Result of extending x on the left with copies of bit 0 of x to form a signed integer value having unbounded range.

**EXTS8(x)**

Result of extending x on the left with copies of bit 0 of x to form an 8-bit signed integer value.

**EXTS16(x)**

Result of extending x on the left with copies of bit 0 of x to form a 16-bit signed integer value.

**EXTS32(x)**

Result of extending x on the left with copies of bit 0 of x to form a 32-bit signed integer value.

**EXTS64(x)**

Result of extending x on the left with copies of bit 0 of x to form a 64-bit signed integer value.

**EXTS128(x)**

Result of extending x on the left with copies of bit 0 of x to form a 128-bit signed integer value.

**EXTZ(x)**

Result of extending x on the left with 0s to form a positive signed integer value having unbounded range.

**EXTZ8(x)**

Result of extending  $x$  on the left with 0s to form an 8-bit unsigned integer value.

**EXTZ16(x)**

Result of extending  $x$  on the left with 0s to form a 16-bit unsigned integer value.

**EXTZ32(x)**

Result of extending  $x$  on the left with 0s to form a 32-bit unsigned integer value.

**EXTZ64(x)**

Result of extending  $x$  on the left with 0s to form a 64-bit unsigned integer value.

**EXTZ128(x)**

Result of extending  $x$  on the left with 0s to form a 128-bit unsigned integer value.

## 6.3 Vector Facility Registers

Figure 97. Vector-Scalar Register elements

### 6.3.1 Vector-Scalar Registers

The *Vector* instructions described in Chapter 6 are defined to operate on the higher-numbered 32 Vector-Scalar Registers (VSRs 32-63), formerly known as Vector Registers (VRs 0-31). See Figure 98. All computations and other data manipulation are performed on data residing in VSRs 32-63, and results are placed into one of VSRs 32-63.

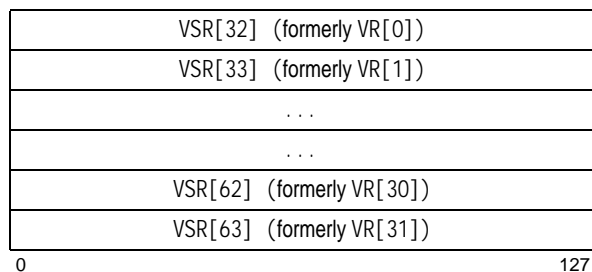

Figure 98. Vector-Scalar Registers

Depending on the instruction, the contents of a VSR are interpreted as a sequence of equal-length elements (bytes, halfwords, or words) or as a quadword. Each of the elements is aligned within the VSR, as shown in Figure 97. Many instructions perform a given operation in parallel on all elements in a VSR. Depending on the instruction, a byte, halfword, or word element can be interpreted as a signed-integer, an unsigned-integer, or a logical value; a word element can also be interpreted as a single-precision floating-point value. In the instruction descriptions, phrases like “signed-integer word element” are used as shorthand for “word element, interpreted as a signed-integer”.

*Load* and *Store* instructions are provided that transfer a byte, halfword, word, or quadword between storage and a VSR.

### 6.3.2 Vector Status and Control Register

The Vector Status and Control Register (VSCR) is a special 32-bit register (not an SPR) that is read and written in a manner similar to the FPSCR in the Power ISA scalar floating-point unit. Special instructions (*mfvscr* and *mtvscr*) are provided to move the VSCR from and to a VSR. When moved to or from a VSR, the 32-bit VSCR is right justified in the 128-bit VSR. When moved to a VSR, bits 0:95 of the VSR are cleared (set to 0).

Figure 99. Vector Status and Control Register

The bit definitions for the VSCR are as follows.

Bit(s)	Description
96:110	Reserved
111	<b>Vector Non-Java Mode (NJ)</b>  This bit controls how denormalized values are handled by <i>Vector Floating-Point</i> instructions. 0 Denormalized values are handled as specified by Java and the IEEE standard; see Section 6.6.1. 1 If an element in a source VSR contains a denormalized value, the value 0 is used instead. If an instruction causes an Underflow Exception, the corresponding element in the target VSR is set to 0. In both cases the 0 has the same sign as the denormalized or underflowing value.
112:126	Reserved

127 **Vector Saturation** (SAT)

Every vector instruction having “Saturate” in its name implicitly sets this bit to 1 if any result of that instruction “saturates”; see Section 6.8. *mtvscr* can alter this bit explicitly. This bit is sticky; that is, once set to 1 it remains set to 1 until it is set to 0 by an *mtvscr* instruction.

After the *mtvscr* instruction executes, the result in the target VSR will be architecturally precise. That is, it will reflect all updates to the SAT bit that could have been made by vector instructions logically preceding it in the program flow, and further, it will not reflect any SAT updates that may be made to it by vector instructions logically following it in the program flow. To implement this, processors may choose to make the *mtvscr* instruction execution serializing within the vector unit, meaning that it will stall vector instruction execution until all preceding vector instructions are complete and have updated the architectural machine state. This is permitted in order to simplify implementation of the sticky status bit (SAT) which would otherwise be difficult to implement in an out-of-order execution machine. The implication of this is that reading the VSCR can be much slower than typical Vector instructions, and therefore care must be taken in reading it, as advised in Section 6.5.1, to avoid performance problems.

The *mtvscr* is context synchronizing. This implies that all Vector instructions logically preceding an *mtvscr* in the program flow will execute in the architectural context (NJ mode) that existed prior to completion of the *mtvscr*, and that all instructions logically following the *mtvscr* will execute in the new context (NJ mode) established by the *mtvscr*.

**6.3.3 VR Save Register**

The VR Save Register (VRSAVE) is a 32-bit register in the fixed-point processor provided for application and operating system use; see Section 3.2.3.

**Programming Note**

VRSAVE can be used to indicate which VSRs are currently being used by a program. If this is done, the operating system could save only those VSRs when an “interrupt” occurs (see Book III), and could restore only those VSRs when resuming the interrupted program.

If this approach is taken it must be applied rigorously; if a program fails to indicate that a given VSR is in use, software errors may occur that will be difficult to detect and correct because they are timing-dependent.

Some operating systems save and restore VRSAVE only for programs that also use other VSRs.

## 6.4 Vector Storage Access Operations

The *Vector Storage Access* instructions provide the means by which data can be copied from storage to a VSR or from a VSR to storage. Instructions are provided that access byte, halfword, word, and quadword storage operands. These instructions differ from the fixed-point and floating-point *Storage Access* instructions in that vector storage operands are assumed to be aligned, and vector storage accesses are performed as if the appropriate number of low-order bits of the specified effective address (EA) were zero. For example, the low-order bit of EA is ignored for halfword *Vector Storage Access* instructions, and the low-order four bits of EA are ignored for quadword *Vector Storage Access* instructions. The effect is to load or store the storage operand of the specified length that contains the byte addressed by EA.

If a storage operand is unaligned, additional instructions must be used to ensure that the operand is correctly placed in a VSR or in storage. Instructions are provided that shift and merge the contents of two VSRs, such that an unaligned quadword storage operand can be copied between storage and the VSRs in a relatively efficient manner.

As shown in Figure 97, the elements in VSRs are numbered; the high-order (or most significant) byte element is numbered 0 and the low-order (or least significant) byte element is numbered 15. The numbering affects the values that must be placed into the permute control vector for the *Vector Permute* instruction in order for that instruction to achieve the desired effects, as illustrated by the examples in the following subsections.

A vector quadword *Load* instruction for which the effective address (EA) is quadword-aligned places the byte in storage addressed by EA into byte element 0 of the target VSR, the byte in storage addressed by EA+1 into byte element 1 of the target VSR, etc. Similarly, a vector quadword *Store* instruction for which the EA is quadword-aligned places the contents of byte element 0 of the source VSR into the byte in storage addressed by EA, the contents of byte element 1 of the source VSR into the byte in storage addressed by EA+1, etc.

Figure 100 shows an aligned quadword in storage. Figure 101 shows the result of loading that quadword into a VSR or, equivalently, shows the contents that must be in a VSR if storing that VSR is to produce the storage contents shown in Figure 100.

When an aligned byte, halfword, or word storage operand is loaded into a VSR, the element (byte, halfword, or word respectively) that receives the data is the element that would have received the data had the entire aligned quadword containing the storage operand addressed by EA been loaded. Similarly, when a byte, halfword, or word element in a VSR is stored into an aligned storage operand (byte, halfword, or word respectively), the element selected to be stored is the element that would have been stored into the storage operand addressed by EA had the entire VSR been stored to the aligned quadword containing the storage operand addressed by EA. (Byte storage operands are always aligned.)

For aligned byte, halfword, and word storage operands, if the corresponding element number is known when the program is written, the appropriate *Vector Splat* and *Vector Permute* instructions can be used to copy or replicate the data contained in the storage operand after loading the operand into a VSR. An example of this is given in the Programming Note for *Vector Splat*; see page 297. Another example is to replicate the element across an entire VSR before storing it into an arbitrary aligned storage operand of the same length; the replication ensures that the correct data are stored regardless of the offset of the storage operand in its aligned quadword in storage.

## 6.4.1 Accessing Unaligned Storage Operands

Figure 102 shows an unaligned quadword storage operand that spans two aligned quadwords. In the remainder of this section, the aligned quadword that contains the most significant bytes of the unaligned quadword is called the most significant quadword (MSQ) and the aligned quadword that contains the least significant bytes of the unaligned quadword is called the least significant quadword (LSQ). Because the *Vector Storage Access* instructions ignore the low-order bits of the effective address, the unaligned quadword cannot be transferred between storage and a VSR using a single instruction. The remainder of this section gives examples of accessing unaligned quadword storage operands. Similar sequences can be used to access unaligned halfword and word storage operands.

### Programming Note

The sequence of instructions given below is one approach that can be used to load the unaligned quadword shown in Figure 102 into a VSR. In Figure 103 Vhi and Vlo are the VSRs that will receive the most significant quadword and least significant quadword respectively. VSR[VRT+32] is the target VSR.

After the two quadwords have been loaded into Vhi and Vlo, using *Load Vector Indexed* instructions, the alignment is performed by shifting the 32-byte quantity Vhi || Vlo left by an amount determined by the address of the first byte of the desired data. The shifting is done using a *Vector Permute* instruction for which the permute control vector is generated by a *Load Vector for Shift Left* instruction. The *Load Vector for Shift Left* instruction uses the same address specification as the *Load Vector Indexed* instruction that loads the Vhi register; this is the address of the desired unaligned quadword.

The following sequence of instructions copies the unaligned quadword storage operand into register Vt.

```
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
l vx  Vhi, 0, Rb      # load MSQ
l vsl  Vp, 0, Rb     # set permute control vector
addi  Rb, Rb, 16    # address of LSQ
l vx  Vlo, 0, Rb     # load LSQ
vperm Vt, Vhi, Vlo, Vp # align the data
```

The procedure for storing an unaligned quadword is essentially the reverse of the procedure for loading one. However, a read-modify-write sequence is required that inserts the source quadword into two aligned quadwords in storage. The quadword to be stored is assumed to be in Vs; see Figure 103. The contents of Vs are shifted right and split into two parts, each of which is merged (using a *Vector Select* instruction) with the current contents of the two aligned quadwords (MSQ and LSQ) that will contain the most significant bytes and least significant bytes, respectively, of the unaligned quadword. The resulting two quadwords are stored using *Store Vector Indexed* instructions. A *Load Vector for Shift Right* instruction is used to generate the permute control vector that is used for the shifting. A single register is used for the “shifted” contents; this is possible because the “shifting” is done by means of a right rotation. The rotation is accomplished by specifying Vs for both components of the *Vector Permute* instruction. In addition, the same permute control vector is used on a sequence of 1s and 0s to generate the mask used by the *Vector Select* instructions that do the merging.

The following sequence of instructions copies the contents of Vs into an unaligned quadword in storage.

```
# Assumptions:
# Rb != 0 and contents of Rb = 0xB
lvx      Vhi, 0, Rb      # load current MSQ
lvsr     Vp, 0, Rb      # set permute control vector
addi     Rb, Rb, 16     # address of LSQ
lvx      Vlo, 0, Rb     # load current LSQ
vsplti sb V1s, -1      # generate the select mask bits
vsplti sb V0s, 0
vperm    Vmask, V0s, V1s, Vp # generate the select mask
vperm    Vs, Vs, Vs, Vp  # right rotate the data
vsel     Vlo, Vs, Vlo, Vmask # insert LSQ component
vsel     Vhi, Vhi, Vs, Vmask # insert MSQ component
stvx     Vlo, 0, Rb     # store LSQ
addi     Rb, Rb, -16    # address of MSQ
stvx     Vhi, 0, Rb     # store MSQ
```

## 6.5 Vector Integer Operations

Many of the instructions that produce fixed-point integer results have the potential to compute a result value that cannot be represented in the target format. When this occurs, this unrepresentable intermediate value is converted to a representable result value using one of the following methods.

1. The high-order bits of the intermediate result that do not fit in the target format are discarded. This method is used by instructions having names that include the word "Modulo".
2. The intermediate result is converted to the nearest value that is representable in the target format (i.e., to the minimum or maximum representable value, as appropriate). This method is used by instructions having names that include the word "Saturate". An intermediate result that is forced to the minimum or maximum representable value as just described is said to "saturate".

An instruction for which an intermediate result saturates causes SAT to be set to 1; see Section 6.3.2.

3. If the intermediate result includes non-zero fraction bits it is rounded up to the nearest fixed-point integer value. This method is used by the six *Vector Average Integer* instructions and by the *Vector Multiply-High-Round-Add Signed Halfword Saturate* instruction. The latter instruction then uses method 2, if necessary.

### Programming Note

Because SAT is sticky, it can be used to detect whether any instruction in a sequence of "Saturate"-type instructions produced an inexact result due to saturation. For example, the contents of the VSCR can be copied to a VSR (*mfvsr*), bits other than SAT can be cleared in the VSR (*vand* with a constant), the result can be compared to zero setting CR6 (*vcmpequb*), and a branch can be taken according to whether SAT was set to 1 (*Branch Conditional* that tests CR field 6).

Testing SAT after each "Saturate"-type instruction would degrade performance considerably. Alternative techniques include the following:

- Retain sufficient information at "checkpoints" that the sequence of computations performed between one checkpoint and the next can be redone (more slowly) in a manner that detects exactly when saturation occurs. Test SAT only at checkpoints, or when redoing a sequence of computations that saturated.
- Perform intermediate computations using an element length sufficient to prevent saturation, and then use a *Vector Pack Integer Saturate* instruction to pack the final result to the desired length. (*Vector Pack Integer Saturate* causes results to saturate if necessary, and sets SAT to 1 if any result saturates.)

## 6.5.1 Integer Saturation

Saturation occurs whenever the result of a saturating instruction does not fit in the result field. Unsigned saturation clamps results to zero (0) on underflow and to the maximum positive integer value ( $2^n-1$ , e.g. 255 for byte fields) on overflow. Signed saturation clamps results to the smallest representable negative number ( $-2^{n-1}$ , e.g. -128 for byte fields) on underflow, and to the largest representable positive number ( $2^{n-1}-1$ , e.g. +127 for byte fields) on overflow.

In most cases, the simple maximum/minimum saturation performed by the vector instructions is adequate. However, sometimes, e.g. in the creation of very high quality images, more complex saturation functions must be applied. To support this, the Vector facility provides a mechanism for detecting that saturation has occurred. The VSCR has a bit, SAT, which is set to a one (1) anytime any field in a saturating instruction saturates. SAT can only be cleared by explicitly writing zero to it. Thus SAT accumulates a summary result of any integer overflow or underflow that occurs on a saturating instruction.

Borderline cases that generate results equal to saturation values, for example unsigned  $0+0=0$  and unsigned byte  $1+254=255$ , are not considered saturation conditions and do not cause SAT to be set.

SAT can be set by the following types of instructions:

- *Move To VSCR*
- *Vector Add Integer with Saturation*
- *Vector Subtract Integer with Saturation*
- *Vector Multiply-Add Integer with Saturation*
- *Vector Multiply-Sum with Saturation*
- *Vector Sum-Across with Saturation*
- *Vector Pack with Saturation*
- *Vector Convert to Fixed-point with Saturation*

Note that only instructions that explicitly call for “saturation” can set SAT. “Modulo” integer instructions and floating-point arithmetic instructions never set SAT.

### Programming Note

The SAT state can be tested and used to alter program flow by moving the VSCR to a VSR (with *mfvscr*), then masking out bits 0:126 (to clear undefined and reserved bits) and performing a vector compare equal-to unsigned byte w/record (*vcmpequb*.) with zero to get a testable value into the condition register for consumption by a subsequent branch.

Since *mfvscr* will be slow compared to other Vector instructions, reading and testing SAT after each instruction would be prohibitively expensive. Therefore, software is advised to employ strategies that minimize checking SAT. For example: checking SAT periodically and backtracking to the last checkpoint to identify exactly which field in which instruction saturated; or, working in an element size sufficient to prevent any overflow or underflow during intermediate calculations, then packing down to the desired element size as the final operation (the vector pack instruction saturates the results and updates SAT when a loss of significance is detected).

## 6.6 Vector Floating-Point Operations

### 6.6.1 Floating-Point Overview

Unless  $NJ=1$  (see Section 6.3.2), the floating-point model provided by the Vector Facility conforms to The Java Language Specification (hereafter referred to as “Java”), which is a subset of the default environment specified by the IEEE standard (i.e., by ANSI/IEEE Standard 754-1985, “IEEE Standard for Binary Floating-Point Arithmetic”). For aspects of floating-point behavior that are not defined by Java but are defined by the IEEE standard, vector floating-point conforms to the IEEE standard. For aspects of floating-point behavior that are defined neither by Java nor by the IEEE standard but are defined by the “C9X Floating-Point Proposal” (hereafter referred to as “C9X”), vector floating-point conforms to C9X.

The single-precision floating-point data format, value representations, and computational models defined in Chapter 4. “Floating-Point Facility” on page 135 apply to vector floating-point except as follows.

- In general, no status bits are set to reflect the results of floating-point operations. The only exception is that SAT may be set by the *Vector Convert To Fixed-Point Word* instructions.
- With the exception of the two *Vector Convert To Fixed-Point Word* instructions and three of the four *Vector Round to Floating-Point Integer* instructions, all vector floating-point instructions that round use the rounding mode Round to Nearest.
- Floating-point exceptions (see Section 6.6.2) cannot cause the system error handler to be invoked.

#### Programming Note

If a function is required that is specified by the IEEE standard, is not supported by the Vector Facility, and cannot be emulated satisfactorily using the functions that are supported by the Vector Facility, the functions provided by the Floating-Point Facility should be used; see Chapter 4.

### 6.6.2 Floating-Point Exceptions

The following floating-point exceptions may occur during execution of vector floating-point instructions.

- NaN Operand Exception
- Invalid Operation Exception
- Zero Divide Exception
- Log of Zero Exception
- Overflow Exception
- Underflow Exception

If an exception occurs, a result is placed into the corresponding target element as described in the following subsections. This result is the default result specified by Java, the IEEE standard, or C9X, as applicable.

Recall that denormalized source values are treated as if they were zero when  $NJ=1$ . This has the following consequences regarding exceptions.

- Exceptions that can be caused by a zero source value can be caused by a denormalized source value when  $NJ=1$ .
- Exceptions that can be caused by a nonzero source value cannot be caused by a denormalized source value when  $NJ=1$ .

#### 6.6.2.1 NaN Operand Exception

A NaN Operand Exception occurs when a source value for any of the following instructions is a NaN.

- A vector instruction that would normally produce floating-point results
- Either of the two *Vector Convert To Fixed-Point Word* instructions
- Any of the four *Vector Floating-Point Compare* instructions

The following actions are taken:

If the vector instruction would normally produce floating-point results, the corresponding result is a source NaN selected as follows. In all cases, if the selected source NaN is a Signaling NaN it is converted to the corresponding Quiet NaN (by setting the high-order bit of the fraction field to 1) before being placed into the target element.

if the element in  $VSR[VRA+32]$  is a NaN  
 then the result is that NaN  
 else if the element in  $VSR[VRB+32]$  is a NaN  
 then the result is that NaN  
 else if the element in  $VSR[VRC+32]$  is a NaN  
 then the result is that NaN  
 else if Invalid Operation exception  
 (Section 6.6.2.2)  
 then the result is the QNaN 0x7FC0\_0000

If the instruction is either of the two *Vector Convert To Fixed-Point Word* instructions, the corresponding result is 0x0000\_0000. SAT is not affected.

If the instruction is *Vector Compare Bounds Floating-Point*, the corresponding result is 0xC000\_0000.

If the instruction is one of the other *Vector Floating-Point Compare* instructions, the corresponding result is 0x0000\_0000.

### 6.6.2.2 Invalid Operation Exception

An Invalid Operation Exception occurs when a source value or set of source values is invalid for the specified operation. The invalid operations are:

- Magnitude subtraction of infinities
- Multiplication of infinity by zero
- Reciprocal square root estimate of a negative, nonzero number or -infinity.
- Log base 2 estimate of a negative, nonzero number or -infinity.

The corresponding result is the QNaN 0x7FC0\_0000.

### 6.6.2.3 Zero Divide Exception

A Zero Divide Exception occurs when a *Vector Reciprocal Estimate Floating-Point* or *Vector Reciprocal Square Root Estimate Floating-Point* instruction is executed with a source value of zero.

The corresponding result is an infinity, where the sign is the sign of the source value.

### 6.6.2.4 Log of Zero Exception

A Log of Zero Exception occurs when a *Vector Log Base 2 Estimate Floating-Point* instruction is executed with a source value of zero.

The corresponding result is -Infinity.

## 6.6.2.5 Overflow Exception

An Overflow Exception occurs under either of the following conditions.

- For a vector instruction that would normally produce floating-point results, the magnitude of what would have been the result if the exponent range were unbounded exceeds that of the largest finite floating-point number for the target floating-point format.
- For either of the two *Vector Convert To Fixed-Point Word* instructions, either a source value is an infinity or the product of a source value and  $2^{UM}$  is a number too large in magnitude to be represented in the target fixed-point format.

The following actions are taken:

1. If the vector instruction would normally produce floating-point results, the corresponding result is an infinity, where the sign is the sign of the intermediate result.
2. If the instruction is *Vector Convert To Unsigned Fixed-Point Word Saturate*, the corresponding result is 0xFFFF\_FFFF if the source value is a positive number or +infinity, and is 0x0000\_0000 if the source value is a negative number or -infinity. SAT is set to 1.
3. If the instruction is *Vector Convert To Signed Fixed-Point Word Saturate*, the corresponding result is 0x7FFF\_FFFF if the source value is a positive number or +infinity., and is 0x8000\_0000 if the source value is a negative number or -infinity. SAT is set to 1.

## 6.6.2.6 Underflow Exception

An Underflow Exception can occur only for vector instructions that would normally produce floating-point results. It is detected before rounding. It occurs when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded is less in magnitude than the smallest normalized floating-point number for the target floating-point format.

The following actions are taken:

1. If  $NJ=0$ , the corresponding result is the value produced by denormalizing and rounding the intermediate result.
2. If  $NJ=1$ , the corresponding result is a zero, where the sign is the sign of the intermediate result.

## 6.7 Vector Storage Access Instructions

The *Vector Storage Access* instructions compute the effective address (EA) of the storage to be accessed as described in Section 1.10.3, “Effective Address Calculation” on page 30. The low-order bits of the EA that would correspond to an unaligned storage operand are ignored.

The *Load Vector Element Indexed* and *Store Vector Element Indexed* instructions transfer a byte, halfword, or word element between storage and a VSR. The *Load Vector Indexed* and *Store Vector Indexed* instructions transfer an aligned quadword between storage and a VSR.

### 6.7.1 Storage Access Exceptions

Storage accesses will cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (*Store* only), or if the program attempts to access storage that is unavailable.

## 6.7.2 Vector Load Instructions

The aligned byte, halfword, word, or quadword in storage addressed by EA is loaded into VSR[VRT+32].

### Programming Note

The *Load Vector Element* instructions load the specified element into the same location in the target register as the location into which it would be loaded using the *Load Vector* instruction.

### Load Vector Element Byte Indexed X-form

lvebx                  VRT,RA,RB

31	VRT	RA	RB	7	
0	6	11	16	21	31

```
if MSR.VEC=0 then Vector_Unavailable()
```

```
EA ← ((RA=0) ? 0 : GPR[RA]) + GPR[RB]
eb ← EA.bit[60:63]
```

```
VSR[VRT+32] ← undefined
if Big-Endian byte ordering then
    VSR[VRT+32].byte[eb] ← MEM(EA, 1)
else
    VSR[VRT+32].byte[15-eb] ← MEM(EA, 1)
```

Let EA be the sum (RA|0) + (RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access, the contents of the byte in storage at address EA are placed into byte eb of VSR[VRT+32]. The remaining bytes of VSR[VRT+32] are set to undefined values.

If Little-Endian byte ordering is used for the storage access, the contents of the byte in storage at address EA are placed into byte 15-eb of VSR[VRT+32]. The remaining bytes of VSR[VRT+32] are set to undefined values.

### Special Registers Altered:

None

### Register Data Layout for lvebx

**Load Vector Element Halfword Indexed X-form**

lvehx                    VRT,RA,RB

31	VRT	RA	RB	39	/
0	6	11	16	21	31

```
if MSR.VEC=0 then Vector_Unavailable()
```

```
EA ← ((RA=0) ? 0 : GPR[RA]) + GPR[RB]
```

```
EA ← EA & 0xFFFF_FFFF_FFFF_FFFE
```

```
eb ← EA.bit[60:63]
```

```
VSR[VRT+32] ← undefined
```

```
if Big-Endian byte ordering then
```

```
  VSR[VRT+32].byte[eb:eb+1] ← MEM(EA, 2)
```

```
else
```

```
  VSR[VRT+32].byte[14-eb:15-eb] ← MEM(EA, 2)
```

Let EA be the result of ANDing 0xFFFF\_FFFF\_FFFF\_FFFE with the sum (RA|0) + (RB).

Let eb be bits 60:63 of EA.

If Big-Endian byte ordering is used for the storage access,

- the contents of the byte in storage at address EA are placed into byte eb of VSR[VRT+32],
- the contents of the byte in storage at address EA+1 are placed into byte eb+1 of VSR[VRT+32], and
- the remaining bytes of VSR[VRT+32] are set to undefined values.

If Little-Endian byte ordering is used for the storage access,

- the contents of the byte in storage at address EA are placed into byte 15-eb of VSR[VRT+32],
- the contents of the byte in storage at address EA+1 are placed into byte 14-eb of VSR[VRT+32], and
- the remaining bytes of VSR[VRT+32] are set to undefined values.

The contents of the quadword in storage at address EA are placed into VSR[VRT+32].

**lvxl** provides a hint that the quadword in storage addressed by EA will probably not be needed again by the program in the near future.

**Special Registers Altered:**

None

**Register Data Layout for lvx & lvxl****Programming Note**

On some implementations, the hint provided by the **lvxl** instruction and the corresponding hint provided by the **stvxl** instruction are applied to the entire cache block containing the specified quadword. On such implementations, the effect of the hint may be to cause that cache block to be considered a likely candidate for replacement when space is needed in the cache for a new block. Thus, on such implementations, the hint should be used with caution if the cache block containing the quadword also contains data that may be needed by the program in the near future. Also, the hint may be used before the last reference in a sequence of references to the quadword if the subsequent references are likely to occur sufficiently soon that the cache block containing the quadword is not likely to be displaced from the cache before the last reference.

## 6.7.3 Vector Store Instructions

Some portion or all of the contents of  $VSR[VRS+32]$  are stored into the aligned byte, halfword, word, or quadword in storage addressed by EA.

### Programming Note

The *Store Vector Element* instructions store the specified element into the same storage location as the location into which it would be stored using the *Store Vector* instruction.

### Store Vector Element Byte Indexed X-form

stvebx                    VRS,RA,RB

31	VRS	RA	RB	135	/
0	6	11	16	21	31

**Register Data Layout for stvx & stvxl**

## 6.7.4 Vector Alignment Support Instructions

### Programming Note

The *lvsl* and *lvslr* instructions can be used to create the permute control vector to be used by a subsequent *vperm* instruction (see page 301). Let *X* and *Y* be the contents of *VSR[VRA+32]* and *VSR[VRB+32]* specified by the *vperm*. The control vector created by *lvsl* causes the *vperm* to select the high-order 16 bytes of the result of shifting the 32-byte value *X || Y* left by *sh* bytes. The control vector created by *lvslr* causes the *vperm* to select the low-order 16 bytes of the result of shifting *X || Y* right by *sh* bytes.

### Programming Note

Examples of uses of *lvsl*, *lvslr*, and *vperm* to load and store unaligned data are given in Section 6.4.1.

These instructions can also be used to rotate or shift the contents of a VSR left (*lvsl*) or right (*lvslr*) by *sh* bytes. For rotating, the VSR to be rotated should be specified as both *VSR[VRA+32]* and *VSR[VRB+32]* for *vperm*. For shifting left, *VSR[VRB+32]* for *vperm* should be a register containing all zeros and *VSR[VRA+32]* should contain the value to be shifted, and vice versa for shifting right.

## 6.8 Vector Permute and Formatting Instructions

### 6.8.1 Vector Pack Instructions

#### Vector Pack Pixel VX-form

vpkpx                    VRT,VRA,VRB

4	VRT	VRA	VRB	782
0	6	11	16	21                    31

if MSR.VEC=0 then Vector\_Unavailable()

vsrc.qword[0] ← VSR[VRA+32]

vsrc.qword[1] ← VSR[VRB+32]

do i = 0 to 7

VSR[VRT+32].hword[i].bit[0] ← vsrc.word[i].bit[7]

VSR[VRT+32].hword[i].bit[1:5] ← vsrc.word[i].bit[8:12]

VSR[VRT+32].hword[i].bit[6:10] ← vsrc.word[i].bit[16:20]

VSR[VRT+32].hword[i].bit[11:15] ← vsrc.word[i].bit[24:28]

end

Let vsrc be the concatenation of the contents of VSR[VRA+32] followed by the contents of VSR[VRB+32].

For each integer value i from 0 to 7, do the following.

The contents of word element i of vsrc are packed to produce a 16-bit value as described below.

– bit 7 of the first byte (bit 7 of the word)

– bits 0:4 of the second byte (bits 8:12 of the word)

– bits 0:4 of the third byte (bits 16:20 of the word)

– bits 0:4 of the fourth byte (bits 24:28 of the word)

The result is placed into halfword element i of VSR[VRT+32].

```
  VSR[VRT+32].word[i].byte[3] ← EXTZ8(src.bit[11:15])
```

```
end
```

For each integer value *i* from 0 to 3, do the following.

The contents of halfword element *i*+4 of VSR[VRB+32] are unpacked as follows.

- sign-extend bit 0 of the halfword to 8 bits
- zero-extend bits 1:5 of the halfword to 8 bits
- zero-extend bits 6:10 of the halfword to 8 bits
- zero-extend bits 11:15 of the halfword to 8 bits

The result is placed in word element *i* of VSR[VRT+32].

					127

**Programming Note**

The source and target elements can be considered to be 16-bit and 32-bit “pixels” respectively, having the formats described in the Programming Note for the *Vector Pack Pixel* instruction on page 283.

**Programming Note**

Notice that the unpacking done by the *Vector Unpack Pixel* instructions does not reverse the packing done by the *Vector Pack Pixel* instruction. Specifically, if a 16-bit pixel is unpacked to a 32-bit pixel which is then packed to a 16-bit pixel, the resulting 16-bit pixel will not, in general, be equal to the original 16-bit pixel (because, for each channel except the first, *Vector Unpack Pixel* inserts high-order bits while *Vector Pack Pixel* discards low-order bits).

## 6.8.3 Vector Merge Instructions

### Vector Merge High Byte VX-form

vmrghb VRT,VRA,VRB

4	VRT	VRA	VRB	12
0	6	11	16	21
				31

if MSR.VEC=0 then Vector\_Unavailable()

```
do i = 0 to 7
  VSR[VRT+32].hword[i].byte[0] ← VSR[VRA+32].byte[i]
  VSR[VRT+32].hword[i].byte[1] ← VSR[VRB+32].byte[i]
end
```

For each integer value  $i$  from 0 to 7, do the following.

The contents of byte element  $i$  of VSR[VRA+32] are placed into byte element  $2 \times i$  of VSR[VRT+32].

The contents of byte element  $i$  of VSR[VRB+32] are placed into byte element  $2 \times i + 1$  of VSR[VRT+32].

#### Special Registers Altered:

None

### Vector Merge Low Byte VX-form

vmrglb VRT,VRA,VRB

4	VRT	VRA	VRB	268
0	6	11	16	21
				31

if MSR.VEC=0 then Vector\_Unavailable()

```
do i = 0 to 7
  VSR[VRT+32].hword[i].byte[0] ← VSR[VRA+32].byte[i+8]
  VSR[VRT+32].hword[i].byte[1] ← VSR[VRB+32].byte[i+8]
end
```

For each integer value  $i$  from 0 to 7, do the following.

The contents of byte element  $i+8$  of VSR[VRA+32] are placed into byte element  $2 \times i$  of VSR[VRT+32].

The contents of byte element  $i+8$  of VSR[VRB+32] are placed into byte element  $2 \times i + 1$  of VSR[VRT+32].

## 6.8.4 Vector Splat Instructions

### Programming Note

The *Vector Splat* instructions can be used in preparation for performing arithmetic for which one source vector is to consist of elements that all have the same value (e.g., multiplying all elements of a VSR by a constant).

#### Vector Splat Byte VX-form

vspltb                      VRT,VRB,UIM

if MSR\_VEC=0 then Vector\_Unavailable()

```
b ← UIM || 0b000
do i = 0 to 15
    VSR[VRT+32].byte[i] ← VSR[VRB+32].bit[b+7]
end
```

For each integer value *i* from 0 to 15, do the following.  
The contents of byte element UIM in VSR[VRB+32] are placed into byte element *i* of VSR[VRT+32].

#### Special Registers Altered:

None

#### Vector Splat Halfword VX-form

vsplth                      VRT,VRB,UIM

if MSR\_VEC=0 then Vector\_Unavailable()

```
b ← UIM || 0b0000
do i = 0 to 7
    VSR[VRT+32].hword[i] ← VSR[VRB+32].bit[b+15]
end
```

For each integer value *i* from 0 to 7, do the following.  
The contents of halfword element UIM in VSR[VRB+32] are placed into halfword element *i* of VSR[VRT+32].

#### Special Registers Altered:

**Register Data Layout for vspltisw**

## 6.8.5 Vector Permute Instruction

The *Vector Permute* instruction allows any byte in two source VSRs to be copied to any byte in the target VSR. The bytes in a third source VSR specify from which byte in the first two source VSRs the corresponding target byte is to be copied. The contents of the third source VSR are sometimes referred to as the “permute control vector”.

### Vector Permute VA-form

vperm VRT,VRA,VRB,VRC

0	4	VRT	VRA	VRB	VRC	43	31
	6	11	16	21	26		

if MSR.VEC=0 then Vector\_Unavailable()

```
vsrc.qword[0] ← VSR[VRA+32]
vsrc.qword[1] ← VSR[VRB+32]
```

```
do i = 0 to 15
  index ← VSR[VRC+32].byte[i].bit[3:7]
  VSR[VRT+32].byte[i] ← src.byte[index]
end
```

Let the source vector be the concatenation of the contents of VSR[VRA+32] followed by the contents of VSR[VRB+32].

For each integer value *i* from 0 to 15, do the following.  
Let *index* be the value specified by bits 3:7 of byte element *i* of VSR[VRC+32].

The contents of byte element *index* of *src* are placed into byte element *i* of VSR[VRT+32].

#### Special Registers Altered:

None

#### Programming Note

See the Programming Notes with the *Load Vector for Shift Left* and *Load Vector for Shift Right* instructions on page 281 for examples of uses of *vperm*.

### Vector Permute Right-indexed VA-form

vpermr VRT,VRA,VRB,VRC

0	4	VRT	VRA	VRB	VRC	59	31
	6	11	16	21	26		

if MSR.VEC=0 then Vector\_Unavailable()

```
vsrc.qword[0] ← VSR[VRA+32]
vsrc.qword[1] ← VSR[VRB+32]
```

```
do i = 0 to 15
  index ← VSR[VRC+32].byte[i].bit[3:7]
  VSR[VRT+32].byte[i] ← src.byte[31-index]
end
```

Let the source vector be the concatenation of the contents of VSR[VRA+32] followed by the contents of VSR[VRB+32].

For each integer value *i* from 0 to 15, do the following.  
Let *index* be the value specified by bits 3:7 of byte element *i* of VSR[VRC+32].

The contents of byte element 31-*index* of *src* are placed into byte element *i* of VSR[VRT+32].

#### Special Registers Altered:

	0	

## 6.8.7 Vector Shift Instructions

The *Vector Shift* instructions rotate or shift the contents of a VSR or a pair of VSRs left or right by a specified number of bytes (*vslo*, *vsro*, *vsldoi*) or bits (*vsli*, *vsr*). Depending on the instruction, this “shift count” is specified either by the contents of a VSR or by an immediate field in the instruction. In the former case, 7 bits of the shift count register give the shift count in bits ( $0 \leq \text{count} \leq 127$ ). Of these 7 bits, the high-order 4 bits give the number of complete bytes by which to shift and are used by *vslo* and *vsro*; the low-order 3 bits give the number of remaining bits by which to shift and are used by *vsli* and *vsr*.

### Programming Note

A pair of these instructions, specifying the same shift count register, can be used to shift the contents of a VSR left or right by the number of bits (0-127) specified in the shift count register. The following example shifts the contents of register  $V_x$  left by the number of bits specified in register  $V_y$  and places the result into register  $V_z$ .

```
vsli 0    Vz, Vx, Vy
vspl tb  Vy, Vy, 15
vsli     Vz, Vz, Vy
```

### Vector Shift Left Double by Bit Immediate VN-form

	0	8	16	24	32	40	48	56	64	72	80	88	96	104	112	120	127

**Programming Note**

Assume *vSRC* contains a vector of packed 7-bit values, A located in bits 0:6, B located in bits 7:13, C located in bits 14:20, etc..

```
# vSRC = { 0bAAAAAAB, 0bBBBBBCC, 0bCCCCDDD, 0bDDDEEEE,
#         0bEEEEFFF, 0bFGGGGGG, 0bGHHHHHH, 0bIIIIIIJ,
#         0bJJJJJKK, 0bKKKKLLL, 0bLLLLMMM, 0bMMMMNNN,
#         0bNNOOOOO, 0bPPPPPPP, 0bQQQQQQR, 0bRRRRRSS };
```

Assume the following registers are pre-loaded as follows,

```
# vSHCNT1 = { 0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x07,
#            0x07, 0x07, 0x07, 0x07, 0x07, 0x07, 0x07 };
# vSHCNT2 = { 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x01,
#            0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x07 };
# vSHCNT3 = { 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00, 0x00,
#            0x00, 0x00, 0x00, 0x00, 0x00, 0x01, 0x02 };
# vMASK = { 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F,
#           0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F, 0x7F };
```

The leftmost seven packed 7-bit values can be unpacked into byte elements 0 to 6 using *vsvr* with *vSHCNT1*.

```
vsvr  vTMP1, vSRC, vSHCT1 # vTMP1 = { 0b0AAAAAA, 0bABBBBBB, 0bCCCCCCC, 0bDDDDDDD,
#         0bEEEEEEE, 0bFFFFFFF, 0bFGGGGGG, 0bHHHHHHH,
#         0bIIIIIIJ, 0bJJJJJKK, 0bKKKKLLL, 0bLLLLMMM,
#         0bMMMMNNN, 0bNNOOOOO, 0bPPPPPPP, 0bQQQQQQR };
```

The next seven packed 7-bit values can then be unpacked into byte elements 7 to 13 using *vsvr* with *vSHCNT2*.

```
vsvr  vTMP2, vTMP1, vSHCT2 # vTMP2 = { 0b0AAAAAA, 0bABBBBBB, 0bCCCCCCC, 0bDDDDDDD,
#         0bEEEEEEE, 0bFFFFFFF, 0bFGGGGGG, 0bHHHHHHH,
#         0bIIIIIIJ, 0bJJJJJKK, 0bKKKKKKK, 0bLLLLLLL,
#         0bMMMMMM, 0bMMMMMM, 0bMMMMMM, 0bMMMMMM };
```

The next two packed 7-bit values can then be unpacked into byte elements 14 to 15 using *vsvr* with *vSHCNT3*.

```
vsvr  vTMP3, vTMP2, vSHCT3 # vTMP3 = { 0b0AAAAAA, 0bABBBBBB, 0bCCCCCCC, 0bDDDDDDD,
#         0bEEEEEEE, 0bFFFFFFF, 0bFGGGGGG, 0bHHHHHHH,
#         0bIIIIIIJ, 0bJJJJJKK, 0bKKKKKKK, 0bLLLLLLL,
#         0bMMMMMM, 0bMMMMMM, 0bMMMMMM, 0bMMMMMM };
```

The most-significant bit in each byte element is masked off to produce a vector of sixteen unsigned byte elements.

```
vand  vTMP4, vTMP3, vMASK # vTMP4 = { 0b0AAAAAA, 0b0BBBBBB, 0b0CCCCC, 0b0DDDDDD,
#         0b0EEEEEE, 0b0FFFFFF, 0b0GGGGGG, 0b0HHHHHH,
#         0b0IIIIII, 0b0JJJJJJ, 0b0KKKKKK, 0b0LLLLLL,
#         0b0MMMMM, 0b0NNNNN, 0b0OOOOO, 0b0PPPPPP };
```

The vector of sixteen unsigned byte elements can be further unpacked to two vectors of eight unsigned halfword elements using a *vupkhsb* and a *vupklsh*.

```
vupkhsb vTMP5, vTMP4 # vTMP5 = { 0b00000000_0AAAAAA, 0b00000000_0BBBBBB, ... };
vupklsh vTMP6, vTMP4 # vTMP6 = { 0b00000000_0IIIIII, 0b00000000_0JJJJJJ, ... };
```

The resultant two vectors of eight unsigned halfword elements can then be further unpacked to four vectors of four unsigned word elements using two *vupksh* and two *vupklsh* instructions.

```
vupksh vRESULT0, vTMP5 # vRESULT0 = { 0b00000000_00000000_00000000_0AAAAAA, ... };
vupklsh vRESULT1, vTMP5 # vRESULT1 = { 0b00000000_00000000_00000000_0EEEEEE, ... };
vupksh vRESULT2, vTMP6 # vRESULT2 = { 0b00000000_00000000_00000000_0IIIIII, ... };
vupklsh vRESULT3, vTMP6 # vRESULT3 = { 0b00000000_00000000_00000000_0MMMMMM, ... };
```

## 6.8.8 Vector Extract Element Instructions

## 6.9 Vector Integer Instructions

### 6.9.1 Vector Integer Arithmetic Instructions

#### 6.9.1.1 Vector Integer Add Instructions

##### Vector Add & Write Carry-out Unsigned Word VX-form

vaddcuw                      VRT,VRA,VRB

4	VRT	VRA	VRB	384
0	6	11	16	21
				31

```

if MSR_VEC=0 then Vector_Unavailable()

do i = 0 to 3
  src1 ← EXTZ(VSR[VRA+32].word[i])
  src2 ← EXTZ(VSR[VRB+32].word[i])

  VSR[VRT+32].word[i] ← CHOP32((src1 + src2) >> 32)
end
    
```

For each integer value *i* from 0 to 3, do the following.  
 The unsigned integer value in word element *i* in VSR[VRA+32] is added to the unsigned integer value in word element *i* in VSR[VRB+32]. The carry out of the 32-bit sum is zero-extended to 32 bits and placed into word element *i* of VSR[VRT+32].

**Special Registers Altered:**  
 None

##### Vector Add Signed Byte Saturate VX-form

vaddsb                      VRT,VRA,VRB

4	VRT	VRA	VRB	768
0	6	11	16	21
				31

```

if MSR_VEC=0 then Vector_Unavailable()

do i = 0 to 15
  src1 ← EXTZ(VSR[VRA+32].byte[i])
  src2 ← EXTZ(VSR[VRB+32].byte[i])

  VSR[VRT+32].byte[i] ← si8_CLAMP(src1 + src2)
end
    
```

For each integer value *i* from 0 to 15, do the following.  
 The signed integer value in byte element *i* of VSR[VRA+32] is added to the signed integer value in byte element *i* of VSR[VRB+32].

- If the sum is greater than  $2^7-1$  the result saturates to  $2^7-1$  and SAT is set to 1.
- If the sum is less than  $-2^7$  the result saturates to  $-2^7$  and SAT is set to 1.

The result is placed into byte element *i* of VSR[VRT+32].

**Special Registers Altered:**  
 SAT

vaddeuqm       vS1, vA1, vB1, vC2    # bits 128: 255 of sum
vaddecuq       vC1, vA1, vB1, vC2    # carry out of bit 128 of sum
vaddeuqm       vS0, vA0, vB0, vC1    # bits 0: 127 of sum
```

### 6.9.1.2 Vector Integer Subtract Instructions

#### Vector Subtract & Write Carry-Out Unsigned Word VX-form

vsubcuw                    VRT,VRA,VRB

4	VRT	VRA	VRB	1408
0	6	11	16	21
				31

```

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 3
  src1 ← EXTZ(VSR[VRA+32].word[i])
  src2 ← EXTZ(-VSR[VRB+32].word[i])

  VSR[VRT+32].word[i] ← EXTZ32((src1+src2+1) >> 32)
end
    
```

For each integer value *i* from 0 to 3, do the following.  
 The unsigned integer value in word element *i* of VSR[VRB+32] is subtracted from the unsigned integer value in word element *i* in VSR[VRA+32]. The complement of the borrow out of bit 0 of the 32-bit difference is zero-extended to 32 bits and placed into word element *i* of VSR[VRT+32].

**Special Registers Altered:**  
 None

#### Vector Subtract Signed Byte Saturate VX-form

vsubsb                    VRT,VRA,VRB

4	VRT	VRA	VRB	1792
0	6	11	16	21
				31

```

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 15
  src1 ← EXTZ(VSR[VRA+32].byte[i])
  src2 ← EXTZ(VSR[VRB+32].byte[i])

  VSR[VRT+32].byte[i] ← si8_CLAMP(src1 + -src2 + 1)
end
    
```

For each integer value *i* from 0 to 15, do the following.  
 The signed integer value in byte element *i* in VSR[VRB+32] is subtracted from the signed integer value in byte element *i* in VSR[VRA+32].

- If the intermediate result is greater than 127 the result saturates to 127 and SAT is set to 1.
- If the intermediate result is less than -128 the result saturates to -128 and SAT is set to 1.

The result is placed into byte element *i* of VSR[VRT+32].

**Special Registers Altered:**  
 SAT

src3	VSR[VRC+32]
result	VSR[VRT+32]
0	127

**Programming Note**

The *Vector Subtract Unsigned Quadword* instructions support efficient wide-integer subtraction. The following code sequence can be used to implement a 512-bit signed or unsigned subtract operation.

```

vsubuqm   vS3, vA3, vB3      # bits 384:511 of difference
vsubcuq   vC3, vA3, vB3      # carry out of bit 384 of difference
vsubecuqm vS2, vA2, vB2, vC3 # bits 256:383 of difference
vsubecuq  vC2, vA2, vB2, vC3 # carry out of bit 256 of difference
vsubecuqm vS1, vA1, vB1, vC2 # bits 128:255 of difference
vsubecuq  vC1, vA1, vB1, vC2 # carry out of bit 128 of difference
vsubecuqm vS0, vA0, vB0, vC1 # bits 0:127 of difference
  
```

### 6.9.1.3 Vector Integer Multiply Instructions

#### Vector Multiply Even Signed Byte VX-form

vmulesb VRT,VRA,VRB

4	VRT	VRA	VRB	776
0	6	11	16	21
				31

```

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 7
  src1 ← EXTS(VSR[VRA+32].byte[2i])
  src2 ← EXTS(VSR[VRB+32].byte[2i])

  VSR[VRT+32].hword[i] ← CHOP16(src1 × src2)
end
    
```

For each integer value *i* from 0 to 7, do the following.  
 The signed integer value in byte element *i*×2 of VSR[VRA+32] is multiplied by the signed integer value in byte element *i*×2 of VSR[VRB+32].  
 The 16-bit product is placed into halfword element *i* of VSR[VRT+32].

**Special Registers Altered:**  
None

#### Vector Multiply Odd Signed Byte VX-form

vmulosb VRT,VRA,VRB

4	VRT	VRA	VRB	264
0	6	11	16	21
				31

```

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 7
  src1 ← EXTS(VSR[VRA+32].byte[2i+1])
  src2 ← EXTS(VSR[VRB+32].byte[2i+1])

  VSR[VRT+32].hword[i] ← CHOP16(src1 × src2)
end
    
```

For each integer value *i* from 0 to 7, do the following.  
 The signed integer value in byte element *i*×2+1 of VSR[VRA+32] is multiplied by the signed integer value in byte element *i*×2+1 of VSR[VRB+32].  
 The 16-bit product is placed into halfword element *i* of VSR[VRT+32].

**Special Registers Altered:**  
None

### 6.9.1.4 Vector Integer Multiply-Add/Sum Instructions

#### Vector Multiply-High-Add Signed Halfword Saturate VA-form

vmhaddshs VRT,VRA,VRB,VRC

4	VRT	VRA	VRB	VRC	32
0	6	11	16	21	26 31

```

if MSR_VEC=0 then Vector_Unavailable()

do i = 0 to 7
  src1 ← EXTS(VSR[VRA+32].hword[i])
  src2 ← EXTS(VSR[VRB+32].hword[i])
  src3 ← EXTS(VSR[VRC+32].hword[i])

  result ← ((src1 × src2) >> 15) + src3
  VSR[VRT+32].hword[i] ← si16_CLAMP(result)
  VSCR.SAT ← sat_flag
end
    
```

For each integer value *i* from 0 to 7, do the following.

The signed integer value in halfword element *i* of VSR[VRA+32] is multiplied by the signed integer value in halfword element *i* of VSR[VRB+32], producing a 32-bit signed integer product.

Bits 0:16 of the product are added to the signed integer value in halfword element *i* of VSR[VRC+32].

- If the intermediate result is greater than  $2^{15}-1$  the result saturates to  $2^{15}-1$  and SAT is set to 1.
- If the intermediate result is less than  $-2^{15}$  the result saturates to  $-2^{15}$  and SAT is set to 1.

The low-order 16 bits of the result are placed into halfword element *i* of VSR[VRT+32].

**Special Registers Altered:**

SAT

#### Vector Multiply-High-Round-Add Signed Halfword Saturate VA-form

vmhraddshs VRT,VRA,VRB,VRC

4	VRT	VRA	VRB	VRC	33
0	6	11	16	21	26 31

```

if MSR_VEC=0 then Vector_Unavailable()

do i = 0 to 7
  src1 ← EXTS(VSR[VRA+32].hword[i])
  src2 ← EXTS(VSR[VRB+32].hword[i])
  src3 ← EXTS(VSR[VRC+32].hword[i])

  result ← (((src1 × src2) + 0x0000_4000) >> 15) + src3
  VSR[VRT+32].hword[i] ← si16_CLAMP(result)
  VSCR.SAT ← sat_flag
end
    
```

For each integer value *i* from 0 to 7, do the following.

The signed integer value in halfword element *i* of VSR[VRA+32] is multiplied by the signed integer value in halfword element *i* of VSR[VRB+32], producing a 32-bit signed integer product.

The value 0x0000\_4000 is added to the product.

Bits 0:16 of the 32-bit sum are added to the signed integer value in halfword element *i* of VSR[VRC+32].

- If the intermediate result is greater than  $2^{15}-1$  the result saturates to  $2^{15}-1$  and SAT is set to 1.
- If the intermediate result is less than  $-2^{15}$  the result saturates to  $-2^{15}$  and SAT is set to 1.

The low-order 16 bits of the result are placed into halfword element *i* of VSR[VRT+32].

The quotient of src1 divided by src2 is placed into VSR[VRT+32].

The quotient is the unique unsigned integer that satisfies

$$\text{di vi dend} = (\text{quotient} \times \text{di vi sor}) + r$$

where  $0 \leq r < \text{di vi sor}$ .

If the quotient cannot be represented in 128 bits, or if an attempt is made to perform the division

$$\langle \text{anything} \rangle \div 0$$

then the contents of VSR[VRT+32] are undefined.

## 6.9.1.6 Vector Integer Modulo Instructions

### Vector Modulo Signed Word VX-form

vmodsw VRT,VRA,VRB

4	VRT	VRA	VRB	1931
0	6	11	16	31

if MSR.VEC=0 then Vector\_Unavailable()

do i = 0 to 3

  di vi dend ← EXTS(VSR[VRA+32].word[i])

  di vi sor ← EXTS(VSR[VRB+32].word[i])

  VSR[VRT+32].word[i] ← CHOP32(di vi dend % di vi sor)

end

For each integer value i from 0 to 3, do the following.

The signed integer in word element i of VSR[VRA+32] is divided by the signed integer in word element i of VSR[VRB+32].

The remainder is the unique signed integer that satisfies

$$\begin{aligned} \text{quotient} &= \text{di vi dend} \div \text{di vi sor} \\ \text{remainder} &= \text{di vi dend} - (\text{quotient} \times \text{di vi sor}) \end{aligned}$$

where  $0 \leq \text{remainder} < |\text{di vi sor}|$  if the dividend is nonnegative, and  $-|\text{di vi sor}| < \text{remainder} \leq 0$  if the dividend is negative.

If an attempt is made to perform any of the modulo operations

$$\begin{aligned} 0x8000_0000 \% -1 \\ \langle \text{anything} \rangle \% 0 \end{aligned}$$

then the remainder is undefined.

The remainder is placed into word element i of VSR[VRT+32]

### 6.9.1.11 Vector Integer Absolute Difference Instructions

This section describes a set of instructions that return the absolute value of the difference of integer values.

#### Vector Absolute Difference Unsigned Byte VX-form

vabsdub VRT,VRA,VRB

4	VRT	VRA	VRB	1027
0	6	11	16	21
31				

if MSR.VEC=0 then Vector\_Unavailable()

do i = 0 to 15

src1 ← EXTZ(VSR[VRA+32].byte[i])

src2 ← EXTZ(VSR[VRB+32].byte[i])

if src1 > src2 then

VSR[VRT+32].byte[i] ← CHOP8(src1 + -src2 + 1)

else

VSR[VRT+32].byte[i] ← CHOP8(src2 + -src1 + 1)

end

For each integer value i from 0 to 15, do the following.

Let src1 be the unsigned integer value in byte element i of VSR[VRA+32].

Let src2 be the unsigned integer value in byte element i of VSR[VRB+32].

src1 is subtracted by src2.

The absolute value of the difference is placed into byte element i of VSR[VRT+32].

#### Special Registers Altered:

### 6.9.3 Vector Integer Compare Instructions

The *Vector Integer Compare* instructions compare two VSRs element by element, interpreting the elements as unsigned or signed-integers depending on the instruction, and set the corresponding element of the target VSR to all 1s if the relation being tested is true and to all 0s if the relation being tested is false.

If Rc=1 CR Field 6 is set to reflect the result of the comparison, as follows.

**Bit Description**

- 0 The relation is true for all element pairs (i.e., VSR[VRT+32] is set to all 1s)
- 1 0
- 2 The relation is false for all element pairs (i.e., VSR[VRT+32] is set to all 0s)
- 3 0

**Programming Note**

*vcmpequb*[], *vcmpequh*[], *vcmpequw*[], and *vcmpequd*[] can be used for unsigned or signed-integers.

**Vector Compare Equal Unsigned Byte VC-form**

*vcmpequb* VRT,VRA,VRB (Rc=0)  
*vcmpequb.* VRT,VRA,VRB (Rc=1)

if MSR\_VEC=0 then Vector\_Unavailable()

all\_true ← 1  
 all\_false ← 1

```
do i = 0 to 15
  src1 ← VSR[VRA+32].byte[i]

## 6.9.4 Vector Logical Instructions

### Extended mnemonics for vector logical operations

Extended mnemonics are provided that use the Vector OR and Vector NOR instructions to copy the contents of one VSR to another, with and without complementing. These are shown as examples with the two instructions.

#### Vector Move Register

Several vector instructions can be coded in a way such that they simply copy the contents of one VSR to another. An extended mnemonic is provided to convey the idea that no computation is

being performed but merely data movement (from one register to another).

The following instruction copies the contents of register Vy to register Vx.

`vmr Vx,Vy` (equivalent to: `vor Vx,Vy,Vy`)

#### Vector Complement Register

The *Vector NOR* instruction can be coded in a way such that it complements the contents of one VSR and places the result into another VSR. An extended mnemonic is provided that allows this operation to be coded easily.

The following instruction complements the contents of register Vy and places the result into register Vx.

`vnot Vx,Vy` (equivalent to: `vnor Vx,Vy,Vy`)

## 6.9.5.2 Vector Integer Rotate Left then AND with Mask Instructions

### Vector Rotate Left Word then AND with Mask VX-form

vrlwnm                    VRT,VRA,VRB

4	VRT	VRA	VRB	389
0	6	11	16	21
				31

if MSR.VEC=0 then Vector\_Unavailable()

do i = 0 to 3

src1.word[0] ← VSR[VRA+32].word[i]

src1.word[1] ← VSR[VRA+32].word[i]

src2 ← VSR[VRB+32].word[i]

b ← src2.bit[11:15]

e ← src2.bit[19:23]

n ← src2.bit[27:31]

r ← src1.bit[n:n+31]

m ← MASK(b, e)

VSR[VRT+32].word[i] ← r & m

end

For each integer value i from 0 to 3, do the following.

Let src1 be the contents of word element i of VSR[VRA+32].

Let src2 be the contents of word element i of VSR[VRB+32].

Let mb be the contents of bits 11: 15 of src2.

Let me be the contents of bits 19: 23 of src2.

Let sh be the contents of bits 27: 31 of src2.

src1 is rotated left sh bits.

A mask is generated having 1-bits from bit mb through bit me and 0-bits elsewhere.

The rotated data are ANDed with the generated mask.

The result is placed into word element i of VSR[VRT+32].

**Vector Multiply-Add Floating-Point VA-form**

vmaddfp VRT,VRA,VRC,VRB

4	VRT	VRA	VRB	VRC	46
0	6	11	16	21	26 31

```
if MSR_VEC=0 then Vector_Unavailable()
```

```
do i = 0 to 3
  src1 ← VSR[VRA+32].word[i]
  src2 ← VSR[VRB+32].word[i]
  src3 ← VSR[VRC+32].word[i]
  result ← bfp32_MULTIPLY_ADD(src1,src3,src2)
  VSR[VRT+32].word[i] ← result
end
```

For each integer value  $i$  from 0 to 3, do the following.

Let  $src1$  be the single-precision floating-point value in word element  $i$  of  $VSR[VRA+32]$ .

Let  $src2$  be the single-precision floating-point value in word element  $i$  of  $VSR[VRB+32]$ .

Let  $src3$  be the single-precision floating-point value in word element  $i$  of  $VSR[VRC+32]$ .

$src1$  is multiplied by  $src3$ .

$src2$  is added to the infinitely-precise product.

The intermediate result is rounded to the nearest single-precision floating-point number and placed into word element  $i$  of  $VSR[VRT+32]$ .

**Special Registers Altered:**

None

**Programming Note**

To use a multiply-add to perform an IEEE or Java compliant multiply, the addend must be  $-0.0$ . This is necessary to insure that the sign of a zero result will be correct when the product is  $-0.0$  ( $+0.0 + -0.0 \geq +0.0$ , and  $-0.0 + -0.0 \geq -0.0$ ). When the sign of a resulting  $0.0$  is not important, then  $+0.0$  can be used as an addend which may, in some cases, avoid the need for a second register to hold a  $-0.0$  in addition to the integer floating-point  $+0.0$  that may already be available.

**Vector Negative Multiply-Subtract Floating-Point VA-form**

vnmsubfp VRT,VRA,VRC,VRB

4	VRT	VRA	VRB	VRC	47
0	6	11	16	21	26 31

```

## 6.10.2 Vector Floating-Point Maximum/Minimum Instructions

### Vector Maximum Floating-Point VX-form

vmaxfp                    VRT,VRA,VRB

4	VRT	VRA	VRB	1034	31
0	6	11	16	21	31

```

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 3
  src1 ← VSR[VRA+32].word[i]
  src2 ← VSR[VRB+32].word[i]
  VSR[VRT+32].word[i] ← bfp32_MAXIMUM(src1, src2)
end

```

For each integer value *i* from 0 to 3, do the following.  
Let *src1* be the single-precision floating-point value in word element *i* of VSR[VRA+32].

Let *src2* be the single-precision floating-point value in word element *i* of VSR[VRB+32].

*src1* is compared to *src2*.

The larger of the two values is placed into word element *i* of VSR[VRT+32].

The maximum of +0.0 and -0.0 is +0.0. The maximum of any value and a NaN is a QNaN.

#### Special Registers Altered:

None

### Vector Minimum Floating-Point VX-form

vminfp                    VRT,VRA,VRB

4	VRT	VRA	VRB	1098	31
0	6	11	16	21	31

```

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 3
  src1 ← VSR[VRA+32].word[i]
  src2 ← VSR[VRB+32].word[i]
  VSR[VRT+32].word[i] ← bfp32_MINIMUM(src1, src2)
end

```

For each integer value *i* from 0 to 3, do the following.  
Let *src1* be the single-precision floating-point value in word element *i* of VSR[VRA+32].

Let *src2* be the single-precision floating-point value in word element *i* of VSR[VRB+32].

*src1* is compared to *src2*.

The smaller of the two values is placed into word element *i* of VSR[VRT+32].

The minimum of +0.0 and -0.0 is -0.0. The minimum of any value and a NaN is a QNaN.

## 6.10.3 Vector Floating-Point Rounding and Conversion Instructions

### 6.10.3.1 Vector Floating-Point Conversion Instructions

**Vector Convert with round to zero from floating-point To Signed Word format Saturate VX-form**

vctxsx                    VRT,VRB,UIM

4	VRT	UIM	VRB	970
0	6	11	16	31

if MSR.VEC=0 then Vector\_Unavailable()

```
do i = 0 to 3
  src ← VSR[VRB+32].word[i]
  VSR[VRT+32].word[i] ← si_32_CONVERT_FROM_BFP32(src, UIM)
end
```

For each integer value  $i$  from 0 to 3, do the following.

Let  $src$  be the signed floating-point value in word element  $i$  of  $VSR[VRB+32]$ .

$src$  is multiplied by  $2^{UIM}$ . The product is converted to a 32-bit signed fixed-point integer using the rounding mode Round toward Zero.

- If the intermediate result is greater than  $2^{31}-1$  the result saturates to  $2^{31}-1$ .
- If the intermediate result is less than  $-2^{31}$  the result saturates to  $-2^{31}$ .

The result is placed into word element  $i$  of  $VSR[VRT+32]$ .

### 6.10.3.2 Vector Floating-Point Round to Integral Instructions

#### Vector Round to Floating-Point Integer toward -Infinity VX-form

vrfim VRT,VRB

```

if MSR_VEC=0 then Vector_Unavailable()

do i = 0 to 3
  src ← VSR[VRB+32].word[i]
  VSR[VRT+32].word[i] ← bfp32_ROUND_TO_INTEGER_FLOOR(src)
end
    
```

For each integer value *i* from 0 to 3, do the following.  
Let *src* be the single-precision floating-point value in element *i* of VSR[VRB+32].

*src* is rounded to a single-precision floating-point integer using the rounding mode Round toward -Infinity.

The result is placed into the corresponding word element *i* of VSR[VRT+32].

#### Vector Round to Floating-Point Integer Nearest VX-form

vrfin VRT,VRB

```

if MSR_VEC=0 then Vector_Unavailable()

do i = 0 to 3
  src ← VSR[VRB+32].word[i]
  VSR[VRT+32].word[i] ← bfp32_ROUND_TO_INTEGER_NEAREST(src)
end
    
```

For each integer value *i* from 0 to 3, do the following.  
Let *src* be the single-precision floating-point value in element *i* of VSR[VRB+32].

*src* is rounded to a single-precision floating-point integer using the rounding mode Round to Nearest.

The result is placed into the corresponding word element *i* of VSR[VRT+32].

#### Special Registers Altered:

	0	32	64	96
				127

#### Programming Note

The *Vector Convert To Fixed-Point Word* instructions support only the rounding mode Round toward Zero. A floating-point number can be converted to a fixed-point integer using any of the other three rounding modes by executing the appropriate *Vector Round to Floating-Point Integer* instruction before the *Vector Convert To Fixed-Point Word* instruction.

#### Programming Note

The fixed-point integers used by the *Vector Convert* instructions can be interpreted as consisting of 32-UIM integer bits followed by UIM fraction bits.

## 6.10.4 Vector Floating-Point Compare Instructions

The *Vector Floating-Point Compare* instructions compare two VSRs word element by word element, interpreting the elements as single-precision floating-point numbers. With the exception of the *Vector Compare Bounds Floating-Point* instruction, they set the target VSR, and CR Field 6 if Rc=1, in the same manner as do the *Vector Integer Compare* instructions; see Section 6.9.3.

The *Vector Compare Bounds Floating-Point* instruction sets the target VSR, and CR Field 6 if Rc=1, to indicate whether the elements in VSR[VRA+32] are within the bounds specified by the corresponding element in VSR[VRB+32], as explained in the instruction description. A single-precision floating-point value *x* is said to be “within the bounds” specified by a single-precision floating-point value *y* if  $-y \leq x \leq y$ .

### Vector Compare Bounds Floating-Point VC-form

vcmpbfp VRT,VRA,VRB (Rc=0)  
vcmpbfp. VRT,VRA,VRB (Rc=1)

4	VRT	VRA	VRB	Rc	966
0	6	11	16	21 22	31

```
if MSR_VEC=0 then Vector_Unavailable()
```

```
do i = 0 to 3
  src1 ← VSR[VRA+32].word[i]
  src2 ← VSR[VRB+32].word[i]
  le ← bool_COMPARE_LE_BFP32(src1,src2)
  ge ← bool_COMPARE_GE_BFP32(src1,src2)
  VSR[VRT+32].word[i] ← -le || -ge || 300
end
if Rc=1 then do
  ib ← (VSR[VRT+32]=0)
  CR6 ← 0b00 || ib || 0b0
end
```

For each integer value *i* from 0 to 3, do the following.  
Let *src1* be the single-precision floating-point value in element *i* of VSR[VRA+32].

Let *src2* be the single-precision floating-point value in element *i* of VSR[VRB+32].

*src1* is compared to *src2*.

A 2-bit value is formed that indicates whether *src1* is within the bounds specified by *src2*, as follows.

- Bit 0 of the 2-bit value is set to 0 if *src1* is less than or equal to *src2*, and is set to 1 otherwise.

- Bit 1 of the 2-bit value is set to 0 if *src1* is greater than or equal to the negation of *src2*, and is set to 1 otherwise.

The 2-bit value is placed into the high-order two bits of word element *i* of VSR[VRT+32] and the remaining bits of element *i* are set to 0.

If Rc=1, CR field 6 is set as follows.

#### Bit Description

- 0 Set to 0
- 1 Set to 0
- 2 Set to indicate whether all four elements in VSR[VRA+32] are within the bounds specified by the corresponding element in VSR[VRB+32], otherwise set to 0.
- 3 Set to 0

#### Special Registers Altered:

CR field 6 . . . . . (if Rc=1)

#### Programming Note

Each single-precision floating-point value in VSR[VRB+32] should be non-negative; if it is negative, the corresponding element in VSR[VRA+32] will necessarily be out of bounds.

One exception to this is when the value of an element in VSR[VRB+32] is -0.0 and the value of the corresponding element in VSR[VRA+32] is either +0.0 or -0.0. +0.0 and -0.0 compare equal to -0.0.

#### Register Data Layout for vcmpbfp[.]

## 6.10.5 Vector Floating-Point Estimate Instructions

### *Vector 2 Raised to the Exponent Estimate Floating-Point VX-form*

vexptefp            VRT,VRB

4	VRT	///	VRB	394
0	6	11	16	21
				31

```

if MSR.VEC=0 then Vector_Unavailable()

do i = 0 to 3
  src ← VSR[VRB+32].word[i]
  VSR[VRT+32].word[i] ← bfp32_POWER2_ESTIMATE(src)
end

```

For each integer value  $i$  from 0 to 3, do the following.  
 The single-precision floating-point estimate of 2 raised to the power of single-precision floating-point element  $i$  of  $VSR[VRB+32]$  is placed into word element  $i$  of  $VSR[VRT+32]$ .

Let  $x$  be any single-precision floating-point input value. Unless  $x < -146$  or the single-precision floating-point result of computing 2 raised to the power  $x$  would be a zero, an infinity, or a QNaN, the estimate has a relative error in precision no greater than one part in 16. The most significant 12 bits of the estimate's significand are monotonic. An integral input value returns an integral value when the result is representable.

The result for various special cases of the source value is given below.

Value	Result
-Infinity	+0
-0	+1
+0	+1
+Infinity	+Infinity
NaN	QNaN

#### Special Registers Altered:

None

#### Register Data Layout for vexptefp

### Vector Log Base 2 Estimate Floating-Point VX-form

vlogefp VRT,VRB

if MSR\_VEC=0 then Vector\_Unavailable()

```
do i = 0 to 3
  src ← VSR[VRB+32].word[i]
  VSR[VRT+32].word[i] ← bfp32_LOG_BASE2_ESTIMATE(src)
end
```

For each integer value *i* from 0 to 3, do the following.  
 The single-precision floating-point estimate of the base 2 logarithm of single-precision floating-point element *i* of VSR[VRB+32] is placed into the corresponding word element *i* of VSR[VRT+32].

Let *x* be any single-precision floating-point input value. Unless  $|x-1|$  is less than or equal to 0.125 or the single-precision floating-point result of computing the base 2 logarithm of *x* would be an infinity or a QNaN, the estimate has an absolute error in precision (absolute value of the difference between the estimate and the infinitely precise value) no greater than  $2^{-5}$ . Under the same conditions, the estimate has a relative error in precision no greater than one part in 8.

The most significant 12 bits of the estimate's significand are monotonic. The estimate is exact if  $x=2^y$ , where *y* is an integer between -149 and +127 inclusive. Otherwise the value placed into the element of VSR[VRT+32] may vary between implementations, and between different executions on the same implementation.

The result for various special cases of the source value is given below.

Value	Result
-Infinity	QNaN
< 0	QNaN
- 0	- Infinity
+0	- Infinity
+Infinity	+Infinity
NaN	QNaN

**Special Registers Altered:**  
None

#### Register Data Layout for vlogefp

**Vector Reciprocal Estimate Floating-Point VX-form**

vrefp                    VRT,VRB

0	4	VRT	///	VRB	266	31
	6		11	16	21

```

```
do i = 0 to 3
  src ← VSR[VRB+32].word[i]
  VSR[VRT+32].word[i] ← bfp32_RECIPROCAL_ESTIMATE(src)
end
```

For each integer value  $i$  from 0 to 3, do the following.  
The single-precision floating-point estimate of the reciprocal of single-precision floating-point element  $i$  of VSR[VRB+32] is placed into word element  $i$  of VSR[VRT+32].

Unless the single-precision floating-point result of computing the reciprocal of a value would be a zero, an infinity, or a QNaN, the estimate has a relative error in precision no greater than one part in 4096.

Note that results may vary between implementations, and between different executions on the same implementation.

The result for various special cases of the source value is given below.

Value	Result
- Infinity	-0
- 0	- Infinity
+0	+ Infinity
+Infinity	+0
NaN	QNaN

**Special Registers Altered:**

None

### 6.11.1 Vector AES Instructions

This section describes a set of instructions that support the Federal Information Processing Standards Publica-

tion 197 Advanced Encryption Standard for encryption and decryption.

#### Vector AES Cipher VX-form

vcipher VRT,VRA,VRB

4	VRT	VRA	VRB	1288
0	6	11	16	31

if MSR.VEC=0 then Vector\_Unavailable()

```
State ← VSR[VRA+32]
RoundKey ← VSR[VRB+32]
vtemp1 ← SubBytes(State)
vtemp2 ← ShiftRows(vtemp1)
vtemp3 ← MixColumns(vtemp2)
VSR[VRT+32] ← vtemp3 ^ RoundKey
```

Let State be the contents of VSR[VRA+32], representing the intermediate state array during AES cipher operation.

Let RoundKey be the contents of VSR[VRB+32], representing the round key.

One round of an AES cipher operation is performed on the intermediate State array, sequentially applying the transforms, SubBytes(), ShiftRows(), MixColumns(), and AddRoundKey(), as defined in FIPS-197.

The result is placed into VSR[VRT+32], representing the new intermediate state of the cipher operation.

#### Special Registers Altered:

None

#### Vector AES Cipher Last VX-form

vcipherlast VRT,VRA,VRB

4	VRT	VRA	VRB	1289
0	6	11	16	31

if MSR.VEC=0 then Vector\_Unavailable()

```
State ← VSR[VRA+32]
RoundKey ← VSR[VRB+32]
vtemp1 ← SubBytes(State)
vtemp2 ← ShiftRows(vtemp1)
VSR[VRT+32] ← vtemp2 ^ RoundKey
```

Let State be the contents of VSR[VRA+32], representing the intermediate state array during AES cipher operation.

Let RoundKey be the contents of VSR[VRB+32], representing the round key.

The final round in an AES cipher operation is performed on the intermediate State array, sequentially applying the transforms, SubBytes(), ShiftRows(), AddRoundKey(), as defined in FIPS-197.

The result is placed into VSR[VRT+32], representing the final state of the cipher operation.

#### Special Registers Altered:

None

**Vector AES Inverse Cipher VX-form**

vncipher                    VRT,VRA,VRB

4	VRT	VRA	VRB	1352
0	6	11	16	21
31				

if MSR.VEC=0 then Vector\_Unavailable()

```

State ← VSR[VRA+32]
RoundKey ← VSR[VRB+32]
vtemp1 ← InvShiftRows(State)
vtemp2 ← InvSubBytes(vtemp1)
vtemp3 ← vtemp2 ^ RoundKey
VSR[VRT+32] ← InvMixColumns(vtemp3)

```

Let State be the contents of VSR[VRA+32], representing the intermediate state array during AES inverse cipher operation.

Let RoundKey be the contents of VSR[VRB+32], representing the round key.

One round of an AES inverse cipher operation is performed on the intermediate State array, sequentially applying the transforms, InvShiftRows(), InvSubBytes(), AddRoundKey(), and InvMixColumns(), as defined in FIPS-197.

The result is placed into VSR[VRT+32], representing the new intermediate state of the inverse cipher operation.

**Special Registers Altered:**

None

**Vector AES Inverse Cipher Last VX-form**

vncipherlast                    VRT,VRA,VRB

4	VRT	VRA	VRB	1353
0	6	11	16	21
31				

if MSR.VEC=0 then Vector\_Unavailable()

```

State ← VSR[VRA+32]
RoundKey ← VSR[VRB+32]
vtemp1 ← InvShiftRows(State)
vtemp2 ← InvSubBytes(vtemp1)
VSR[VRT+32] ← vtemp2 ^ RoundKey

```

Let State be the contents of VSR[VRA+32], representing the intermediate state array during AES inverse cipher operation.

Let RoundKey be the contents of VSR[VRB+32], representing the round key.

The final round in an AES inverse cipher operation is performed on the intermediate State array, sequentially applying the transforms, InvShiftRows(), InvSubBytes(), and AddRoundKey(), as defined in FIPS-197.

The result is placed into VSR[VRT+32], representing the final state of the inverse cipher operation.

## 6.11.2 Vector SHA-256 and SHA-512 Sigma Instructions

This section describes a set of instructions that support the Federal Information Processing Standards Publication 180-3 Secure Hash Standard.

### Vector SHA-512 Sigma Doubleword VX-form

vshasigmad VRT,VRA,ST,SIX

	4	VRT	VRA	ST	SIX	1730	
0	6	11	16	17	21	31	

```

if MSR_VEC=0 then Vector_Unavailable()

do i = 0 to 1
  src ← VSR[VRA+32].dword[i]

  if ST=0 & SIX.bit[2xi]=0 then // SHA-512 σ0 function
    VSR[VRT+32].dword[i] ← (src >> 1) ^
                          (src >> 8) ^
                          (src >> 7)

  if ST=0 & SIX.bit[2xi]=1 then // SHA-512 σ1 function
    VSR[VRT+32].dword[i] ← (src >> 19) ^
                          (src >> 61) ^
                          (src >> 6)

  if ST=1 & SIX.bit[2xi]=0 then // SHA-512 Σ0 function
    VSR[VRT+32].dword[i] ← (src >> 28) ^
                          (src >> 34) ^
                          (src >> 39)

  if ST=1 & SIX.bit[2xi]=1 then // SHA-512 Σ1 function
    VSR[VRT+32].dword[i] ← (src >> 14) ^
                          (src >> 18) ^
                          (src >> 41)
end

```

For each integer value  $i$  from 0 to 1, do the following.

When  $ST=0$  and bit  $2xi$  of  $SIX$  is 0, a SHA-512  $\sigma_0$  function is performed on the contents of doubleword element  $i$  of  $VSR[VRA+32]$  and the result is placed into doubleword element  $i$  of  $VSR[VRT+32]$ .

When  $ST=0$  and bit  $2xi$  of  $SIX$  is 1, a SHA-512  $\sigma_1$  function is performed on the contents of doubleword element  $i$  of  $VSR[VRA+32]$  and the result is placed into doubleword element  $i$  of  $VSR[VRT+32]$ .

When  $ST=1$  and bit  $2xi$  of  $SIX$  is 0, a SHA-512  $\Sigma_0$  function is performed on the contents of doubleword element  $i$  of  $VSR[VRA+32]$  and the result is placed into doubleword element  $i$  of  $VSR[VRT+32]$ .

When  $ST=1$  and bit  $2xi$  of  $SIX$  is 1, a SHA-512  $\Sigma_1$  function is performed on the contents of doubleword element  $i$  of  $VSR[VRA+32]$  and the result is placed into doubleword element  $i$  of  $VSR[VRT+32]$ .

Bits 1 and 3 of  $SIX$  are reserved.

## 6.11.3 Vector Binary Polynomial Multiplication Instructions

This section describes a set of binary polynomial multiply-sum instructions. Corresponding elements are multiplied and the exclusive-OR of each even-odd pair of

products sum, useful for a variety of finite field arithmetic operations.

### Vector Polynomial Multiply-Sum Byte VX-form

vpmsumb VRT,VRA,VRB

4	VRT	VRA	VRB	1032
0	6	11	16	21
				31

if MSR.VEC=0 then Vector\_Unavailable()

```

do i = 0 to 15
  prod[i].bit[0:14] ← 0
  srcA ← VSR[VRA+32].byte[i]
  srcB ← VSR[VRB+32].byte[i]
  do j = 0 to 7
    do k = 0 to j
      gbit ← srcA.bit[k] & srcB.bit[j-k]
      prod[i].bit[j] ← prod[i].bit[j] ^ gbit
    end
  end
  do j = 8 to 14
    do k = j-7 to 7
      gbit ← (srcA.bit[k] & srcB.bit[j-k])
      prod[i].bit[j] ← prod[i].bit[j] ^ gbit
    end
  end
end
do i = 0 to 7
  VSR[VRT+32].hword[i] ← 0b0 || (prod[2*i] ^ prod[2*i+1])
end

```

For each integer value  $i$  from 0 to 15, do the following.

Let  $\text{prod}[i]$  be the 15-bit result of a binary polynomial multiplication of the contents of byte element  $i$  of  $\text{VSR}[VRA+32]$  and the contents of byte element  $i$  of  $\text{VSR}[VRB+32]$ .

For each integer value  $i$  from 0 to 7, do the following.

The exclusive-OR of  $\text{prod}[2i]$  and  $\text{prod}[2i+1]$  is placed in bits 1:15 of halfword element  $i$  of  $\text{VSR}[VRT+32]$ . Bit 0 of halfword element  $i$  of  $\text{VSR}[VRT+32]$  is set to 0.

## 6.12 Vector Bit Manipulation Instructions

### 6.12.1 Vector Gather Bits Instructions

#### Vector Gather Bits by Bytes by Doubleword VX-form

vgbbd		VRT,VRB				
4	VRT	///	VRB	1292	31	
0	6	11	16	21		

if MSR\_VEC=0 then Vector\_Unavailable()

```

do i = 0 to 1
  do j = 0 to 7
    do k = 0 to 7
      b ← VSR[VRB+32].dword[i].byte[k].bit[j]
      VSR[VRT+32].dword[i].byte[j].bit[k] ← b
    end
  end
end
end
    
```

Let src be the contents of VSR[VRB+32], composed of two doubleword elements numbered 0 and 1.

Let each doubleword element be composed of eight bytes numbered 0 through 7.

An 8-bit × 8-bit bit-matrix transpose is performed on the contents of each doubleword element of VSR[VRB+32] (see Figure 104).

For each integer value i from 0 to 1, do the following,  
 The contents of bit 0 of each byte of doubleword element i of VSR[VRB+32] are concatenated and placed into byte 0 of doubleword element i of VSR[VRT+32].

The contents of bit 1 of each byte of doubleword element i of VSR[VRB+32] are concatenated and placed into byte 1 of doubleword element i of VSR[VRT+32].

The contents of bit 2 of each byte of doubleword element i of VSR[VRB+32] are concatenated and placed into byte 2 of doubleword element i of VSR[VRT+32].

The contents of bit 3 of each byte of doubleword element i of VSR[VRB+32] are concatenated and placed into byte 3 of doubleword element i of VSR[VRT+32].

The contents of bit 4 of each byte of doubleword element i of VSR[VRB+32] are concatenated and placed into byte 4 of doubleword element i of VSR[VRT+32].

The contents of bit 5 of each byte of doubleword element i of VSR[VRB+32] are concatenated and placed into byte 5 of doubleword element i of VSR[VRT+32].

The contents of bit 6 of each byte of doubleword element i of VSR[VRB+32] are concatenated and placed into byte 6 of doubleword element i of VSR[VRT+32].

The contents of bit 7 of each byte of doubleword element i of VSR[VRB+32] are concatenated and placed into byte 7 of doubleword element i of VSR[VRT+32].

```

For each integer value *i* from 0 to 1, do the following.

Starting from the right, for each bit in doubleword element *i* of VSR[VRB+32] that is equal to 1, place the contents of the corresponding bit in doubleword element *i* of VSR[VRA+32] into the rightmost unoccupied bit of doubleword element *i* of VSR[VRT+32]. Any bits in doubleword element *i* of VSR[VRT+32] to the left of the most-significant bit copied are set to 0.

src2		VSR[VRB+32]
result		VSR[VRT+32]
	0	127

**Programming Note**

The fact that the permuted bit is 0 if the corresponding index value exceeds 127 permits the permuted bits to be selected from a 256-bit quantity, using a single index register. For example, assume that the 256-bit quantity *Q*, from which the permuted bits are to be selected, is in registers *v2* (high-order 128 bits of *Q*) and *v3* (low-order 128 bits of *Q*), that the index values are in register *v1*, with each byte of *v1* containing a value in the range 0:255, and that each byte of register *v4* contains the value 128. The following code sequence selects eight permuted bits from *Q* and places them into the low-order byte of *v6*.

```
vbpermq v6,v1,v2 # select from high-order half of Q
vxor v0,v1,v4 # adjust index values
vbpermq v5,v0,v3 # select from low-order half of Q
vor v6,v6,v5 # merge the two selections
```

## 6.13 Vector Mask Manipulation Instructions

### 6.13.1 Vector Mask Move Instructions

### 6.13.3 Vector Count Mask Bits Instructions

The *Vector Count Mask Bits* instructions count the number of true (or false) mask bits (bit 0 of each element) in a VSR and place the count in the leftmost byte of a GPR (i.e., can be used by *Load VSX Vector with Length* and *Store Vector with Length*).

#### Vector Count Mask Bits Byte VX-form

vcntmbb RT,VRB,MP

if MSR\_VEC=0 then Vector\_Unavailable()

```
count = 0
do i = 0 to 15
  count ← count + EXTZ8(VSR[VRB+32].byte[i].bit[0]=MP)
end
```

GPR[RT] ← count << 56

The number of byte elements having bit 0 set to the value MP in VSR[VRB+32] is placed into bits 0:7 of GPR[RT]. Bits 8:63 of GPR[RT] are set to 0.

#### Special Registers Altered:

None

#### Vector Count Mask Bits Halfword VX-form

vcntmbh RT,VRB,MP

if MSR\_VEC=0 then Vector\_Unavailable()

```
count = 0
do i = 0 to 7
  count ← count + EXTZ64(VSR[VRB+32].hword[i].bit[0]=MP)
```

GPR[RT] ← count << 57

The number of halfword elements having bit 0 set to the value MP in VSR[VRB+32] is placed into bits 0:6 of GPR[RT]. Bits 7:63 of GPR[RT] are set to 0.

## 6.15 Decimal Integer Instructions

A *valid encoding* of a packed decimal integer value requires the following properties.

- Each of the 31 4-bit digits of the operand's magnitude (bits 0:123) must be in the range 0-9.
- The sign code (bits 124:127) must be in the range 10-15.

Source operands with sign codes of 0b1010, 0b1100, 0b1110, and 0b1111 are interpreted as positive values.

Source operands with sign codes of 0b1011 and 0b1101 are interpreted as negative values.

Positive and zero results are encoded with a either sign code of 0b1100 or 0b1111, depending on the preferred sign (indicated as an immediate operand).

Negative results are encoded with a sign code of 0b1101.

### 6.15.1 Decimal Integer Arithmetic Instructions

The *Decimal Integer Arithmetic* instructions operate on decimal integer values only in signed packed decimal format. Signed packed decimal format consists of 31 4-bit base-10 digits of magnitude and a trailing 4-bit

sign code. Operations are performed as sign-magnitude, and produce a decimal result placed in a VSR (i.e., *bcdadd*, *bcdsub*).

**Decimal Add Modulo VX-form**

bcdadd. VRT,VRA,VRB,PS

4	VRT	VRA	VRB	1 PS	1
0	6	11	16	21 22 23	31

if MSR.VEC=0 then Vector\_Unavailable()

VSR[VRT+32] ← bcd\_ADD(VSR[VRA+32], VSR[VRB+32], PS)

CR.bit[56] ← inv\_flag ? 0b0 : lt\_flag  
 CR.bit[57] ← inv\_flag ? 0b0 : gt\_flag  
 CR.bit[58] ← inv\_flag ? 0b0 : eq\_flag  
 CR.bit[59] ← ox\_flag | inv\_flag

Let src1 be the decimal integer value in VSR[VRA+32].  
 Let src2 be the decimal integer value in VSR[VRB+32].

src1 is added to src2.

If the unbounded result is equal to zero, do the following.

If PS=0, the sign code of the result is set to 0b1100.  
 If PS=1, the sign code of the result is set to 0b1111.

CR field 6 is set to 0b0010.

If the unbounded result is greater than zero, do the following.

If PS=0, the sign code of the result is set to 0b1100.  
 If PS=1, the sign code of the result is set to 0b1111.

If the operation overflows, CR field 6 is set to 0b0101. Otherwise, CR field 6 is set to 0b0100.

If the unbounded result is less than zero, do the following.

The sign code of the result is set to 0b1101.

If the operation overflows, CR field 6 is set to 0b1001. Otherwise, CR field 6 is set to 0b1000.

The low-order 31 digits of the magnitude of the result are placed in bits 0: 123 of VSR[VRT+32].

The sign code is placed in bits 124: 127 of VSR[VRT+32].

If either src1 or src2 is an *invalid encoding* of a 31-digit signed decimal value, the result is undefined and CR field 6 is set to 0b0001.**Special Registers Altered:**

CR field 6

**Decimal Subtract Modulo VX-form**

bcdsub. VRT,VRA,VRB,PS

4	VRT	VRA	VRB	1 PS	65
0	6	11	16	21 22 23	31

if MSR.VEC=0 then Vector\_Unavailable()

VSR[VRT+32] ← bcd\_SUBTRACT(VSR[VRA+32], VSR[VRB+32], PS)

CR.bit[56] ← inv\_flag ? 0b0 : lt\_flag  
 CR.bit[57] ← inv\_flag ? 0b0 : gt\_flag  
 CR.bit[58] ← inv\_flag ? 0b0 : eq\_flag  
 CR.bit[59] ← ox\_flag | inv\_flag

Let src1 be the decimal integer value in VSR[VRA+32].  
 Let src2 be the decimal integer value in VSR[VRB+32].

src1 is subtracted by src2.

If the unbounded result is equal to zero, do the following.

If PS=0, the sign code of the result is set to 0b1100.  
 If PS=1, the sign code of the result is set to 0b1111.

CR field 6 is set to 0b0010.

If the unbounded result is greater than zero, do the following.

If PS=0, the sign code of the result is set to 0b1100.  
 If PS=1, the sign code of the result is set to 0b1111.

If the operation overflows, CR field 6 is set to 0b0101. Otherwise, CR field 6 is set to 0b0100.

If the unbounded result is less than zero, do the following.

The sign code of the result is set to 0b1101.

If the operation overflows, CR field 6 is set to 0b1001. Otherwise, CR field 6 is set to 0b1000.

The low-order 31 digits of the magnitude of the result are placed in bits 0: 123 of VSR[VRT+32].

The sign code is placed in bits 124: 127 of VSR[VRT+32].

If either src1 or src2 is an *invalid encoding* of a 31-digit signed decimal value, the result is undefined and CR field 6 is set to 0b0001.**Special Registers Altered:**

CR field 6

**Register Data Layout for bcdadd. & bcddsub.**

src1	VSR[VRA+32]
src2	VSR[VRB+32]
result	VSR[VRT+32]
0	127

**Programming Note**

Software should take care when interoperability with the Decimal Floating-Point facilities is required. The register format defined for 31-digit signed decimal values employed by *bcdadd.* and *bcddsub.* is a single 128-bit VSR. The register format defined for 31-digit signed decimal values employed by the *Decimal Floating-Point* instructions *ddedpdq[.]* and *denbcdq[.]* is a pair of 64-bit FPRs. *xxpermdi* can be used to convert between the two register formats as well as move data between the FPR and VSR halves of the Vector-Scalar Registers.

*gew* and *fmgow* are provided to support direct move operations in 32-bit mode.

**Programming Note**

When bit 3 of CR field 6 is set to 1 by *bcdadd.* or *bcddsub.*, either an overflow occurred or one or both operands are not valid encodings of decimal values. Discerning whether an overflow occurred can be accomplished by performing the other decimal instruction on the operands. For example, if *bcdadd.* caused bit 3 of CR field 6 to be set to 1, performing *bcddsub.* on the same set of operands will cause bit 3 of CR field 6 to be set to 1 if and only if one or both of the operands is an invalid encoding. If bit 3 of CR field 6 is not set by *bcddsub.* then the *bcdadd.* can be asserted to have overflowed. Likewise, *bcdadd.* can be used in a similar manner to determine the cause of bit 3 of CR field 6 getting set by a *bcddsub.*

**Programming Note**

*bcddsub.* *vTmp, vA, vB, 0* can be used to compare decimal operands *vA* and *vB*. Bits 0: 2 of CR field 6 will be set to indicate *vA* is less than *vB* (LT), *vA* is greater than *vB* (GT), and *vA* is equal to *vB* (EQ).

*bcddsub.* *vTmp, vA, vA, 0* can be used to test if an operand *vA* is an *invalid encoding* of a decimal value.

```

Let *src* be the national decimal value in VSR[VRB+32].

*src* is placed in VSR[VRT+32] in packed decimal format.

A valid encoding of a national decimal value requires the following.

- The contents of halfword 7 (sign code) must be either 0x002B or 0x002D.
- The contents of halfwords 0 to 6 must be in the range 0x0030 to 0x0039.

National decimal values having a sign code of 0x002B are interpreted as positive values.

National decimal values having a sign code of 0x002D are interpreted as negative values.

For each integer value *i* from 0 to 23, do the following.

The contents of nibble element *i* of VSR[VRT+32] are set to 0x0.

For each integer value *i* from 0 to 6, do the following.

The contents of nibble 3 of halfword element *i* of *src* are placed into nibble element *i*+24 of VSR[VRT+32].

For PS=0, the contents of nibble element 31 (i.e., sign code) of VSR[VRT+32] are set to 0xC for positive values and to 0xD for negative values.

For PS=1, the contents of nibble element 31 (i.e., sign code) of VSR[VRT+32] are set to 0xF for positive values and to 0xD for negative values.

CR field 6 is set to reflect *src* compared to zero.

If *src* is an *invalid encoding* of a national decimal value, the contents of VSR[VRT+32] are undefined and CR field 6 is set to 0b0001.

Let src be the zoned decimal value in VSR[VRB+32].

src is placed in VSR[VRT+32] in packed decimal format.

When PS=0, do the following.

A valid encoding of a zoned decimal value requires the following.

- The contents of bits 0:3 of byte 15 (sign code) can be any value in the range 0x0 to 0xF.
- The contents of bits 0:3 of bytes 0 to 14 must be the value 0x3.
- The contents of bits 4:7 of bytes 0 to 15 must be a value in the range 0x0 to 0x9.

Zoned decimal values having a sign code of 0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xA, or 0xB are interpreted as positive values.

Zoned decimal values having a sign code of 0x4, 0x5, 0x6, 0x7, 0xC, 0xD, 0xE, or 0xF are interpreted as negative values.

When PS=1, do the following.

A valid encoding of a zoned decimal source operand requires the following.

- The contents of bits 0:3 of byte 15 (sign code) must be a value in the range 0xA to 0xF.
- The contents of bits 0:3 of bytes 0 to 14 must be the value 0xF.
- The contents of bits 4:7 of bytes 0 to 15 must be a value in the range 0x0 to 0x9.

Zoned decimal source operands having a sign code of 0xA, 0xC, 0xE, or 0xF are interpreted as positive values.

Zoned decimal source operands having a sign code of 0xB or 0xD are interpreted as negative values.

Positive packed decimal results are returned with a sign code of 0xC.

Negative packed decimal results are returned with a sign code of 0xD.

For each integer value i from 0 to 14,

The contents of nibble element i of VSR[VRT+32] are set to 0x0.

For each integer value i from 0 to 15,

The contents of nibble 1 of byte element i of src are placed into nibble element i+15 of VSR[VRT+32].

CR field 6 is set to reflect src compared to zero.

If src is an *invalid encoding* of a zoned decimal value, the contents of VSR[VRT+32] are undefined and CR field 6 is set to 0b0001.

```

Let *src* be the packed decimal value in VSR[VRB+32].

*src* is placed into VSR[VRT+32] in zoned decimal format.

A valid encoding of a signed packed decimal value requires the following.

- The contents of nibble 31 (sign code) must be a value in the range 0xA to 0xF.

- The contents of each nibble 0-30 must be a value in the range 0x0 to 0x9.

Packed decimal values with sign codes of 0xA, 0xC, 0xE, or 0xF are interpreted as positive values.

Packed decimal values with sign codes of 0xB or 0xD are interpreted as negative values.

Values greater in magnitude than  $10^{16} - 1$  are too large to be represented in zoned decimal format.

For PS=0, do the following.

The leftmost nibble of each digit 0-14 of the zoned decimal result is set to 0x3.

Positive zoned decimal results are returned with a sign code of 0x3.

Negative zoned decimal results are returned with a sign code of 0x7.

For PS=1, do the following.

The leftmost nibble of each digit 0-14 of the zoned decimal result is set to 0xF.

Positive zoned decimal results are returned with a sign code of 0xC.

Negative zoned decimal results are returned with a sign code of 0xD.

For each integer value *i* from 0 to 15, do the following.

The rightmost nibble of each digit *i* of the zoned decimal result is set to the contents of nibble *i*+15 of *src*.

The result is placed into VSR[VRT+32].

CR field 6 is set to reflect *src* compared to zero, including whether or not *src* is too large to be represented in zoned decimal format.

If *src* is an *invalid encoding* of a packed decimal value, the contents of VSR[VRT+32] are undefined and CR field 6 is set to 0b0001.

Let  $n$  be the signed integer value in byte element 7 of  $\text{VSR}[\text{VRA}+32]$ .

Let  $\text{src}$  be the signed packed decimal value in  $\text{VSR}[\text{VRB}+32]$ .

A valid encoding of a signed packed decimal value requires the following.

- The contents of nibble 31 (sign code) must be a value in the range 0xA to 0xF.
- The contents of each nibble 0-30 must be a value in the range 0x0 to 0x9.

Packed decimal source operands with sign codes of 0xA, 0xC, 0xE, or 0xF are interpreted as positive values.

Packed decimal source operands with sign codes of 0xB or 0xD are interpreted as negative values.

If  $n$  is greater than zero,  $\text{src}$  is shifted left  $n$  digits. Zeros are supplied to vacated digits on the right. If any non-zero digits are shifted out, an overflow occurs.

If  $n$  is less than zero,  $\text{src}$  is shifted right  $-n$  digits. Zeros are supplied to vacated digits on the left.

If the packed decimal value in  $\text{VSR}[\text{VRB}+32]$  is negative, the sign code of the result is set to 0b1101.

If the packed decimal value in  $\text{VSR}[\text{VRB}+32]$  is positive, the sign code of the result is set to 0b1100 if  $\text{PS}=0$  and is set to 0b1111 if  $\text{PS}=1$ .

The shifted result is placed into  $\text{VSR}[\text{VRT}+32]$ .

CR field 6 is set to reflect  $\text{src}$  compared to zero, including whether or not significant digits were shifted out when the shift count is positive (i.e., left shift operation).

If  $\text{src}$  is an *invalid encoding* of a packed decimal value, the contents of  $\text{VSR}[\text{VRT}+32]$  are undefined and CR field 6 is set to 0b0001.

## Chapter 7. Vector-Scalar Extension Facility

### 7.1 Introduction

#### 7.1.1 Overview of the Vector-Scalar Extension

Vector-Scalar Extension (VSX) provides facilities supporting vector and scalar binary floating-point operations. The following VSX features are provided to increase opportunities for vectorization.

- A unified register file, a set of Vector-Scalar Registers (VSR), supporting both scalar and vector operations is provided, eliminating the overhead of vector-scalar data transfer through storage.
- Support for word-aligned storage accesses for both scalar and vector operations is provided.
- Robust support for IEEE-754 for both vector and scalar floating-point operations is provided.

Combining the Floating-Point Registers (FPR) defined in Chapter 4. Floating-Point Facility and the Vector Registers (VR) defined in Chapter 6. Vector Facility provides additional registers to support more aggressive compiler optimizations for both vector and scalar operations.

##### 7.1.1.1 Compatibility with Floating-Point and Decimal Floating-Point Operations

The instruction sets defined in Chapter 4. Floating-Point Facility and Chapter 5. Decimal Floating-Point retain their definition with one primary difference. The FPRs are mapped to doubleword element 0 of VSRs 0-31. The contents of doubleword 1 of the VSR corresponding to a source FPR specified by an instruction are ignored. The contents of doubleword 1 of a VSR corresponding to the target FPR specified by an instruction are set to 0.

#### Programming Note

Application binary interfaces extended to support VSX require special care of vector data written to VSRs 0-31 (i.e., VSRs corresponding to FPRs). Legacy scalar function calls employ doubleword-based loads and stores to preserve the contents of any nonvolatile registers. This has the adverse effect of not preserving the contents of doubleword 1 of these VSRs.

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

##### 7.1.1.2 Compatibility with Vector Operations

The instruction set defined in Chapter 6. Vector Facility, retains its definition with one primary difference. The VRs are mapped to VSRs 32-63.

## 7.2 VSX Registers

### 7.2.1 Vector-Scalar Registers

Sixty-four 128-bit VSRs are provided. See Figure 105. All VSX floating-point computations and other data manipulation are performed on data residing in Vector-Scalar Registers, and results are placed into a VSR.

Depending on the instruction, the contents of a VSR are interpreted as a sequence of equal-length elements (words or doublewords) or as a quadword. Each of the elements is aligned within the VSR, as shown in Figure 106. Many instructions perform a given operation in parallel on all elements in a VSR.

Depending on the instruction, a word element can be interpreted as a signed integer word (SW), an unsigned integer word (UW), a logical mask value (MW), or a single-precision floating-point value (SP); a doubleword element can be interpreted as a doubleword signed integer (SD), a doubleword unsigned integer (UD), a doubleword mask (DM), or a double-precision floating-point value (DP). In the instructions descriptions, phrases like *signed integer word element* are used as shorthand for *word element, interpreted as a signed integer*.

*Load* and *Store* instructions are provided that transfer a byte, a specified number of bytes (up to 16), a halfword, a word, a doubleword, or a quadword between storage and a VSR, or an octword between storage and a pair of VSRs.

Figure 105. Vector-Scalar Registers

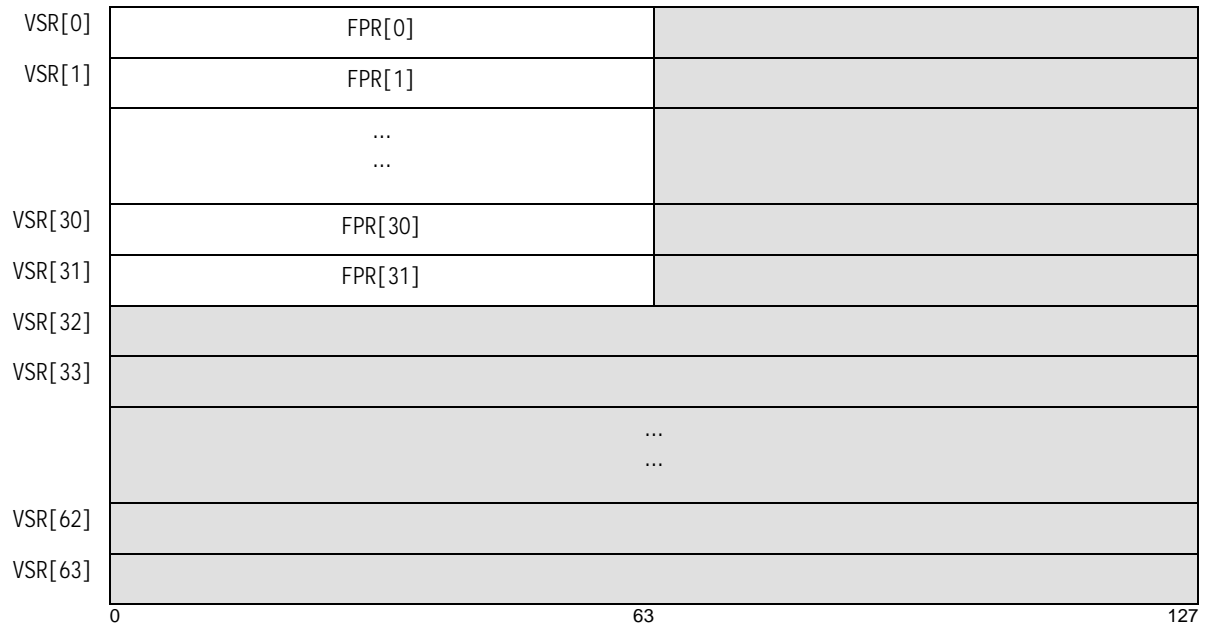

Figure 106. Vector-Scalar Register Elements

#### 7.2.1.1 Floating-Point Registers

Chapter 4. Floating-Point Facility provides 32 64-bit FPRs. Chapter 5. Decimal Floating-Point also employs FPRs in decimal floating-point (DFP) operations. When VSX is implemented, the 32 FPRs are mapped to doubleword 0 of VSRs 0-31. For example, FPR[0] is located in doubleword element 0 of VSR[0], FPR[1] is located in doubleword element 0 of VSR[1], and so forth.

All instructions that operate on an FPR are redefined to operate on doubleword element 0 of the corresponding VSR. The contents of doubleword element 1 of the VSR corresponding to a source FPR or FPR pair for these instructions are ignored and the contents of doubleword element 1 of the VSR

corresponding to the target FPR or FPR pair for these instructions are set to 0.

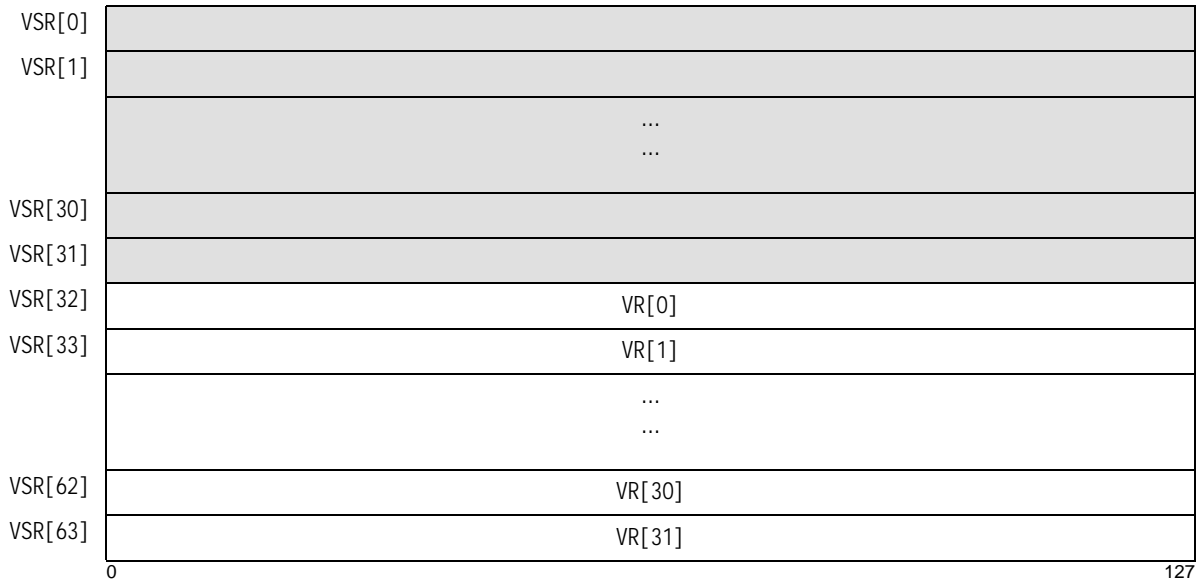

**Figure 107. Floating-Point Registers as part of VSRs**

### 7.2.1.2 Vector Registers

Chapter 6. Vector Facility provides 32 128-bit VRs. When VSX is implemented, the 32 VRs are mapped to VSRs 32-63. For example, VR[0] is located in VSR[32], VR[1] is located in VSR[33], and so forth.

All instructions that operate on a VR are redefined to operate on the corresponding VSR.

**Figure 108.** Vector Registers as part of VSRs

### 7.2.1.3 VSX Accumulators

Eight 512-bit Accumulators (ACC) are provided. Each ACC contains four 128-bit rows.

$$\begin{aligned} \text{ACC}[i][0] &= \text{ACC}[i].\text{bit}[0:127] \\ \text{ACC}[i][1] &= \text{ACC}[i].\text{bit}[128:255] \\ \text{ACC}[i][2] &= \text{ACC}[i].\text{bit}[256:383] \\ \text{ACC}[i][3] &= \text{ACC}[i].\text{bit}[384:511] \end{aligned}$$

Each ACC is associated with four VSRs in the following manner.

$$\begin{aligned} \text{ACC}[0][0] &\leftrightarrow \text{VSR}[0] \\ \text{ACC}[0][1] &\leftrightarrow \text{VSR}[1] \\ \text{ACC}[0][2] &\leftrightarrow \text{VSR}[2] \\ \text{ACC}[0][3] &\leftrightarrow \text{VSR}[3] \\ \\ \text{ACC}[1][0] &\leftrightarrow \text{VSR}[4] \\ \text{ACC}[1][1] &\leftrightarrow \text{VSR}[5] \\ \text{ACC}[1][2] &\leftrightarrow \text{VSR}[6] \\ \text{ACC}[1][3] &\leftrightarrow \text{VSR}[7] \\ \\ &: \quad : \\ \\ \text{ACC}[i][0] &\leftrightarrow \text{VSR}[4i] \\ \text{ACC}[i][1] &\leftrightarrow \text{VSR}[4i+1] \\ \text{ACC}[i][2] &\leftrightarrow \text{VSR}[4i+2] \\ \text{ACC}[i][3] &\leftrightarrow \text{VSR}[4i+3] \\ \\ &: \quad : \\ \\ \text{ACC}[7][0] &\leftrightarrow \text{VSR}[28] \\ \text{ACC}[7][1] &\leftrightarrow \text{VSR}[29] \\ \text{ACC}[7][2] &\leftrightarrow \text{VSR}[30] \\ \text{ACC}[7][3] &\leftrightarrow \text{VSR}[31] \end{aligned}$$

While the ACCs are treated as separate registers from the VSRs,  $\text{ACC}[i]$  may use its associated VSRs  $4i$  to  $4i+3$  as scratch space. That is, when  $\text{ACC}[i]$  contains defined data, the contents of VSRs  $4i$  to  $4i+3$  are undefined until either a *VSX Move From ACC* instruction is used to copy the contents of  $\text{ACC}[i]$  to VSRs  $4i$  to  $4i+3$  or some other instruction directly writes to one of these VSRs.

Any instruction that targets any VSR(s) associated with an ACC causes the contents of that ACC to be undefined. If the instruction is not *xxmfacc*, the target VSR(s) will contain defined data generated by the instruction, and the contents of the other VSRs associated with the ACC will be undefined. If the instruction is *xxmfacc*, all four VSRs associated with the ACC will contain defined data if the ACC contained defined data, and will have undefined contents otherwise.

Any instruction that targets an ACC causes any subsequent use of that ACC as a source operand to be defined, but causes the contents of all VSRs associated with the ACC to be undefined.

#### Programming Note

Application software must strictly adhere to the programming model described in this section to guarantee compatibility with future versions of the architecture.

For this version of the architecture, the hardware implementation provides the effect of  $\text{ACC}[i]$  and VSRs  $4i$  to  $4i+3$  logically containing the same data. Being subject to change in future versions of this architecture, application software must not rely on this behavior. However, system software that handles context save/restore operations need only save and restore data from and to the VSRs (that is, the most current data between the VSRs and associated ACCs will be provided by the hardware implementation). The Accumulators introduce no new logical state at this time. However, future versions of the architecture may define new architectural state or re-define the backing state of the ACC registers. In turn, this may require changes to the system software to support programs written according to this version of the architecture.

The following instructions can be used to copy the contents of an ACC into its associated VSRs.

#### *VSX Move From Accumulator (xxmfacc)*

The contents of the source ACC are copied into the VSRs associated with the target ACC.

The following instructions can be used to initialize the contents of an ACC.

#### *VSX Move To Accumulator (xxmtacc)*

The contents of the VSRs associated with the target ACC are copied into the target ACC.

#### *VSX Set ACC to Zero (xxsetaccz)*

The target ACC is set to 0.

#### *[Prefixed Masked] VSX Vector 4-bit Signed Integer GER (rank-8) ([pm]xvi4ger8)*

The sum of the eight outer products of the 4-bit signed integer values in the two vector source operands are placed into the target ACC.

#### *[Prefixed Masked] VSX Vector 8-bit Signed/Unsigned Integer GER (rank-4) ([pm]xvi8ger4)*

The sum of the four outer products of the 8-bit signed and unsigned integer values in the two vector source operands are placed into the target ACC.

*[Prefixed Masked] VSX Vector 16-bit Signed Integer GER (rank-2) ([pm]xvi16ger2s)*

The sum of the two outer products of the 16-bit signed integer values in the two vector source operands are placed into the target ACC.

*[Prefixed Masked] VSX Vector 16-bit Floating-Point GER (rank-2) ([pm]xvf16ger2)*

The sum of the two outer products of the 16-bit floating-point values in the two vector source operands are placed into the target ACC.

*[Prefixed Masked] VSX Vector bfloat16 GER (rank-2) ([pm]xvbf16ger2)*

The sum of the two outer products of the bfloat16 values in the two vector source operands are placed into the target ACC.

*[Prefixed Masked] VSX Vector 32-bit Floating-Point GER (rank-1) ([pm]xvf32ger)*

The outer product of the 32-bit floating-point values in the two vector source operands is placed into the target ACC.

*[Prefixed Masked] VSX Vector 64-bit Floating-Point GER (rank-1) ([pm]xvf64ger)*

The outer product of the 64-bit floating-point values in the two vector source operands is placed into the target ACC.

## 7.2.2 Floating-Point Status and Control Register

The Floating-Point Status and Control Register (FPSCR) controls the handling of floating-point exceptions and records status resulting from the floating-point operations. Bits 0:19 and 32:55 are status bits. Bits 56:63 are control bits.

The exception status bits in the FPSCR (bits 35:44, 53:55) are sticky; that is, once set to 1 they remain set to 1 until they are set to 0 by an *mcrfs*, *mtfsfi*, *mtfsf*, or *mtfsb0* instruction. The exception summary bits in the FPSCR (FX, FEX, and VX, which are bits 32:34) are not considered to be “exception status bits”, and only FX is sticky.

### Programming Note

Access to *Move To FPSCR* and *Move From FPSCR* instructions requires FP=1.

FEX and VX are simply the ORs of other FPSCR bits. Therefore these two bits are not listed among the FPSCR bits affected by the various instructions.

The bit definitions for the FPSCR are as follows.

### Bit(s) Definition

0:28    **Decimal Floating-Point Rounding Control** (DRN)  
This field is not used by VSX instructions.

32    **Floating-Point Exception Summary** (FX)  
Every floating-point instruction, except *mtfsfi* and *mtfsf*, implicitly sets FX to 1 if that instruction causes any of the floating-point exception bits in the FPSCR to change from 0 to 1. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* can alter FX explicitly.

### Programming Note

FX is defined not to be altered implicitly by *mtfsfi* and *mtfsf* because permitting these instructions to alter FX implicitly can cause a paradox. An example is an *mtfsfi* or *mtfsf* instruction that supplies 0 for FX and 1 for 0X, and is executed when 0X=0. See also the Programming Notes with the definition of these two instructions.

33    **Floating-Point Enabled Exception Summary** (FEX)  
This bit is the OR of all the floating-point exception bits masked by their respective enable bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter FEX explicitly.

### Bit(s) Definition

34    **Floating-Point Invalid Operation Exception Summary** (VX)  
This bit is the OR of all the Invalid Operation exception bits. *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, and *mtfsb1* cannot alter VX explicitly.

35    **Floating-Point Overflow Exception** (0X)  
This bit is set to 1 when a VSX *Scalar Floating-Point Arithmetic*, VSX *Vector Floating-Point Arithmetic*, VSX *Scalar DP-SP Conversion* or VSX *Vector DP-SP Conversion* class instruction causes an Overflow exception. See Section 7.4.3 , “Floating-Point Overflow Exception” on page 548.

This bit can be set to 0 or 1 by a *Move To FPSCR* class instruction.

36    **Floating-Point Underflow Exception** (UX)  
This bit is set to 1 when a VSX *Scalar Floating-Point Arithmetic*, VSX *Vector Floating-Point Arithmetic*, VSX *Scalar DP-SP Conversion* or VSX *Vector DP-SP Conversion* class instruction causes an Underflow exception. See Section 7.4.4 , “Floating-Point Underflow Exception” on page 554.

This bit can be set to 0 or 1 by a *Move To FPSCR* class instruction.

37    **Floating-Point Zero Divide Exception** (ZX)  
This bit is set to 1 when a VSX *Scalar Floating-Point Arithmetic* or VSX *Vector Floating-Point Arithmetic* class instruction causes a Zero Divide exception. See Section 7.4.2 , “Floating-Point Zero Divide Exception” on page 545.

This bit can be set to 0 or 1 by a *Move To FPSCR* class instruction.

38    **Floating-Point Inexact Exception** (XX)  
This bit is set to 1 when a VSX *Scalar Floating-Point Arithmetic*, VSX *Vector Floating-Point Arithmetic*, VSX *Scalar Integer Conversion*, VSX *Vector Integer Conversion*, VSX *Scalar Round to Floating-Point Integer*, or VSX *Vector Round to Floating-Point Integer* class instruction causes an Inexact exception. See Section 7.4.5 , “Floating-Point Inexact Exception” on page 560.

This bit can be set to 0 or 1 by a *Move To FPSCR* class instruction.

See Section 7.3.2.6 on page 524. This bit is not sticky.</p> <p>See the definition of XX, above, regarding the relationship between FI and XX.</p>

**Bit(s) Definition**

**47:51 Floating-Point Result Flags (FPRF)**  
*VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer* class instructions set this field based on the result placed into the target register and on the target precision, except that if any portion of the result is undefined then the value placed into FPRF is undefined.

For *VSX Scalar Convert Double-Precision to Integer* class instructions, the value placed into FPRF is undefined.

Additional details are as follows.

Result Flags					Result Value Class
C	FL	FG	FE	FU	
1	0	0	0	1	Quiet NaN
0	1	0	0	1	- Infinity
0	1	0	0	0	- Normalized Number
1	1	0	0	0	- Denormalized Number
1	0	0	1	0	- Zero
0	0	0	1	0	+ Zero
1	0	1	0	0	+ Denormalized Number
0	0	1	0	0	+ Normalized Number
0	0	1	0	1	+ Infinity

**Table 2. Floating-Point Result Flags**

**47 Floating-Point Result Class Descriptor (C)**  
*VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer* class instructions set this bit with the FPCC bits, to indicate the class of the result as shown in Table 2, “Floating-Point Result Flags,” on page 511.

**48:51 Floating-Point Condition Code (FPCC)**  
*VSX Scalar Compare Double-Precision* instruction sets one of the FPCC bits to 1 and the other three FPCC bits to 0 based on the relative values of the operands being compared.

*VSX Scalar Floating-Point Arithmetic, VSX Scalar DP-SP Conversion, VSX Scalar Convert Integer to Double-Precision, and VSX Scalar Round to Double-Precision Integer* class instructions set the FPCC bits with

the C bit, to indicate the class of the result as shown in Table 2, “Floating-Point Result Flags,” on page 511. Note that in this case the high-order three bits of the FPCC retain their relational significance indicating that the value is less than, greater than, or equal to zero.

**48 Floating-Point Less Than or Negative (FL)**

**49 Floating-Point Greater Than or Positive (FG)**

**50 Floating-Point Equal or Zero (FE)**

**51 Floating-Point Unordered or NaN (FU)**

**52 Reserved**

**53 Floating-Point Invalid Operation Exception (Software-Defined Condition) (VXSOFI)**

This bit can be altered only by *mcrfs*, *mtfsfi*, *mtfsf*, *mtfsb0*, or *mtfsb1*. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 533.

**Programming Note**

VXSOFI can be used by software to indicate the occurrence of an arbitrary, software-defined, condition that is to be treated as an Invalid Operation exception. For example, the bit could be set by a program that computes a base 10 logarithm if the supplied input is negative.

**54 Floating-Point Invalid Operation Exception (Invalid Square Root) (VXSORT)**

This bit is set to 1 when a *VSX Scalar Floating-Point Arithmetic* or *VSX Vector Floating-Point Arithmetic* class instruction causes a Invalid Square Root type Invalid Operation exception. See Section 7.4.1, “Floating-Point Invalid Operation Exception” on page 533.

This bit can be set to 0 or 1 by a *Move To FPSCR* class instruction.

Bit(s)	Definition	Bit(s)	Definition
55	<p><b>Floating-Point Invalid Operation Exception (Invalid Integer Convert) (VXCVI)</b></p> <p>This bit is set to 1 when a <i>VSX Scalar Convert Double-Precision to Integer</i>, <i>VSX Vector Convert Double-Precision to Integer</i>, or <i>VSX Vector Convert Single-Precision to Integer</i> class instruction causes a Invalid Integer Convert type Invalid Operation exception. See Section 7.4.1 , “Floating-Point Invalid Operation Exception” on page 533.</p> <p>This bit can be set to 0 or 1 by a <i>Move To FPSCR</i> class instruction.</p>	60	<p><b>Floating-Point Inexact Exception Enable (XE)</b></p> <p>This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Inexact exceptions. See Section 7.4.5 , “Floating-Point Inexact Exception” on page 560.</p>
56	<p><b>Floating-Point Invalid Operation Exception Enable (VE)</b></p> <p>This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Invalid Operation exceptions. See Section 7.4.1 , “Floating-Point Invalid Operation Exception” on page 533.</p>	61	<p><b>Floating-Point Non-IEEE Mode (NI)</b></p> <p>Floating-point non-IEEE mode is optional. If floating-point non-IEEE mode is not implemented, this bit is treated as reserved, and the remainder of the definition of this bit does not apply.</p> <p>If floating-point non-IEEE mode is implemented, this bit has the following meaning.</p> <p>0The processor is not in floating-point non-IEEE mode (i.e., all floating-point operations conform to the IEEE standard).</p> <p>1The processor is in floating-point non-IEEE mode.</p> <p>When the processor is in floating-point non-IEEE mode, the remaining FPSCR bits is permitted to have meanings different from those given in this document, and floating-point operations need not conform to the IEEE standard. The effects of executing a given floating-point instruction with NI=1, and any additional requirements for using non-IEEE mode, are implementation-dependent. The results of executing a given instruction in non-IEEE mode is permitted to vary between implementations, and between different executions on the same implementation.</p>
57	<p><b>Floating-Point Overflow Exception Enable (OE)</b></p> <p>This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Overflow exceptions. See Section 7.4.3 , “Floating-Point Overflow Exception” on page 548.</p>		
58	<p><b>Floating-Point Underflow Exception Enable (UE)</b></p> <p>This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Underflow exceptions. See Section 7.4.4 , “Floating-Point Underflow Exception” on page 554.</p>		
59	<p><b>Floating-Point Zero Divide Exception Enable (ZE)</b></p> <p>This bit is used by <i>VSX Scalar Floating-Point</i> and <i>VSX Vector Floating-Point</i> class instructions to enable trapping on Zero Divide exceptions. See Section 7.4.2 , “Floating-Point Zero Divide Exception” on page 545.</p>		

**Programming Note**

When the processor is in floating-point non-IEEE mode, the results of floating-point operations is permitted to be approximate, and performance for these operations might be better, more predictable, or less data-dependent than when the processor is not in non-IEEE mode. For example, in non-IEEE mode an implementation is permitted to return 0 instead of a denormalized number and return a large number instead of an infinity.

**62:63 Floating-Point Rounding Control (RN)**

This field is used by *VSX Scalar Floating-Point* and *VSX Vector Floating-Point* class instructions that round their result and the rounding mode is not implied by the opcode.

This bit can be explicitly set or reset by a new Move To FPSCR class instruction.

See Section 7.3.2.6 , “Rounding” on page 524.

- 00 Round to Nearest Even
- 01 Round toward Zero
- 10 Round toward +Infinity
- 11 Round toward -Infinity

## 7.3 VSX Operations

### 7.3.1 VSX Floating-Point Arithmetic Overview

This section describes the floating-point arithmetic and exception model supported by Vector-Scalar Extension. Except for extensions to support 32-bit single-precision floating-point vector operations, the models are identical to that described in Chapter 4. Floating-Point Facility.

The processor (augmented by appropriate software support, where required) implements a floating-point system compliant with the ANSI/IEEE Standard 754-1985, *IEEE Standard for Binary Floating-Point Arithmetic* (hereafter referred to as *the IEEE standard*). That standard defines certain required "operations" (addition, subtraction, and so on). Herein, the term, floating-point operation, is used to refer to one of these required operations and to additional operations defined (e.g., those performed by *Multiply-Add* or *Reciprocal Estimate* instructions). A Non-IEEE mode is also provided. This mode, which is permitted to produce results not in strict compliance with the IEEE standard, allows shorter latency.

Instructions are provided to perform arithmetic, rounding, conversion, comparison, and other operations in VSRs; to move floating-point data between storage and these registers.

These instructions are divided into two categories.

- computational instructions

The computational instructions are those that perform addition, subtraction, multiplication, division, extracting the square root, rounding, conversion, comparison, and combinations of these operations. These instructions provide the floating-point operations. There are two forms of computational instructions, scalar, which perform a single floating-point operation, and vector, which perform either two double-precision floating-point operations or four single-precision operations. Computational instructions place status information into the Floating-Point Status and Control Register. They are the instructions described in Sections 7.6.1.3 through 7.6.1.8.2.

- noncomputational instructions

The noncomputational instructions are those that perform loads and stores, move the contents of a VSR to another floating-point register possibly altering the sign, and select the value from one of two VSRs based on the value in a third VSR. The

operations performed by these instructions are not considered floating-point operations. These instructions do not alter the Floating-Point Status and Control Register. They are the instructions listed in Sections 7.6.1.1, 7.6.1.2.1, and 7.6.1.13 through .

A floating-point number consists of a signed exponent and a signed significand. The quantity expressed by this number is the product of the significand and the number  $2^{\text{exponent}}$ . Encodings are provided in the data format to represent finite numeric values,  $\pm$ Infinity, and values that are "Not a Number" (NaN). Operations involving infinities produce results obeying traditional mathematical conventions. NaNs have no mathematical interpretation. Their encoding permits a variable diagnostic information field. NaNs might be used to indicate such things as uninitialized variables and can be produced by certain invalid operations.

There is one class of exceptional events that occur during instruction execution that is unique to Vector-Scalar Extension and Floating-Point: the Floating-Point Exception. Floating-point exceptions are signaled with bits set in the FPSCR. They can cause the system floating-point enabled exception error handler to be invoked, precisely or imprecisely, if the proper control bits are set.

#### Floating-Point Exceptions

The following floating-point exceptions are detected by the processor:

- Invalid Operation exception (VX)
  - SNaN (VXSNAN)
  - Infinity-Infinity (VXI SI)
  - Infinity $\neq$ Infinity (VXI DI)
  - Zero $\div$ Zero (VXZDZ)
  - Infinity $\times$ Zero (VXI MZ)
  - Invalid Compare (VXVC)
  - Software-Defined Condition (VXSOFT)
  - Invalid Square Root (VXSQRT)
  - Invalid Integer Convert (VXCVI)
- Zero Divide exception (ZX)
- Overflow exception (OX)
- Underflow exception (UX)
- Inexact exception (XX)

Each floating-point exception, and each category of Invalid Operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. See Section 7.2.2, "Floating-Point Status and Control Register" on page 509 for a description of these exception and enable bits, and Section 7.3.3, "VSX Floating-Point Execution Models" on page 527 for a detailed discussion of floating-point exceptions, including the effects of the enable bits.

## 7.3.2 VSX Floating-Point Data

### 7.3.2.1 Data Format

This architecture defines the representation of a floating-point value in five different binary fixed-length formats, 16-bit half-precision format, 16-bit bfloat16 format, 32-bit single-precision format, 64-bit double-precision format, and 128-bit quad-precision format. The half-precision format is used for half-precision floating-point data in storage and registers. The bfloat16 format is used for bfloat16 floating-point data in storage and registers. The single-precision format is used for single-precision floating-point data in storage and registers. The double-precision format is used for double-precision floating-point data in storage and registers. The quad-precision format is used for quad-precision floating-point data in storage and registers.

The lengths of the exponent and the fraction fields differ between these five formats. The structure of the half-precision, bfloat16, single-precision, double-precision, and quad-precision formats is shown

Figure 109, Figure 111, Figure 112, Figure 113, and Figure 113, respectively.

Values in floating-point format are composed of three fields:

S	sign bit
EXP	exponent+bias
FRACTI ON	fraction

Representation of numeric values in the floating-point formats consists of a sign bit (S), a biased exponent (EXP), and the fraction portion (FRACTI ON) of the significand. The significand consists of a leading implied bit concatenated on the right with the FRACTI ON. This leading implied bit is 1 for normalized numbers and 0 for denormalized (subnormal) numbers or zero and is located in the unit bit position (that is, the first bit to the left of the binary point). Values representable within the three floating-point formats can be specified by the parameters listed in Table 3.

**Table 3. Binary floating-point fields**

### 7.3.2.2 Value Representation

This architecture defines numeric and nonnumeric values representable within each of the three supported formats. The numeric values are approximations to the real numbers and include the normalized numbers, denormalized numbers, and zero values. The nonnumeric values representable are the infinities and the Not a Numbers (NaNs). The infinities are adjoined to the real numbers, but are not numbers themselves, and the standard rules of arithmetic do not hold when they are used in an operation. They are related to the real numbers by order alone. It is possible however to define restricted operations among numbers and infinities as defined below. The relative location on the real number line for each of the defined entities is shown in Figure 114.

**Figure 114. Approximation to real numbers**

The NaNs are not related to the numeric values or infinities by order or value but are encodings used to convey diagnostic information such as the representation of uninitialized variables.

The following is a description of the different floating-point values defined in the architecture:

#### Binary floating-point numbers

Machine representable values used as approximations to real numbers. Three categories of numbers are supported: normalized numbers, denormalized numbers, and zero values.

#### Normalized numbers ( $\pm$ NOR)

These are values that have a biased exponent value in the range:

- 1 to 30 in half-precision format
- 1 to 254 in bfloat16 format
- 1 to 254 in single-precision format
- 1 to 2046 in double-precision format
- 1 to 32766 in quad-precision format

They are values in which the implied unit bit is 1. Normalized numbers are interpreted as follows:

$$\text{NOR} = (-1)^s \times 2^E \times (1.\text{fraction})$$

where  $s$  is the sign,  $E$  is the unbiased exponent, and  $1.\text{fraction}$  is the significand, which is composed of a leading unit bit (implied bit) and a fraction part.

#### Zero values ( $\pm$ 0)

These are values that have a biased exponent value of zero and a fraction value of zero. Zeros can have a positive or negative sign. The sign of zero is ignored by comparison operations (that is, comparison regards +0 as equal to -0).

#### Denormalized numbers ( $\pm$ DEN)

These are values that have a biased exponent value of zero and a nonzero fraction value. They are nonzero numbers smaller in magnitude than the representable normalized numbers. They are values in which the implied unit bit is 0. Denormalized numbers are interpreted as follows:

$$\text{DEN} = (-1)^s \times 2^{\text{Emin}} \times (0.\text{fraction})$$

where  $\text{Emin}$  is the minimum representable exponent value.

- 14 for half-precision
- 126 for bfloat16
- 126 for single-precision
- 1022 for double-precision
- 16382 for quad-precision.

#### Infinities ( $\pm$ INF)

These are values that have the maximum biased exponent value:

- 31 in half-precision format
- 255 in bfloat16 format
- 255 in single-precision format
- 2047 in double-precision format
- 32767 in quad-precision format

and a zero fraction value. They are used to approximate values greater in magnitude than the maximum normalized value.

Infinity arithmetic is defined as the limiting case of real arithmetic, with restricted operations defined among numbers and infinities. Infinities and the real numbers can be related by ordering in the affine sense:

$$-\text{Infinity} < \text{every finite number} < +\text{Infinity}$$

Arithmetic on infinities is always exact and does not signal any exception, except when an exception occurs due to the invalid operations as described in Section 7.4.1, "Floating-Point Invalid Operation Exception" on page 533.

For comparison operations, +Infinity compares equal to +Infinity and -Infinity compares equal to -Infinity.

### Not a Numbers (NaNs)

These are values that have the maximum biased exponent value and a nonzero fraction value. The sign bit is ignored (that is, NaNs are neither positive nor negative). If the high-order bit of the fraction field is 0, the NaN is a *Signaling NaN*; otherwise it is a *Quiet NaN*.

Signaling NaNs are used to signal exceptions when they appear as operands of computational instructions.

Quiet NaNs are used to represent the results of certain invalid operations, such as invalid arithmetic operations on infinities or on NaNs, when Invalid Operation exception is disabled (VE=0). Quiet NaNs propagate through all floating-point operations except ordered comparison and conversion to integer. Quiet NaNs do not signal exceptions, except for ordered comparison and conversion to integer operations. Specific encodings in QNaNs can thus be preserved through a sequence of floating-point operations, and used to convey diagnostic information to help identify results from invalid operations.

Assume the following generic arithmetic templates.

**f(src1, src3, src2)**  
ex: result t = (src1 x src3) - src2

**f(src1, src2)**  
ex: result t = src1 x src2  
ex: result t = src1 + src2

**f(src1)**  
ex: result t = f(src1)

When a QNaN is the result of a floating-point operation because one of the operands is a NaN or because a QNaN was generated due to a trap-disabled Invalid Operation exception, the following rule is applied to determine the NaN with the high-order fraction bit set to 1 that is to be stored as the result.

```

if src1 is a NaN
  then result t = Quiet(src1)
else if src2 is a NaN (if there is a src2)
  then result t = Quiet(src2)
else if src3 is a NaN (if there is a src3)
  then result t = Quiet(src3)
else if disabled invalid operation exception
  then result t = generated QNaN

```

where  $Quiet(x)$  means  $x$  if  $x$  is a QNaN and  $x$  converted to a QNaN if  $x$  is an SNaN. Any instruction that generates a QNaN as the result of a disabled Invalid Operation exception generates the value,

0x7E00 for half-precision results,

0x7FC0 for bfloat16 results,

0x7FC0\_0000 for single-precision results,

0x7FF8\_0000\_0000\_0000 for double-precision results,

0x7FFF\_8000\_0000\_0000\_0000\_0000\_0000\_0000 for quad-precision results.

Note that the M-form multiply-add-type instructions use the B source operand to specify *src3* and the T target operand to specify *src2*, whereas A-form multiply-add-type instructions use the B source operand to specify *src2* and the T target operand to specify *src3*.

A double-precision NaN is considered to be representable in single-precision format if and only if the low-order 29 bits of the double-precision NaN's fraction are zero.

### 7.3.2.3 Sign of Result

The following rules govern the sign of the result of an arithmetic, rounding, or conversion operation, when the operation does not yield an exception. They apply even when the operands or results are zeros or infinities.

- The sign of the result of an add operation is the sign of the operand having the larger absolute value. If both operands have the same signs, the sign of the result of an add operation is the same as the sign of the operands. The sign of the result of the subtract operation  $x-y$  is the same as the sign of the result of the add operation  $x+(-y)$ .

When the sum of two operands with opposite sign, or the difference of two operands with the same signs, is exactly zero, the sign of the result is positive in all rounding modes except Round toward  $-\infty$ , in which mode the sign is negative.

- The sign of the result of a multiply or divide operation is the Exclusive OR of the signs of the operands.
- The sign of the result of a *Square Root* or *Reciprocal Square Root Estimate* operation is always positive, except that the square root of  $-0$  is  $-0$  and the reciprocal square root of  $-0$  is  $-\infty$ .
- The sign of the result of a *Convert From Integer* or *Round to Floating-Point Integer* operation is the sign of the operand being converted.

For the *Multiply-Add* instructions, the rules given above are applied first to the multiply operation and then to the add or subtract operation (one of the inputs to the add or subtract operation is the result of the multiply operation).

### 7.3.2.4 Normalization and Denormalization

The intermediate result of an arithmetic instruction can require normalization and/or denormalization as described below. Normalization and denormalization do not affect the sign of the result.

When an arithmetic or rounding instruction produces an intermediate result which carries out of the significand, or in which the significand is nonzero but has a leading zero bit, it is not a normalized number and must be normalized before it is stored. For the carry-out case, the significand is shifted right one bit, with a one shifted into the leading significand bit, and the exponent is incremented by one. For the leading-zero case, the significand is shifted left while decrementing its exponent by one for each bit shifted, until the leading significand bit becomes one. The Guard bit and the Round bit (see Section 7.3.3.1, “VSX Execution Model for IEEE Operations” on page 527) participate in the shift with zeros shifted into the Round bit. The exponent is regarded as if its range were unlimited.

After normalization, or if normalization was not required, the intermediate result can have a nonzero significand and an exponent value that is less than the minimum value that can be represented in the format specified for the result. In this case, the intermediate result is said to be “Tiny” and the stored result is determined by the rules described in Section 7.4.4 ,

“Floating-Point Underflow Exception” on page 554. These rules can require denormalization.

A number is denormalized by shifting its significand right while incrementing its exponent by 1 for each bit shifted, until the exponent is equal to the format’s minimum value. If any significant bits are lost in this shifting process, “Loss of Accuracy” has occurred (See Section 7.4.4 , “Floating-Point Underflow Exception” on page 554) and Underflow exception is signaled.

#### Engineering Note

When denormalized numbers are operands of multiply, divide, and square root operations, some implementations might prenormalize the operands internally before performing the operations.

### 7.3.2.5 Data Handling and Precision

Scalar double-precision floating-point data is represented in double-precision format in VSRs and storage.

Vector double-precision floating-point data is represented in double-precision format in VSRs and storage.

Scalar single-precision floating-point data is represented in double-precision format in VSRs and in single-precision format in storage.

Vector single-precision floating-point data is represented in single-precision format in VSRs and storage.

Double-precision operands may be used as input for double-precision scalar arithmetic operations.

Double-precision operands may be used as input for single-precision scalar arithmetic operations when trapping on overflow and underflow exceptions is disabled.

Single-precision operands may be used as input for double-precision and single-precision scalar arithmetic operations.

Double-precision operands may be used as input for double-precision vector arithmetic operations.

Single-precision operands may be used as input for single-precision vector arithmetic operations.

Instructions are also provided for manipulations which do not require double-precision or single-precision. In addition, instructions are provided to access an integer representation in GPRs.

## Half-Precision Operands

Instructions are provided to convert between half-precision and single-precision formats for vector data in VSRs and between half-precision and double-precision formats for scalar data. Note that scalar double-precision format is identical to scalar single-precision format.

An instruction is provided to explicitly convert half-precision format operands in a VSR to single-precision format. Scalar single-precision floating-point is enabled with six types of instruction.

1. *VSX Scalar Convert Half-Precision to Double-Precision format XX2-form*

The half-precision floating-point value in the rightmost halfword in doubleword element 0 of the source VSR is placed into the doubleword element 0 of the target VSR in double-precision format.

2. *VSX Scalar Convert with round Double-Precision to Half-Precision format XX2-form*

The double-precision value in doubleword element 0 of the source VSR is rounded to half-precision, checking the exponent for half-precision range and handling any exceptions according to respective enable bits, and places the result into the rightmost halfword of doubleword element 0 of the target VSR in half-precision format.

Source operand values greater in magnitude than  $2^{39}$  when Overflow is enabled ( $OE=1$ ) produce undefined results because the value cannot be scaled into the half-precision normalized range.

Source operand values smaller in magnitude than  $2^{-38}$  when Underflow is enabled ( $UE=1$ ) produce undefined results because the value cannot be scaled into the half-precision normalized range.

3. *VSX Vector Convert Half-Precision to Single-Precision format XX2-form*

The half-precision floating-point value in the rightmost halfword of each word element of the source VSR is placed into the corresponding word element of the target VSR in single-precision format.

4. *VSX Vector Convert with round Single-Precision to Half-Precision format XX2-form*

The single-precision floating-point value in each word element  $i$  of the source VSR is rounded to half-precision and placed into the rightmost

halfword of the corresponding word element of the target VSR in half-precision format.

## bfloat16 Operands

Instructions are provided to convert between bfloat16 and single-precision formats for vector data in VSRs.

An instruction is provided to explicitly convert bfloat16 format operands in a VSR to single-precision format.

1. *VSX Vector Convert Half-Precision to Single-Precision format XX2-form*

The bfloat16 floating-point value in the rightmost halfword of each word element of the source VSR is placed into the corresponding word element of the target VSR in single-precision format.

2. *VSX Vector Convert with round Single-Precision to Half-Precision format XX2-form*

The single-precision floating-point value in each word element  $i$  of the source VSR is rounded to bfloat16 precision and placed into the rightmost halfword of the corresponding word element of the target VSR in bfloat16 format.

## Single-Precision Operands

For single-precision scalar data, a conversion from single-precision format to double-precision format is performed when loading from storage into a VSR and a conversion from double-precision format to single-precision format is performed when storing from a VSR to storage. No floating-point exceptions are caused by these instructions.

Instructions are provided to convert between single-precision and double-precision formats for scalar and vector data in VSRs.

An instruction is provided to explicitly convert a double format operand in a VSR to single-precision. Scalar single-precision floating-point is enabled with six types of instructions.

1. *Load VSX Scalar Single-Precision*

**[p]lxssp** and **lxssp** access a floating-point operand in single-precision format in storage, converts it to double-precision format, and loads it into a VSR. No floating-point exceptions are caused by these instructions.

2. *VSX Scalar Round to Single-Precision XX2-form*

**xsrsp** rounds a double-precision operand to single-precision, checking the exponent for single-precision range and handling any

exceptions according to respective enable bits, and places that operand into a VSR in double-precision format. For results produced by single-precision arithmetic instructions, single-precision loads, and other instances of **xsrsp**, **xsrsp** does not alter the value. Values greater in magnitude than  $2^{319}$  when Overflow is enabled (OE=1) produce undefined results because the value cannot be scaled back into the normalized range. Values smaller in magnitude than  $2^{-318}$  when Underflow is enabled (UE=1) produce undefined results because the value cannot be scaled back into the normalized range.

### 3. VSX Scalar Convert Single-Precision to Double-Precision format

*VSX Scalar Convert Single-Precision to Double-Precision format XX2-form (xscvspdp)* accesses a floating-point operand in single-precision format from word element 0 of the source VSR, converts it to double-precision format, and places it into doubleword element 0 of the target VSR.

*VSX Scalar Convert Single-Precision to Double-Precision format Non-signalling XX2-form (xscvspdpn)* accesses a floating-point operand in single-precision format from word element 0 of the source VSR, converts it to double-precision format, and places it into doubleword element 0 of the target VSR. **xscvspdpn** does not set any exception status (i.e., VXSNaN).

### 4. VSX Scalar Convert Double-Precision to Single-Precision format [ Non-Signalling ]

*VSX Scalar Convert with round Double-Precision to Single-Precision format XX2-form (xscvdp)* rounds the double-precision floating-point value in doubleword element 0 of the source VSR to single-precision, and places the result into word elements 0 and 1 of the target VSR in single-precision format. This function would be used to port scalar floating-point data to a format compatible for single-precision vector operations. Values greater in magnitude than  $2^{319}$  when Overflow is enabled (OE=1) produce undefined results because the value cannot be scaled back into the normalized range. Values smaller in magnitude than  $2^{-318}$  when Underflow is enabled (UE=1) produce undefined results because the value cannot be scaled back into the normalized range.

*VSX Scalar Convert Scalar Single-Precision to Vector Single-Precision format Non-signalling*

1. VSX Scalar Single-Precision Arithmetic instructions:  
**xsaddsp**, **xsdivsp**, **xsmulsp**, **xsresp**, **xssubsp**, **xsmaddasp**, **xsmaddmsp**, **xsmsubasp**, **xsmsubmsp**, **xsnmaddasp**, **xsnmaddmsp**, **xsnmsubasp**, **xsnmsubmsp**

*XX2-form (xscvdpn)* directly converts the single-precision floating-point value represented in double-precision format in doubleword element 0 of the source VSR to single-precision format, without rounding, and places the result into word elements 0 and 1 of the target VSR in single-precision format. **xscvdpn** does not set any exception status (i.e., VXSNaN).

### 5. VSX Scalar Single-Precision Arithmetic<sup>[1]</sup>

This form of instruction takes operands from the VSRs in double format, performs the operation as if it produced an intermediate result having infinite precision and unbounded exponent range, and then coerces this intermediate result to fit in single-precision format. Status bits, in the FPSCR and optionally in the Condition Register, are set to reflect the single-precision result. The result is then placed into the target VSR in double-precision format. The result lies in the range supported by the single format.

If any input value is not representable in single-precision format and either OE=1 or UE=1, the result placed into the target VSR and the setting of status bits in the FPSCR are undefined.

For **xsrsp** or **xsrqrtesp**, if the input value is finite and has an unbiased exponent greater than +127, the input value is interpreted as an Infinity.

### 6. Store VSX Scalar Single-Precision

*Store VSX Scalar Single-Precision DS-form (stxssp)*, *Prefixed Store VSX Scalar Single-Precision 8LS:D-form (pstxssp)*, and *Store VSX Scalar Single-Precision Indexed X-form (stxssp)* convert a single-precision value that is in double-precision format to single-precision format and stores that operand into storage. No floating-point exceptions are caused by these instructions. (The value being stored is effectively assumed to be the result of an instruction of one of the preceding five types.)

When the result of a *Load VSX Scalar Single-Precision (lxssp)*, a *VSX Scalar Round to Single-Precision (xsrsp)*, or a *VSX Scalar Single-Precision Arithmetic* instruction is stored in a VSR, the low-order 29 bits of FRACTI ON are zero.

**Programming Note**

*VSX Scalar Round to Single-Precision (xsrsp)* is provided to allow value conversion from double-precision to single-precision with appropriate exception checking and rounding. *xsrsp* should be used to convert double-precision floating-point values to single-precision values prior to storing them into single format storage elements or using them as operands for single-precision arithmetic instructions. Values produced by single-precision load and arithmetic instructions are already single-precision values and can be stored directly into single format storage elements, or used directly as operands for single-precision arithmetic instructions, without preceding the store, or the arithmetic instruction, by an *xsrsp*.

**Programming Note**

A single-precision value can be used in double-precision scalar arithmetic operations.

Except for *xsrsp* or *xsrqrtesp*, any double-precision value can be used in single-precision scalar arithmetic operations when OE=0 and UE=0. When OE=1 or UE=1, or if the instruction is *xsrsp* or *xsrqrtesp*, source operands must be representable in single-precision format.

Some implementations may execute single-precision arithmetic instructions faster than double-precision arithmetic instructions. Therefore, if double-precision accuracy is not required, single-precision data and instructions should be used.

**Programming Note**

Both single-precision and double-precision forms are provided for most scalar floating-point instructions. Some scalar floating-point instructions are only provided in double-precision form since their operation is identical to the equivalent scalar single-precision operation.

Of the operations for which only a double-precision form of the instruction is provided,

- instructions that return the absolute value, the negative absolute value, or the negated value (*xsnabsdp*, *xsabsdp*, *xsnegdp*) can be used to perform these operations on scalar single-precision operands,
- instructions that perform a comparison (*xscmpodp*, *xscmpudp*) can be used to perform these operations on scalar single-precision operands,
- instructions that determine the maximum (*xsmaxdp*) or minimum (*xsmindp*) can be used to perform these operations on scalar single-precision operands, and
- instructions that perform an extraction or insertion of the exponent or significand (*xscmpexpdp*, *xsiexpdp*, *xststdcsp*, *xststdcsp*, *xsxexpdp*, *xsxsigdp*) can be used to perform these operations on scalar single-precision operands.

**Integer-Valued Operands**

Instructions are provided to round floating-point operands to integer values in floating-point format. To facilitate exchange of data between the floating-point and integer processing, instructions are provided to convert between floating-point double and single-precision format and integer word and doubleword format in a VSR. Computation on integer-valued operands can be performed using arithmetic instructions of the required precision. (The results might not be integer values.) The three groups of instructions provided specifically to support integer-valued operands are described below.

## 1. Rounding to a floating-point integer

*VSX Scalar Round to Double-Precision Integer*<sup>[1]</sup> instructions round a double-precision operand to an integer value in double-precision format. These instructions can also be used for single-precision operands represented in double-precision format.

*VSX Vector Round to Double-Precision Integer*<sup>[1]</sup> instructions round each double-precision vector operand element to an integer value in double-precision format.

*VSX Vector Round to Single-Precision Integer*<sup>[2]</sup> instructions round each single-precision vector operand element to an integer value in single-precision format.

Except for *xsrpic*, *xvrpic*, and *xvrspic*, rounding is performed using the rounding mode specified by the opcode. For *xsrpic*, *xvrpic*, and *xvrspic*, rounding is performed using the rounding mode specified by RN.

*VSX Round to Floating-Point Integer*<sup>[3]</sup> instructions can cause Invalid Operation (VXSNAN) exceptions.

*xsrpic*, *xvrpic*, and *xvrspic* can also cause Inexact exception.

See Sections 7.3.2.6 and 7.3.3.1 for more information about rounding.

## 2. Converting floating-point format to integer format

*VSX Scalar Double-Precision to Integer Format Conversion*<sup>[4]</sup> instructions convert a double-precision operand to 32-bit or 64-bit signed or unsigned integer format. These instructions can also be used for single-precision operands represented in double-precision format.

*VSX Vector Double-Precision to Integer Format Conversion*<sup>[5]</sup> instructions convert either double-precision or single-precision vector operand elements to 32-bit or 64-bit signed or unsigned integer format.

*VSX Vector Single-Precision to Integer Doubleword Format Conversion*<sup>[6]</sup> instructions converts the single-precision value in each odd-numbered word element of the source vector operand to a 64-bit signed or unsigned integer format.

*VSX Vector Single-Precision to Integer Word Format Conversion*<sup>[7]</sup> instructions converts the single-precision value in each word element of the source vector operand to either a 32-bit signed or unsigned integer format.

Rounding is performed using Round Towards Zero rounding mode. These instructions can cause Invalid Operation (VXSNAN, VXCVI) and Inexact exceptions.

## 3. Converting integer format to floating-point format

*VSX Scalar Integer Doubleword to Double-Precision Format Conversion*<sup>[8]</sup> instructions convert a 64-bit signed or unsigned integer to a double-precision floating-point value and returns the result in double-precision format.

*VSX Scalar Integer Doubleword to Single-Precision Format Conversion*<sup>[9]</sup> instructions converts a 64-bit signed or unsigned integer to a single-precision floating-point value and returns the result in double-precision format.

*VSX Vector Integer Doubleword to Double-Precision Format Conversion*<sup>[10]</sup> instructions converts the 64-bit signed or unsigned integer in each doubleword element in the source vector operand to double-precision floating-point format.

*VSX Vector Integer Doubleword to Single-Precision Format Conversion*<sup>[11]</sup>

1. *VSX Scalar Round to Double-Precision Integer* instructions:

*xsrpic, xsrdpic, xsrdpim, xsrdpiz, xsrdpic*

1. *VSX Vector Round to Double-Precision Integer* instructions:

*xvrpic, xvrdpic, xvrdpim, xvrdpiz, xvrdpic*

2. *VSX Vector Round to Single-Precision Integer* instructions:

*xvrspi, xvrspic, xvrspim, xvrspic, xvrspic*

3. *VSX Round to Floating-Point Integer* instructions:

*xsrpic, xsrdpic, xsrdpim, xsrdpiz, xsrdpic, xvrdpic, xvrdpim, xvrdpiz, xvrdpic, xvrspic, xvrspic, xvrspim, xvrspic, and xvrspic*

4. *VSX Scalar Double-Precision to Integer Format Conversion* instructions:

*xscvdpixds, xscvdpixws, xscvdpixds, xscvdpixws*

5. *VSX Vector Double-Precision to Integer Format Conversion* instructions:

*xvcvdpixds, xvcvdpixws, xvcvdpixds, xvcvdpixws*

6. *VSX Vector Single-Precision to Integer Doubleword Format Conversion* instructions:

*xvcvpsixds, xvcvpsixds*

7. *VSX Vector Single-Precision to Integer Word Format Conversion* instructions:

*xvcvpsixws, xvcvpsixws*

8. *VSX Scalar Integer Doubleword to Double-Precision Format Conversion* instructions:

*xscvixddp, xscvixddp*

9. *VSX Scalar Integer Doubleword to Single-Precision Format Conversion* instructions:

*xscvixdsp, xscvixdsp*

10. *VSX Vector Integer Doubleword to Double-Precision Format Conversion* instructions:

*xscvixddp, xscvixddp*

11. *VSX Vector Integer Doubleword to Single-Precision Format Conversion* instructions:

*xscvixdsp, xscvixdsp*

instructions convert the 64-bit signed or unsigned integer in each doubleword element in the source vector operand to single-precision floating-point format.

*VSX Vector Integer Word to Single-Precision Format Conversion*<sup>1</sup> instructions convert the 32-bit signed or unsigned integer in each word element in the source vector operand to single-precision floating-point format.

Rounding is performed using the rounding mode specified in RN. Because of the limitations of the source format, only an Inexact exception can be generated.

### 7.3.2.6 Rounding

The material in this section applies to operations that have numeric operands (that is, operands that are not infinities or NaNs). Rounding the intermediate result of such an operation can cause an Overflow exception, an Underflow exception, or an Inexact exception. The remainder of this section assumes that the operation causes no exceptions and that the result is numeric. See Section 7.3.2.2, “Value Representation” and Section 7.4, “VSX Floating-Point Exceptions” for the cases not covered here.

The floating-point arithmetic, and rounding and conversion instructions round their intermediate results. With the exception of the estimate instructions, these instructions produce an intermediate result that can be regarded as having unbounded precision and exponent range. All but two groups of these instructions normalize or denormalize the intermediate result prior to rounding and then place the final result into the target element of the target VSR in half-precision, bfloat16, single-precision, double-precision, or quad-precision format.

The scalar round to double-precision integer, vector round to double-precision integer, and convert double-precision to integer instructions with biased exponents ranging from 1022 through 1074 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 1075. (Intermediate results with biased exponents 1075 or larger are already integers, and with biased exponents 1021 or less round to zero.) After rounding, the final result for round to double-precision integer instructions is normalized and put in double-precision format, and, for the convert double-precision to integer instructions, is converted to a signed or unsigned integer.

The vector round to single-precision integer and vector convert single-precision to integer instructions with biased exponents ranging from 126 through 178 are prepared for rounding by repetitively shifting the significand right one position and incrementing the biased exponent until it reaches a value of 179. (Intermediate results with biased exponents 179 or larger are already integers, and with biased exponents 125 or less round to zero.) After rounding, the final result for vector round to single-precision integer is normalized and put in double-precision format, and for vector convert single-precision to integer is converted to a signed or unsigned integer.

FR and FI generally indicate the results of rounding. Each of the scalar instructions which rounds its intermediate result sets these bits. There are no vector instructions that modify FR and FI. If the fraction is incremented during rounding, FR is set to 1, otherwise FR is set to 0. If the result is inexact, FI is set to 1, otherwise FI is set to zero. The scalar round to double-precision integer instructions are exceptions to this rule, setting FR and FI to 0. The scalar double-precision estimate instructions set FR and FI to undefined values. The remaining scalar floating-point instructions do not alter FR and FI.

Four user-selectable rounding modes are provided through the Floating-Point Rounding Control field in the FPSCR. See Section 7.2.2, “Floating-Point Status and Control Register” on page 509. These are encoded as follows.

RN	Rounding Mode
00	Round to Nearest Even
01	Round towards Zero
10	Round towards +Infinity
11	Round towards -Infinity

A fifth rounding mode is provided in the round to floating-point integer instructions (Section 7.6.1.8.2 on page 578), Round to Nearest Away.

A sixth rounding mode is provided in the quad-precision floating-point instructions, Round to Odd.

1. *VSX Vector Integer Word to Single-Precision Format Conversion* instructions: *xscvswsp*, *xscvuwsp*

**Programming Note**

Round to Odd rounding mode is useful when the results of a Quad-Precision Arithmetic instruction are required to be rounded to a shorter precision while avoiding a double rounding error. In this case, the rounding mode of the Quad-Precision Arithmetic instruction is overridden as Round To Odd by setting the R0 bit in the instruction encoding to 1, then the result of that Quad-Precision Arithmetic instruction can be rounded to the desired shorter precision using the rounding mode specified in RN by following with a VSX Scalar Round Quad-Precision to Double-Extended-Precision for 15-bit exponent range and 64-bit significand precision, VSX Scalar Round Quad-Precision to Double-Precision for 11-bit exponent range and 53-bit significand precision, or VSX Scalar Round Quad-Precision to Single-Precision for 8-bit exponent range and 24-bit significand precision. For example,

```
xsaddqpo Tx, A, B      ; use Round to Odd override (R0=1)
xsrqpxp  Tdxp, Tx     ; final QP result rounded to DXP
```

To return a quad-precision result rounded to double-precision requires a 3-instruction sequence,

```
xsaddqpo Tx, A, B      ; use Round to Odd override (R0=1)
xscvqdpd Temp, Tx     ; QP result rounded & converted to DP
xscvdpqp Tdp, Temp     ; final QP result rounded to DP
```

To return a quad-precision result rounded to single-precision requires a 4-instruction sequence,

```
xsaddqpo Tx, A, B      ; use Round to Odd override (R0=1)
xscvqdpd Temp, Tx     ; QP result rounded to DP using Round to Odd & converted to DP format
xsrsp    Temp, Temp    ; DP result is rounded to SP
xscvdpqp Tsp, Temp     ; final QP result rounded to SP
```

Let  $Z$  be the intermediate arithmetic result or the operand of a convert operation. If  $Z$  can be represented exactly in the target format, the result in all rounding modes is  $Z$  as represented in the target format. If  $Z$  cannot be represented exactly in the target format, let  $Z1$  and  $Z2$  bound  $Z$  as the next larger and next smaller numbers representable in the target format. Then  $Z1$  or  $Z2$  can be used to approximate the result in the target format.

Figure 115 shows the relation of  $Z$ ,  $Z1$ , and  $Z2$  in this case. The following rules specify the rounding in the four modes.

See Section 7.3.3.1, “VSX Execution Model for IEEE Operations” on page 527 for a detailed explanation of rounding.

Figure 115 also summarizes the rounding actions for floating-point intermediate result for all supported rounding modes.

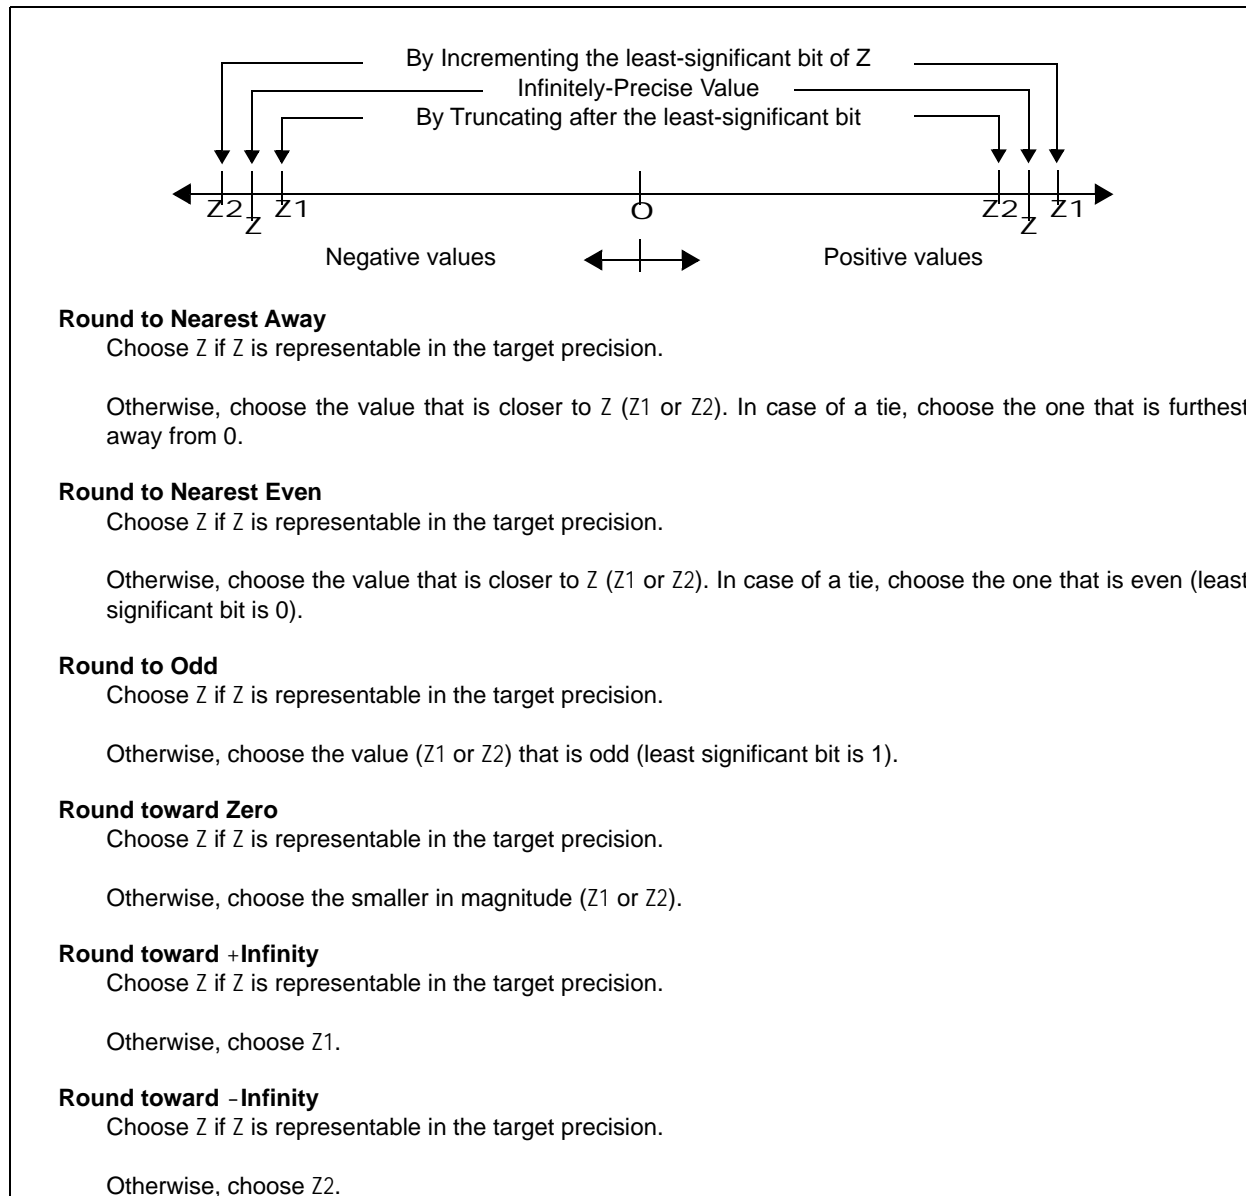

Figure 115. Selection of Z1 and Z2

### 7.3.3 VSX Floating-Point Execution Models

All implementations of this architecture must provide the equivalent of the following execution models to ensure that identical results are obtained.

Special rules are provided in the definition of the computational instructions for the infinities, denormalized numbers and NaNs. The material in the remainder of this section applies to instructions that have numeric operands and a numeric result (that is, operands and result that are not infinities or NaNs), and that cause no exceptions. See Section 7.3.2.2 and Section 7.3.3 for the cases not covered here.

Although the double-precision format specifies an 11-bit exponent, exponent arithmetic makes use of two additional bits to avoid potential transient overflow and underflow conditions. One extra bit is required when denormalized double-precision numbers are prenormalized. The second bit is required to permit the computation of the adjusted exponent value in the following cases when the corresponding exception enable bit is 1:

- Underflow during multiplication using a denormalized operand.
- Overflow during division using a denormalized divisor.
- Underflow during division using denormalized dividend and a large divisor.

The IEEE standard includes 32-bit and 64-bit arithmetic. The standard requires that single-precision arithmetic be provided for single-precision operands.

VSX defines both scalar and vector double-precision floating-point operations to operate only on double-precision operands. VSX also defines vector single-precision floating-point operations to operate only on single-precision operands.

#### 7.3.3.1 VSX Execution Model for IEEE Operations

IEEE-conforming significand arithmetic is considered to be performed with a floating-point accumulator having the following format, where bits 0: p-1 comprise the significand of the intermediate result (where p is the length of the significand).

**Figure 116. IEEE quad-precision (binary128) floating-point execution model (p=113)**

**Figure 117. IEEE double-extended-precision floating-point execution model (p=64)**

**Figure 118. IEEE double-precision (binary64) floating-point execution model (p=53)**

**Figure 119. IEEE single-precision (binary32) floating-point execution model (p=24)**

The S bit is the sign bit.

The C bit is the carry bit, which captures the carry out of the significand.

The L bit is the leading unit bit of the significand, which receives the implicit bit from the operand.

For the quad-precision execution model, FRACTION is a 112-bit field that accepts the fraction of the operand.

For the double-extended-precision execution model, FRACTION is a 63-bit field that accepts the fraction of the operand. This model is used only by the *VSX Scalar Round to Double-Extended-Precision* instruction.

For the double-precision execution model, FRACTION is a 52-bit field that accepts the fraction of the operand.

For the single-precision execution model, FRACTION is a 23-bit field that accepts the fraction of the operand.

The Guard (G), Round (R), and Sticky (X) bits are extensions to the low-order bits of the accumulator to provide the effect of an unbounded significand. The G and R bits are required for postnormalization of the result. The G, R, and X bits are required during rounding to determine if the intermediate result is equally near the two nearest representable values. The X bit serves as an extension to the G and R bits by representing the logical OR of all bits that appear to the low-order side of the R bit, resulting from either shifting the accumulator right or to other generation of low-order result bits. The G and R bits participate in the left shifts with zeros being shifted into the R bit. Table 4 shows the significance of the G, R, and X bits with respect to the intermediate result (IR), the representable number

next lower in magnitude (NL), and the representable number next higher in magnitude (NH).

G	R	X	Interpretation
0	0	0	IR is exact
0	0	1	IR closer to NL
0	1	0	
0	1	1	
1	0	0	IR midway between NL and NH
1	0	1	IR closer to NH
1	1	0	
1	1	1	

**Table 4. Interpretation of G, R, and X bits**

Table 5 shows the positions of the Guard, Round, and Sticky bits for quad-precision, double-extended precision, double-precision and single-precision floating-point numbers relative to the accumulator illustrated in Figures 116, 117, 118, and 119.

Format	Guard	Round	Sticky
Double	G bit	R bit	X bit
Single	24	25	OR of bits 26:52, G, R, X

**Table 5. Location of the Guard, Round, and Sticky bits in the IEEE execution model**

The significand of the intermediate result is prepared for rounding by shifting its contents right, if required, until the least significant bit to be retained is in the low-order bit position of the fraction.

Six rounding modes are provided as described in Section 7.3.2.6, “Rounding” on page 524. The rules for rounding in each mode are as follows.

- **Round to Nearest Even**  
If IR is exact, choose IR.  
Otherwise, if IR is closer to NL, choose NL.  
Otherwise, if IR is closer to NH, choose NH.  
Otherwise, if IR is midway between NL and NH, choose whichever of NL and NH is even.
- **Round towards Zero**  
If IR is exact, choose IR.  
Otherwise, choose NL.
- **Round towards +Infinity**  
If IR is exact, choose IR.  
Otherwise, if positive, choose NH.  
Otherwise, if negative, choose NL.

- **Round towards -Infinity**  
If IR is exact, choose IR.  
Otherwise, if positive, choose NL.  
Otherwise, if negative, choose NH.
- **Round to Nearest Away**  
If IR is exact, choose IR.  
Otherwise, if G=0, choose NL.  
Otherwise, if G=1, choose NH.
- **Round to Odd**  
If IR is exact, choose IR.  
Otherwise, choose NL, and if G=1, R=1, or X=1, the least-significant bit of the result is set to 1.

Four of the rounding modes are user-selectable through RN.

RN	Rounding Mode
0b00	Round to Nearest Even
0b01	Round toward Zero
0b10	Round toward +Infinity
0b11	Round toward -Infinity

Round to Nearest Away is provided in the *VSX Round to Floating-Point Integer* instructions (Section 7.6.1.8.2 on page 578).

Round to Odd is provided in the *VSX Quad-Precision Floating-Point Arithmetic* instructions as an override to the rounding mode selected by RN with the rules for rounding as follows.

If G=1, R=1, or X=1, the result is inexact.

If rounding results in a carry into C, the significand is shifted right one position and the exponent is incremented by one. This yields an inexact result, and possibly also exponent overflow. Fraction bits are stored to the target VSR.

### 7.3.3.2 VSX Execution Model for Multiply-Add Type Instructions

This architecture provides a special form of instruction that performs up to three operations in one instruction (a multiplication, an addition, and a negation). With this added capability comes the special ability to produce a more exact intermediate result as input to the rounder. 32-bit arithmetic is similar, except that the FRACTION field is smaller.

Multiply-add significand arithmetic is considered to be performed with a floating-point accumulator having the

following format, where bits 0:106 comprise the significand of the intermediate result.

**Figure 120. Multiply-add 64-bit execution model**

The first part of the operation is a multiplication. The multiplication has two 53-bit significands as inputs, which are assumed to be prenormalized, and produces a result conforming to the above model. If there is a carry out of the significand (into the C bit), the significand is shifted right one position, shifting the L bit (leading unit bit) into the most significant bit of the FRACTION and shifting the C bit (carry out) into the L bit. All 106 bits (L bit, the FRACTION) of the product take part in the add operation. If the exponents of the two inputs to the adder are not equal, the significand of the operand with the smaller exponent is aligned (shifted) to the right by an amount that is added to that exponent to make it equal to the other input's exponent. Zeros are shifted into the left of the significand as it is aligned and bits shifted out of bit 105 of the significand are ORed into the X' bit. The add operation also produces a result conforming to the above model with the X' bit taking part in the add operation.

The result of the addition is then normalized, with all bits of the addition result, except the X' bit, participating in the shift. The normalized result serves as the intermediate result that is input to the rounder.

For rounding, the conceptual Guard, Round, and Sticky bits are defined in terms of accumulator bits. Figure 6 shows the positions of the Guard, Round, and Sticky bits for double-precision and single-precision floating-point numbers in the multiply-add execution model.

Format	Guard	Round	Sticky
Double	53	54	OR of 55:105, X'
Single	24	25	OR of 26:105, X'

**Table 6. Location of the Guard, Round, and Sticky bits in the multiply-add execution model**

The rules for rounding the intermediate result are the same as those given in Section 7.3.3.1.

If the instruction is a negative multiply-add or negative multiply-subtract type instruction, the final result is negated.

## 7.4 VSX Floating-Point Exceptions

This architecture defines the following floating-point exceptions under the IEEE-754 exception model:

- Invalid Operation exception

- SNaN
- Infinity-Infinity
- Infinity÷Infinity
- Zero÷Zero
- Infinity×Zero
- Invalid Compare
- Software-Defined Condition
- Invalid Square Root
- Invalid Integer Convert

- Zero Divide exception
- Overflow exception
- Underflow exception
- Inexact exception

These exceptions, other than Invalid Operation exception resulting from a Software-Defined Condition, can occur during execution of computational instructions. An Invalid Operation exception resulting from a Software-Defined Condition occurs when a *Move To FPSCR* instruction sets VXSOF to 1.

Each floating-point exception, and each category of Invalid Operation exception, has an exception bit in the FPSCR. In addition, each floating-point exception has a corresponding enable bit in the FPSCR. The exception bit indicates the occurrence of the corresponding exception. Instructions that modify Accumulators produce results as if all exceptions are disabled. For other VSX instructions, if an exception occurs, the corresponding enable bit governs the result produced by the instruction. For all VSX instructions in which an exception occurs, the corresponding enable bit in conjunction with the FE0 and FE1 bits (see page 532) governs whether and how the system floating-point enabled exception error handler is invoked. In general, the enabling specified by the enable bit is of invoking the system error handler, not of permitting the exception to occur. The occurrence of an exception depends only on the instruction and its inputs, not on the setting of any control bits. The only deviation from this general rule is that the occurrence

of an Underflow exception depends on the setting of the enable bit.

A single instruction, other than *mtfsfi* or *mtfsf*, can set more than one exception bit only in the following cases:

- An Inexact exception can be set with an Overflow exception.
- An Inexact exception can be set with an Underflow exception.
- An Invalid Operation exception (SNaN) is set with an Invalid Operation exception (Infinity×0) for multiply-add class instructions for which the values being multiplied are infinity and zero and the value being added is an SNaN.
- An Invalid Operation exception (SNaN) can be set with an Invalid Operation exception (Invalid Compare) for ordered comparison instructions.
- An Invalid Operation exception (SNaN) can be set with an Invalid Operation exception (Invalid Integer Convert) for convert to integer instructions.

When an exception occurs, the writing of a result to the target register can be suppressed, or a result can be delivered, depending on the exception and type of instruction.

Instructions that modify Accumulators always write the target register. For other VSX instructions, the writing of a result to the target register is suppressed for certain kinds of exceptions, based on whether the instruction is a vector or a scalar instruction, so that there is no possibility that one of the operands is lost. For other kinds of exceptions from the VSX instructions that don't modify Accumulators and also depending on whether the instruction is a vector or a scalar instruction, a result is generated and written to the destination specified by the instruction causing the exception. The result can be a different value for the enabled and disabled conditions for some of these exceptions (for instructions other than those which update Accumulators). Table 7 lists the types of exceptions and indicates whether a result is written to the target VSR or suppressed.

On exception type...	Scalar Instruction Results	Vector Instruction Non-Accumulator Results	Vector Instruction Accumulator Results
Enabled Invalid Operation	suppressed	suppressed	written

**Table 7. Exception Types Result Suppression**

On exception type...	Scalar Instruction Results	Vector Instruction Non-Accumulator Results	Vector Instruction Accumulator Results
Enabled Zero Divide	suppressed	suppressed	written
Enabled Overflow	written	suppressed	written
Enabled Underflow	written	suppressed	written
Enabled Inexact	written	suppressed	written
Disabled Invalid Operation	written	written	written
Disabled Zero Divide	written	written	written
Disabled Overflow	written	written	written
Disabled Underflow	written	written	written
Disabled Inexact	written	written	written

**Table 7. Exception Types Result Suppression**

The subsequent sections define each of the floating-point exceptions and specify the action that is taken when they are detected.

The IEEE standard specifies the handling of exceptional conditions in terms of *traps* and *trap handlers*. In this architecture, instructions that modify Accumulators always generate the default result value with the expectation that if the exception is enabled, software will emulate the instruction with scalar instructions to get the desired result. For instructions that do not modify Accumulators, an FPSCR exception enable bit of 1 causes generation of the result value specified in the IEEE standard for the trap enabled case with the expectation that software will revise the result. For instructions that do not modify Accumulators, an FPSCR exception enable bit of 0 causes generation of the default result value specified for the trap disabled (or no trap occurs or trap is not implemented) case, with the expectation that the exception is not detected by software and the default result will be used. The result to be delivered in each case for each exception is described in the following sections.

The IEEE default behavior when an exception occurs is to generate a default value and not to notify software. In this architecture, if the IEEE default behavior when an exception occurs is required for all exceptions, all FPSCR exception enable bits must be set to 0, and Ignore Exceptions Mode (see below) should be used. In this case, the system floating-point enabled exception error handler is not invoked, even if floating-point exceptions occur: software can inspect the FPSCR exception bits, if necessary, to determine whether exceptions have occurred.

In this architecture, if software is to be notified that a given kind of exception has occurred, the corresponding FPSCR exception enable bit must be

set to 1, and a mode other than Ignore Exceptions Mode must be used. In this case, the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The system floating-point enabled exception error handler is also invoked if a *Move To FPSCR* instruction causes an exception bit and the corresponding enable bit both to be 1. The *Move To FPSCR* instruction is considered to cause the enabled exception.

The FE0 and FE1 bits control whether and how the system floating-point enabled exception error handler is invoked if an enabled floating-point exception occurs. The location of these bits and the requirements for altering them are described in Book III. The system floating-point enabled exception error handler is never invoked because of a disabled floating-point exception. The effects of the four possible settings of these bits are as follows.

#### FE0 FE1 Description

0	0	<b>Ignore Exceptions Mode</b> Floating-point exceptions do not cause the system floating-point enabled exception error handler to be invoked.
0	1	<b>Imprecise Nonrecoverable Mode</b> The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. It may not be possible to identify the excepting instruction or the data that caused the exception. Results produced by the excepting instruction might have been used by or might have affected subsequent instructions that are executed before the error handler is invoked.

**FE0 FE1 Description**

- 1 0 **Imprecise Recoverable Mode**  
The system floating-point enabled exception error handler is invoked at some point at or beyond the instruction that caused the enabled exception. Sufficient information is provided to the error handler for it to identify the excepting instruction, the operands, and correct the result. No results produced by the excepting instruction have been used by or affected subsequent instructions that are executed before the error handler is invoked.
- 1 1 **Precise Mode**  
The system floating-point enabled exception error handler is invoked precisely at the instruction that caused the enabled exception.

For all floating-point instructions except those that specify an Accumulator as the target, the question of whether a floating-point result is stored, and what value is stored, is governed by the FPSCR exception enable bits, as described in the subsections of this section. For floating-point instructions that specify an Accumulator as the target, floating-point results are computed as if all FPSCR exception enable bits are set to zero, and are always stored in the target Accumulator, regardless of the contents of the FPSCR exception enable bits. In all cases, the question of whether a floating-point result is stored, and what value is stored, is not affected by the value of the FE0 and FE1 bits.

The subsections of this section do not explicitly cover the floating-point instructions that specify an Accumulator as the target. For those instructions, the subsections are to be interpreted as applying independently to the computation of the result for each element of the target Accumulator assuming the corresponding enable bit is zero, where the meaning of “element” is implied by the name of the instruction..

In all cases in which the system floating-point enabled exception error handler is invoked, all instructions before the instruction at which the system floating-point enabled exception error handler is invoked have been completed, and no instruction after the instruction at which the system floating-point enabled exception error handler is invoked has begun execution. The instruction at which the system floating-point enabled exception error handler is invoked has completed if it is the excepting instruction, and there is only one such instruction. Otherwise, it has not begun execution, or has been partially executed in some cases, as described in Book III.

**Programming Note**

In any of the three non-Precise modes, a *Floating-Point Status and Control Register* instruction can be used to force any exceptions, because of instructions initiated before the *Floating-Point Status and Control Register* instruction, to be recorded in the FPSCR. (This forcing is superfluous for Precise Mode.)

In both Imprecise modes, a *Floating-Point Status and Control Register* instruction can be used to force any invocations of the system floating-point enabled exception error handler that result from instructions initiated before the *Floating-Point Status and Control Register* instruction to occur. This forcing has no effect in Ignore Exceptions Mode, and is superfluous for Precise Mode.

The last sentence of the paragraph preceding this Programming Note can apply only in the Imprecise modes, or if the mode has just been changed from Ignore Exceptions Mode to some other mode. It always applies in the latter case.

To obtain the best performance across the widest range of implementations, the programmer should obey the following guidelines.

- If the IEEE default results are acceptable to the application, Ignore Exceptions Mode should be used with all FPSCR exception enable bits set to 0.
- If the IEEE default results are not acceptable to the application, Imprecise Nonrecoverable Mode should be used, or Imprecise Recoverable Mode if recoverability is needed, with FPSCR exception enable bits set to 1 for those exceptions for which the system floating-point enabled exception error handler is to be invoked.
- Ignore Exceptions Mode should not, in general, be used when any FPSCR exception enable bits are set to 1.
- Precise Mode can degrade performance in some implementations, perhaps substantially, and therefore should be used only for debugging and other specialized applications.

## 7.4.1 Floating-Point Invalid Operation Exception

### 7.4.1.1 Definition

An Invalid Operation exception occurs when an operand is invalid for the specified operation. The invalid operations are:

#### SNaN

Any floating-point operation on a Signaling NaN.

#### Infinity–Infinity

Magnitude subtraction of infinities.

#### Infinity÷Infinity

Floating-point division of infinity by infinity.

#### Zero÷Zero

Floating-point division of zero by zero.

#### Infinity × Zero

Floating-point multiplication of infinity by zero.

#### Invalid Compare

Floating-point ordered comparison involving a NaN.

#### Invalid Square Root

Floating-point square root or reciprocal square root of a nonzero negative number.

#### Invalid Integer Convert

Floating-point-to-integer convert involving a number too large in magnitude to be represented in the target format, or involving an infinity or a NaN.

An Invalid Operation exception also occurs when an *mtfsfi*, *mtfsf*, or *mtfsb1* instruction is executed that sets VXSOF to 1 (Software-Defined Condition).

The action to be taken depends on the setting of the Invalid Operation Exception Enable bit of the FPSCR.

### 7.4.1.2 Action for VE=1

When Invalid Operation exception is enabled (VE=1) and an Invalid Operation exception occurs, the following actions are taken:

For any of the following instructions,

*VSX Scalar Floating-Point Arithmetic* instructions  
*VSX Scalar DP-SP Conversion* instructions  
*VSX Scalar Convert Floating-Point to Integer* instructions  
*VSX Scalar Round to Floating-Point Integer* instructions

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXISI	(if Infinity–Infinity)
VXIDI	(if Infinity÷Infinity)
VXZDZ	(if Zero÷Zero)
VXIMZ	(if Infinity×Zero)
VXSQRT	(if Invalid Square Root)
VXCVI	(if Invalid Integer Convert)

2. Update of VSR[XT] is suppressed.
3. FR and FI are set to zero.
4. FPRF is unchanged.

For *VSX Scalar Floating-Point Compare* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXVC	(if Invalid Compare)

2. FR, FI, and C are unchanged.
3. FPCC is set to reflect unordered.

For any of the following instructions,

*VSX Scalar Quad-Precision Arithmetic* instructions:

***x saddqp[o]***, ***x sdivqp[o]***, ***x smulqp[o]***, ***x ssqrtqp[o]***, ***x ssubqp[o]***  
***x smaddqp[o]***, ***x smsubqp[o]***, ***x snmaddqp[o]***, ***x snmsubqp[o]***

*VSX Scalar Quad-Precision Convert to Integer* instructions:

***x scvqpsdz***, ***x scvqpswz***, ***x scvqpudz***, ***x scvqpuwz***

*VSX Scalar Round Quad-Precision to Double-Extended-Precision* (***x srqpxp***)

*VSX Scalar Round to Quad-Precision Integer* (***x srqpi***)

*VSX Scalar Round to Quad-Precision Integer with Inexact* (***x srqpix***)

*VSX Scalar Convert with round Quad-Precision to Double-Precision format [using round to Odd]*  
(***x scvqpdpo***)

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXI SI	(if Infinity - Infinity)
VXI DI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXI MZ	(if Infinity × Zero)
VXSQRT	(if Invalid Square Root)
VXCVI	(if Invalid Integer Convert)

2. VSR[VRT+32] is not modified.
3. FR and FI are set to zero. FPRF is not modified.

For any of the following instructions,

*VSX Scalar Compare Ordered Quad-Precision* (***x scmpoqp***)

*VSX Scalar Compare Unordered Quad-Precision* (***x scmpuqp***)

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXVC	(if Invalid Compare)

2. FR, FI, and C are not modified. FPCC is set to reflect unordered.

For any of the following instructions,

*VSX Scalar Convert Half-Precision to Double-Precision format (xscvhpdp)*  
*VSX Scalar Convert with round Double-Precision to Half-Precision format (xscvdphp)*

do the following.

1. VXSNaN is set to 1.
2. VSR[XT] is not modified.
3. FR and FI are set to 0. FPRF is not modified.

For any of the following instructions,

*VSX Vector Convert Half-Precision to Single-Precision format (xvcvhpsp)*  
*VSX Vector Convert with round Single-Precision to Half-Precision format (xvcvsphp)*  
*VSX Vector Convert with round Single-Precision to bfloat16 format (xvcvsbf16)*

do the following.

1. VXSNaN is set to 1.
2. VSR[XT] is not modified.
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Floating-Point Arithmetic instructions:*  
*VSX Vector Floating-Point Compare instructions:*  
*VSX Vector DP-SP Conversion instructions:*  
*VSX Vector Convert Floating-Point to Integer instructions:*  
*VSX Vector Round to Floating-Point Integer instructions:*

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.
 

VXSNaN	(if SNaN)
VXI SI	(if Infinity – Infinity)
VXI DI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXI MZ	(if Infinity × Zero)
VXVC	(if Invalid Compare)
VXSQRT	(if Invalid Square Root)
VXCVI	(if Invalid Integer Convert)
2. Update of VSR[XT] is suppressed for all vector elements.
3. FR and FI are unchanged.
4. FPRF is unchanged.

### 7.4.1.3 Action for VE=0

When Invalid Operation exception is disabled (VE=0) and an Invalid Operation exception occurs, the following actions are taken:

For the *VSX Scalar Convert with round Double-Precision to Single-Precision format* (**xscvdpsp**) instruction:

1. VXSNaN is set to 1.
2. The single-precision representation of a Quiet NaN is placed into word elements 0 and 1 of VSR[XT]. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class of the result (Quiet NaN).

For the *VSX Vector Single-Precision Arithmetic* instructions, *VSX Vector Single-Precision Maximum/Minimum* instructions, the *VSX Vector Convert with round Double-Precision to Single-Precision format* (**xvcvdpsp**) instruction, and the *VSX Vector Round to Single-Precision Integer* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
 

VXSNaN	(if SNaN)
VXI SI	(if Infinity – Infinity)
VXI DI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXI MZ	(if Infinity × Zero)
VXSQRT	(if Invalid Square Root)
2. The single-precision representation of a Quiet NaN is placed into its respective word element of VSR[XT], and for **xvcvdpsp**, is also placed into bits 32:63 of its respective doubleword element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For the *VSX Scalar Double-Precision Arithmetic* instructions, *VSX Scalar Double-Precision Maximum/Minimum* instructions, the *VSX Scalar Convert Single-Precision to Double-Precision format* (**xscvspdp**) instruction, and the *VSX Scalar Round to Double-Precision Integer* instructions:

1. One or two of the following Invalid Operation exceptions are set to 1.
 

VXSNaN	(if SNaN)
VXI SI	(if Infinity – Infinity)
VXI DI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXI MZ	(if Infinity × Zero)
VXSQRT	(if Invalid Square Root)
2. The double-precision representation of a Quiet NaN is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FR and FI are set to 0.
4. FPRF is set to indicate the class of the result (Quiet NaN).

For any of the following instructions,

*VSX Scalar Quad-Precision Arithmetic instructions:*

***x saddqp[o]***, ***x sdivqp[o]***, ***x smulqp[o]***, ***x ssqrtqp[o]***, ***x ssubqp[o]***  
***x smaddqp[o]***, ***x smsubqp[o]***, ***x smaddqp[o]***, ***x snmsubqp[o]***

*VSX Scalar Quad-Precision Round to Integer (xsrqpi)*

*VSX Scalar Quad-Precision Round to Integer with Inexact (xsrqpix)*

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXI SI	(if Infinity - Infinity)
VXI DI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXI MZ	(if Infinity × Zero)
VXSQRT	(if Invalid Square Root)

2. The quad-precision representation of a Quiet NaN is placed into VSR[VRT+32].
3. FR and FI are set to 0. FPRF is set to indicate the class of the result (Quiet NaN).

For *VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)*, do the following.

1. VXSNAN is set to 1.
2. The Quiet NaN is placed into VSR[VRT+32] in quad-precision format.
3. FR and FI are set to 0. FPRF is set to indicate the class of the result (Quiet NaN).

For any of the following instructions,

*VSX Scalar Compare Ordered Quad-Precision (xscmpoqp)*

*VSX Scalar Compare Unordered Quad-Precision (xscmpuqp)*

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXVC	(if Invalid Compare)

2. FR, FI and C are unchanged. FPCC is set to reflect unordered.

For *VSX Scalar Convert with round Quad-Precision to Double-Precision format [using round to Odd] (xscvqdp[o])*, do the following.

1. VXSNAN is set to 1.
2. The double-precision Quiet NaN result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.

0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is set to indicate the class of the result (Quiet NaN).

For *VSX Scalar Convert with round to zero Quad-Precision to Signed Doubleword format (xscvqpsdz)*, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
 VXCVI        (if Invalid Integer Convert)

2. 0x7FFF\_FFFF\_FFFF\_FFFF is placed into doubleword element 0 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a positive number or +Infinity.

0x8000\_0000\_0000\_0000 is placed into doubleword element 0 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a negative number, -Infinity, or NaN.

0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is undefined.

For *VSX Scalar Convert with round to zero Quad-Precision to Signed Word format (xscvqpswz)*, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
 VXCVI        (if Invalid Integer Convert)

2. 0x7FFF\_FFFF is placed into word element 1 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a positive number or +Infinity.

0x8000\_0000 is placed into word element 1 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a negative number, -Infinity, or NaN.

0x0000\_0000 is placed into word elements 0, 2, and 3 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is undefined.

For *VSX Scalar Convert with round to zero Quad-Precision to Unsigned Doubleword format (xscvqpudz)*, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
 VXCVI        (if Invalid Integer Convert)

2. 0xFFFF\_FFFF\_FFFF\_FFFF is placed into doubleword element 0 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a positive number or +Infinity.

0x0000\_0000\_0000\_0000 is placed into doubleword element 0 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a negative number, -Infinity, or NaN.

0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is undefined.

For *VSX Scalar Convert with round to zero Quad-Precision to Unsigned Word format (xscvqpuwz)*, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXCVI	(if Invalid Integer Convert)

2. 0xFFFF\_FFFF is placed into word element 1 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a positive number or +Infinity.

0x0000\_0000 is placed into word element 1 of VSR[VRT+32] if the quad-precision operand in VSR[VRB+32] is a negative number, -Infinity, or NaN.

0x0000\_0000 is placed into word elements 0, 2, and 3 of VSR[VRT+32].

3. FR and FI are set to 0. FPRF is undefined.

For *VSX Scalar Convert with round Double-Precision to Half-Precision format (xscvdphp)*, do the following.

1. VXSNAN is set to 1.
2. The half-precision representation of a Quiet NaN is placed into the rightmost halfword of doubleword element 0 of VSR[XT]. The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0. The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FR and FI are set to 0. FPRF is set to indicate the class of the result (Quiet NaN).

For *VSX Scalar Convert Half-Precision to Double-Precision format (xscvhdpd)*, do the following.

1. VXSNAN is set to 1.
2. The double-precision representation of a Quiet NaN is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FR and FI are set to 0. FPRF is set to indicate the class of the result (Quiet NaN).

For any of the following instructions,

*VSX Vector Double-Precision Arithmetic* instructions  
*VSX Vector Double-Precision Maximum/Minimum* instructions  
*VSX Vector Convert Single-Precision to Double-Precision format (xvcvspdp)*  
*VSX Vector Round to Double-Precision Integer* instructions

do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXI SI	(if Infinity – Infinity)
VXI DI	(if Infinity ÷ Infinity)
VXZDZ	(if Zero ÷ Zero)
VXI MZ	(if Infinity × Zero)
VXSQRT	(if Invalid Square Root)

2. The double-precision representation of a Quiet NaN is placed into its respective doubleword element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For the *VSX Scalar Convert with round to zero Double-Precision to Signed Doubleword format (xscvdpsxd)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
VXCVI        (if Invalid Integer Convert)

2. 0x7FFF\_FFFF\_FFFF\_FFFF is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

0x8000\_0000\_0000\_0000 is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of doubleword element 1 of VSR[XT] are set to 0.

3. FR and FI are set to 0.
4. FPRF is undefined.

For the *VSX Scalar Convert with round to zero Double-Precision to Unsigned Doubleword format (xscvdpuxd)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
VXCVI        (if Invalid Integer Convert)

2. 0xFFFF\_FFFF\_FFFF\_FFFF is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

0x0000\_0000\_0000\_0000 is placed into doubleword element 0 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of doubleword element 1 of VSR[XT] are set to 0.

3. FR and FI are set to 0.
4. FPRF is undefined.

For the *VSX Scalar Convert with round to zero Double-Precision to Signed Word format (xscvdpswx)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
VXCVI        (if Invalid Integer Convert)

2. 0x7FFF\_FFFF is placed into word elements 0 and 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

0x8000\_0000 is placed into word elements 0 and 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of word elements 2 and 3 of VSR[XT] are set to 0.

3. FR and FI are set to 0.
4. FPRF is undefined.

For the *VSX Scalar Convert with round to zero Double-Precision to Unsigned Word format (xscvdpuxw)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)  
VXCVI (if Invalid Integer Convert)

2. 0xFFFF\_FFFF is placed into word elements 0 and 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a positive number or +Infinity.

0x0000\_0000 is placed into word elements 0 and 1 of VSR[XT] if the double-precision operand in doubleword element 0 of VSR[XB] is a negative number, -Infinity, or NaN.

The contents of word elements 2 and 3 of VSR[XT] are set to 0.

3. FR and FI are set to 0.
4. FPRF is undefined.

For the *VSX Vector Convert with round to zero Double-Precision to Signed Doubleword format (xvcvdpsxd)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)  
VXCVI (if Invalid Integer Convert)

2. 0x7FFF\_FFFF\_FFFF\_FFFF is placed into doubleword element *i* of VSR[XT] if the double-precision operand in the corresponding doubleword element of VSR[XB] is a positive number or +Infinity.

0x8000\_0000\_0000\_0000 is placed into its respective doubleword element *i* of VSR[XT] if the double-precision operand in the corresponding doubleword element of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert with round to zero Double-Precision to Unsigned Doubleword format (xvcvdpuxd)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)  
VXCVI (if Invalid Integer Convert)

2. 0xFFFF\_FFFF\_FFFF\_FFFF is placed into doubleword element *i* of VSR[XT] if the double-precision operand in doubleword element *i* of VSR[XB] is a positive number or +Infinity.

0x0000\_0000\_0000\_0000 is placed into doubleword element *i* of VSR[XT] if the double-precision operand in doubleword element *i* of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert with round to zero Double-Precision to Signed Word format (xvcvdpsxw)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
 VXCVI        (if Invalid Integer Convert)

2. 0x7FFF\_FFFF is placed into word elements  $i \times 2$  and  $i \times 2 + 1$  of VSR[XT] if the double-precision operand in doubleword element  $i$  of VSR[XB] is a positive number or +Infinity.

0x8000\_0000 is placed into word elements  $i \times 2$  and  $i \times 2 + 1$  of VSR[XT] if the double-precision operand in doubleword element  $i$  of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert with round to zero Double-Precision to Unsigned Word format (xvcvdpuxw)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
 VXCVI        (if Invalid Integer Convert)

2. 0xFFFF\_FFFF is placed into word elements  $i \times 2$  and  $i \times 2 + 1$  of VSR[XT] if the double-precision operand in doubleword element  $i$  of VSR[XB] is a positive number or +Infinity.

0x0000\_0000 is placed into word elements  $i \times 2$  and  $i \times 2 + 1$  of VSR[XT] if the double-precision operand in doubleword element  $i$  of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert with round to zero Single-Precision to Signed Doubleword format (xvcvpspxd)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN      (if SNaN)  
 VXCVI        (if Invalid Integer Convert)

2. 0x7FFF\_FFFF\_FFFF\_FFFF is placed into doubleword element  $i$  of VSR[XT] if the single-precision operand in word element  $i \times 2$  of VSR[XB] is a positive number or +Infinity.

0x8000\_0000\_0000\_0000 is placed into doubleword element  $i$  of VSR[XT] if the single-precision operand in word element  $i \times 2$  of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert with round to zero Single-Precision to Unsigned Doubleword format (xvcvspuxd)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)  
VXCVI (if Invalid Integer Convert)

2. 0xFFFF\_FFFF\_FFFF\_FFFF is placed into doubleword element  $i$  of VSR[XT] if the single-precision operand in word element  $i \times 2$  of VSR[XB] is a positive number or +Infinity.

0x0000\_0000\_0000\_0000 is placed into doubleword element  $i$  of VSR[XT] if the single-precision operand in word element  $i \times 2$  of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert with round to zero Single-Precision to Signed Word format (xvcvpsxw)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)  
VXCVI (if Invalid Integer Convert)

2. 0x7FFF\_FFFF is placed into word element  $i$  of VSR[XT] if the single-precision operand in word element  $i$  of VSR[XB] is a positive number or +Infinity.

0x8000\_0000 is placed into word element  $i$  of VSR[XT] if the single-precision operand in word element  $i$  of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Vector Convert with round to zero Single-Precision to Unsigned Word format (xvcvspuxw)* instruction, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)  
VXCVI (if Invalid Integer Convert)

2. 0xFFFF\_FFFF is placed into word element  $i$  of VSR[XT] if the single-precision operand in the corresponding word element  $2 \times i$  of VSR[XB] is a positive number or +Infinity.

0x0000\_0000 is placed into word element  $i$  of VSR[XT] if the single-precision operand in word element  $2 \times i$  of VSR[XB] is a negative number, -Infinity, or NaN.

3. FR, FI, and FPRF are not modified.

For the *VSX Scalar Floating-Point Compare* instructions, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN (if SNaN)  
VXCVI (if Invalid Integer Convert)

2. FR, FI and C are unchanged.

3. FPCC is set to reflect unordered.

For the *VSX Vector Compare Single-Precision* instructions, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXCVI	(if Invalid Integer Convert)

2. 0x0000\_0000 is placed into its respective word element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For the *Vector Double-Precision Compare* instructions, do the following.

1. One or two of the following Invalid Operation exceptions are set to 1.

VXSNAN	(if SNaN)
VXCVI	(if Invalid Integer Convert)

2. 0x0000\_0000\_0000\_0000 is placed into its respective doubleword element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Convert with round Single-Precision to Half-Precision format (xvcvsphp)*  
*VSX Vector Convert with round Single-Precision to bfloat16 format (xvcvsxbf16)*

do the following.

1. VXSNAN is set to 1.
2. The half-precision representation of a Quiet NaN is placed into the rightmost halfword of its respective word element of VSR[XT]. The contents of the leftmost halfword of its respective word element of VSR[XT] are set to 0.
3. FR, FI, and FPRF are not modified.

For *VSX Vector Convert Half-Precision to Single-Precision format (xvcvhpsp)*, do the following.

1. VXSNAN is set to 1.
2. The half-precision representation of a Quiet NaN is placed into the respective word element of VSR[XT].
3. FR, FI, and FPRF are not modified.

## 7.4.2 Floating-Point Zero Divide Exception

### 7.4.2.1 Definition

A Zero Divide exception occurs when a *VSX Floating-Point Divide* instruction is executed with a zero divisor value and a finite nonzero dividend value.

A Zero Divide exception also occurs when a *VSX Floating-Point Reciprocal Estimate* instruction or a *VSX Floating-Point Reciprocal Square Root Estimate* instruction is executed with an operand value of zero.

The action to be taken depends on the setting of the Zero Divide Exception Enable bit of the FPSCR.

### 7.4.2.2 Action for ZE=1

When Zero Divide exception is enabled (ZE=1) and a Zero Divide exception occurs, the following actions are taken:

For any of the following instructions,

*VSX Scalar Divide Double-Precision* (***xdivdp***)  
*VSX Scalar Divide Single-Precision* (***xdivsp***)  
*VSX Scalar Divide Quad-Precision* (***xdivqp***)

*VSX Scalar Reciprocal Estimate Double-Precision* (***xredp***)  
*VSX Scalar Reciprocal Estimate Single-Precision* (***xresp***)

*VSX Scalar Reciprocal Square Root Estimate Double-Precision* (***xrsqrtdp***)  
*VSX Scalar Reciprocal Square Root Estimate Single-Precision* (***xrsqrtesp***)

do the following.

1. ZX is set to 1.
2. VSR[XT] is not modified.
3. FR and FI are set to 0. FPRF is unchanged.

For any of the following instructions,

*VSX Vector Divide Double-Precision* (***xvdivdp***)  
*VSX Vector Divide Single-Precision* (***xvdivsp***)

*VSX Vector Reciprocal Estimate Double-Precision* (***xvredp***)  
*VSX Vector Reciprocal Estimate Single-Precision* (***xvresp***)

*VSX Vector Reciprocal Square Root Estimate Double-Precision* (***xvrsqrtdp***)  
*VSX Vector Reciprocal Square Root Estimate Single-Precision* (***xvrsqrtesp***)

do the following.

1. ZX is set to 1.
2. VSR[XT] is not modified.
3. FR and FI are unchanged. FPRF is unchanged.

### 7.4.2.3 Action for ZE=0

When Zero Divide exception is disabled (ZE=0) and a Zero Divide exception occurs, the following actions are taken:

For any of the following instructions,

*VSX Scalar Divide Double-Precision (xsdivdp)*

*VSX Scalar Divide Single-Precision (xsdivsp)*

do the following.

1. ZX is set to 1.
2. An Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FR and FI are set to 0. FPRF is set to indicate the class and sign of the result ( $\pm$  Infinity).

For *VSX Scalar Divide Quad-Precision (xsdivqp)*, do the following.

1. ZX is set to 1.
2. An Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into VSR[VRT+32] in quad-precision format.
3. FR and FI are set to 0. FPRF is set to indicate the class and sign of the result ( $\pm$  Infinity).

For *VSX Vector Divide Double-Precision (xvdivdp)*, do the following.

1. ZX is set to 1.
2. For each vector element causing a Zero Divide exception, an Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into its respective doubleword element of VSR[XT] in double-precision format.
3. FR, FI, and FPRF are not modified.

For *VSX Vector Divide Single-Precision (xvdivsp)*, do the following.

1. ZX is set to 1.
2. For each vector element causing a Zero Divide exception, an Infinity, having a sign determined by the XOR of the signs of the source operands, is placed into its respective word element of VSR[XT] in single-precision format.
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Scalar Reciprocal Estimate Double-Precision* (***xsredp***)  
*VSX Scalar Reciprocal Estimate Single-Precision* (***xsresp***)

*VSX Scalar Reciprocal Square Root Estimate Double-Precision* (***xsrsqrtdp***)  
*VSX Scalar Reciprocal Square Root Estimate Single-Precision* (***xsrsqrtesp***)

do the following.

1. ZX is set to 1.
2. An Infinity, having the sign of the source operand, is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FR and FI are set to 0. FPRF is set to indicate the class and sign of the result ( $\pm$  Infinity).

For any of the following instructions,

*VSX Vector Reciprocal Estimate Double-Precision* (***xsredp***)

*VSX Vector Reciprocal Square Root Estimate Double-Precision* (***xsrsqrtdp***)

do the following.

1. ZX is set to 1.
2. For each vector element causing a Zero Divide exception, an Infinity, having the sign of the source operand, is placed into its respective doubleword element of VSR[XT] in double-precision format.
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Reciprocal Estimate Single-Precision* (***xsresp***)

*VSX Vector Reciprocal Square Root Estimate Single-Precision* (***xsrsqrtesp***)

do the following.

1. ZX is set to 1.
2. For each vector element causing a Zero Divide exception, an Infinity, having the sign of the source operand, is placed into its respective word element of VSR[XT] in single-precision format.
3. FR, FI, and FPRF are not modified.

## 7.4.3 Floating-Point Overflow Exception

### 7.4.3.1 Definition

An Overflow exception occurs when the magnitude of what would have been the rounded result if the exponent range were unbounded exceeds that of the largest finite number of the specified result precision.

The action to be taken depends on the setting of the Overflow Exception Enable bit of the FPSCR.

### 7.4.3.2 Action for OE=1

When Overflow exception is enabled (OE=1) and an Overflow exception occurs, the following actions are taken:

For the *VSX Vector round and Convert Double-Precision to Single-Precision format* (**xscvdp**) instruction:

1. 0X is set to 1.
2. If the unbiased exponent of the normalized intermediate result is less than or equal to 318 ( $E_{\max}+192$ ), the exponent is adjusted by subtracting 192. Otherwise the result is undefined.
3. The adjusted rounded result is placed into word elements 0 and 1 of VSR[XT] in single-precision format. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For any of the following instructions,

*VSX Scalar Double-Precision Arithmetic* instructions

**xsadddp, xsdivdp, xsmuldp, xssubdp**  
**xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp**  
**xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp**

*VSX Vector Reciprocal Estimate Double-Precision* (**xsredp**)

do the following.

1. 0X is set to 1.
2. The exponent of the normalized intermediate result is adjusted by subtracting 1536.
3. The adjusted rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
4. FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For any of the following instructions,

*VSX Scalar Single-Precision Arithmetic instructions*  
***xsaddsp, xsdivsp, xsmulsp, xssubsp***  
***xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp***  
***xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp***

*VSX Scalar Reciprocal Estimate Single-Precision (xsresp)*

*VSX Vector Reciprocal Square Root Estimate Single-Precision (xsrsqrtesp)*

*VSX Scalar Round to Single-Precision (xsrsp)*

do the following.

1. 0X is set to 1.
2. The exponent is adjusted by subtracting 192.
3. The adjusted and rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
4. FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For any of the following instructions,

*VSX Scalar Quad-Precision Arithmetic instructions*  
***xsaddqp[o], xsdivqp[o], xsmulqp[o], xssqrtqp[o], xssubqp[o]***  
***xsmaddqp[o], xsmsubqp[o], xsnmaddqp[o], xsnmsubqp[o]***

*VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)*

do the following.

1. 0X is set to 1.
2. The exponent is adjusted by subtracting 24576.
3. The adjusted, rounded result is placed into VSR[VRT+32] in quad-precision format.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For *VSX Scalar Convert with round Quad-Precision to Double-Precision format* [using round to Odd] (***xscvqdp***), do the following.

1. 0X is set to 1.
2. The exponent is adjusted by subtracting 1536. If the adjusted exponent is greater than +1023 ( $E_{max}$ ), the result is undefined.
3. The adjusted, rounded result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.  
  
0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For *VSX Scalar Convert with round Double-Precision to Half-Precision format (xscvdphp)*, do the following.

1. 0X is set to 1.
2. The exponent is adjusted by subtracting 24. If the adjusted exponent is greater than +15 ( $E_{max}$ ), the result is undefined.
3. The adjusted, rounded result is placed into rightmost halfword of doubleword element 0 of VSR[XT] in half-precision format.

The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0.

The contents of doubleword element 1 of VSR[XT] are set to 0.

4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For any of the following instructions,

*VSX Vector Double-Precision Arithmetic instructions*  
***xvadddp, xvdivdp, xvmuldp, xvredp, xvsubdp,***  
***xvmaddadp, xsmaddmdp, xvmsubadp, xvmsubmdp,***  
***xvnmaddadp, xvnmaddmdp, xvnmsubadp, xvnmsubmdp***

*VSX Vector Single-Precision Arithmetic instructions*  
***xvaddsp, xvdivsp, xvmulsp, xvresp, xvsubsp***  
***xvmaddasp, xvmaddmsp, xvmsubasp, xvmsubmsp***  
***xvnmaddasp, xvnmaddmsp, xvnmsubasp, xvnmsubmsp***

*VSX Vector round and Convert Double-Precision to Single-Precision format (xvcvdpsp)*

do the following.

1. 0X is set to 1.
2. VSR[XT] is not modified.
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Convert with round Single-Precision to Half-Precision format (xvcvsphp)*  
*VSX Vector Convert with round Single-Precision to bfloat16 format (xvcvspsbf16)*

do the following.

1. 0X is set to 1.
2. VSR[XT] is not modified.
3. FR, FI, and FPRF are not modified.

### 7.4.3.3 Action for OE=0

When Overflow exception is disabled (OE=0) and an Overflow exception occurs, the following actions are taken:

1. OX and XX are set to 1.
2. The result is determined by the rounding mode (RN) and the sign of the intermediate result as follows:

**Round to Nearest Even**

For negative overflow, the result is -Infinity.  
For positive overflow, the result is +Infinity.

**Round toward Zero**

For negative overflow, the result is the format's most negative finite number.  
For positive overflow, the result is the format's most positive finite number.

**Round toward +Infinity**

For negative overflow, the result is the format's most negative finite number.  
For positive overflow, the result is +Infinity.

**Round toward -Infinity**

For negative overflow, the result is -Infinity.  
For positive overflow, the result is the format's most positive finite number.

For *VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdpdp)*:

3. The result is placed into word elements 0 and 1 of VSR[XT] as a single-precision value. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Double-Precision Arithmetic instructions*

***x saddp, xsdivp, xsmuldp, xsredp, xssubdp  
xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp  
xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp***

*VSX Scalar Single-Precision Arithmetic instructions*

***x saddsp, xsdivsp, xsmulsp, xsresp, xssubsp  
xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp  
xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp***

do the following.

3. The result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are set to 0.
4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Quad-Precision Arithmetic* instructions  
***x saddqp[o]***, ***x sdivqp[o]***, ***x smulqp[o]***, ***x ssubqp[o]***  
***x smaddqp[o]***, ***x smsubqp[o]***, ***x snmaddqp[o]***, ***x snmsubqp[o]***

*VSX Scalar Quad-Precision Round to Double-Extended-Precision* (***xsrqpxp***)

do the following.

3. The result is placed into VSR[VRT+32] in quad-precision format.
4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar Convert with round Quad-Precision to Double-Precision format* (***xscvqdpd***), do the following.

3. The result is placed into doubleword element 0 of VSR[VRT+32] as a double-precision value.  
 0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar Convert with round Double-Precision to Half-Precision format* (***xscvdphp***), do the following.

3. The result is placed into the rightmost halfword of doubleword element 0 of VSR[XT] as a half-precision value.  
 The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0.  
 The contents of doubleword element 1 of VSR[XT] are set to 0.
4. FR is undefined. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

For *VSX Vector Double-Precision Arithmetic* instructions  
***xv adddp***, ***xv divdp***, ***xv muldp***, ***xv redp***, ***xv subdp***  
***xvm addadp***, ***xvm addmdp***, ***xvmsubadp***, ***xvmsubmdp***  
***xvnmaddadp***, ***xvnmaddmdp***, ***xvnmsubadp***, ***xvnmsubmdp***

do the following.

3. For each vector element causing an Overflow exception, the result is placed into its respective doubleword element of VSR[XT] in double-precision format.
4. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Single-Precision Arithmetic instructions*  
***xvaddsp, xvdivsp, xvmulsp, xvresp, xvsubsp***  
***xvmaddasp, xvmaddmsp, xvmsubasp, xvmsubmsp***  
***xvnmaddasp, xvnmaddmsp, xvnmsubasp, xvnmsubmsp***

*VSX Vector round and Convert Double-Precision to Single-Precision format (***xvcvdp***)*

do the following.

3. For each vector element causing an Overflow exception, the result is placed into its respective word element of VSR[XT] in single-precision format, and for ***xvcvdp***, is also placed into bits 32:63 of its respective doubleword element of VSX[XT].
4. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Convert with round Single-Precision to Half-Precision format (***xvcvsph***)*  
*VSX Vector Convert with round Single-Precision to bfloat16 format (***xvcvsph16***)*

do the following.

3. For each vector element causing an Overflow exception, the result is placed into the rightmost halfword of its respective word element of VSR[XT] in half-precision format.  
  
The contents of the leftmost halfword of its respective word element of VSR[XT] are set to 0.
4. FR, FI, and FPRF are not modified.

## 7.4.4 Floating-Point Underflow Exception

### 7.4.4.1 Definition

Underflow exception is defined separately for the enabled and disabled states:

**Enabled:**

Underflow occurs when the intermediate result is “Tiny”.

**Disabled:**

Underflow occurs when the intermediate result is “Tiny” and there is “Loss of Accuracy”.

A *tiny* result is detected before rounding, when a nonzero intermediate result computed as though both the precision and the exponent range were unbounded would be less in magnitude than the smallest normalized number.

If the intermediate result is tiny and Underflow exception is disabled (UE=0), the intermediate result is denormalized (see Section 7.3.2.4 , “Normalization and Denormalization” on page 519) and rounded (see Section 7.3.2.6 , “Rounding” on page 524) before being placed into the target VSR.

*Loss of accuracy* is detected when the delivered result value differs from what would have been computed were both the precision and the exponent range unbounded.

The action to be taken depends on the setting of the Underflow Exception Enable bit of the FPSCR.

### 7.4.4.2 Action for UE=1

When Underflow exception is enabled (UE=1) and an Underflow exception occurs, the following actions are taken:

For *VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdp)*, do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 192. If the adjusted unbiased exponent is less than -126 ( $E_{min}$ ), the result is undefined.
3. The adjusted rounded result is placed into word elements 0 and 1 of VSR[XT] in single-precision format. The contents of word elements 2 and 3 of VSR[XT] are undefined.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For any of the following instructions,

*VSX Scalar Double-Precision Arithmetic instructions*

***xsadddp, xsdivdp, xsmuldp, xssubdp***  
***xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp***  
***xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp***

*VSX Scalar Double-Precision Reciprocal Estimate (***xsredp***)*

do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 1536.
3. The adjusted rounded result is placed into word elements 0 and 1 of VSR[XT] in single-precision format. The contents of word elements 2 and 3 of VSR[XT] are set to 0
4. FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For any of the following instructions,

*VSX Scalar Quad-Precision Arithmetic instructions*

***xsaddqp[o], xsdivqp[o], xsmulqp[o], xssubqp[o]***  
***xsmaddqp[o], xsmsubqp[o], xsnmaddqp[o], xsnmsubqp[o]***

*VSX Scalar Round Quad-Precision to Double-Extended-Precision (***xsrqpxp***)*

do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 24576.
3. The adjusted, rounded result is placed into VSR[VRT+32] in quad-precision format.
4. FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For *VSX Scalar Convert with round Quad-Precision to Double-Precision format [using round to Odd] (***xscvqdp[o]***)*, do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 1536. If the adjusted unbiased exponent is less than -1022 (Emi n), the result is undefined.
3. The adjusted, rounded result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.  
  
0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For any of the following instructions,

*VSX Scalar Single-Precision Arithmetic instructions*

***xsaddsp, xsdivsp, xsmulsp, xssubsp***  
***xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp***  
***xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp***

*VSX Scalar Single-Precision Reciprocal Estimate (xsresp)*

do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 192. If the adjusted unbiased exponent is less than -126 ( $E_{min}$ ), the result is undefined.
3. The adjusted rounded result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

#### Programming Note

The FR and FI bits are provided to allow the system floating-point enabled exception error handler, when invoked because of an Underflow exception, to simulate a “trap disabled” environment. That is, the FR and FI bits allow the system floating-point enabled exception error handler to unround the result, thus allowing the result to be denormalized and correctly rounded.

For *VSX Scalar Convert with round Double-Precision to Half-Precision with round (xscvdphp)*, do the following.

1. UX is set to 1.
2. The exponent of the normalized intermediate result is adjusted by adding 24. If the adjusted unbiased exponent is less than -14, the result is undefined.
3. The adjusted, rounded result is placed into rightmost halfword of doubleword element 0 of VSR[XT] in half-precision format.  
  
The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0.  
  
The contents of doubleword element 1 of VSR[XT] are set to 0.
4. Unless the result is undefined, FPRF is set to indicate the class and sign of the result ( $\pm$ Normal Number).

For any of the following instructions,

VSX Vector Double-Precision Arithmetic instructions

***xvadddp, xvdivdp, xvmuldp, xvsubdp***  
***xvmaddadp, xvmaddmdp, xvmsubadp, xvmsubmdp***  
***xvnmaddadp, xvnmaddmdp, xvnmsubadp, xvnmsubmdp***

VSX Vector Single-Precision Arithmetic instructions

***xvaddsp, xvdivsp, xvmulsp, xvsubsp***  
***xvmaddasp, xvmaddmsp, xvmsubasp, xvmsubmsp***  
***xvnmaddasp, xvnmaddmsp, xvnmsubasp, xvnmsubmsp***

VSX Vector Reciprocal Estimate Double-Precision (***xvredp***)

VSX Vector Reciprocal Estimate Single-Precision (***xvresp***)

VSX Vector round and Convert Double-Precision to Single-Precision format (***xvcvdpssp***)

VSX Vector Convert with round Single-Precision to Half-Precision format (***xvcvshp***)

VSX Vector Convert with round Single-Precision to bfloat16 format (***xvcvspbf16***)

do the following.

1. UX is set to 1.
2. VSR[XT] is not modified.
3. FR, FI, and FPRF are not modified.

#### 7.4.4.3 Action for UE=0

When Underflow exception is disabled (UE=0) and an Underflow exception occurs, the following actions are taken:

For VSX Scalar round and Convert Double-Precision to Single-Precision format (***xscvdpssp***), do the following.

1. UX is set to 1.
2. The result is placed into word elements 0 and 1 of VSR[XT] as a single-precision value. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

VSX Scalar Double-Precision Arithmetic instructions

***xsadddp, xsdivdp, xsmuldp, xssubdp***  
***xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp***  
***xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp***

VSX Scalar Single-Precision Arithmetic instructions

***xsaddsp, xsdivsp, xsmulsp, xssubsp***  
***xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp***  
***xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp***

VSX Scalar Reciprocal Estimate Double-Precision (***xsredp***)

VSX Scalar Reciprocal Estimate Single-Precision (***xsresp***)

do the following.

1. UX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Quad-Precision Arithmetic* instructions  
***x*saddqp[o], *x*sdivqp[o], *x*smulqp[o], *x*ssubqp[o]  
*x*smaddqp[o], *x*smsubqp[o], *x*snmaddqp[o], *x*snmsubqp[o]**

*VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)*

do the following.

1. UX is set to 1.
2. The result is placed into VSR[VRT+32] in quad-precision format.
3. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar Convert with round Quad-Precision to Double-Precision format (xscvqdp)*, do the following.

1. UX is set to 1.
2. The result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.  
 0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
3. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar Convert with round Double-Precision to Half-Precision format (xscvdphp)*, do the following.

1. UX is set to 1.
2. The result is placed into the rightmost halfword of doubleword element 0 of VSR[XT] as a half-precision value.  
 The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0.  
 The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Vector Double-Precision Arithmetic* instructions  
***x*vadddp, *x*vdivdp, *x*vmuldp, *x*vsubdp  
*x*vmaddadp, *x*vmaddmdp, *x*vmsubadp, *x*vmsubmdp  
*x*vnmaddadp, *x*vnmaddmdp, *x*vnmsubadp, *x*vnmsubmdp**

*VSX Vector Reciprocal Estimate Double-Precision (xvredp)*

do the following.

1. UX is set to 1.
2. For each vector element causing an Underflow exception, the result is placed into its respective doubleword element of VSR[XT] in double-precision format.
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Single-Precision Arithmetic instructions*

***xvaddsp, xvdivsp, xvmulsp, xvsubsp  
xvmaddasp, xvmaddmsp, xvmsubasp, xvmsubmsp  
xvnmaddasp, xvnmaddmsp, xvnmsubasp, xvnmsubmsp***

*VSX Vector Reciprocal Estimate Single-Precision (**xvresp**)*

*VSX Vector round and Convert Double-Precision to Single-Precision format (**xvcvdpsp**)*

do the following.

1. UX is set to 1.
2. For each vector element causing an Underflow exception, the result is placed into its respective word element of VSR[XT] in single-precision format, and for **xvcvdpsp**, is also placed into bits 32:63 of its respective doubleword element of VSR[XT].
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Convert with round Single-Precision to Half-Precision format (**xvcvsphp**)*

*VSX Vector Convert with round Single-Precision to bfloat16 format (**xvcvsbf16**)*

do the following.

1. UX is set to 1.
2. For each vector element causing an Underflow exception, the result is placed into the rightmost halfword of its respective word element of VSR[XT] in half-precision format.

The contents of the leftmost halfword of its respective word element of VSR[XT] are set to 0.

3. FR, FI, and FPRF are not modified.

## 7.4.5 Floating-Point Inexact Exception

### 7.4.5.1 Definition

An Inexact exception occurs when one of two conditions occur during rounding:

1. The rounded result differs from the intermediate result assuming both the precision and the exponent range of the intermediate result to be unbounded. In this case the result is said to be inexact. (If the rounding causes an enabled Overflow exception or an enabled Underflow exception, an Inexact exception also occurs only if the significands of the rounded result and the intermediate result differ.)
2. The rounded result overflows and Overflow exception is disabled.

The action to be taken depends on the setting of the Inexact Exception Enable bit of the FPSCR.

### 7.4.5.2 Action for XE=1

#### Programming Note

In some implementations, enabling Inexact exceptions can degrade performance more than does enabling other types of floating-point exception.

When Inexact exception is enabled (XE=1) and an Inexact exception occurs, the following actions are taken:

For the *VSX Scalar round and Convert Double-Precision to Single-Precision format* (**xscvdpdp**) instruction, do the following.

1. XX is set to 1.
2. The result is placed into word elements 0 and 1 of VSR[XT] in single-precision format. The contents of word elements 2-3 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Double-Precision Arithmetic* instructions  
**xsadddp, xssubdp, xsmuldp, xsdivdp, xssqrtsp**  
**xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp**  
**xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp**

*VSX Scalar Single-Precision Arithmetic* instructions  
**xsaddsp, xssubsp, xsmulsp, xsdivsp, xssqrtsp**  
**xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp**  
**xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp**

*VSX Scalar Reciprocal Estimate* instructions  
**xsredp, xsrsqrtedp, xsresp, xsrsqrtesp**

*VSX Scalar Round to Single-Precision* (**xsrsp**)

*VSX Scalar Round to Double-Precision Integer Exact using Current rounding mode* (**xsrpic**)

*VSX Scalar Convert with round Signed Doubleword to Double-Precision format* (**xscvxdpdp**)  
*VSX Scalar Convert with round Signed Doubleword to Single-Precision format* (**xscvxdsp**)

*VSX Scalar Convert with round Unsigned Doubleword to Double-Precision format* (**xscvuxdpdp**)  
*VSX Scalar Convert with round Unsigned Doubleword to Single-Precision format* (**xscvuxdsp**)

do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] in double-precision format. The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Convert with round to zero Double-Precision to Signed Word format* (**xscvdpsxws**)  
*VSX Scalar Convert with round to zero Double-Precision to Unsigned Word format* (**xscvdpuxws**)

do the following.

1. XX is set to 1.
2. The result is placed into word element 1 of VSR[XT]. The contents of word elements 0, 2, and 3 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Quad-Precision Arithmetic instructions*  
**x saddqp[o]**, **x sdivqp[o]**, **x smulqp[o]**, **x ssqrtqp[o]**, **x ssubqp[o]**  
**x smaddqp[o]**, **x smsubqp[o]**, **x snmaddqp[o]**, **x snmsubqp[o]**

*VSX Scalar Round to Quad-Precision Integer with Inexact* (**xsrqpix**)

*VSX Scalar Round Quad-Precision to Double-Extended Precision* (**xsrqpxp**)

do the following.

1. XX is set to 1.
2. The result is placed into VSR[VRT+32] in quad-precision format.
3. FR is set to indicate if the rounded result was incremented. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar Convert with round Quad-Precision to Double-Precision format* (**xscvqpdp**), do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.  
 0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
3. FR is set to indicate if the rounded result was incremented. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar truncate & Convert Quad-Precision to Signed Doubleword* (**xscvqpsdz**), do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] in signed integer format.  
0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
3. FR is set to 0. FI is set to 1. FPRF is undefined.

For *VSX Scalar truncate & Convert Quad-Precision to Signed Word* (**xscvqpswz**), do the following.

1. XX is set to 1.
2. The result is placed into word element 1 of VSR[XT] in signed integer format.  
0x0000\_0000 is placed into word elements 0, 2, and 3 of VSR[VRT+32].
3. FR is set to 0. FI is set to 1. FPRF is undefined.

For *VSX Scalar truncate & Convert Quad-Precision to Unsigned Doubleword* (**xscvqpudz**), do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] in unsigned integer format.  
0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
3. FR is set to 0. FI is set to 1. FPRF is undefined.

For *VSX Scalar truncate & Convert Quad-Precision to Unsigned Word* (**xscvqpuwz**), do the following.

1. XX is set to 1.
2. The result is placed into word element 1 of VSR[XT] in unsigned integer format.  
0x0000\_0000 is placed into word elements 0, 2, and 3 of VSR[VRT+32].
3. FR is set to 0. FI is set to 1. FPRF is undefined.

For *VSX Scalar Convert with round Double-Precision to Half-Precision truncate* (**xscvdphp**), do the following.

1. XX is set to 1.
2. The result is placed into the rightmost halfword of doubleword element 0 of VSR[XT] as a half-precision value.  
The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0.  
The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FR is set to indicate if the rounded result was incremented. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Double-Precision Arithmetic instructions*

***xsadddp, xssubdp, xsmuldp, xsdivdp, xssqrtsp  
xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp  
xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp***

*VSX Scalar Single-Precision Arithmetic instructions*

***xsaddsp, xssubsp, xsmulsp, xsdivsp, xssqrtsp  
xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp  
xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp***

*VSX Scalar Reciprocal Estimate instructions*

***xsredp, xsrsqrtedp, xsresp, xsrsqrtesp***

*VSX Scalar Round to Single-Precision (**xsrsp**)*

*VSX Scalar Round to Double-Precision Integer Exact using Current rounding mode (**xsrpic**)*

*VSX Scalar Convert with round Signed Doubleword to Double-Precision format (**xscvsxddp**)*

*VSX Scalar Convert with round Unsigned Doubleword to Double-Precision format (**xscvuxddp**)*

*VSX Scalar Convert with round Signed Doubleword to Single-Precision format (**xscvsxdsp**)*

*VSX Scalar Convert with round Unsigned Doubleword to Single-Precision format (**xscvuxdsp**)*

do the following.

1. XX is set to 1.
2. VSR[XT] is not modified.
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Convert with round Single-Precision to Half-Precision format (**xvcvsphp**)*

*VSX Vector Convert with round Single-Precision to bfloat16 format (**xvcvsxbf16**)*

do the following.

1. XX is set to 1.
2. VSR[XT] is not modified.
3. FR, FI, and FPRF are not modified.

### 7.4.5.3 Action for XE=0

When Inexact exception is disabled (XE=0) and an Inexact exception occurs, the following actions are taken:

For *VSX Scalar round and Convert Double-Precision to Single-Precision format (xscvdpsp)*, do the following.

1. XX is set to 1.
2. The result is placed into word elements 0 and 1 of VSR[XT] as a single-precision value. The contents of word elements 2-3 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Double-Precision Arithmetic instructions*  
***x sadddp, xssubdp, xsmuldp, xsdivdp, xssqrtsp***  
***xsmaddadp, xsmaddmdp, xsmsubadp, xsmsubmdp***  
***xsnmaddadp, xsnmaddmdp, xsnmsubadp, xsnmsubmdp***

*VSX Scalar Single-Precision Arithmetic instructions*  
***x saddsp, xssubsp, xsmulsp, xsdivsp, xssqrtsp***  
***xsmaddasp, xsmaddmsp, xsmsubasp, xsmsubmsp***  
***xsnmaddasp, xsnmaddmsp, xsnmsubasp, xsnmsubmsp***

*VSX Scalar Round to Single-Precision (xsrsp)*

*VSX Scalar Round to Double-Precision Integer Exact using Current rounding mode (xsrpic)*

*VSX Scalar Convert with round Signed Doubleword to Double-Precision format (xscvsxddp)*  
*VSX Scalar Convert with round Unsigned Doubleword to Double-Precision format (xscvuxddp)*

do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[XT] as a double-precision value. The contents of doubleword element 1 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar Convert with round to zero Double-Precision To Signed Word format (xscvdpsxws)*  
*VSX Scalar Convert with round to zero Double-Precision To Unsigned Word format (xscvdpuxws)*

do the following.

1. XX is set to 1.
2. The result is placed into word elements 0 and 1 of VSR[XT]. The contents of word elements 2 and 3 of VSR[XT] are set to 0.
3. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar Convert with round Quad-Precision to Double-Precision format (xscvqdp)*, do the following.

1. XX is set to 1.
2. The result is placed into the rightmost halfword of doubleword element 0 of VSR[XT] as a half-precision value.

The contents of the leftmost 3 halfwords of doubleword element 0 of VSR[XT] are set to 0.

The contents of doubleword element 1 of VSR[XT] are set to 0.

3. FR is set to indicate if the rounded result was incremented. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Vector Double-Precision Arithmetic* instructions

***xvadddp, xvsubdp, xvmuldp, xvdivdp, xvsqrtdp  
xvmaddadp, xvmaddmdp, xvmsubadp, xvmsubmdp  
xvmaddadp, xvmaddmdp, xvnmsubadp, xvnmsubmdp***

do the following.

1. XX is set to 1.
2. For each vector element causing an Inexact exception, the result is placed into its respective doubleword element of VSR[XT] in double-precision format.
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Scalar Quad-Precision Arithmetic* instructions

***xsaddqp[o], xsdivqp[o], xsmulqp[o], xssqrtp[o], xssubqp[o]  
xsmaddqp[o], xsmsubqp[o], xsnmaddqp[o], xsnmsubqp[o]***

*VSX Scalar Round Quad-Precision to Double-Extended-Precision (xsrqpxp)*

*VSX Scalar Round to Quad-Precision Integer with Inexact (xsrqpix)*

do the following.

1. XX is set to 1.
2. The result is placed into VSR[VRT+32] in quad-precision format.
3. FR is set to indicate if the rounded result was incremented. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For *VSX Scalar round & Convert Quad-Precision to Double-Precision (xscvqdp)*, do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format.

0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].

3. FR is set to indicate if the rounded result was incremented. FI is set to 1. FPRF is set to indicate the class and sign of the result.

For any of the following instructions,

*VSX Scalar truncate & Convert Quad-Precision to Signed Doubleword* (***xscvqpsdz***)  
*VSX Scalar truncate & Convert Quad-Precision to Signed Word* (***xscvqpswz***)

do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[VRT+32] in signed integer format.  
 0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
3. FR is set to 0. FI is set to 1. FPRF is undefined.

For any of the following instructions,

*VSX Scalar truncate & Convert Quad-Precision to Unsigned Doubleword* (***xscvqpudz***)  
*VSX Scalar truncate & Convert Quad-Precision to Unsigned Word* (***xscvqpuwz***)

do the following.

1. XX is set to 1.
2. The result is placed into doubleword element 0 of VSR[VRT+32] in unsigned integer format.  
 0x0000\_0000\_0000\_0000 is placed into doubleword element 1 of VSR[VRT+32].
3. FR is set to 0. FI is set to 1. FPRF is undefined.

For any of the following instructions,

*VSX Vector Convert with round Single-Precision to Half-Precision format* (***xvcvspbp***)  
*VSX Vector Convert with round Single-Precision to bfloat16 format* (***xvcvspbf16***)

do the following.

1. XX is set to 1.
2. For each vector element causing an Inexact exception, the result is placed into the rightmost halfword of its respective word element of VSR[XT] in half-precision format.  
 The contents of the leftmost halfword of its respective word element of VSR[XT] are set to 0.
3. FR, FI, and FPRF are not modified.

For any of the following instructions,

*VSX Vector Single-Precision Arithmetic instructions*  
***xvaddsp, xvsubsp, xvmulsp, xvdivsp, xvsqrtsp***  
***xvmaddasp, xvmaddmsp, xvmsubasp, xvmsubmsp***  
***xvnmaddasp, xvnmaddmsp, xvnmsubasp, xvnmsubmsp***

do the following.

1. XX is set to 1.
2. For each vector element causing an Inexact exception, the result is placed into its respective word element of VSR[XT] in single-precision format.
3. FR, FI, and FPRF are not modified.

## 7.5 VSX Storage Access Operations

The *VSX Storage Access* instructions compute the effective address (EA) of the storage to be accessed as described in Power ISA Book I.

### 7.5.1 Accessing Aligned Storage Operands

The following quadword-aligned array, AW, consists of 8 halfwords.

```
short  AW[4] = { 0x0001_0203,
                 0x0405_0607,
                 0x0809_0A0B,
                 0x0C0D_0E0F };
```

Figure 121 illustrates the Big-Endian storage image of array AW.

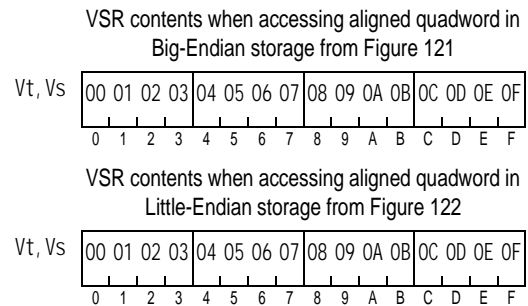

**Figure 121. Big-Endian storage image of array AW**

Figure 122 illustrates the Little-Endian storage image of array AW.

**Figure 122. Little-Endian storage image of array AW**

Figure 123 shows the result of loading that quadword into a VSR or, equivalently, shows the contents that must be in a VSR if storing that VSR is to produce the storage contents shown in Figure 121 for Big-Endian. Note that Figure shows the effect of loading the quadword from both Big-Endian storage and Little-Endian storage.

**Figure 123. Vector-Scalar Register contents for aligned quadword Load or Store VSX Vector**

## 7.5.2 Accessing Unaligned Storage Operands

The following array, B, consists of 5 word elements.

```
int B[5];
B[0] = 0x01234567;
B[1] = 0x00112233;
B[2] = 0x44556677;
B[3] = 0x8899AABB;
B[4] = 0xCCDDEEFF;
```

Figure 124 illustrates both Big-Endian and Little-Endian storage images of array B.

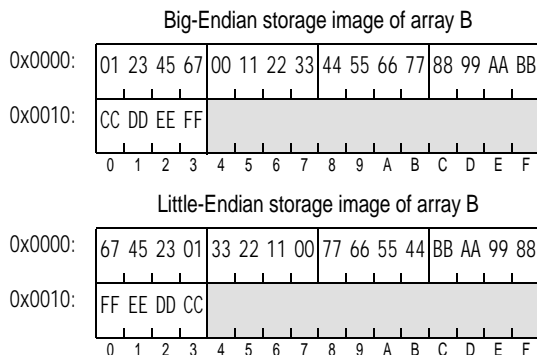

Figure 124.Storage images of array B

Though this example shows the array starting at a quadword-aligned address, if the subject data of interest are elements 1 through 4, accessing elements 1 through 4 of array B involves an unaligned quadword storage access that spans two aligned quadwords.

### Loading an Unaligned Quadword from Big-Endian Storage

Loading elements from elements 1 through 4 of B (see Figure 124) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using Big-Endian byte ordering.

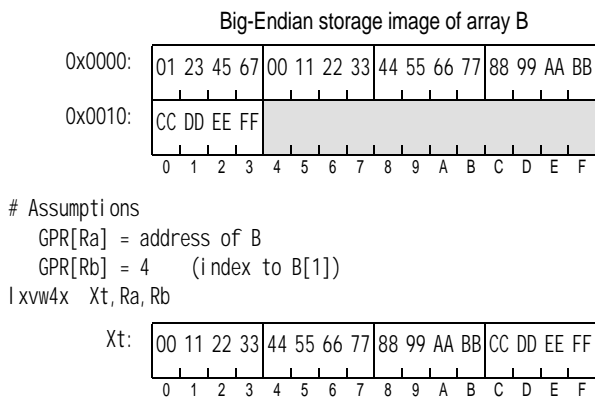

Figure 125.Process to load unaligned quadword from Big-Endian storage using Load VSX Vector Word\*4 Indexed

### Loading an Unaligned Quadword from Little-Endian Storage

Loading elements from elements 1 through 4 of B (see Figure 124) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using Little-Endian byte ordering.

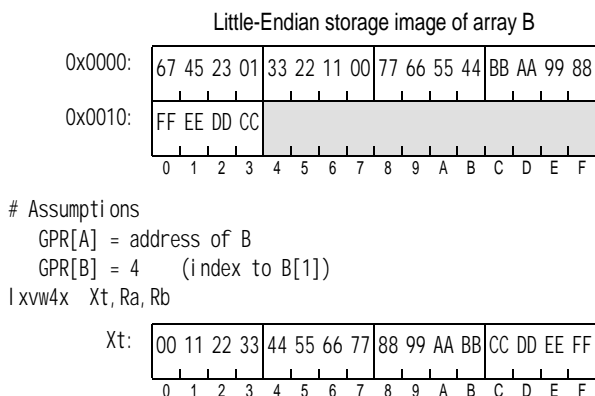

Figure 126.Process to load unaligned quadword from Little-Endian storage using Load VSX Vector Word\*4 Indexed

**Storing an Unaligned Quadword to Big-Endian Storage**

Storing a VSR to elements 1 through 4 of B (see Figure 124) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using Big-Endian byte ordering.

# Assumptions  
 GPR[Ra] = address of B  
 GPR[Rb] = 4 (index to B[1])

stxvw4x Xs, Ra, Rb

**Figure 127. Process to store unaligned quadword to Big-Endian storage using Store VSX Vector Word\*4 Indexed**

**Storing an Unaligned Quadword to Little-Endian Storage**

Storing a VSR to elements 1 through 4 of B (see Figure 124) into VR[VT] involves an unaligned quadword storage access.

VSX supports word-aligned vector and scalar storage accesses using Little-Endian byte ordering.

# Assumptions  
 GPR[A] = address of B  
 GPR[B] = 4 (index to B[1])

stxvw4x Xs, Ra, Rb

**Figure 128. Process to store unaligned quadword to Little-Endian storage Store VSX Vector Word\*4 Indexed**

**7.5.3 Storage Access Exceptions**

Storage accesses cause the system data storage error handler to be invoked if the program is not allowed to modify the target storage (*Store* only), or if the program attempts to access storage that is unavailable.

## 7.6 VSX Instruction Set

### 7.6.1 VSX Instruction Set Summary

#### 7.6.1.1 VSX Storage Access Instructions

*Load VSX Scalar* instructions place a copy of the contents of the addressed byte, halfword, word, or doubleword in storage into the left-most doubleword element of the target VSR. For integer byte, halfword, and word forms, the data are placed into the rightmost byte, halfword, or word of the doubleword, and the leftmost bits of the doubleword are set to 0 (or set to the copy of the sign bit for *lxiwax*). For the single-precision floating-point word form, the data is converted to double-precision format and placed into the doubleword. The contents of the right-most doubleword element of the target VSR are set to 0.

*Store VSX Scalar* instructions place a copy of the contents of the leftmost doubleword element (or portions of) in the source VSR into the addressed byte, halfword, word or doubleword in storage. For integer byte, halfword, and word forms, the rightmost byte, halfword, or word of the doubleword are stored.

*Load VSX Vector* instructions load a quadword from storage as a vector of 16 byte elements, 8 halfword elements, 4 word elements, 2 doubleword elements or a quadword element into a VSR.

*Load VSX Vector & Splat* instructions load a word or doubleword from storage and replicate the data into the 4 words or 2 doublewords of a VSR.

*Store VSX Vector* instructions store a vector of 16 byte elements, 8 halfword elements, 4 word elements, 2 doubleword elements or a quadword element from a VSR into a quadword in storage.

*Load VSX Vector with Length* instruction loads from 0 to 16 bytes into a VSR.

*Store VSX Vector with Length* instruction stores from 0 to 16 bytes from a VSR.

*Load VSX Vector Paired* instructions load an octword (32 bytes) from storage into two sequential VSRs (i.e., a vector of 32 byte elements, 16 halfword elements, 8 word elements, 4 doubleword elements or 2 quadword elements).

*VSX Vector Store Paired* instructions store the contents of two sequential VSRs into an octword (32 bytes) in storage (i.e., a vector of 32 byte elements, 16 halfword elements, 8 word elements, 4 doubleword elements or 2 quadword elements).

## 7.6.1.4 VSX Binary Floating-Point Compare Instructions

### 7.6.1.4.1 VSX Scalar BFP Compare Instructions

Mnemonic	Instruction Name	Page
xscmpodp	VSX Scalar Compare Ordered Double-Precision	684
xscmpoqp	VSX Scalar Compare Ordered Quad-Precision	686
xscmpudp	VSX Scalar Compare Unordered Double-Precision	687
xscmpuqp	VSX Scalar Compare Unordered Quad-Precision	689

**Table 27. VSX Scalar BFP Compare Instructions**

Mnemonic	Instruction Name	Page
xscmpeqdp	VSX Scalar Compare Equal Double-Precision	678
xscmpeqqp	VSX Scalar Compare Equal Quad-Precision	679
xscmpgedp	VSX Scalar Compare Greater Than or Equal Double-Precision	680
xscmpgeqp	VSX Scalar Compare Greater Than or Equal Quad-Precision	681
xscmpgtdp	VSX Scalar Compare Greater Than Double-Precision	682
xscmpgtqp	VSX Scalar Compare Greater Than Quad-Precision	683

**Table 28. VSX Scalar BFP Predicate Compare Instructions**

Mnemonic	Instruction Name	Page
xsmaxcdp	VSX Scalar Maximum Type-C Double-Precision	744
xsmaxcqp	VSX Scalar Maximum Type-C Quad-Precision	746
xsmaxdp	VSX Scalar Maximum Double-Precision	742
xsmajdp	VSX Scalar Maximum Type-J Double-Precision	748
xsmincdp	VSX Scalar Minimum Type-C Double-Precision	752
xsmincqp	VSX Scalar Minimum Type-C Quad-Precision	754
xsmindp	VSX Scalar Minimum Double-Precision	750
xsminjdp	VSX Scalar Minimum Type-J Double-Precision	755

**Table 29. VSX Scalar BFP Maximum/Minimum Instructions**

### 7.6.1.4.2 VSX Vector BFP Compare Instructions

Mnemonic	Instruction Name	Page
xvcmpeqdp[.]	VSX Vector Compare Equal To Double-Precision	841
xvcmpeqsp[.]	VSX Vector Compare Equal To Single-Precision	842
xvcmpgedp[.]	VSX Vector Compare Greater Than or Equal To Double-Precision	843
xvcmpgesp[.]	VSX Vector Compare Greater Than or Equal To Single-Precision	844
xvcmpgtdp[.]	VSX Vector Compare Greater Than Double-Precision	845
xvcmpgtsp[.]	VSX Vector Compare Greater Than Single-Precision	846

**Table 30. VSX Vector BFP Predicate Compare Instructions**

Mnemonic	Instruction Name	Page
xvmaxdp	VSX Vector Maximum Double-Precision	912
xvmaxsp	VSX Vector Maximum Single-Precision	914
xvmindp	VSX Vector Minimum Double-Precision	916
xvminsp	VSX Vector Minimum Single-Precision	918

**Table 31. VSX Vector BFP Maximum/Minimum Instructions**

### 7.6.1.5 VSX Binary Floating-Point Round to Shorter Precision Instructions

Mnemonic	Instruction Name	Page
xsrqpxp	VSX Scalar Round Quad-Precision to Double-Extended-Precision	804
xsrsp	VSX Scalar Round to Single-Precision	806

**Table 32.VSX Scalar BFP Round to Shorter Precision Instructions**

### 7.6.1.6 VSX Binary Floating-Point Convert to Shorter Precision Instructions

Mnemonic	Instruction Name	Page
xscvdphp	VSX Scalar Convert with round Double-Precision to Half-Precision format	691
xscvdpsp	VSX Scalar Convert with round Double-Precision to Single-Precision format	693
xscvdpspn	VSX Scalar Convert Scalar Single-Precision to Vector Single-Precision format Non-signalling	694
xscvqdp[o]	VSX Scalar Convert with round Quad-Precision to Double-Precision format [using round to Odd]	806

**Table 33.VSX Scalar BFP Convert to Shorter Precision Instructions**

Mnemonic	Instruction Name	Page
xvcvspbf16	VSX Vector Convert with round Single-Precision to bfloat16 format	859
xvcvdpsp	VSX Vector Convert with round Double-Precision to Single-Precision format	849
xvcvspfp	VSX Vector Convert with round Single-Precision to Half-Precision format	861

**Table 34.VSX Vector BFP Convert to Shorter Precision Instructions**

### 7.6.1.7 VSX Binary Floating-Point Convert to Longer Precision Instructions

Mnemonic	Instruction Name	Page
xscvdpqp	VSX Scalar Convert Double-Precision to Quad-Precision format	692
xscvhdpd	VSX Scalar Convert Half-Precision to Double-Precision format	703
xscvspdp	VSX Scalar Convert Single-Precision to Double-Precision format	717
xscvspdpn	VSX Scalar Convert Single-Precision to Double-Precision format Non-signalling	718

**Table 35.VSX Scalar BFP Convert to Longer Precision Instructions**

Mnemonic	Instruction Name	Page
xvcvhpsp	VSX Vector Convert Half-Precision to Single-Precision format	858
xvcvbf16spn	VSX Vector Convert bfloat16 to Single-Precision format Non-signaling	848
xvcvspdp	VSX Vector Convert Single-Precision to Double-Precision format	860

**Table 36.VSX Vector BFP Convert to Longer Precision Instructions**

## 7.6.1.8 VSX Binary Floating-Point Round to Integral Instructions

### 7.6.1.8.1 VSX Scalar BFP Round to Integral Instructions

Mnemonic	Instruction Name	Page
xsrdpi	VSX Scalar Round to Double-Precision Integer using round to Nearest Away	794
xsrdpic	VSX Scalar Round to Double-Precision Integer exact using Current rounding mode	795
xsrdpim	VSX Scalar Round to Double-Precision Integer using round toward -Infinity	796
xsrdpip	VSX Scalar Round to Double-Precision Integer using round toward +Infinity	797
xsrdpiz	VSX Scalar Round to Double-Precision Integer using round toward Zero	798
xsrqpi	VSX Scalar Round to Quad-Precision Integer	802
xsrqpix	VSX Scalar Round to Quad-Precision Integer with Inexact	802
xvrdpi	VSX Vector Round to Double-Precision Integer using round to Nearest Away	945
xvrdpic	VSX Vector Round to Double-Precision Integer Exact using Current rounding mode	946
xvrdpim	VSX Vector Round to Double-Precision Integer using round toward -Infinity	947
xvrdpip	VSX Vector Round to Double-Precision Integer using round toward +Infinity	948
xvrdpiz	VSX Vector Round to Double-Precision Integer using round toward Zero	948

**Table 37. VSX Scalar BFP Round to Integer Instructions**

### 7.6.1.8.2 VSX Vector BFP Round to Integral Instructions

Mnemonic	Instruction Name	Page
xvrdpi	VSX Vector Round to Double-Precision Integer using round to Nearest Away	945
xvrdpic	VSX Vector Round to Double-Precision Integer Exact using Current rounding mode	946
xvrdpim	VSX Vector Round to Double-Precision Integer using round toward -Infinity	947
xvrdpip	VSX Vector Round to Double-Precision Integer using round toward +Infinity	948
xvrdpiz	VSX Vector Round to Double-Precision Integer using round toward Zero	948
xvrspi	VSX Vector Round to Single-Precision Integer using round to Nearest Away	951
xvrspic	VSX Vector Round to Single-Precision Integer Exact using Current rounding mode	952
xvrspim	VSX Vector Round to Single-Precision Integer using round toward -Infinity	953
xvrspip	VSX Vector Round to Single-Precision Integer using round toward +Infinity	954
xvrspiz	VSX Vector Round to Single-Precision Integer using round toward Zero	954

**Table 38. VSX Vector BFP Round to Integer Instructions**

## 7.6.1.9 VSX Binary Floating-Point Convert To Integer Instructions

### 7.6.1.9.1 VSX Scalar BFP Convert To Integer Instructions

Mnemonic	Instruction Name	Page
xscvdpsxds	VSX Scalar Convert with round to zero Double-Precision to Signed Doubleword format	695
xscvdpsxws	VSX Scalar Convert with round to zero Double-Precision to Signed Word format	697
xscvdpuxds	VSX Scalar Convert with round to zero Double-Precision to Unsigned Doubleword format	699
xscvdpuxws	VSX Scalar Convert with round to zero Double-Precision to Unsigned Word format	701
xscvqpsdz	VSX Scalar Convert with round to zero Quad-Precision to Signed Doubleword format	705
xscvqpsqz	VSX Scalar Convert with round to zero Quad-Precision to Signed Quadword	707
xscvqpswz	VSX Scalar Convert with round to zero Quad-Precision to Signed Word format	709
xscvqpudz	VSX Scalar Convert with round to zero Quad-Precision to Unsigned Doubleword format	711
xscvqpuqz	VSX Scalar Convert with round to zero Quad-Precision to Unsigned Quadword	713
xscvqpuwz	VSX Scalar Convert with round to zero Quad-Precision to Unsigned Word format	715

**Table 39. VSX Scalar BFP Convert to Integer Instructions**

### 7.6.1.9.2 VSX Vector BFP Convert To Integer Instructions

Mnemonic	Instruction Name	Page
xvcvdpdxds	VSX Vector Convert with round to zero Double-Precision to Signed Doubleword format	850
xvcvdpdxws	VSX Vector Convert with round to zero Double-Precision to Signed Word format	852
xvcvdpuxds	VSX Vector Convert with round to zero Double-Precision to Unsigned Doubleword format	854
xvcvdpuxws	VSX Vector Convert with round to zero Double-Precision to Unsigned Word format	856
xvcvspdxds	VSX Vector Convert with round to zero Single-Precision to Signed Doubleword format	862
xvcvspdxws	VSX Vector Convert with round to zero Single-Precision to Signed Word format	864
xvcvspuxds	VSX Vector Convert with round to zero Single-Precision to Unsigned Doubleword format	866
xvcvspuxws	VSX Vector Convert with round to zero Single-Precision to Unsigned Word format	868

**Table 40.VSX Vector BFP Convert To Integer Instructions**

### 7.6.1.10 VSX Binary Floating-Point Convert From Integer Instructions

#### 7.6.1.10.1 VSX Scalar BFP Convert From Integer Instructions

Mnemonic	Instruction Name	Page
xscvsdq	VSX Scalar Convert Signed Doubleword to Quad-Precision format	722
xscvsqq	VSX Scalar Convert with round Signed Quadword to Quad-Precision	719
xscvsxddp	VSX Scalar Convert with round Signed Doubleword to Double-Precision format	720
xscvsxdsp	VSX Scalar Convert with round Signed Doubleword to Single-Precision format	721
xscvudq	VSX Scalar Convert Unsigned Doubleword to Quad-Precision format	722
xscvuqq	VSX Scalar Convert with round Unsigned Quadword to Quad-Precision format	723
xscvuxddp	VSX Scalar Convert with round Unsigned Doubleword to Double-Precision format	723
xscvuxdsp	VSX Scalar Convert with round Unsigned Doubleword to Single-Precision format	724

**Table 60.VSX Vector Load Special Value Instruction**

## 7.6.2 VSX Instruction Description Conventions

### 7.6.2.1 VSX Instruction RTL Operators

#### **x.bit[y:z]**

Return the contents of bits y: z of x.

#### **x.word[y:z]**

Return the contents of word elements y: z of x.

#### **x.dword[y:z]**

Return the contents of doubleword elements y: z of x.

#### **x = y**

The value of y is placed into x.

#### **x |= y**

The value of y is ORed with the value x and placed into x.

#### **~x**

Return the one's complement of x.

#### **!x**

Return 1 if the contents of x are equal to 0, otherwise return 0.

#### **x || y**

Return the value of x concatenated with the value of y. For example, 0b010 || 0b111 is the same as 0b010111.

#### **x ^ y**

Return the value of x exclusive ORed with the value of y.

#### **x ? y : z**

If the value of x is true, return the value of y, otherwise return the value z.

#### **x+y**

x and y are integer values.

Return the sum of x and y.

#### **x-y**

x and y are integer values.

Return the difference of x and y.

#### **x!=y**

x and y are integer values.

Return 1 if x is not equal to y, otherwise return 0.

#### **x<=y**

x and y are integer values.

Return 1 if x is less than or equal to y, otherwise return 0.

#### **x>=y**

x and y are integer values.

Return 1 if x is greater than or equal to y, otherwise return 0.

## 7.6.2.2 VSX Instruction RTL Function Calls

### `bfloat16_CONVERT_FROM_BFP(x)`

`x` is a floating-point value represented in the working format.

If `x.class.SNaN=1` or `x.class.QNaN=1`, do the following.

Bit 0 of result is set to the value of `x.sign`.

Bits 1:8 of result are set to the value `0b11111111`.

Bits 9:15 of result are set to the value of bits 1:7 of `x.significand`.

Otherwise, if `x.class.Infinity=1`, do the following.

Bit 0 of result is set to the value of `x.sign`.

Bits 1:8 of result are set to the value `0b11111111`.

Bits 9:15 of result are set to 0.

Otherwise, if `x.class.Zero=1`, do the following.

Bit 0 of result is set to the value of `x.sign`.

Bits 9:15 of result are set to 0.

Otherwise, if `x.exponent` is less than -126, do the following.

Bit 0 of result is set to the value of `x.sign`.

`sh_cnt` is set to the difference,  $-126 - x.exponent$ .

Bits 1:8 of result are set to `0b00000000`.

Bits 9:15 of result are set to bits 1:7 of `x.significand` shifted right by `sh_cnt` bits.

Otherwise, do the following.

Bit 0 of result is set to the value of `x.sign`.

Bits 1:8 of result are set to the sum,  $x.exponent + 127$ .

Bits 9:15 of result are set to bits 1:7 of `x.significand`.

Return result (bfloat16 format)

### `bfp_ABSOLUTE(x)`

`x` is a binary floating-point value represented in the binary floating-point working format.

Return `x` with sign set to 0.

### `bfp_ADD(x, y)`

`x` is a binary floating-point value represented in the binary floating-point working format.

`y` is a binary floating-point value represented in the binary floating-point working format.

If `x` or `y` is an SNaN, `vxsnan_flag` is set to 1.

If `x` is an infinity and `y` is an infinity of the opposite sign, `vxisi_flag` is set to 1.

If `x` is a QNaN, return `x`.

Otherwise, if `x` is an SNaN, return `x` represented as a QNaN.

Otherwise, if `y` is a QNaN, return `y`.

Otherwise, if `y` is an SNaN, return `y` represented as a QNaN.

Otherwise, if `x` and `y` are infinities of opposite sign, return the standard QNaN.

Otherwise, return the normalized sum of `x` and `y`, having unbounded range and precision.

**bfp\_COMPARE\_EQ(x, y)**

x is a binary floating-point value represented in the binary floating-point working format.  
y is a binary floating-point value represented in the binary floating-point working format.

Return 0b0 if x is NaN or y is a NaN.  
Otherwise, return 0b1 if x is a Zero and y is a Zero.  
Otherwise, return 0b1 if x is equal to y.  
Otherwise, return 0b0.

**bfp\_COMPARE\_GT(x, y)**

x is a binary floating-point value represented in the binary floating-point working format.  
y is a binary floating-point value represented in the binary floating-point working format.

Return 0b0 if x is NaN or y is a NaN.  
Otherwise, return 0b0 if x is a Zero and y is a Zero.  
Otherwise, return 0b1 if x is greater than y.  
Otherwise, return 0b0.

**bfp\_COMPARE\_LT(x, y)**

x is a binary floating-point value represented in the binary floating-point working format.  
y is a binary floating-point value represented in the binary floating-point working format.

Return 0b0 if x is NaN or y is a NaN.  
Otherwise, return 0b0 if x is a Zero and y is a Zero.  
Otherwise, return 0b1 if x is less than y.  
Otherwise, return 0b0.

**bfp\_CONVERT\_FROM\_BFLOAT16(x)**

x is a floating-point value represented in bfloat16 format.

Let *sign* be the contents of bit 0 of x.  
Let *exponent* be the contents of bits 1:8 of x.  
Let *fraction* be the contents of bits 9:15 of x.

Let *result.sign* be set to 0.  
Let *result.exponent* be set to 0.  
Let *result.significand* be set to 0.  
Let *result.class.SNaN* be set to 0.  
Let *result.class.QNaN* be set to 0.  
Let *result.class.Infinity* be set to 0.  
Let *result.class.Zero* be set to 0.  
Let *result.class.Denormal* be set to 0.  
Let *result.class.Normal* be set to 0.

If x is an SNaN, do the following.  
*result.class.SNaN* is set to 1.  
*result.sign* is set to the value of *sign*.

The contents of *result.significand* are set to 0.  
The contents of bits 1:7 of *result.significand* are set to the value of *fraction*.

Otherwise, if x is a QNaN, do the following.  
*result.class.QNaN* is set to 1.  
*result.sign* is set to the value of *sign*.

The contents of *result.significand* are set to 0.  
The contents of bits 1:7 of *result.significand* are set to the value of *fraction*.

Otherwise, if x is an Infinity value, do the following.  
*result.class.Infinity* is set to 1.

result. sign is set to the value of sign.

Otherwise, if  $x$  is a Zero value, do the following.

result. class. Zero is set to 1.

result. sign is set to the value of sign.

Otherwise, if  $x$  is a Denormal value, do the following.

result. class. Denormal is set to 1.

result. sign is set to the value of sign.

result. exponent is set to the value -126.

The contents of bits 1:7 of result. significand are set to the value of fraction.

result. significand is shifted left until the contents bit 0 of result. significand are equal to 1.

result. exponent is decremented by the number of bits result. significand was shifted.

Otherwise, do the following.

result. class. Normal is set to 1.

result. sign is set to the value of sign.

result. exponent is set to the value of exponent subtracted by 127.

The contents of bit 0 of result. significand are set to 1.

The contents of bits 1:7 of result. significand are set to the value of fraction.

Return result (binary floating-point working format).

#### **bfp\_CONVERT\_FROM\_BFP16( $x$ )**

$x$  is a floating-point value represented in half-precision format.

Let exponent be the contents of bits 1:5 of  $x$ .

Let fraction be the contents of bits 6:15 of  $x$ .

Let result. sign be set to 0.

Let result. exponent be set to 0.

Let result. significand be set to 0.

Let result. class. SNaN be set to 0.

Let result. class. QNaN be set to 0.

Let result. class. Infinity be set to 0.

Let result. class. Zero be set to 0.

Let result. class. Denormal be set to 0.

Let result. class. Normal be set to 0.

If  $x$  is a SNaN, do the following.

result. class. SNaN is set to 1.

result. sign is set to the contents of bit 0 of  $x$ .

The contents of bit 0 of result. significand are set to 0.

The contents of bits 1:10 of result. significand are set to the value of fraction.

Otherwise, if  $x$  is a QNaN, do the following.

result. class. QNaN is set to 1.

result. sign is set to the contents of bit 0 of  $x$ .

The contents of bit 0 of result. significand are set to 0.

The contents of bits 1:10 of result. significand are set to the value of fraction.

Otherwise, if  $x$  is an Infinity value, do the following.

result. class. Infinity is set to 1.

result. sign is set to the contents of bit 0 of  $x$ .

Otherwise, if  $x$  is a Zero value, do the following.

- result.class.Zero is set to 1.
- result.sign is set to the contents of bit 0 of  $x$ .

Otherwise, if  $x$  is a Denormal value, do the following.

- result.class.Denormal is set to 1.
- result.sign is set to the contents of bit 0 of  $x$ .
- result.exp is set to the value -14.

- The contents of bit 0 of result.significand are set to 0.
- The contents of bits 1:10 of result.significand are set to the value of fraction.

- result.significand is shifted left until the contents bit 0 of result.significand are equal to 1.
- result.exponent is decremented by the the number of bits result.significand was shifted.

Otherwise, do the following.

- result.class.Normal is set to 1.
- result.sign is set to the contents of bit 0 of  $x$ .
- result.exp is set to the value of exponent subtracted by 15.

- The contents of bit 0 of result.significand are set to 1.
- The contents of bits 1:10 of result.significand are set to the value of fraction.

Return result.

#### **bfp\_CONVERT\_FROM\_BFP32( $x$ )**

$x$  is a floating-point value represented in single-precision format.

- Let exponent be the contents of bits 1:8 of  $x$ .
- Let fraction be the contents of bits 9:31 of  $x$ .

- Let result.sign be initialized to 0.
- Let result.exponent be initialized to 0.
- Let result.significand be initialized to 0.
- Let result.class.SNaN be initialized to 0.
- Let result.class.QNaN be initialized to 0.
- Let result.class.Infinity be initialized to 0.
- Let result.class.Zero be initialized to 0.
- Let result.class.Denormal be initialized to 0.
- Let result.class.Normal be initialized to 0.

If  $x$  is a SNaN, do the following.

- result.class.SNaN is set to 1.
- result.sign is set to the contents of bit 0 of  $x$ .

- The contents of bit 0 of result.significand are set to 0.
- The contents of bits 1:23 of result.significand are set to the value of fraction.

Otherwise, if  $x$  is a QNaN, do the following.

- result.class.QNaN is set to 1.
- result.sign is set to the contents of bit 0 of  $x$ .

- The contents of bit 0 of result.significand are set to 0.
- The contents of bits 1:23 of result.significand are set to the value of fraction.

Otherwise, if  $x$  is an Infinity value, do the following.

- result.class.Infinity is set to 1.
- result.sign is set to the contents of bit 0 of  $x$ .

Otherwise, if  $x$  is a Zero value, do the following.

result.class.Zero is set to 1.  
 result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Denormal value, do the following.

result.class.Denormal is set to 1.  
 result.sign is set to the contents of bit 0 of x.  
 result.exponent is set to the value -126.

The contents of bit 0 of result.significand are set to 0.  
 The contents of bits 1:23 of result.significand are set to the value of fraction.

result.significand is shifted left until the contents bit 0 of result.significand are equal to 1.  
 result.exponent is decremented by the the number of bits result.significand was shifted.

Otherwise, do the following.

result.class.Normal is set to 1.  
 result.sign is set to the contents of bit 0 of x.  
 result.exponent is set to the value of exponent subtracted by 127.

The contents of bit 0 of result.significand are set to 1.  
 The contents of bits 1:23 of result.significand are set to the value of fraction.

Return result.

#### **bfp\_CONVERT\_FROM\_BFP64(x)**

x is a binary floating-point value represented in double-precision format.

Let exponent be the contents of bits 1:11 of x.  
 Let fraction be the contents of bits 12:63 of x.

result.sign is initialized to 0.  
 result.exponent is initialized to 0.  
 result.significand is initialized to 0.  
 result.class.SNaN is initialized to 0.  
 result.class.QNaN is initialized to 0.  
 result.class.Infinity is initialized to 0.  
 result.class.Zero is initialized to 0.  
 result.class.Denormal is initialized to 0.  
 result.class.Normal is initialized to 0.

If x is a SNaN, do the following.

result.class.SNaN is set to 1.  
 result.sign is set to the contents of bit 0 of x.  
 The contents of bit 0 of result.significand are set to 0.  
 The contents of bits 1:52 of result.significand are set to the value of fraction.  
 The contents of the rest of result.significand are set to 0.

Otherwise, if x is a QNaN, do the following.

result.class.QNaN is set to 1.  
 result.sign is set to the contents of bit 0 of x.  
 The contents of bit 0 of result.significand are set to 0.  
 The contents of bits 1:52 of result.significand are set to the value of fraction.  
 The contents of the rest of result.significand are set to 0.

Otherwise, if x is an Infinity, do the following.

result.class.Infinity is set to 1.  
 result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Zero, do the following.

result.class.Zero is set to 1.

result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Denormal, do the following.

result.class.Denormal is set to 1.

result.sign is set to the contents of bit 0 of x.

result.exp is set to the value -1022.

The contents of bit 0 of result.significand are set to 0.

The contents of bits 1:52 of result.significand are set to the value of fraction.

The contents of the rest of result.significand are set to 0.

result.significand is shifted left until the contents bit 0 of result.significand are equal to 1.

result.exponent is decremented by the the number of bits result.significand was shifted.

Otherwise, do the following.

result.class.Normal is set to 1.

result.sign is set to the contents of bit 0 of x.

result.exp is set to the value of exponent subtracted by 1023.

The contents of bit 0 of result.significand are set to 1.

The contents of bits 1:52 of result.significand are set to the value of fraction.

The contents of the rest of result.significand are set to 0.

Return result (i.e., the value x in the binary floating-point working format).

#### bfp\_CONVERT\_FROM\_BFP128(x)

x is a binary floating-point value represented in quad-precision format.

Let exponent be the contents of bits 1:15 of x.

Let fraction be the contents of bits 16:127 of x.

result.sign is initialized to 0.

result.exponent is initialized to 0.

result.significand is initialized to 0.

result.class.SNaN is initialized to 0.

result.class.QNaN is initialized to 0.

result.class.Infinity is initialized to 0.

result.class.Zero is initialized to 0.

result.class.Denormal is initialized to 0.

result.class.Normal is initialized to 0.

If x is a SNaN, do the following.

result.class.SNaN is set to 1.

result.sign is set to the contents of bit 0 of x.

The contents of bit 0 of result.significand are set to 0.

The contents of bits 1:112 of result.significand are set to the value of fraction.

The contents of the rest of result.significand are set to 0.

Otherwise, if x is a QNaN, do the following.

result.class.QNaN is set to 1.

result.sign is set to the contents of bit 0 of x.

The contents of bit 0 of result.significand are set to 0.

The contents of bits 1:112 of result.significand are set to the value of fraction.

The contents of the rest of result.significand are set to 0.

Otherwise, if x is an Infinity, do the following.

result.class.Infinity is set to 1.

result.sign is set to the contents of bit 0 of x.

Otherwise, if x is a Zero, do the following.

result.class.Zero is set to 1.

result.sign is set to the contents of bit 0 of x.

Otherwise, if  $x$  is a Denormal, do the following.

result.class.Denormal is set to 1.

result.sign is set to the contents of bit 0 of  $x$ .

result.exp is set to the value -16382.

The contents of bit 0 of result.significand are set to 0.

The contents of bits 1:112 of result.significand are set to the value of fraction.

The contents of the rest of result.significand are set to 0.

result.significand is shifted left until the contents bit 0 of result.significand are equal to 1.

result.exponent is decremented by the the number of bits result.significand was shifted.

Otherwise, do the following.

result.class.Normal is set to 1.

result.sign is set to the contents of bit 0 of  $x$ .

result.exp is set to the value of exponent subtracted by 16383.

The contents of bit 0 of result.significand are set to 1.

The contents of bits 1:112 of result.significand are set to the value of fraction.

The contents of the rest of result.significand are set to 0.

Return result (i.e., the value  $x$  in the binary floating-point working format).

#### **bfp\_CONVERT\_FROM\_SI64( $x$ )**

$x$  is an integer value represented in signed doubleword integer format.

result.sign is initialized to 0.

result.exponent is initialized to 0.

result.significand is initialized to 0.

result.class.SNaN is initialized to 0.

result.class.QNaN is initialized to 0.

result.class.Infinity is initialized to 0.

result.class.Zero is initialized to 0.

result.class.Denormal is initialized to 0.

result.class.Normal is initialized to 0.

If  $x$  is equal to 0x0000\_0000\_0000\_0000,

result.class.Zero is set to 1.

Otherwise, do the following.

result.class.Normal is set to 1.

result.sign is set to the contents of bit 0 of  $x$ .

result.exponent is set to the value 64.

Bits 0:64 of result.significand are set to the value of  $x$  sign-extended to 65 bits.

If bit 0 of result.significand is equal to 1,

result.sign is set to 1, and

result.significand is set to the value of the two's complement of result.significand.

If bit 0 of result.significand is equal to 0,

result.significand is shifted left until bit 0 of result.significand is equal to 1, and

result.exponent is decremented by the number of bits result.significand is shifted.

Return result (i.e., the value  $x$  in the binary floating-point working format).

#### **bfp\_CONVERT\_FROM\_SI128( $x$ )**

$x$  is a 128-bit signed integer value.

result.sign is initialized to 0.

result.exponent is initialized to 0.

result.significand is initialized to 0.

result.class.SNaN is initialized to 0.

result class.QNaN is initialized to 0.  
 result class.Infinity is initialized to 0.  
 result class.Zero is initialized to 0.  
 result class.Denormal is initialized to 0.  
 result class.Normal is initialized to 0.

If  $x$  is equal to 0x0000\_0000\_0000\_0000\_0000\_0000\_0000\_0000,  
 result class.Zero is set to 1.

Otherwise, do the following.

result class.Normal is set to 1.  
 result sign is set to the contents of bit 0 of  $x$ .  
 result exponent is set to the value 128.  
 Bits 0:128 of result signifi cand are set to the value of  $x$  sign-extended to 129 bits.

If bit 0 of result signifi cand is equal to 1,  
 result sign is set to 1, and  
 result signifi cand is set to the value of the two's complement of result signifi cand.

If bit 0 of result signifi cand is equal to 0,  
 result signifi cand is shifted left until bit 0 of result signifi cand is equal to 1, and  
 result exponent is decremented by the number of bits result signifi cand is shifted.

Return result (i.e., the value  $x$  in the binary floating-point working format).

#### **bfp\_CONVERT\_FROM\_UI 64( $x$ )**

$x$  is an integer value represented in unsigned doubleword integer format.

Return  $x$  in the binary floating-point working format.

result sign is initialized to 0.  
 result exponent is initialized to 0.  
 result signifi cand is initialized to 0.  
 result class.SNaN is initialized to 0.  
 result class.QNaN is initialized to 0.  
 result class.Infinity is initialized to 0.  
 result class.Zero is initialized to 0.  
 result class.Denormal is initialized to 0.  
 result class.Normal is initialized to 0.

If  $x$  is equal to 0x0000\_0000\_0000\_0000, do the following.  
 result class.Zero is set to 1.

Otherwise, do the following.

result class.Normal is set to 1.  
 result sign is set to 0.  
 result exponent is set to the value 64.  
 Bits 0:64 of result signifi cand is set to the value of  $x$  zero-extended to 65 bits.

If bit 0 of result signifi cand is equal to 0, result signifi cand is shifted left until bit 0 of result signifi cand is equal to 1 and result exponent is decremented by the number of bits result signifi cand is shifted.

Return result (i.e., the value  $x$  in the binary floating-point working format).

#### **bfp\_CONVERT\_FROM\_UI 128( $x$ )**

$x$  is a 128-bit unsigned integer value.

result sign is initialized to 0.

resul t. exponent is initialized to 0.  
 resul t. si gni fi cand is initialized to 0.  
 resul t. cl ass. SNaN is initialized to 0.  
 resul t. cl ass. QNaN is initialized to 0.  
 resul t. cl ass. Infi ni ty is initialized to 0.  
 resul t. cl ass. Zero is initialized to 0.  
 resul t. cl ass. Denormal is initialized to 0.  
 resul t. cl ass. Normal is initialized to 0.

If  $x$  is equal to 0x0000\_0000\_0000\_0000\_0000\_0000\_0000\_0000, do the following.

resul t. cl ass. Zero is set to 1.

Otherwise, do the following.

resul t. cl ass. Normal is set to 1.

resul t. si gn is set to 0.

resul t. exponent is set to the value 128.

Bits 0:128 of resul t. si gni fi cand are set to the value of  $x$  zero-extended to 129 bits.

If bit 0 of resul t. si gni fi cand is equal to 0,

resul t. si gni fi cand is shifted left until bit 0 of resul t. si gni fi cand is equal to 1 and resul t. exponent is decremented by the number of bits resul t. si gni fi cand is shifted.

Return resul t (i.e., the value  $x$  in the binary floating-point working format).

#### **bfp\_DENORM( $x$ , $y$ )**

$x$  is an integer value specifying the target format's  $E_{min}$  value.

$y$  is a binary floating-point value that is represented in the binary floating-point working format.

If  $y$ . exponent is less than  $E_{min}$ , let  $sh\_cnt$  be the value  $E_{min} - y$ . exponent.

Otherwise, let  $sh\_cnt$  be the value 0.

$y$ . si gni fi cand, having unbounded precision, is shifted right by  $sh\_cnt$  bits.

$y$ . exponent is incremented by  $sh\_cnt$ .

Return  $y$  in the binary floating-point working format.

#### **bfp\_DIVIDE( $x$ , $y$ )**

$x$  is a binary floating-point value that is represented in the binary floating-point working format.

$y$  is a binary floating-point value that is represented in the binary floating-point working format.

If  $x$  or  $y$  is an SNaN,  $vxsnan\_flag$  is set to 1.

Otherwise, if  $x$  and  $y$  are infinities,  $vxidi\_flag$  is set to 1.

Otherwise, if  $x$  and  $y$  are zeros,  $vxzdz\_flag$  is set to 1.

Otherwise, if  $x$  is a finite value and  $y$  is a zero,  $zx\_flag$  is set to 1.

If  $x$  is a QNaN, return  $x$ .

Otherwise, if  $x$  is an SNaN, return  $x$  represented as a QNaN.

Otherwise, if  $y$  is a QNaN, return  $y$ .

Otherwise, if  $y$  is an SNaN, return  $y$  represented as a QNaN.

Otherwise, if  $x$  and  $y$  are infinities, return the standard QNaN.

Otherwise, if  $x$  and  $y$  are zeros, return the standard QNaN.

Otherwise, if  $y$  is a zero, return infinity, having the sign of the exclusive-OR of the signs of  $x$  and  $y$ .

Otherwise, return the normalized quotient of  $x \div y$ , having unbounded range and precision.

#### **bfp\_INFINITY**

The value +Infinity represented in the binary floating-point working format.

#### **bfp\_INITIALIZE( $x$ )**

Let  $x$ . si gn be set to 0.

Let x. exponent be set to 0.  
 Let x. signifi cand be set to 0.  
 Let x. class. SNaN be set to 0.  
 Let x. class. QNaN be set to 0.  
 Let x. class. Infinity be set to 0.  
 Let x. class. Zero be set to 0.  
 Let x. class. Denormal be set to 0.  
 Let x. class. Normal be set to 0.

Return x.

#### **bfp\_MULTIPLY(x, y)**

x is a binary floating-point value represented in the binary floating-point working format.  
 y is a binary floating-point value represented in the binary floating-point working format.

If x or y is an SNaN, vxsnan\_flg is set to 1.  
 Otherwise, if x is an infinity and y is a zero, vximz\_flg is set to 1.  
 Otherwise, if x is a zero and y is an infinity, vximz\_flg is set to 1.

If x is a QNaN, return x.  
 Otherwise, if x is an SNaN, return x represented as a QNaN.  
 Otherwise, if y is a QNaN, return y.  
 Otherwise, if y is an SNaN, return y represented as a QNaN.  
 Otherwise, if x is an infinity and y is a zero, return the standard QNaN.  
 Otherwise, if x is a zero and y is an infinity, return the standard QNaN.  
 Otherwise, return the normalized product of  $x \times y$ , having unbounded range and precision.

#### **bfp\_MULTIPLY\_ADD(x, y, z)**

x is a binary floating-point value represented in the binary floating-point working format.  
 y is a binary floating-point value represented in the binary floating-point working format.  
 z is a binary floating-point value represented in the binary floating-point working format.

If x, y, or z is an SNaN, vxsnan\_flg is set to 1.  
 Otherwise, if x is an infinity and y is a zero, vximz\_flg is set to 1.  
 Otherwise, if x is a zero and y is an infinity, vximz\_flg is set to 1.  
 Otherwise, if z and the product of  $x \times y$  are Infinity values having opposite signs, vxisi\_flg is set to 1.

If x is a QNaN, return x.  
 Otherwise, if x is an SNaN, return x represented as a QNaN.  
 Otherwise, if z is a QNaN, return z.  
 Otherwise, if z is an SNaN, return z represented as a QNaN.  
 Otherwise, if y is a QNaN, return y.  
 Otherwise, if y is an SNaN, return y represented as a QNaN.  
 Otherwise, if x is an infinity and y is a zero, return the standard QNaN.  
 Otherwise, if x is a zero and y is an infinity, return the standard QNaN.  
 Otherwise, if z and the product of  $x \times y$  are Infinity values having opposite signs, return the standard QNaN.  
 Otherwise, return the sum of z and the normalized product of  $x \times y$ , having unbounded range and precision.

#### **bfp\_NEGATE(x)**

x is a binary floating-point value that is represented in the binary floating-point working format.

If x is not a NaN, return x with its sign complemented. Otherwise, return x.

#### **bfp\_NMAX\_BFLOAT16**

Return the largest positive normalized bfloat16 floating-point value (i.e.,  $2^{128} - 2^{128-8}$ ) represented in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFLOAT16(0x7F7F)
```

**bfp\_NMAX\_BFP16**

Return the largest positive normalized half-precision floating-point value (i.e.,  $2^{16}-2^{16-11}$ ), represented in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFP16(0x7BFF)
```

**bfp\_NMAX\_BFP64**

Return the largest finite double-precision floating-point value (i.e.,  $2^{1024}-2^{1024-53}$ ) in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFP64(0x7FEF_FFFF_FFFF_FFFF)
```

**bfp\_NMAX\_BFP80**

Return the largest finite double-extended-precision floating-point value (i.e.,  $2^{16384}-2^{16384-65}$ ) in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFP80(0x7FFE_FFFF_FFFF_FFFF_FFFF)
```

**bfp\_NMAX\_BFP128**

Return the largest finite quad-precision value (i.e.,  $2^{16384}-2^{16384-113}$ ) in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFP128(0x7FFE_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF_FFFF)
```

**bfp\_NMIN\_BFLOAT16**

Return the smallest positive normalized bfloat16 floating-point value (i.e.,  $2^{-126}$ ), represented in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFLOAT16(0x0080)
```

**bfp\_NMIN\_BFP16**

Return the smallest positive normalized half-precision floating-point value,  $2^{-14}$ , represented in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFP16(0x0400)
```

**bfp\_NMIN\_BFP64**

Return the smallest positive normalized double-precision floating-point value,  $2^{-1022}$ , represented in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFP64(0x0010_0000_0000_0000)
```

**bfp\_NMIN\_BFP80**

Return the smallest positive normalized double-extended-precision floating-point value,  $2^{-16382}$ , represented in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFP80(0x0001_0000_0000_0000_0000)
```

**bfp\_NMIN\_BFP128**

Return the smallest, positive, normalized quad-precision floating-point value,  $2^{-16382}$ , represented in the binary floating-point working format.

```
return bfp_CONVERT_FROM_BFP128(0x0001_0000_0000_0000_0000_0000_0000_0000)
```

**bfp\_QUI ET(x)**

x is a Signalling NaN.

Return x converted to a Quiet NaN with x.cl ass. QNaN set to 1 and x.cl ass. SNaN set to 0.

**bfp\_ROUND\_CEIL(p, x)**

$x$  is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.  $x$  must be rounded as presented, without prenormalization.

$p$  is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return the smallest floating-point number having unbounded exponent range and a significand with a width of  $p$  bits that is greater or equal in value to  $x$ .

$inc\_flag$  is set to 1 if the magnitude of the value returned is greater than  $x$ .

$xx\_flag$  is set to 1 if the value returned is not equal to  $x$ .

**bfp\_ROUND\_FLOOR(p, x)**

$x$  is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision. The value must be rounded as presented, without prenormalization.

$p$  is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return the largest floating-point number having unbounded exponent range and a significand with a width of  $p$  bits that is lesser or equal in value to  $x$ .

$inc\_flag$  is set to 1 if the magnitude of the value returned is greater than  $x$ .

$xx\_flag$  is set to 1 if the value returned is not equal to  $x$ .

**bfp\_ROUND\_TO\_BFLOAT16(rmode, x)**

$x$  is a normalized binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.

$rmode$  is a 2-bit integer value specifying one of four rounding modes.

$rmode=0b00$	Round to Nearest Even
$rmode=0b01$	Round towards Zero
$rmode=0b10$	Round towards +Infinity
$rmode=0b11$	Round towards -Infinity

If  $x$  is a QNaN, Infinity, or Zero, return  $x$ . Otherwise, if  $x$  is an SNaN, set  $vxsnan\_flag$  to 1 and return the corresponding QNaN representation of  $x$ . Otherwise, return the value  $x$  rounded to bfloat16 format's exponent range and significand precision represented in the floating-point working format using the rounding mode specified by  $rmode$ .

```

if x.class.SNaN then do
    vxsnan_flag ← 1

return(result)

```

**bfp\_ROUND\_TO\_BFP16\_CEIL(x)**

x is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.

Return the smallest floating-point number having unbounded exponent range but half-precision significand precision that is greater or equal in value to x.

If the magnitude of the value returned is greater than  $x$ , `inc_flag` is set to 1.

If the value returned is not equal to  $x$ , `xx_flag` is set to 1.

#### **bfp\_ROUND\_TO\_BFP16\_FLOOR( $x$ )**

$x$  is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.

Return the largest floating-point number having unbounded exponent range but half-precision significand precision that is lesser or equal in value to  $x$ .

If the magnitude of the value returned is greater than  $x$ , `inc_flag` is set to 1.

If the value returned is not equal to  $x$ , `xx_flag` is set to 1.

#### **bfp\_ROUND\_TO\_BFP16\_NEAR\_EVEN( $x$ )**

$x$  is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.

Return the floating-point number having unbounded exponent range but half-precision significand precision that is nearest in value to  $x$  (in case of a tie, the floating-point number having unbounded exponent range but half-precision significand precision with the least-significant bit equal to 0 is used).

If the magnitude of the value returned is greater than  $x$ , `inc_flag` is set to 1.

If the value returned is not equal to  $x$ , `xx_flag` is set to 1.

#### **bfp\_ROUND\_TO\_BFP16\_TRUNC( $x$ )**

$x$  is a normalized floating-point value represented in the binary floating-point working format, having unbounded exponent range and significand precision.

Return the largest floating-point number having unbounded exponent range but half-precision significand precision that is lesser or equal in value to  $x$  if  $x > 0$ , or the smallest floating-point number having unbounded exponent range but half-precision significand precision that is greater or equal in value to  $x$  if  $x < 0$ .

If the magnitude of the value returned is greater than  $x$ , `inc_flag` is set to 1.

If the value returned is not equal to  $x$ , `xx_flag` is set to 1.

#### **bfp\_ROUND\_TO\_BFP32\_SIGNIFICAND( $x$ )**

$x$  is a normalized binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.

Return the value  $x$  rounded to 24-bit significand precision under control of the rounding mode specified in `RN`, retaining unbounded exponent range, represented in the binary floating-point working format.

```
rmode ← FPSCR.RN
```

```
if x.class.QNaN | x.class.Infinity | x.class.Zero then return x
```

```
if rmode=0b00 then r ← bfp_ROUND_NEAR_EVEN(24, x)

**bfp\_ROUND\_TO\_INTEGER(rmode, x)**

x is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.

If x is an SNaN, vxshnan\_flag is set to 1.

If x is a QNaN, return x.

Otherwise, if x is an SNaN, return x represented as a QNaN.

Otherwise, if x is an Infinity, return x.

Otherwise, do the following.

```

If rmode=0b000 (Round to Nearest Even),
    return the double-precision floating-point integer value that is nearest in value to x (in case of a tie, the
    double-precision floating-point integer value with the least-significant bit equal to 0 is used).

If rmode=0b001 (Round towards Zero),
    return the largest double-precision floating-point integer value that is lesser or equal in value to x if x>0,
    or the smallest double-precision floating-point integer value that is greater or equal in value to x if x<0.

If rmode=0b010 (Round towards +Infinity),
    return the smallest double-precision floating-point integer value that is greater or equal in value to x.

If rmode=0b011 (Round towards -Infinity),
    return the largest double-precision floating-point integer value that is lesser or equal in value to x.

If rmode=0b100 (Round to Nearest Away),
    return the double-precision floating-point integer value that is nearest in value to x (in case of a tie, the
    double-precision floating-point integer value that is furthest away from 0 is used).

```

inc\_flag is set to 1 if the magnitude of the value returned is greater than x.

xx\_flag is set to 1 if the value returned is not equal to x.

**bfp\_ROUND\_ODD(p, x)**

x is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision. x must be rounded as presented, without prenormalization.

p is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return x with bit p-1 of the significand set to 1 if any of the bits to the right of bit p-1 of the significand of x are equal to 1, and all bits to the right of bit p-1 of the significand of the value returned are set to 0. Otherwise return x with all bits to the right of bit p-1 of the significand set to 0.

inc\_flag is set to 1 if the magnitude of the value returned is greater than x.

xx\_flag is set to 1 if the value returned is not equal to x.

**bfp\_ROUND\_NEAR\_EVEN(p, x)**

x is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision. x must be rounded as presented, without prenormalization.

$p$  is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return the floating-point number having unbounded exponent range and a significand with a width of  $p$  bits that is nearest in value to  $x$  (in case of a tie, the floating-point number having unbounded exponent range and a  $p$ -bit significand with the least-significant bit equal to 0 is used).

$inc\_flag$  is set to 1 if the magnitude of the value returned is greater than  $x$ .

$xx\_flag$  is set to 1 if the value returned is not equal to  $x$ .

#### **bfp\_ROUND\_TRUNC( $p, x$ )**

$x$  is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.  $x$  must be rounded as presented, without prenormalization.

$p$  is an integer value specifying the precision (i.e., number of bits) the significand is rounded to.

Return the largest floating-point number having unbounded exponent range and a significand with a width of  $p$  bits that is lesser or equal in value to  $x$  if  $x > 0$ , or the smallest floating-point number having unbounded exponent range but double-precision significand precision that is greater or equal in value to  $x$  if  $x < 0$ .

$inc\_flag$  is set to 1 if the magnitude of the value returned is greater than  $x$ .

$xx\_flag$  is set to 1 if the value returned is not equal to  $x$ .

#### **bfp\_SQUARE\_ROOT( $x$ )**

$x$  is a binary floating-point value that is represented in the binary floating-point working format and has unbounded exponent range and significand precision.

If  $x$  is an SNaN,  $vxsnan\_flag$  is set to 1.

Otherwise, if  $x$  is negative and non-zero,  $vxsqrt\_flag$  is set to 1.

If  $x$  is a QNaN, return  $x$ .

Otherwise, if  $x$  is an SNaN, return  $x$  represented as a QNaN.

Otherwise, if  $x$  is -Zero, return -Zero.

Otherwise, if  $x$  is negative, return the standard QNaN.

Otherwise, return the normalized square root of  $x$ , represented in the binary floating-point working format, having unbounded range and precision.

#### **bfp16\_CONVERT\_FROM\_BFP( $x$ )**

$x$  is a floating-point value represented in the binary floating-point working format.

If  $x$ .class.QNaN=1, do the following.

Bit 0 of result is set to the value of  $x$ .sign.

Bits 1:5 of result are set to the value 0b11111.

Bits 6:15 of result are set to the value of bits 1:10 of  $x$ .significand.

Otherwise, if  $x$ .class.Infinity=1, do the following.

Bit 0 of result is set to the value of  $x$ .sign.

Bits 1:5 of result are set to the value 0b11111.

Bits 6:15 of result are set to 0.

Otherwise, if  $x$ .class.Zero=1, do the following.

Bit 0 of result is set to the value of  $x$ .sign.

Bits 1:15 of result are set to 0.

Otherwise, if  $x$ .exponent is less than -14 and  $UE=0$ , do the following.

Bit 0 of result is set to the value of  $x$ .sign.

$sh\_cnt$  is set to the difference,  $-14 - x$ .exponent.

Bits 1:5 of result are set to 0b00000.

Bits 6:15 of result are set to bits 1:10 of  $x$ .significand shifted right by  $sh\_cnt$  bits.

Otherwise, if  $x$ .exponent is less than -14 and  $UE=1$ , result is undefined.  
 Otherwise, if  $x$ .exponent is greater than 15 and  $OE=1$ , result is undefined.

Otherwise, do the following.

- Bit 0 of result is set to the value of  $x$ .sign.
- Bits 1:5 of result are set to the sum,  $x$ .exponent + 15.
- Bits 6:15 of result are set to bits 1:10 of  $x$ .significand.

Return result.

#### **bfp32\_ABSOLUTE(x)**

$x$  is a floating-point value represented in single-precision format.

Return  $x$  with its sign set to 0.

#### **bfp32\_CONVERT\_FROM\_BFP(x)**

$x$  is a floating-point value represented in the binary floating-point working format.

If  $x$ .class.QNaN=1, do the following.

- Bit 0 of result is set to the value of  $x$ .sign.
- Bits 1:8 of result are set to the value 0b1111\_1111.
- Bits 9:31 of result are set to the value of bits 1:23 of  $x$ .significand.

Otherwise, if  $x$ .class.Infinity=1, do the following.

- Bit 0 of result is set to the value of  $x$ .sign.
- Bits 1:9 of result are set to the value 0b1111\_1111.
- Bits 9:31 of result are set to 0.

Otherwise, if  $x$ .class.Zero=1, do the following.

- Bit 0 of result is set to the value of  $x$ .sign.
- Bits 1:31 of result are set to 0.

Otherwise, if  $x$ .exponent is less than -126 and  $UE=0$ , do the following.

- Bit 0 of result is set to the value of  $x$ .sign.
- sh\_cnt is set to the difference,  $-126 - x$ .exponent.
- Bits 1:8 of result are set to 0b0000\_0000.
- Bits 9:31 of result are set to bits 1:23 of  $x$ .significand shifted right by sh\_cnt bits.

Otherwise, if  $x$ .exponent is less than -126 and  $UE=1$ , result is undefined.

Otherwise, if  $x$ .exponent is greater than 127 and  $OE=1$ , result is undefined.

Otherwise, do the following.

- Bit 0 of result is set to the value of  $x$ .sign.
- Bits 1:8 of result are set to the sum,  $x$ .exponent + 127.
- Bits 9:31 of result are set to bits 1:23 of  $x$ .significand.

Return result.

#### **bfp32\_CONVERT\_FROM\_BFP64(x)**

$x$  is a single-precision floating-point value in double-precision format.

Returns the value  $x$  in single-precision format.  $x$  must be representable in single-precision, or else result returned is undefined.  $x$  may require denormalization. No rounding is performed. If  $x$  is a SNaN, it is converted to a single-precision SNaN having the same payload as  $x$ .

```
sign ← x.bit[0]

Otherwise, return  $y$ .

#### **bfp128\_ABSOLUTE( $x$ )**

$x$  is a floating-point value represented in quad-precision format.

Return  $x$  with its sign set to 0.

#### **bfp128\_CONVERT\_FROM\_BFP( $x$ )**

$x$  is a quad-precision floating-point value that is represented in the binary floating-point working format.

If  $x$  is a QNaN,

the contents of bit 0 of result are set to the value of  $x$ . sign,

the contents of bits 1:15 of result are set to the value 0b111\_1111\_1111\_1111, and

the contents of bits 16:127 of result are set to the value of bits 1:112 of  $x$ . significand.

Otherwise, if  $x$  is a Zero,

the contents of bit 0 of result are set to the value of  $x$ . sign, and

the contents of bits 1:15 of result are set to the value 0b000\_0000\_0000\_0000, and

the contents of bits 16:127 of result are set to the value 0x0000\_0000\_0000\_0000\_0000\_0000\_0000\_0000.

Otherwise, if  $x$  is an Infinity,

the contents of bit 0 of result are set to the value of  $x$ . sign,

the contents of bits 1:15 of result are set to the value 0b111\_1111\_1111\_1111, and

the contents of bits 16:127 of result are set to the value 0x0000\_0000\_0000\_0000\_0000\_0000\_0000\_0000.

Otherwise, do the following.

If the exponent of  $x$  is less than -16382,

the contents of bit 0 of result are set to the value of  $x$ . sign,

the contents of bits 1:15 of result are set to the value 0b000\_0000\_0000\_0000, and

the contents of bits 16:127 of result are set to the value of bits 1:112 of the significand of  $x$  shifted right by  $N$  bits, where  $N$  is the value -16382 subtracted by the value of the exponent of  $x$ .

Otherwise,

the contents of bit 0 of result are set to the value of  $x$ . sign,

the contents of bits 1:15 of result are set to the sum of the exponent of  $x$  and 16383, and

the contents of bits 16:127 of result are set to the value of bits 1:112 of the significand of  $x$ .

Return result (i.e.,  $x$  in quad-precision format).

#### **bfp128\_NEGATE( $x$ )**

$x$  is a floating-point value represented in quad-precision format.

Return  $x$  with its sign complemented.

#### **bfp128\_NEGATIVE\_ABSOLUTE( $x$ )**

$x$  is a floating-point value represented in quad-precision format.

Return  $x$  with its sign set to 1.

#### **si\_64\_CONVERT\_FROM\_BFP( $x$ )**

$x$  is an integer value represented in the binary floating-point working format.

Return the value  $x$  in signed doubleword integer format.

**ui 64\_CONVERT\_FROM\_BFP(x)**

x is an integer value represented in the binary floating-point working format.

Return the value x in 64-bit unsigned integer format.

**bfp128\_MAXIMUM\_TYPE\_C(x, y)**

x is a binary floating-point value that is represented in quad-precision format.

y is a binary floating-point value that is represented in quad-precision format.

If x or y is an SNaN, vxsnan\_flag is set to 1.

If x or y is a NaN, return y.

Otherwise, if x is greater than y, return x.

Otherwise, return y.

**bfp128\_MAXIMUM\_TYPE\_J(x, y)**

x is a binary floating-point value that is represented in quad-precision format.

y is a binary floating-point value that is represented in quad-precision format.

If x or y is an SNaN, vxsnan\_flag is set to 1.

If x is a NaN, return x.

Otherwise, if y is a NaN, return y.

Otherwise, if both x and y are Zero and either x or y is a +Zero, return +Zero.

Otherwise, if both x and y are Zero and both x and y are -Zero, return -Zero.

Otherwise, if x is greater than y, return x.

Otherwise, return y.

**bfp128\_MINIMUM\_TYPE\_C(x, y)**

x is a binary floating-point value that is represented in quad-precision format.

y is a binary floating-point value that is represented in quad-precision format.

If x or y is an SNaN, vxsnan\_flag is set to 1.

If x or y is a NaN, return y.

Otherwise, if x is less than y, return x.

Otherwise, return y.

**bfp128\_MINIMUM\_TYPE\_J(x, y)**

x is a binary floating-point value that is represented in quad-precision format.

y is a binary floating-point value that is represented in quad-precision format.

If x or y is an SNaN, vxsnan\_flag is set to 1.

If x is a NaN, return x.

Otherwise, if y is a NaN, return y.

Otherwise, if both x and y are Zero and either x or y is a -Zero, return -Zero.

Otherwise, if both x and y are Zero and both x and y are +Zero, return +Zero.

Otherwise, if x is less than y, return x.

Otherwise, return y.

**EXTZ32(x)**

Result of extending the b-bit value x on the left with 32-b zeros, forming a 32-bit value.

$b \leftarrow \text{LENGTH}(x)$

result.t.bit[0:31-b]  $\leftarrow$  0

result.t.bit[32-b:31]  $\leftarrow$  x

**EXTZ64(x)**

Result of extending the b-bit value x on the left with 64-b zeros, forming a 64-bit value.

```

b ← LENGTH(x)
result.t.bi t[0: 63-b] ← 0
result.t.bi t[64-b: 63] ← x

```

**EXTZ128(x)**

Result of extending the b-bit value x on the left with 128-b zeros, forming a 128-bit value.

```

b ← LENGTH(x)
result.t.bi t[0: 127-b] ← 0
result.t.bi t[128-b: 127] ← x

```

**fprf\_CLASS\_BFP16(x)**

x is a floating-point value represented in half-precision format.

Return the 5-bit code that specifies the sign and class of x.

```

Return 0b10001 if x is a Quiet NaN.
Return 0b01001 if x is a negative infinity.
Return 0b00101 if x is a positive infinity.
Return 0b10010 if x is a negative zero.
Return 0b00010 if x is a positive zero.
Return 0b11000 if x is a negative denormal value as represented in half-precision format.
Return 0b10100 if x is a positive denormal value as represented in half-precision format.
Return 0b01000 if x is a negative normal value as represented in half-precision format.
Return 0b00100 if x is a positive normal value as represented in half-precision format.

```

**fprf\_CLASS\_BFP32(x)**

x is a floating-point value represented in single-precision format.

Return the 5-bit code that specifies the sign and class of x.

```

Return 0b10001 if x is a Quiet NaN.
Return 0b01001 if x is a negative infinity.
Return 0b00101 if x is a positive infinity.
Return 0b10010 if x is a negative zero.
Return 0b00010 if x is a positive zero.
Return 0b11000 if x is a negative denormal value as represented in single-precision format.
Return 0b10100 if x is a positive denormal value as represented in single-precision format.
Return 0b01000 if x is a negative normal value as represented in single-precision format.
Return 0b00100 if x is a positive normal value as represented in single-precision format.

```

**fprf\_CLASS\_BFP64(x)**

x is a floating-point value represented in double-precision format.

Return the 5-bit code that specifies the sign and class of x.

```

Return 0b10001 if x is a Quiet NaN.
Return 0b01001 if x is a negative infinity.
Return 0b00101 if x is a positive infinity.
Return 0b10010 if x is a negative zero.
Return 0b00010 if x is a positive zero.
Return 0b11000 if x is a negative denormal value as represented in double-precision format.
Return 0b10100 if x is a positive denormal value as represented in double-precision format.
Return 0b01000 if x is a negative normal value as represented in double-precision format.
Return 0b00100 if x is a positive normal value as represented in double-precision format.

```

**fprf\_CLASS\_BFP128(x)**

x is binary floating-point value that is represented in quad-precision format.

Return the 5-bit characterization of the sign and class of x.

Return 0b10001 if x is a Quiet NaN.  
 Return 0b01001 if x is negative and an infinity.  
 Return 0b01000 if x is negative and a normal number.  
 Return 0b11000 if x is negative and a denormal number.  
 Return 0b10010 if x is negative and a zero.  
 Return 0b00010 if x is positive and a zero.  
 Return 0b10100 if x is positive and a denormal number.  
 Return 0b00100 if x is positive and a normal number.  
 Return 0b00101 if x is positive and an infinity.

**IsInf(x)**

Return 1 if x is an Infinity, otherwise return 0.

**IsNaN(x)**

Return 1 if x is either an SNaN or a QNaN, otherwise return 0.

**IsNeg(x)**

Return 1 if x is a negative, nonzero value, otherwise return 0.

**IsSNaN(x)**

Return 1 if x is an SNaN, otherwise return 0.

**IsZero(x)**

Return 1 if x is a Zero, otherwise return 0.

**reset\_xflags()**

vxsnan\_flag is set to 0.  
 vxi\_mz\_flag is set to 0.  
 vxi\_di\_flag is set to 0.  
 vxi\_si\_flag is set to 0.  
 vxzdz\_flag is set to 0.  
 vxsqrt\_flag is set to 0.  
 vxcvi\_flag is set to 0.  
 vxvc\_flag is set to 0.  
 ox\_flag is set to 0.  
 ux\_flag is set to 0.  
 xx\_flag is set to 0.  
 zx\_flag is set to 0.

**SetFX(x)**

x is one of the exception flags in the FPSCR.

If the contents of x is 0, FX and x are set to 1.

**si128\_CONVERT\_FROM\_BFP(x)**

x is an integer value represented in the binary floating-point working format.

If x is a NaN,

vxcvi\_flag is set to 1,  
 vxsnan\_flag is set to 1 if x is an SNaN, and  
 return 0x8000\_0000\_0000\_0000\_0000\_0000\_0000,

Otherwise, do the following.

Let rnd be the value x truncated to an integral value.

Let exponent be the unbiased exponent of rnd.

Let signifiand be the significand of rnd.

If rnd is greater than  $2^{127} - 1$ ,

vxcvi\_flag is set to 1, and  
return 0x7FFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF.

Otherwise, if rnd is less than  $-2^{127}$ ,  
vxcvi\_flag is set to 1, and  
return 0x8000\_0000\_0000\_0000\_0000\_0000\_0000\_0000.

Otherwise,  
xx\_flag is set to 1 if rnd is inexact,  
inc\_flag is set to 0,  
significand is shifted right by the difference 127-exponent with 0s shifted in,  
if rnd is negative, significand is negated, and  
return bits 0:127 of significand.

#### si 32\_CHOP(x)

x is a signed integer value.

Return the rightmost 32 bits of x in 32-bit signed integer format.

#### si 32\_CLAMP(x)

x is a signed integer value.

If x is greater than  $2^{31}-1$ , result is the value  $2^{31}-1$ , and SAT is set to 1.

Otherwise, if x is less than  $-2^{31}$ , result is the value  $-2^{31}$ , and SAT is set to 1.

Otherwise, result is x.

Return x in 32-bit signed integer format.

#### ui 128\_CONVERT\_FROM\_BFP(x)

x is an integer value represented in the binary floating-point working format.

If x is a NaN,  
vxcvi\_flag is set to 1,  
vxsnan\_flag is set to 1 if x is an SNaN, and  
return 0x0000\_0000\_0000\_0000\_0000\_0000\_0000\_0000,

Otherwise, do the following.  
Let rnd be the value x truncated to an integral value.

Let exponent be the unbiased exponent of rnd.  
Let significand be the significand of rnd.

If rnd is greater than  $2^{128}-1$ ,  
vxcvi\_flag is set to 1, and  
return 0xFFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF.

Otherwise, if rnd is less than 0,  
vxcvi\_flag is set to 1, and  
return 0x0000\_0000\_0000\_0000\_0000\_0000\_0000\_0000.

Otherwise,  
xx\_flag is set to 1 if rnd is inexact,  
inc\_flag is set to 0,  
significand is shifted right by the difference 127-exponent with 0s shifted in, and  
return bits 0:127 of significand.

## 7.6.3 VSX Instruction Descriptions

### Load VSX Scalar Doubleword DS-form

lxsdsd VRT,DS(RA)

57	VRT	RA	DS	2
0	6	11	16	30 31

### Prefix Load VSX Scalar Doubleword 8LS:D-form

plxsdsd VRT,D(RA),R

Prefix:

1	0	0	//	R	//	d0
0	6	8	9	11	12	14
31						

Suffix:

42	VRT	RA	d1
0	6	11	16
31			

if MSR.VSX=0 then VSX\_Unavailable()

if "lxsdsd" then

EA ← (RA|0) + EXTS64(DS||0b00)

if "plxsdsd" & R=0 then

EA ← (RA|0) + EXTS64(d0||d1)

if "plxsdsd" & R=1 then

EA ← CIA + EXTS64(d0||d1)

VSR[VRT+32].dword[0] ← MEM(EA, 8)

VSR[VRT+32].dword[1] ← 0x0000\_0000\_0000\_0000

Let XT be the value VRT + 32.

For **lxsdsd**, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value DS||0b00, sign-extended to 64 bits.

For **plxsdsd** with R=0, let the effective address (EA) be the sum of the contents of register RA, or the value 0 if RA=0, and the value d0||d1, sign-extended to 64 bits.

For **plxsdsd** with R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0||d1, sign-extended to 64 bits.

When Big-Endian byte ordering is employed, the contents of the doubleword in storage at address EA are placed into load\_data in such an order that;

- the contents of the byte in storage at address EA are placed into byte 0 of load\_data,
- the contents of the byte in storage at address EA+1 are placed into byte 1 of load\_data, and so forth until
- the contents of the byte in storage at address EA+7 are placed into byte 7 of load\_data. When Little-Endian byte ordering is employed, let load\_data be the contents of the doubleword in storage at address EA such that;
- the contents of the byte in storage at address EA are placed into byte 7 of load\_data,
- the contents of the byte in storage at address EA+1 are placed into byte 6 of load\_data, and so forth until
- the contents of the byte in storage at address EA+7 are placed into byte 0 of load\_data.

load\_data is placed into doubleword element 0 of VSR[VRT+32].

The contents of doubleword element 1 of VSR[VRT+32] are set to 0.

For **plxsdsd**, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

**Load VSX Scalar Single-Precision Indexed X-form**

lxsspx XT,RA,RB

if MSR.VSX=0 then VSX\_Unavailable()

EA ← ((RA=0) ? 0 : GPR[RA]) + GPR[RB]

load\_data ← MEM(EA, 4)  
 result ← bfp\_CONVERT\_FROM\_BFP32(MEM(EA, 4))  
 VSR[VRT+32].dword[0] ← bfp64\_CONVERT\_FROM\_BFP(result)  
 VSR[VRT+32].dword[1] ← 0x0000\_0000\_0000\_0000

Let XT be the value 32×TX + T.

Let EA be the sum of the contents of GPR[RA], or 0 if RA is equal to 0, and the contents of GPR[RB].

When Big-Endian byte ordering is employed, the contents of the word in storage at address EA are placed into load\_data in such an order that;

- the contents of the byte in storage at address EA are placed into byte 0 of load\_data,
- the contents of the byte in storage at address EA+1 are placed into byte 1 of load\_data,
- the contents of the byte in storage at address EA+2 are placed into byte 2 of load\_data, and
- the contents of the byte in storage at address EA+3 are placed into byte 3 of load\_data.

When Little-Endian byte ordering is employed, the contents of the word in storage at address EA are placed into load\_data in such an order that;

- the contents of the byte in storage at address EA are placed into byte 3 of load\_data,
- the contents of the byte in storage at address EA+1 are placed into byte 2 of load\_data,
- the contents of the byte in storage at address EA+2 are placed into byte 1 of load\_data, and
- the contents of the byte in storage at address EA+3 are placed into byte 0 of load\_data.

load\_data, interpreted as a single-precision floating-point value, is placed in doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

**Load VSX Vector Paired DQ-form**

lxvp                    XTp,DQ(RA)

**Prefix Load VSX Vector Paired 8LS:D-form**

plxvp                    XTp,D(RA),R

Prefix:

Suffix:

if MSR.VSX=0 then VSX\_Unavailable()

EAbase ← (RA=0) ? 0 : GPR[RA]

if "lxvp" then

EAdisp ← EXTS64(DQ || 0b0000)

if "plxvp" then

EAdisp ← EXTS64(d0 || d1)

if "lxvp" then EA ← EAbase + EAdisp

if "plxvp" &amp; R=0 then EA ← EAbase + EAdisp

if "plxvp" &amp; R=1 then EA ← CIA + EAdisp

load\_data ← MEM(EA, 32)

VSR[32×TX+2×Tp] ← load\_data.bit[ 0:127]

VSR[32×TX+2×Tp+1] ← load\_data.bit[128:255]

Let XTp be the value 32×TX + 2×Tp (i.e., only even values of XTp can be encoded in the instruction).

Let EAbase be the contents of GPR[RA], or 0 if RA=0.

For *lxvp*, let the effective address (EA) be the sum of the integer value in GPR[RA], or 0 if RA=0, and the value DQ||0b0000, sign-extended to 64 bits.

For *plxvp*, if R=0, let the effective address (EA) be the sum of the integer value in GPR[RA], or 0 if RA=0, and the value d0||d1, sign-extended to 64 bits.

For *plxvp*, if R=1, let the effective address (EA) be the sum of the address of the instruction and the value d0||d1, sign-extended to 64 bits.

**VSR Data Layout for [p]lxvp**

When Big-Endian byte ordering is employed, the contents of the octword in storage at address EA are placed into load\_data in such an order that;

- the contents of the byte in storage at address EA are placed into byte 0 of load\_data,
- the contents of the byte in storage at address EA+1 are placed into byte 1 of load\_data, and so forth until
- the contents of the byte in storage at address EA+31 are placed into byte 31 of load\_data.

When Little-Endian byte ordering is employed, the contents of the octword in storage at address EA are placed into load\_data in such an order that;

- the contents of the byte in storage at address EA are placed into byte 31 of load\_data,
- the contents of the byte in storage at address EA+1 are placed into byte 30 of load\_data, and so forth until
- the contents of the byte in storage at address EA+31 are placed into byte 0 of load\_data.

Bits 0-127 of load\_data are placed into VSR[XTp].

Bits 128-255 of load\_data is placed into VSR[XTp+1].

For *plxvp*, if R is equal to 1 and RA is not equal to 0, the instruction form is invalid.

**Special Registers Altered**

None

**Store VSX Vector with Length Left-justified X-form**

stxvll XS,RA,RB

if SX=0 & MSR.VSX=0 then VSX\_Unavailable()  
 if SX=1 & MSR.VEC=0 then Vector\_Unavailable()

EA ← (RA=0) ? 0 : GPR[RA]

nb ← EXTZ(GPR[RB].bit[0:7])  
 if nb>16 then nb ← 16

if nb>0 then do i = 0 to nb-1  
 MEM(EA+i,1) ← VSR[32×SX+S].byte[i]  
 end

Let XS be the value 32×SX + S.

Let the effective address (EA) be the contents of GPR[RA], or 0 if RA is equal to 0.

Let nb be the unsigned integer value in bits 0:7 of GPR[RB].

If nb is equal to 0, the storage access is not performed.

Otherwise, do the following.

If nb less than 16, the contents of the leftmost nb bytes of VSR[XS] are placed in storage starting at address EA.

Otherwise, the contents of VSR[XS] are placed into the quadword in storage at address EA.

Data is stored from VSR[XS] into storage in Big-Endian byte ordering (i.e., the contents of byte element 0 of VSR[XS] are placed into the byte in storage at address EA, the contents of byte element 1 of VSR[XS] are placed into the byte in storage at address EA+1, and so forth).

If the contents of bits 8:63 of GPR[RB] are not equal to 0, the results are boundedly undefined.

**Special Registers Altered:**

- Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
- Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	The double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
A(x, y)	Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision. Note: If $x = -y$ , v is considered to be an exact-zero-difference result (Rezd).
Q(x)	Return a QNaN with the payload of x.
v	The intermediate result having unbounded significand precision and unbounded exponent range.

**Explanation:**

- This situation cannot occur.
- v The precise intermediate result defined in the instruction having unbounded range and precision.
- den(x) The significand of x is shifted right by the amount of the difference between the target rounding precision  $E_{\text{mi } n}$  and the unbiased exponent of x. The unbiased exponent of the denormalized value is  $E_{\text{mi } n}$ . The significand of the denormalized value has unbounded significand precision.
  - $E_{\text{mi } n} = -16382$  (quad-precision)
  - $E_{\text{mi } n} = -16382$  (double-extended-precision)
  - $E_{\text{mi } n} = -1022$  (double-precision)
  - $E_{\text{mi } n} = -126$  (single-precision)
- Rezd Exact-zero-difference result. Applies only to add operations involving source operands having the same magnitude and different signs or subtract operations involving source operands having the same magnitude and same signs. Whether +Zero or -Zero is returned is controlled by the setting of the rounding mode in RN, even when the rounding mode is overridden to Round to Odd.
- rnd(x) The significand of x is rounded to the target rounding precision according to the rounding mode specified in FPSCR. RN. Exponent range of the rounded result is unbounded. See Section 7.3.2.6.
- $N_{\text{max}}$  Largest (in magnitude) representable normalized number in the target rounding precision format.
  - $N_{\text{max}} = \pm 2^{+16383} \times 1.\text{FFFFFFFFFFFFFFFFFFFFFFFF}$  (quad-precision)
  - $N_{\text{max}} = \pm 2^{+16383} \times 1.\text{FFFFFFFFFFFFFFFF000000000000}$  (double-extended-precision)
  - $N_{\text{max}} = \pm 2^{+1023} \times 1.\text{FFFFFFFFFFFFFFFF0000000000000000}$  (double-precision)
  - $N_{\text{max}} = \pm 2^{+127} \times 1.\text{FFFFFF000000000000000000000000}$  (single-precision)
- $N_{\text{mi } n}$  Smallest (in magnitude) representable normalized number in the target rounding precision format.
  - $N_{\text{mi } n} = \pm 2^{-16382} \times 1.000000000000000000000000000000$  (quad-precision)
  - $N_{\text{mi } n} = \pm 2^{-16382} \times 1.000000000000000000000000000000$  (double-extended-precision)
  - $N_{\text{mi } n} = \pm 2^{-1022} \times 1.000000000000000000000000000000$  (double-precision)
  - $N_{\text{mi } n} = \pm 2^{-126} \times 1.000000000000000000000000000000$  (single-precision)
- ul p Least significant bit in the target precision format's significand (Unit in the Last Position).

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src2 is added<sup>[1]</sup> to src1, producing a sum having unbounded range and precision.

The sum is normalized<sup>[2]</sup>.

See Table 64, “Actions for xsaddsp,” on page 673.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

**Special Registers Altered**

```
FPRF FR FI
FX OX UX XX VXSNAN VXISI
```

**Programming Note**

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

**VSR Data Layout for xsaddsp**

- Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
- Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	The double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
A(x, y)	Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision. Note: If $x = -y$ , v is considered to be an exact-zero-difference result (Rezd).
Q(x)	Return a QNaN with the payload of x.
v	The intermediate result having unbounded significand precision and unbounded exponent range.

**Table 64.Actions for xsaddsp**

 VSR[VRT+32] ← result  
 FPSCR.FPRF ← fprf\_CLASS\_BFP128(result)  
 end  
 FPSCR.FR ← (vx\_flag=0) & inc\_flag  
 FPSCR.FI ← (vx\_flag=0) & xx\_flag

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1 or src2 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src1 and src2 are Infinity values having opposite signs, an Invalid Operation exception occurs and VXISI is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src2 is a Quiet NaN, the result is src2.

Otherwise, if src1 and src2 are Infinity values having opposite signs, the result is the default Quiet NaN<sup>1</sup>.

Otherwise, do the following.

The normalized sum of src2 added to src1 is produced with unbounded significand precision and exponent range.

See Table 65, “Actions for xsaddqp[o],” on page 675.

If the intermediate result is *Tiny* (i.e., the unbiased exponent is less than -16382) and UE=0, the significand is shifted right N bits, where N is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If R0=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. The intermediate result is rounded to quad-precision using the specified rounding mode.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

**Special Registers Altered:**

	QNaN	v ← src1								v ← src1 vxsnan_flg ← 1
SNaN	v ← quiet(src1) vxsnan_flg ← 1									

**Explanation:**

src1     The quad-precision floating-point value in VSR[VRA+32].

src2     The quad-precision floating-point value in VSR[VRB+32].

dNaN     Default quiet NaN (0x7FFF\_8000\_0000\_0000\_0000\_0000).

NZF     Nonzero finite number.

Rezd     Exact-zero-difference result (addition of two finite numbers having same magnitude and opposite signs).

add(x, y)     The floating-point value y is added<sup>1</sup> to the floating-point value x. Return the normalized<sup>2</sup> sum, having unbounded significand precision and exponent range.

          When x = -y, v is considered to be an exact-zero-difference result (Rezd).

quiet(x)     Convert x to the corresponding Quiet NaN by setting the most significant fraction bit to 1.

v         The intermediate result having unbounded significand precision and unbounded exponent range.

**Table 65. Actions for xsaddqp[o]**

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate difference.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

Let XT be the value  $32 \times TX + T$ .

Let XB be the value  $32 \times BX + B$ .

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src is an SNaN, the result is the half-precision representation of that SNaN converted to a QNaN.

Otherwise, if src is a QNaN, the result is the half-precision representation of that QNaN.

Otherwise, if src is an Infinity, the result is the half-precision representation of Infinity with the same sign as src.

Otherwise, if src is a Zero, the result is the half-precision representation of Zero with the same sign as src.

Otherwise, the result is the half-precision representation of src rounded to half-precision using the rounding mode specified by RN.

The result is zero-extended and placed into doubleword element 0 of VSR[XT].

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in half-precision. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

#### Special Registers Altered:

FPRF FR FI

FX VXSNAN OX UX XX

#### Programming Note

This instruction can be used to operate on a single-precision source operand.

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

if MSR.VSX=0 then VSX\_Unavailable()

reset\_xflags()

src ← bfp\_CONVERT\_FROM\_BFP64(VSR[32×BX+B].dword[0])  
 result ← bfp32\_CONVERT\_FROM\_BFP(src)

VSR[32×TX+T].word[0] ← result  
 VSR[32×TX+T].word[1] ← result  
 VSR[32×TX+T].word[2] ← 0x0000\_0000  
 VSR[32×TX+T].word[3] ← 0x0000\_0000

Let XT be the value 32×TX + T.  
 Let XB be the value 32×BX + B.

Let src be the single-precision floating-point value in doubleword element 0 of VSR[XB] represented in double-precision format.

src is placed into word elements 0 and 1 of VSR[XT] in single-precision format.

The contents of word elements 2 and 3 of VSR[XT] are set to 0.

**Special Registers Altered**  
 None

**Programming Note**

If x is not representable in single-precision, some exponent and/or significand bits will be discarded, likely producing undesirable results. The low-order 29 bits of the significand of x are discarded, more if the unbiased exponent of x is less than -126 (i.e., denormal). Finite values of x having an unbiased exponent less than -150 will return a result of Zero. Finite values of x having an unbiased exponent greater than +127 will result in discarding significant bits of the exponent. SNaN inputs having no significant bits in the upper 23 bits of the significand will return Infinity as the result. No status is set for any of these cases.

**Programming Note**

*xscvdpspn* should be used to convert a scalar double-precision value to vector single-precision format.  
*xscvdpspn* should be used to convert a scalar single-precision value to vector single-precision format.

**Programming Note**

See the Programming Note for the *xscvdpspn* instruction.

**Programming Note**

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

Let XT be the value  $32 \times TX + T$ .

Let XB be the value  $32 \times BX + B$ .

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src is a NaN, the result is the value 0x8000\_0000\_0000\_0000 and VXCVI is set to 1. If src is an SNaN, VXSNAN is also set to 1.

Otherwise, src is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than  $2^{63}-1$ , the result is 0x7FFF\_FFFF\_FFFF\_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than  $-2^{63}$ , the result is 0x8000\_0000\_0000\_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit signed-integer format, and if the result is inexact (i.e., not equal to src), XX is set to 1.

If a trap-enabled invalid operation exception occurs,

- VSR[XT] and FPRF are not modified
- FR and FI are set to 0.

Otherwise,

- The result is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.
- FPRF is set to an undefined value.
- FR is set to indicate if the result was incremented when rounded.
- FI is set to indicate the result is inexact.

See Table 70.

#### Special Registers Altered

FPRF=0bUUUUU FR FI FX XX VXSNAN VXCVI

##### Programming Note

This instruction can be used to operate on a single-precision source operand.

##### Programming Note

**xscvdpsxds** rounds using Round towards Zero rounding mode. For other rounding modes, software must use a *Round to Double-Precision Integer* instruction that corresponds to the desired rounding mode, including **xsrpic** which uses the rounding mode specified by RN.

##### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

#### VSR Data Layout for xscvdpsxds

Let XB be the value  $32 \times BX + B$ .

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src is a NaN, the result is the value 0x0000\_0000\_0000\_0000 and VXCVI is set to 1. If src is an SNaN, VXSNAN is also set to 1.

Otherwise, src is rounded to a floating-point integer using the rounding mode Round Toward Zero.

If the rounded value is greater than  $2^{64}-1$ , the result is 0xFFFF\_FFFF\_FFFF\_FFFF and VXCVI is set to 1.

Otherwise, if the rounded value is less than 0, the result is 0x0000\_0000\_0000\_0000 and VXCVI is set to 1.

Otherwise, the result is the rounded value converted to 64-bit unsigned-integer format, and if the result is inexact (i.e., not equal to src), XX is set to 1.

If a trap-enabled invalid operation exception occurs,

- VSR[XT] and FPRF are not modified
- FR and FI are set to 0.

Otherwise,

- The result is placed into doubleword element 0 of VSR[XT]. The contents of doubleword element 1 of VSR[XT] are set to 0.
- FPRF is set to an undefined value.
- FR is set to indicate if the result was incremented when rounded.
- FI is set to indicate the result is inexact.

See Table 72.

#### Special Registers Altered

FPRF=0bUUUUU FR FI FX XX VXSNAN VXCVI

##### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

##### Programming Note

This instruction can be used to operate on a single-precision source operand.

##### Programming Note

xscvdpuxds rounds using Round towards Zero rounding mode. For other rounding modes, software must use a *Round to Double-Precision Integer* instruction that corresponds to the desired rounding mode, including *xsrpic* which uses the rounding mode specified by RN.

Let XT be the value  $32 \times TX + T$ .

Let XB be the value  $32 \times BX + B$ .

Let src be the half-precision floating-point value in the rightmost halfword of doubleword element 0 of VSR[XB].

If src is an SNaN, the result is the double-precision representation of that SNaN converted to a QNaN.

Otherwise, if src is a QNaN, the result is the double-precision representation of that QNaN.

Otherwise, if src is an Infinity, the result is the double-precision representation of Infinity with the same sign as src.

Otherwise, if src is a Zero, the result is the double-precision representation of Zero with the same sign as src.

Otherwise, if src is a denormal value, the result is the normalized double-precision representation of src.

Otherwise, the result is the double-precision representation of src.

The result is placed into doubleword element 0 of VSR[XT].

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in double-precision format.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified.

FR is set to 0. FI is set to 0.

#### Special Registers Altered:

FPRF FR (set to 0) FI (set to 0)

FX VXSNAN

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

end  
FPSCR.FR ← (vxsnan\_flag=0) & inc\_flag  
FPSCR.FI ← (vxsnan\_flag=0) & xx\_flag

Let src be the quad-precision floating-point value in VSR[VRB+32].

If src is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src is a Signalling NaN, the result is the Quiet NaN corresponding to the Signalling NaN, with the significand truncated to the rounding precision.

Otherwise, if src is a Quiet NaN, then the result is src with the significand truncated to double-precision.

Otherwise, if src is an Infinity or a Zero, the result is src.

Otherwise, do the following.

If src is *Tiny* (i.e., the unbiased exponent is less than -1022) and UE=0, the significand is shifted right N bits, where N is the difference between -1022 and the unbiased exponent of src. The exponent of src is set to the value -1022.

If R0=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to double-precision (i.e., 11-bit exponent range and 53-bit significand precision) using the specified rounding mode.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[VRT+32] in double-precision format. The contents of doubleword element 1 of VSR[VRT+32] are set to 0.

FPRF is set to the class and sign of the result as represented in double-precision format. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

Let *src* be the quad-precision floating-point value in VSR[VRB+32].

If *src* is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN and VXCVI are set to 1.

If *src* is a Quiet NaN or an Infinity, an Invalid Operation exception occurs and VXCVI is set to 1.

If *src* is a NaN, the result is 0x8000\_0000\_0000\_0000.

Otherwise, if *src* is a Zero, the result is 0x0000\_0000\_0000\_0000.

Otherwise, if *src* is +Infinity, the result is 0x7FFF\_FFFF\_FFFF\_FFFF.

Otherwise, if *src* is -Infinity, the result is 0x8000\_0000\_0000\_0000.

Otherwise, do the following.

Let *rnd* be the value *src* truncated to a floating-point integer.

If *rnd* is greater than  $+2^{63}-1$ , an Invalid Operation exception occurs, VXCVI is set to 1, and the result is 0x7FFF\_FFFF\_FFFF\_FFFF.

Otherwise, if *rnd* is less than  $-2^{63}$ , an Invalid Operation exception occurs, VXCVI is set to 1, and the result is 0x8000\_0000\_0000\_0000.

Otherwise, the result is the value *rnd*, and an Inexact exception occurs if *rnd* is inexact (i.e., *rnd* is not equal to *src*).

The result is placed into doubleword element 0 of VSR[VRT+32] in signed integer format.

The contents of doubleword element 1 of VSR[VRT+32] are set to 0.

FPRF is set to undefined. FR is set to 0. FI is set to indicate if the rounded result is inexact.

If an Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified.

```

Let *src* be the quad-precision floating-point value in VSR[VRB+32].

If *src* is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN and VXCVI are set to 1.

If *src* is a Quiet NaN or an Infinity, an Invalid Operation exception occurs and VXCVI is set to 1.

If *src* is a NaN, the result is  $-2^{127}$ .

Otherwise, if *src* is a Zero, the result is 0.

Otherwise, if *src* is +Infinity, the result is  $2^{127}-1$ .

Otherwise, if *src* is -Infinity, the result is  $-2^{127}$ .

Otherwise, do the following.

Let *rnd* be the value *src* truncated to a floating-point integer.

If *rnd* is greater than  $+2^{127}-1$ , an Invalid Operation exception occurs, VXCVI is set to 1, and the result is  $2^{127}$ .

Otherwise, if *rnd* is less than  $-2^{127}$ , an Invalid Operation exception occurs, VXCVI is set to 1, and the result is  $-2^{127}$ .

Otherwise, the result is the value *rnd*, and an Inexact exception occurs if *rnd* is inexact (i.e., *rnd* is not equal to *src*).

The result is placed into doubleword element 0 of VSR[VRT+32] in signed integer format.

The contents of doubleword element 1 of VSR[VRT+32] are set to 0.

FPRF is set to undefined. FR is set to 0. FI is set to indicate if the rounded result is inexact.

If an Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified.

See Table 75, “Actions for xscvqpsqz,” on page 708.

**Explanation:**

T(x) Places the value x into the target VSR.

Nmi n The smallest signed integer doubleword value,  $-2^{127}$  (0x8000\_0000\_0000\_0000\_0000\_0000\_0000).

Nmax The largest signed integer doubleword value,  $2^{127}-1$  (0x7FFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF).

src The quad-precision floating-point value in VSR[VRB+32].

f2i(x) The quad-precision floating-point integer value x is converted to 128-bit signed integer format.

fx(x) FPSCR.FX is set to 1 if FPSCR.x=0. FPSCR.x is set to 1.

fi(x) FPSCR.FI is set to the value x.

fr(x) FPSCR.FR is set to the value x.

fprf(x) FPSCR.FPRF is set to the value x.

error() The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.

trunc(x) Return the floating-point value x truncated to a floating-point integer.

	1	-	-	fr(0), fi(0), fx(VXCVI), fx(VXSNAN), error()

**Explanation:**

T(x) Places the value x into the target VSR.

Nmi n The smallest unsigned integer doubleword value, 0 (0x0000\_0000\_0000\_0000\_0000\_0000\_0000).

Nmax The largest unsigned integer doubleword value, 2<sup>128</sup>-1 (0xFFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF\_FFFF).

src The quad-precision floating-point value in VSR[VRB+32].

f2i(x) The quad-precision floating-point integer value x is converted to 128-bit unsigned integer format.

fx(x) FPSCR.FX is set to 1 if FPSCR.x=0. FPSCR.x is set to 1.

fi(x) FPSCR.FI is set to the value x.

fr(x) FPSCR.FR is set to the value x.

fprf(x) FPSCR.PPRF is set to the value x.

error() The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.

trunc(x) Return the floating-point value x truncated to a floating-point integer.

FPSCR.FI ← (vx_flag=0) & xx_flag

```

Let *src* be the quad-precision floating-point value in  $VSR[VRB+32]$ .

If *src* is a Signalling NaN, an Invalid Operation exception occurs and  $VXSNAN$  and  $VXCVI$  are set to 1.

If *src* is a Quiet NaN or an Infinity, an Invalid Operation exception occurs and  $VXCVI$  is set to 1.

If *src* is a NaN, the result is  $0x0000_0000_0000_0000$ .

Otherwise, if *src* is a Zero, the result is  $0x0000_0000_0000_0000$ .

Otherwise, if *src* is a positive Infinity, the result is  $0x0000_0000_FFFF_FFFF$ .

Otherwise, do the following.

Let *rnd* be the value *src* truncated to a floating-point integer.

If *rnd* is greater than  $+2^{32}-1$ , an Invalid Operation exception occurs,  $VXCVI$  is set to 1, and the result is  $0x0000_0000_FFFF_FFFF$ .

Otherwise, if *rnd* is less than 0, an Invalid Operation exception occurs,  $VXCVI$  is set to 1, and the result is  $0x0000_0000_0000_0000$ .

Otherwise, the result is the value *rnd*, and an Inexact exception occurs if *rnd* is inexact (i.e., *rnd* is not equal to *src*).

The result is placed into doubleword element 0 of  $VSR[VRT+32]$  in unsigned integer format.

The contents of doubleword element 1 of  $VSR[VRT+32]$  are set to 0.

FPRF is set to undefined. FR is set to 0. FI is set to indicate if the rounded result is inexact.

If an Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs,  $VSR[VRT+32]$  and FPRF are not modified.

See Table 79, “Actions for *xscvqpuz*,” on page 716.

	0	32	127

#### Programming Note

*xscvspdp* can be used to convert a single-precision value in single-precision format to double-precision format for use by Floating-Point scalar single-precision operations.

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

FPSCR.FI ← xx\_flag

Let XT be the value 32×TX + T.

Let XB be the value 32×BX + B.

Let src be the unsigned-integer value in doubleword element 0 of VSR[XB].

src is converted to floating-point format, and rounded to single-precision using the rounding mode specified by RN.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src1 is divided<sup>[1]</sup> by src2, producing a quotient having unbounded range and precision.

The quotient is normalized<sup>[2]</sup>.

See *Actions for xsdivdp* (p. 726).

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception or a trap-enabled zero divide exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

vex_flag ← FPSCR.VE & vx_flag
zex_flag ← FPSCR.ZE & zx_flag
```

```
if vex_flag=0 & zex_flag=0 then do
  VSR[VRT+32] ← result
  FPSCR.FPRF ← fprf_CLASS_BFP128(result)
end
FPSCR.FR ← (vx_flag=0) & (zx_flag=0) & inc_flag
FPSCR.FI ← (vx_flag=0) & (zx_flag=0) & xx_flag
```

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1 or src2 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1

If src1 and src2 are Infinity values, an Invalid Operation exception occurs and VXIDI is set to 1.

If src1 and src2 are Zero values, an Invalid Operation exception occurs and VXZDZ is set to 1.

If src1 is a finite value and src2 is a Zero value, an Zero Divide exception occurs and ZX is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src2 is a Quiet NaN, the result is src2.

Otherwise, if src1 and src2 are Infinity values, or if src1 and src2 are Zero values, the result is the default Quiet NaN<sup>1</sup>.

Otherwise, if src1 is a non-zero value and src2 is a Zero value, the result is an Infinity.

Otherwise, do the following.

The normalized quotient of src1 divided by src2 is produced with unbounded significand precision and exponent range.

See Table 81, “Actions for xsdivqp[o],” on page 728.

If the intermediate result is *Tiny* (i.e., the unbiased exponent is less than -16382) and UE=0, the significand is shifted right N bits, where N is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If R0=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-disabled Zero Divide exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception or a trap-enabled Zero Divide exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

1. The quad-precision default Quiet NaN is the value, 0x7FFF\_8000\_0000\_0000\_0000\_0000.

src1	The quad-precision floating-point value in VSR[VRA+32].
src2	The quad-precision floating-point value in VSR[VRB+32].
dNaN	Default quiet NaN (0x7FFF_8000_0000_0000_0000_0000).
NZF	Nonzero finite number.
Div(x, y)	The floating-point value x is divided <sup>1</sup> by floating-point value y. Return the normalized <sup>2</sup> quotient, having unbounded range and precision.
quiet(x)	Convert x to the corresponding Quiet NaN.
v	The intermediate result having unbounded significand precision and unbounded exponent range.

**Table 81. Actions for xsdivqp[o]**

1. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then subtracted or added as appropriate, depending on the signs of the operands, to form an intermediate difference. All 64 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

src2            The double-precision floating-point value in doubleword element 0 of VSR[XB].

dQNaN          Default quiet NaN (0x7FF8\_0000\_0000\_0000).

NZF            Nonzero finite number.

D(x,y)          Return the normalized quotient of floating-point value x divided by floating-point value y, having unbounded range and precision.

Q(x)            Return a QNaN with the payload of x.

v                The intermediate result having unbounded significand precision and unbounded exponent range.

Table 82.Actions for xsdivsp

```

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

For *xsmaddadp*, do the following.

- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xsmaddmdp*, do the following.

- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied<sup>[1]</sup> by src3, producing a product having unbounded range and precision.

See part 1 of Table 83.

src2 is added<sup>[2]</sup> to the product, producing a sum having unbounded range and precision.

The sum is normalized<sup>[3]</sup>.

See part 2 of Table 83.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

### Special Registers Altered

FPRF FR FI  
FX OX UX XX VXSNAN VXISI VXIMZ

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Programming Note**

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	For <i>xsmaddadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT]. For <i>xsmaddmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3	For <i>xsmaddadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB]. For <i>xsmaddmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x.
A(x,y)	Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision. Note: If x = -y, v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

For *xsmaddasp*, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xsmaddmsp*, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied<sup>[1]</sup> by src3, producing a product having unbounded range and precision.

See part 1 of Table 84, "Actions for xsmadd(a)m<sub>sp</sub>," on page 738.

src2 is added<sup>[2]</sup> to the product, producing a sum having unbounded range and precision.

The sum is normalized<sup>[3]</sup>.

See part 2 of Table 84, "Actions for xsmadd(a)m<sub>sp</sub>," on page 738.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

- Floating-point multiplication is based on exponent addition and multiplication of the significands.
- Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
- Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	For <i>xsmaddasp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT]. For <i>xsmaddmsp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3	For <i>xsmaddasp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB]. For <i>xsmaddmsp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x.
A(x,y)	Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision. Note: If $x = -y$ , v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

end
FPSCR.FR ← (vx_flag=0) & inc_flag
FPSCR.FI ← (vx_flag=0) & xx_flag

```

Let *src1* be the floating-point value in `VSR[VRA+32]` represented in quad-precision format.

Let *src2* be the floating-point value in `VSR[VRT+32]` represented in quad-precision format.

Let *src3* be the floating-point value in `VSR[VRB+32]` represented in quad-precision format.

If either *src1*, *src2*, or *src3* is a Signalling NaN, an Invalid Operation exception occurs and `VXSNAN` is set to 1.

If *src1* is an Infinity value and *src3* is a Zero value, or if *src1* is a Zero value and *src3* is an Infinity value, an Invalid Operation exception occurs and `VXIMZ` is set to 1.

If *src2* and the product of *src1* and *src3* are Infinity values having opposite signs, an Invalid Operation exception occurs and `VXISI` is set to 1.

If *src1* is a Signalling NaN, the result is the Quiet NaN corresponding to *src1*.

Otherwise, if *src1* is a Quiet NaN, the result is *src1*.

Otherwise, if *src2* is a Signalling NaN, the result is the Quiet NaN corresponding to *src2*.

Otherwise, if *src2* is a Quiet NaN, the result is *src2*.

Otherwise, if *src3* is a Signalling NaN, the result is the Quiet NaN corresponding to *src3*.

Otherwise, if *src3* is a Quiet NaN, the result is *src3*.

Otherwise, if *src1* is an Infinity value and *src3* is a Zero value, or if *src1* is a Zero value and *src3* is an Infinity value, the result is the default Quiet NaN<sup>[1]</sup>.

Otherwise, if the product of *src1* and *src3*, and *src2* are Infinity values having opposite signs, the result is the default Quiet NaN.

Otherwise, do the following.

*src1* is multiplied by *src3*, producing a product having unbounded significand precision and exponent range.

See part 1 of Table 83. "Actions for `xsmadd(a|m)dp`".

*src2* is added to the product, producing a sum having unbounded range and precision.

See part 2 of Table 83. "Actions for `xsmadd(a|m)dp`".

If the intermediate result is *Tiny* (i.e., the unbiased exponent is less than -16382) and `UE=0`, the significand is shifted right *N* bits, where *N* is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If `R0=1`, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by `RN`. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is placed into `VSR[VRT+32]` in quad-precision format.

`FPRF` is set to the class and sign of the result. `FR` is set to indicate if the rounded result was incremented. `FI` is set to indicate the result is inexact.

1. The quad-precision default Quiet NaN is the value, `0x7FFF_8000_0000_0000_0000_0000`.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

- v The intermediate result having unbounded range and precision.

**Table 85.Actions for xsmaddqp[o]**

### VSX Scalar Maximum Double-Precision XX3-form

xsmaxdp XT,XA,XB

```

if MSR.VSX=0 then VSX_Unavailable()

reset_xflags()

src1 ← VSR[32×AX+A].dword[0]
src2 ← VSR[32×BX+B].dword[0]
result ← bfp64_MAXIMUM(src1,src2)

if vxsnan_flag=1 then SetFX(FPSCR.VXSNAN)

vex_flag ← FPSCR.VE & vxsnan_flag

if vex_flag=0 then do
    VSR[32×TX+T].dword[0] ← result
    VSR[32×TX+T].dword[1] ← 0x0000_0000_0000_0000
end
    
```

Let XT be the value 32×TX + T.  
 Let XA be the value 32×AX + A.  
 Let XB be the value 32×BX + B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src1 is greater than src2, src1 is placed into doubleword element 0 of VSR[XT]. Otherwise, src2 is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

The maximum of +0 and -0 is +0. The maximum of a QNaN and any value is that value. The maximum of any value and an SNaN is that SNaN converted to a QNaN.

FPRF, FR and FI are not modified.

If a trap-enabled invalid operation exception occurs, VSR[XT] is not modified.

See Table 86.

#### Special Registers Altered

FX VXSNAN

#### Programming Note

This instruction can be used to operate on single-precision source operands.

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

end
```

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

If src1 is less than src2, src1 is placed into doubleword element 0 of VSR[XT] in double-precision format.

Otherwise, src2 is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

The minimum of +0 and -0 is -0. The minimum of a QNaN and any value is that value. The minimum of any value and an SNaN is that SNaN converted to a QNaN.

FPRF, FR and FI are not modified.

If a trap-enabled invalid operation exception occurs, VSR[XT] is not modified.

See Table 90.

#### Special Registers Altered

FX VXSNAN

#### Programming Note

This instruction can be used to operate on single-precision source operands.

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

  FPSCR.FI ← xx_flag
end
else do
  FPSCR.FR ← 0b0
  FPSCR.FI ← 0b0
end

```

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

For *xmsubadp*, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xmsubmdp*, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied<sup>[1]</sup> by src3, producing a product having unbounded range and precision.

See part 1 of Table 94.

src2 is negated and added<sup>[2]</sup> to the product, producing a sum having unbounded range and precision.

The result, having unbounded range and precision, is normalized<sup>[3]</sup>.

See part 2 of Table 94.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	For <i>xsmsubadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT]. For <i>xsmsubmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3	For <i>xsmsubadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB]. For <i>xsmsubmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x.
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If $x = y$ , v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

end

```

Let XT be the value  $32 \times TX + T$ .  
 Let XA be the value  $32 \times AX + A$ .  
 Let XB be the value  $32 \times BX + B$ .

For *xsmsubasp*, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xsmsubmsp*, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied<sup>[1]</sup> by src3, producing a product having unbounded range and precision.

See part 1 of Table 95, "Actions for *xsmsub(a|m)sp*".

src2 is negated and added<sup>[2]</sup> to the product, producing a sum having unbounded range and precision.

The result, having unbounded range and precision, is normalized<sup>[3]</sup>.

See part 2 of Table 95, "Actions for *xsmsub(a|m)sp*".

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

- Floating-point multiplication is based on exponent addition and multiplication of the significands.
- Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
- Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	For <i>xmsubasp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT]. For <i>xmsubmsp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3	For <i>xmsubasp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB]. For <i>xmsubmsp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x.
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If $x = y$ , v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

end
FPSCR.FR ← (vx_flag=0) & inc_flag
FPSCR.FI ← (vx_flag=0) & xx_flag
```

Let *src1* be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let *src2* be the floating-point value in VSR[VRT+32] represented in quad-precision format.

Let *src3* be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either *src1*, *src2*, or *src3* is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If *src1* is an Infinity value and *src3* is a Zero value, or if *src1* is a Zero value and *src3* is an Infinity value, an Invalid Operation exception occurs and VXIMZ is set to 1.

If *src2* and the product of *src1* and *src3* are Infinity values having same signs, an Invalid Operation exception occurs and VXISI is set to 1.

If *src1* is a Signalling NaN, the result is the Quiet NaN corresponding to *src1*.

Otherwise, if *src1* is a Quiet NaN, the result is *src1*.

Otherwise, if *src2* is a Signalling NaN, the result is the Quiet NaN corresponding to *src2*.

Otherwise, if *src2* is a Quiet NaN, the result is *src2*.

Otherwise, if *src3* is a Signalling NaN, the result is the Quiet NaN corresponding to *src3*.

Otherwise, if *src3* is a Quiet NaN, the result is *src3*.

Otherwise, if *src1* is an Infinity value and *src3* is a Zero value, or if *src1* is a Zero value and *src3* is an Infinity value, the result is the default Quiet NaN<sup>[1]</sup>.

Otherwise, if the product of *src1* and *src3*, and *src2* are Infinity values having same signs, the result is the default Quiet NaN.

Otherwise, do the following.

*src1* is multiplied by *src3*, producing a product having unbounded significand precision and exponent range.

See part 1 of Table 96. "Actions for xsmsubqp[o]".

*src2* is negated and added to the product, producing a sum having unbounded range and precision.

See part 2 of Table 96. "Actions for xsmsubqp[o]".

If the intermediate result is *Tiny* (i.e., the unbiased exponent is less than -16382) and UE=0, the significand is shifted right *N* bits, where *N* is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If RO=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

1. The quad-precision default Quiet NaN is the value, 0x7FFF\_8000\_0000\_0000\_0000\_0000.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

src1 is multiplied<sup>[1]</sup> by src2, producing a product having unbounded range and precision.

The product is normalized<sup>[2]</sup>.

See Table 97.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

#### Special Registers Altered

FPRF FR FI  
 FX OX UX XX VXSNAN VXIMZ

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.  
 2. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

FPSCR.FI ← (vx_flag=0) & xx_flag
```

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1 or src2 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src1 is an Infinity value and src2 is a Zero value, or if src1 is a Zero value and src2 is an Infinity value, an Invalid Operation exception occurs and VXIMZ is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src2 is a Quiet NaN, the result is src2.

Otherwise, if src1 is an Infinity value and src2 is a Zero value, or if src1 is a Zero value and src2 is an Infinity value, the result is the default Quiet NaN<sup>1</sup>.

Otherwise, do the following.

The normalized product of src1 multiplied by src2 is produced with unbounded significand precision and exponent range.

See Table 98. "Actions for xsmulqp[o]".

If the intermediate result is *Tiny* (i.e., the unbiased exponent is less than -16382) and UE=0, the significand is shifted right N bits, where N is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If R0=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, "VSX Scalar Floating-Point Final Result," on page 670.

 Let XB be the value 32×BX + B.

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src1 is multiplied<sup>[1]</sup> by src2, producing a product having unbounded range and precision.

The product is normalized<sup>[2]</sup>.

See Table 99, “Actions for xsmulsp,” on page 771.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

#### Special Registers Altered

FPRF FR FI  
 FX OX UX XX VXSNAN VXIMZ

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

end

```

Let XT be the value  $32 \times TX + T$ .  
 Let XA be the value  $32 \times AX + A$ .  
 Let XB be the value  $32 \times BX + B$ .

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

For *xsnmaddadp*, do the following.

- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xsnmaddmdp*, do the following.

- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied<sup>[1]</sup> by src3, producing a product having unbounded range and precision.

See part 1 of Table 100.

src2 is added<sup>[2]</sup> to the product, producing a sum having unbounded range and precision.

The sum is normalized<sup>[3]</sup>.

See part 2 of Table 100.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

- Floating-point multiplication is based on exponent addition and multiplication of the significands.
- Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
- Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

See Table 101, “Scalar Floating-Point Final Result with Negation,” on page 777.

**Explanation:**

src1 The double-precision floating-point value in doubleword element 0 of VSR[XA].

src2 For *xsnmaddadp*, the double-precision floating-point value in doubleword element 0 of VSR[XT]. For *xsnmaddmdp*, the double-precision floating-point value in doubleword element 0 of VSR[XB].

src3 For *xsnmaddadp*, the double-precision floating-point value in doubleword element 0 of VSR[XB]. For *xsnmaddmdp*, the double-precision floating-point value in doubleword element 0 of VSR[XT].

dQNaN Default quiet NaN (0x7FF8\_0000\_0000\_0000).

NZF Nonzero finite number.

Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.

Q(x) Return a QNaN with the payload of x.

A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.  
Note: If  $x = -y$ , v is considered to be an exact-zero-difference result (Rezd).

M(x,y) Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.

p The intermediate product having unbounded range and precision.

v The intermediate result having unbounded range and precision.

**Explanation:**

- The results do not depend on this condition.
- class(x) Classifies the floating-point value x as defined in Table 2, "Floating-Point Result Flags," on page 511.
- error() The system error handler is invoked for the trap-enabled exception if MSR.FE0 and MSR.FE1 are set to any mode other than the ignore-exception mode.
- fi(x) FPSCR.FI is set to the value x.
- fprf(x) FPSCR.FPRF is set to the 5-bit value x..
- fr(x) FPSCR.FR is set to the value x.
- fx(x) FPSCR.FX is set to 1 if FPSCR.x=0. FPSCR.x is set to 1.
- β Wrap adjust, where β = 2<sup>1536</sup> for double-precision and β = 2<sup>192</sup> for single-precision.
- q The value defined in Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669, significand rounded to the target precision, unbounded exponent range.
- r The value defined in Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669, significand rounded to the target precision, bounded exponent range.
- v The precise intermediate result defined in the instruction having unbounded significand precision, unbounded exponent range.
- n(x) The value x is negated by complementing the sign bit of x.
- T(x) The value x is placed in element 0 of VSR[XT] in the target precision format. The contents of the remaining element(s) of VSR[XT] are set to 0.

end

```

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

For *xsnmaddasp*, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xsnmaddmsp*, do the following.

- Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].
- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied<sup>[1]</sup> by src3, producing a product having unbounded range and precision.

See part 1 of Table 102, “Actions for xsnmadd(a|m)sp,” on page 781.

src2 is added<sup>[2]</sup> to the product, producing a sum having unbounded range and precision.

The sum is normalized<sup>[3]</sup>.

See part 2 of Table 102, “Actions for xsnmadd(a|m)sp,” on page 781.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

See Table 101, “Scalar Floating-Point Final Result with Negation,” on page 777.

### Special Registers Altered

FPRF FR FI  
FX OX UX XX VXSNaN VXISI VXIMZ

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	For <b>xsnmaddasp</b> , the double-precision floating-point value in doubleword element 0 of VSR[XT]. For <b>xsnmaddmsp</b> , the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3	For <b>xsnmaddasp</b> , the double-precision floating-point value in doubleword element 0 of VSR[XB]. For <b>xsnmaddmsp</b> , the double-precision floating-point value in doubleword element 0 of VSR[XT].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x.
A(x,y)	Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision. Note: If $x = -y$ , v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

end
FPSCR.FR ← (vx_flag=0) & inc_flag
FPSCR.FI ← (vx_flag=0) & xx_flag
```

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRT+32] represented in quad-precision format.

Let src3 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1, src2, or src3 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src1 is an Infinity value and src3 is a Zero value, or if src1 is a Zero value and src3 is an Infinity value, an Invalid Operation exception occurs and VXIMZ is set to 1.

If src2 and the product of src1 and src3 are Infinity values having opposite signs, an Invalid Operation exception occurs and VXISI is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src2 is a Quiet NaN, the result is src2.

Otherwise, if src3 is a Signalling NaN, the result is the Quiet NaN corresponding to src3.

Otherwise, if src3 is a Quiet NaN, the result is src3.

Otherwise, if src1 is an Infinity value and src3 is a Zero value, or if src1 is a Zero value and src3 is an Infinity value, the result is the default Quiet NaN<sup>1</sup>.

Otherwise, if the product of src1 and src3, and src2 are Infinity values having opposite signs, the result is the default Quiet NaN.

Otherwise, do the following.

src1 is multiplied by src3, producing a product having unbounded significant precision and exponent range.

See part 1 of Table 83. "Actions for xsmadd(a|m)dp".

src2 is added to the product, producing a sum having unbounded range and precision.

See part 2 of Table 83. "Actions for xsmadd(a|m)dp".

If the intermediate result is *Tiny* (i.e., the unbiased exponent is less than -16382) and UE=0, the significand is shifted right N bits, where N is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If R0=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is negated and placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

1. The quad-precision default Quiet NaN is the value, 0x7FFF\_8000\_0000\_0000\_0000\_0000.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

p	-Infinity	$v \leftarrow -\text{Infinity}$					$v \leftarrow \text{dQNaN}$ $\text{vxi\_si\_flag} \leftarrow 1$		
	-NZF	$v \leftarrow \text{Add}(p, src2)$		$v \leftarrow p$		$v \leftarrow \text{Add}(p, src2)$			
	-Zero	$v \leftarrow src2$	$v \leftarrow -\text{Zero}$	$v \leftarrow \text{Rezd}$	$v \leftarrow src2$	$v \leftarrow src2$	$v \leftarrow src2$	$v \leftarrow \text{quiet}(src2)$ $\text{vxsnan\_flag} \leftarrow 1$	
	+Zero		$v \leftarrow \text{Rezd}$	$v \leftarrow +\text{Zero}$					
	+NZF	$v \leftarrow \text{Add}(p, src2)$		$v \leftarrow p$		$v \leftarrow \text{Add}(p, src2)$			
	+Infinity	$v \leftarrow \text{dQNaN}$ $\text{vxi\_si\_flag} \leftarrow 1$						$v \leftarrow +\text{Infinity}$	
QNaN & src1 is a NaN	$v \leftarrow p$								$v \leftarrow p$ $\text{vxsnan\_flag} \leftarrow 1$
QNaN & src1 not a NaN								$v \leftarrow src2$	$v \leftarrow \text{quiet}(src2)$ $\text{vxsnan\_flag} \leftarrow 1$

**Explanation:**

- src1 The quad-precision floating-point value in VSR[VRA+32].
- src2 The quad-precision floating-point value in VSR[VRT+32].
- src3 The quad-precision floating-point value in VSR[VRB+32].
- dQNaN Default quiet NaN (0x7FFF\_8000\_0000\_0000\_0000\_0000).
- NZF Nonzero finite number.
- Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
- quiet(x) Return a QNaN with the payload of x.
- Add(x, y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.  
Note: If  $x = -y$ , v is considered to be an exact-zero-difference result (Rezd).
- Mul(x, y) Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
- p The intermediate product having unbounded range and precision.
- v The intermediate result having unbounded range and precision.

end

```

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

For *xsnmsubadp*, do the following.

- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xsnmsubmdp*, do the following.

- Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].
- Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied<sup>[1]</sup> by src3, producing a product having unbounded range and precision.

See part 1 of Table 104.

src2 is negated and added<sup>[2]</sup> to the product, producing a sum having unbounded range and precision.

The sum is normalized<sup>[3]</sup>.

See part 2 of Table 104.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 101, “Scalar Floating-Point Final Result with Negation,” on page 777.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	For <i>xsnmsubadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT]. For <i>xsnmsubmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB].
src3	For <i>xsnmsubadp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XB]. For <i>xsnmsubmdp</i> , the double-precision floating-point value in doubleword element 0 of VSR[XT].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.
Q(x)	Return a QNaN with the payload of x.
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If $x = y$ , v is considered to be an exact-zero-difference result (Rezd).
M(x,y)	Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.
p	The intermediate product having unbounded range and precision.
v	The intermediate result having unbounded range and precision.

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

For *xsnmsubasp*, do the following.

– Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

– Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

– Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

For *xsnmsubmsp*, do the following.

– Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

– Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

– Let src3 be the double-precision floating-point value in doubleword element 0 of VSR[XT].

src1 is multiplied<sup>[1]</sup> by src3, producing a product having unbounded range and precision.

See part 1 of Table 105, "Actions for *xsnmsub(a)m*sp," on page 790.

src2 is negated and added<sup>[2]</sup> to the product, producing a sum having unbounded range and precision.

The sum is normalized<sup>[3]</sup>.

See part 2 of Table 105, "Actions for *xsnmsub(a)m*sp," on page 790.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is negated and placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

1. Floating-point multiplication is based on exponent addition and multiplication of the significands.
2. Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
3. Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

See Table 101, “Scalar Floating-Point Final Result with Negation,” on page 777.

**Explanation:**

src1      The double-precision floating-point value in VSR[XA].dword[0].

src2      For *xsnmsubasp*, the double-precision floating-point value in VSR[XT].dword[0].  
For *xsnmsubmsp*, the double-precision floating-point value in VSR[XB].dword[0].

src3      For *xsnmsubasp*, the double-precision floating-point value in VSR[XB].dword[0].  
For *xsnmsubmsp*, the double-precision floating-point value in VSR[XT].dword[0].

dQNaN    Default quiet NaN (0x7FF8\_0000\_0000\_0000).

NZF      Nonzero finite number.

Rezd     Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs). Can also occur with two nonzero finite number source operands.

Q(x)     Return a QNaN with the payload of x.

S(x,y)   Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision.  
Note: If x = y, v is considered to be an exact-zero-difference result (Rezd).

M(x,y)   Return the normalized product of floating-point value x and floating-point value y, having unbounded range and precision.

p        The intermediate product having unbounded range and precision.

v        The intermediate result having unbounded range and precision.

FPSCR.FI ← (vx\_flag=0) & xx\_flag

Let src1 be the floating-point value in VSR[VRA+32] represented in quad-precision format.

Let src2 be the floating-point value in VSR[VRT+32] represented in quad-precision format.

Let src3 be the floating-point value in VSR[VRB+32] represented in quad-precision format.

If either src1, src2, or src3 is a Signalling NaN, an Invalid Operation exception occurs and VXSNAN is set to 1.

If src1 is an Infinity value and src3 is a Zero value, or if src1 is a Zero value and src3 is an Infinity value, an Invalid Operation exception occurs and VXIMZ is set to 1.

If src2 and the product of src1 and src3 are Infinity values having same signs, an Invalid Operation exception occurs and VXISI is set to 1.

If src1 is a Signalling NaN, the result is the Quiet NaN corresponding to src1.

Otherwise, if src1 is a Quiet NaN, the result is src1.

Otherwise, if src2 is a Signalling NaN, the result is the Quiet NaN corresponding to src2.

Otherwise, if src2 is a Quiet NaN, the result is src2.

Otherwise, if src3 is a Signalling NaN, the result is the Quiet NaN corresponding to src3.

Otherwise, if src3 is a Quiet NaN, the result is src3.

Otherwise, if src1 is an Infinity value and src3 is a Zero value, or if src1 is a Zero value and src3 is an Infinity value, the result is the default Quiet NaN<sup>[1]</sup>.

Otherwise, if the product of src1 and src3, and src2 are Infinity values having same signs, the result is the default Quiet NaN.

Otherwise, do the following.

src1 is multiplied by src3, producing a product having unbounded significand precision and exponent range.

See part 1 of Table 96. "Actions for xsnmsubqp[o]".

src2 is negated and added to the product, producing a sum having unbounded range and precision.

See part 2 of Table 96. "Actions for xsnmsubqp[o]".

If the intermediate result is *Tiny* (i.e., the unbiased exponent is less than -16382) and UE=0, the significand is shifted right N bits, where N is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If RO=1, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by RN. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Table 62, "Scalar Floating-Point Intermediate Result Handling," on page 669.

The result is negated and placed into VSR[VRT+32] in quad-precision format.

FPRF is set to the class and sign of the result. FR is set to indicate if the rounded result was incremented. FI is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, FR and FI are set to 0.

1. The quad-precision default Quiet NaN is the value, 0x7FFF\_8000\_0000\_0000\_0000\_0000.

If a trap-enabled Invalid Operation exception occurs, VSR[VRT+32] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

Let XT be the value 32×TX + T.

Let XB be the value 32×BX + B.

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

A double-precision floating-point estimate of the reciprocal of src is placed into doubleword element 0 of VSR[XT] in double-precision format.

Unless the reciprocal of src would be a zero, an infinity, or a QNaN, the estimate has a relative error in precision no greater than one part in 16384 of the reciprocal of src. That is,

$$\left| \frac{\text{estimate} - \frac{1}{\text{src}}}{\frac{1}{\text{src}}} \right| \leq \frac{1}{16384}$$

Operation with various special values of the operand is summarized below.

#### VSX Data Layout for xsredp

src	VSR[XB].dword[0]	unused
tgt	VSR[XB].dword[0]	0x0000_0000_0000_0000
0	64	127

Source Value	Result	Exception

```

```
end
```

Let XT be the value 32×TX + T.

Let XB be the value 32×BX + B.

Let src be the double-precision floating-point value in doubleword element 0 of VSR[XB].

The unbounded-precision square root of src is produced.

See Table 107.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[XT] in double-precision format.

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

#### Special Registers Altered

FPRF FR FI FX XX VXSNAN VXSQRT

#### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

#### VSR Data Layout for xssqrtdp

v ← bfp_SQUARE_ROOT(src)
rnd ← bfp_ROUND_TO_BFP128(R0, FPSCR.RN, v)
result ← bfp128_CONVERT_FROM_BFP(rnd)
```

```
if vxsnan_flag=1 then SetFX(FPSCR.VXSNAN)
if vxsqrt_flag=1 then SetFX(FPSCR.VXSQRT)
if xx_flag=1 then SetFX(FPSCR.XX)
```

```
vx_flag ← vxsnan_flag | vxsqrt_flag
vex_flag ← FPSCR.VE & vx_flag
```

```
if vex_flag=0 then do
  VSR[VRT+32] ← result
  FPSCR.FPRF ← fprf_CLASS_BFP128(result)
end
FPSCR.FR ← (vx_flag=0) & inc_flag
FPSCR.FI ← (vx_flag=0) & xx_flag
```

Let *src* be the floating-point value in *VSR[VRB+32]* represented in quad-precision format.

If *src* is a Signalling NaN, an Invalid Operation exception occurs and *VXSNAN* is set to 1.

If *src* is a negative, non-zero value, an Invalid Operation exception occurs and *VXSQRT* is set to 1.

If *src* is a Signalling NaN, the result is the Quiet NaN corresponding to *src*.

Otherwise, if *src* is a Quiet NaN, the result is *src*.

Otherwise, if *src* is a negative value, the result is the default Quiet NaN<sup>1</sup>.

Otherwise, do the following.

The normalized square root of *src* is produced with unbounded significand precision and exponent range.

See Table 108, “Actions for *xssqrtqp[o]*,” on page 813.

If *R0=1*, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by *RN*. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Section 7.3.2.6, “Rounding” on page 524 for a description of rounding modes.

If there is loss of precision, an Inexact exception occurs.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into *VSR[VRT+32]* in quad-precision format.

*FPRF* is set to the class and sign of the result. *FR* is set to indicate if the rounded result was incremented. *FI* is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, *FPRF* is set to an undefined value, and *FR* and *FI* are set to 0.

If a trap-enabled Invalid Operation exception occurs, *VSR[VRT+32]* and *FPRF* are not modified, and *FR* and *FI* are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

- Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
- Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

end
FPSCR.FR ← (vx_flag=0) & inc_flag
FPSCR.FI ← (vx_flag=0) & xx_flag
```

Let *src1* be the floating-point value in *VSR[VRA+32]* represented in quad-precision format.

Let *src2* be the floating-point value in *VSR[VRB+32]* represented in quad-precision format.

If either *src1* or *src2* is a Signalling NaN, an Invalid Operation exception occurs and *VXSNAN* is set to 1.

If *src1* and *src2* are Infinity values having same signs, an Invalid Operation exception occurs and *VXISI* is set to 1.

If *src1* is a Signalling NaN, the result is the Quiet NaN corresponding to *src1*.

Otherwise, if *src1* is a Quiet NaN, the result is *src1*.

Otherwise, if *src2* is a Signalling NaN, the result is the Quiet NaN corresponding to *src2*.

Otherwise, if *src2* is a Quiet NaN, the result is *src2*.

Otherwise, if *src1* and *src2* are Infinity values having same signs, the result is the default Quiet NaN<sup>[1]</sup>.

Otherwise, do the following.

The normalized sum of the negation of *src2* added to *src1* is produced with unbounded significand precision and exponent range.

See Table 111, “Actions for *xssubqp[o]*,” on page 819.

If the intermediate result is *Tiny* (i.e., the unbiased exponent is less than -16382) and *UE=0*, the significand is shifted right *N* bits, where *N* is the difference between -16382 and the unbiased exponent of the intermediate result. The exponent of the intermediate result is set to the value -16382.

If *R0=1*, let the rounding mode be Round to Odd. Otherwise, let the rounding mode be specified by *RN*. Unless the result is an Infinity or a Zero, the intermediate result is rounded to quad-precision using the specified rounding mode.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into *VSR[VRT+32]* in quad-precision format.

*FPRF* is set to the class and sign of the result. *FR* is set to indicate if the rounded result was incremented. *FI* is set to indicate the result is inexact.

If a trap-disabled Invalid Operation exception occurs, *FPRF* is set to an undefined value, and *FR* and *FI* are set to 0.

If a trap-enabled Invalid Operation exception occurs, *VSR[VRT+32]* and *FPRF* are not modified, and *FR* and *FI* are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

Let src1 be the double-precision floating-point value in doubleword element 0 of VSR[XA].

Let src2 be the double-precision floating-point value in doubleword element 0 of VSR[XB].

src2 is negated and added<sup>[1]</sup> to src1, producing the sum, v, having unbounded range and precision.

See Table 112, “Actions for xssubsp,” on page 821.

v is normalized<sup>[2]</sup> and rounded to single-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element 0 of VSR[XT].

The contents of doubleword element 1 of VSR[XT] are set to 0.

FPRF is set to the class and sign of the result as represented in single-precision format. FR is set to indicate if the result was incremented when rounded. FI is set to indicate the result is inexact.

If a trap-enabled invalid operation exception occurs, VSR[XT] and FPRF are not modified, and FR and FI are set to 0.

See Table 63, “VSX Scalar Floating-Point Final Result,” on page 670.

### Special Registers Altered

FPRF FR FI  
FX OX UX XX VXSNAN VXISI

### Programming Note

Previous versions of the architecture allowed the contents of doubleword 1 of the result register to be undefined. However, all processors that support this instruction write 0s into doubleword 1 of the result register, as is required by this version of the architecture.

- Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
- Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Explanation:**

src1	The double-precision floating-point value in doubleword element 0 of VSR[XA].
src2	The double-precision floating-point value in doubleword element 0 of VSR[XB].
dQNaN	Default quiet NaN (0x7FF8_0000_0000_0000).
NZF	Nonzero finite number.
Rezd	Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).
S(x,y)	The floating-point value y is negated and then added to the floating-point value x.
S(x,y)	Return the normalized sum of floating-point value x and negated floating-point value y, having unbounded range and precision. Note: If $x = y$ , v is considered to be an exact-zero-difference result (Rezd).
Q(x)	Return a QNaN with the payload of x.
v	The intermediate result having unbounded significand precision and unbounded exponent range.

Let XT be the value 32×TX + T.

Let XA be the value 32×AX + A.

Let XB be the value 32×BX + B.

For each integer value i from 0 to 1, do the following.

Let src1 be the double-precision floating-point operand in doubleword element i of VSR[XA].

Let src2 be the double-precision floating-point operand in doubleword element i of VSR[XB].

src2 is added<sup>[1]</sup> to src1, producing a sum having unbounded range and precision.

The sum is normalized<sup>[2]</sup>.

See Table 113.

The intermediate result is rounded to double-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into doubleword element i of VSR[XT] in double-precision format.

See Table 114, “Vector Floating-Point Final Result,” on page 832.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT].

**Special Registers Altered**

FX OX UX XX VXSNAN VXISI

**VSX Data Layout for xvadddp**

- Floating-point addition is based on exponent comparison and addition of the two significands. The exponents of the two operands are compared, and the significand accompanying the smaller exponent is shifted right, with its exponent increased by one for each bit shifted, until the two exponents are equal. The two significands are then added or subtracted as appropriate, depending on the signs of the operands, to form an intermediate sum. All 53 bits of the significand as well as all three guard bits (G, R, and X) enter into the computation.
- Floating-point normalization is based on shifting the significand left until the most-significant bit is 1 and decrementing the exponent by the number of bits the significand was shifted.

**Explanation:**

src1 The double-precision floating-point value in doubleword element i of VSR[XA] (where i={0,1}).

src2 The double-precision floating-point value in doubleword element i of VSR[XB] (where i={0,1}).

dQNaN Default quiet NaN (0x7FF8\_0000\_0000\_0000).

NZF Nonzero finite number.

Rezd Exact-zero-difference result (addition of two finite numbers having same magnitude but different signs).

A(x,y) Return the normalized sum of floating-point value x and floating-point value y, having unbounded range and precision.  
Note: If  $x = -y$ , v is considered to be an exact-zero-difference result (Rezd).

Q(x) Return a QNaN with the payload of x.

v The intermediate result having unbounded significand precision and unbounded exponent range.

Let XT be the value  $32 \times TX + T$ .

Let XA be the value  $32 \times AX + A$ .

Let XB be the value  $32 \times BX + B$ .

For each integer value  $i$  from 0 to 3, do the following.

Let  $src1$  be the single-precision floating-point operand in word element  $i$  of  $VSR[XA]$ .

Let  $src2$  be the single-precision floating-point operand in word element  $i$  of  $VSR[XB]$ .

$src2$  is added<sup>[1]</sup> to  $src1$ , producing a sum having unbounded range and precision.

The sum is normalized<sup>[2]</sup>.

See Table 115.

The intermediate result is rounded to single-precision using the rounding mode specified by RN.

See Table 62, “Scalar Floating-Point Intermediate Result Handling,” on page 669.

The result is placed into word element  $i$  of  $VSR[XT]$  in single-precision format.

See Table 114, “Vector Floating-Point Final Result,” on page 832.

If a trap-enabled exception occurs in any element of the vector, no results are written to  $VSR[XT]$ .

Let  $XA$  be the value of  $32 \times AX + A$ . If  $XA$  is in the range  $4 \times AT$  to  $4 \times AT + 3$ , the instruction form is invalid.

Let  $XB$  be the value of  $32 \times BX + B$ . If  $XB$  is in the range  $4 \times AT$  to  $4 \times AT + 3$ , the instruction form is invalid.

Let the contents of  $ACC[AT]$  be a  $4 \times 4$  matrix of single-precision floating-point values.

For *xvbf16ger2*, *xvbf16ger2pp*, *xvbf16ger2pn*, *xvbf16ger2np*, or *xvbf16ger2nn*, let  $PMSK=0b11$ ,  $XMSK=0b1111$ , and  $YMSK=0b1111$ .

For each integer value  $i$  from 0 to 3, and each integer value  $j$  from 0 to 3, do the following.

If bit  $i$  of  $XMSK$  is equal to 1 and bit  $j$  of  $YMSK$  is equal to 1, do the following.

If bit 0 of  $PMSK$  is equal to 1, let  $src10$  be the bfloat16 floating-point value in halfword 0 of word element  $i$  of  $VSR[XA]$  and let  $src20$  be the bfloat16 floating-point value in halfword 0 of word element  $j$  of  $VSR[XB]$ . Otherwise, let  $src10$  be the value 0.0 and let  $src20$  be the value 0.0, causing the product of  $src10$  and  $src20$  to be 0.0.

If bit 1 of  $PMSK$  is equal to 1, let  $src11$  be the bfloat16 floating-point value in halfword 1 of word element  $i$  of  $VSR[XA]$  and let  $src21$  be the bfloat16 floating-point value in halfword 1 of word element  $j$  of  $VSR[XB]$ . Otherwise, let  $src11$  be the value 0.0 and let  $src21$  be the value 0.0, causing the product of  $src11$  and  $src21$  to be 0.0.

Let  $prod$  be the product of  $src10$  and  $src20$ , having infinite precision and unbounded exponent range.

Let  $psum$  be the sum of the product,  $src11$  multiplied by  $src21$ , and  $prod$ , having infinite precision and unbounded exponent range.

Let  $r1$  be the value  $psum$  with its significand rounded to 24-bit precision using the rounding mode specified by  $RN$ , but retaining unbounded exponent range (i.e., cannot overflow or underflow).

For **[pm]xvbf16ger2**, do the following.

Let  $r2$  be the value  $r1$  rounded to 24-bit significand precision and 8-bit exponent range (i.e., single-precision) using the rounding mode specified by  $RN$ .

$r2$  is placed into word element  $j$  of  $ACC[AT][i]$  in single-precision floating-point format.

For **[pm]xvbf16ger2pp**, do the following.

Let  $v2$  be the sum of  $r1$  added to the single-precision floating-point value in word element  $j$  of  $ACC[AT][i]$ , having infinite precision and unbounded exponent range.

Let  $r2$  be the value  $v2$  rounded to 24-bit significand precision and 8-bit exponent range (i.e., single-precision) using the rounding mode specified by  $RN$ .

$r2$  is placed into word element  $j$  of  $ACC[AT][i]$  in single-precision floating-point format.

For **[pm]xvbf16ger2pn**, do the following.

Let  $v2$  be the sum of  $r2$  added to the negation of the single-precision floating-point value in word element  $j$  of  $ACC[AT][i]$ , having infinite precision and unbounded exponent range.

Let  $r2$  be the value  $v2$  rounded to 24-bit significand precision and 8-bit exponent range (i.e., single-precision) using the rounding mode specified by  $RN$ .

$r2$  is placed into word element  $j$  of  $ACC[AT][i]$  in single-precision floating-point format.

For **[pm]xvbf16ger2np**, do the following.

Let  $v2$  be the sum of the negation of  $r2$  added to the single-precision floating-point value in word element  $j$  of  $ACC[AT][i]$ , having infinite precision and unbounded exponent range.

Let  $r3$  be the value  $v3$  rounded to 24-bit significand precision and 8-bit exponent range (i.e., single-precision) using the rounding mode specified by  $RN$ .

$r2$  is placed into word element  $j$  of  $ACC[AT][i]$  in single-precision floating-point format.

For **[pm]xvbf16ger2nn**, do the following.

Let  $v_2$  be the sum of the negation of  $r_2$  added to the negation of the single-precision floating-point value in word element  $j$  of  $\text{ACC}[\text{AT}][i]$ , having infinite precision and unbounded exponent range.

Let  $r_2$  be the value  $v_3$  rounded to 24-bit significand precision and 8-bit exponent range (i.e., single-precision) using the rounding mode specified by RN.

$r_2$  is placed into word element  $j$  of  $\text{ACC}[\text{AT}][i]$  in single-precision floating-point format.

Otherwise, the contents of word element  $j$  of  $\text{ACC}[\text{AT}][i]$  are set to  $0x0000\_0000$ .

Unlike most other *VSX Vector Floating-Point* instructions, this instruction always updates the target register (here,  $\text{ACC}[\text{AT}]$ ), even when a trap-enabled exception occurs. For every multiply-add operation that is performed as part of the execution of this instruction, the operation is performed as if all exception enable bits are zero, and the trap-disabled result is returned. If the operation causes underflow or produces an inexact result, whether the operation causes an Underflow or Inexact exception is based on the actual contents of the Underflow and Overflow Enable bits. Exception status is accumulated and the appropriate exception status bits in the FPSCR are updated at the completion of execution of the instruction. Otherwise, behavior is the same as any vector floating-point instruction that can cause an exception. Taking a Program interrupt on a trap-enabled exception when interrupts are enabled by MSR.FE0 and MSR.FE1 is still supported, albeit with  $\text{ACC}[\text{AT}]$  updated based on a trap-disabled result.

**Programming Note**

Let  $X$  be the  $4 \times 2$  matrix of bfloat16 floating-point values contained in  $VSR[XA]$  in row-major format.  
 Let  $Y$  be the  $4 \times 2$  matrix of bfloat16 floating-point values contained in  $VSR[XB]$  in row-major format.  
 Let  $ACC[AT]$  be the accumulator containing a  $4 \times 4$  matrix of single-precision floating-point values.

`[pm]xvbf16ger2` performs the following form of accumulation of two outer products (rank 2 update).

```
for i=0 to 3, j=0 to 3:
  ACC[AT][i][j] = fmadds(X[i][1], Y[j][1], fmul sx(X[i][0], Y[j][0]))
```

where `fmul sx()` is equivalent to a `fmuls` instruction that rounds the significand of its result to single-precision but retains an exponent having unbounded range.

`[pm]xvbf16ger2pp` performs the following form of accumulation of two outer products (rank 2 update).

```
for i=0 to 3, j=0 to 3:
  ACC[AT][i][j] = fadds(fmadds(X[i][1], Y[j][1], fmul sx(X[i][0], Y[j][0])), ACC[AT][i][j])
```

`[pm]xvbf16ger2pn` performs the following form of accumulation of two outer products (rank 2 update).

```
for i=0 to 3, j=0 to 3:
  ACC[AT][i][j] = fsubs(fmadds(X[i][1], Y[j][1], fmul sx(X[i][0], Y[j][0])), ACC[AT][i][j])
```

`[pm]xvbf16ger2np` performs the following form of accumulation of two outer products (rank 2 update).

```
for i=0 to 3, j=0 to 3:
  ACC[AT][i][j] = fadds(fnmadds(X[i][1], Y[j][1], fmul sx(X[i][0], Y[j][0])), ACC[AT][i][j])
```

`[pm]xvbf16ger2nn` performs the following form of accumulation of two outer products (rank 2 update).

```
for i=0 to 3, j=0 to 3:
  ACC[AT][i][j] = fsubs(fnmadds(X[i][1], Y[j][1], fmul sx(X[i][0], Y[j][0])), ACC[AT][i][j])
```

Let XT be the value 32×TX + T.  
 Let XA be the value 32×AX + A.  
 Let XB be the value 32×BX + B.

For each integer value i from 0 to 1, do the following.  
 Let src1 be the double-precision floating-point operand in doubleword element i of VSR[XA].

Let src2 be the double-precision floating-point operand in doubleword element i of VSR[XB].

src1 is compared to src2.

The contents of doubleword element i of VSR[XT] are set to all 1s if src1 is equal to src2, and is set to all 0s otherwise.

A NaN input causes the comparison to return false for that element.

Two zero inputs of same or different signs return true for that element.

Two infinity inputs of same signs return true for that element.

If Rc=1, CR Field 6 is set as follows.

- Bit 0 is set to indicate all vector elements compared true.
- Bit 1 is set to 0.
- Bit 2 is set to indicate all vector elements compared false.
- Bit 3 is set to 0.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT] and the contents of CR field 6 are undefined if Rc is equal to 1.

Let XT be the value 32×TX + T.  
 Let XA be the value 32×AX + A.  
 Let XB be the value 32×BX + B.

For each integer value i from 0 to 3, do the following.  
 Let src1 be the single-precision floating-point operand in word element i of VSR[XA].

Let src2 be the single-precision floating-point operand in word element i of VSR[XB].

src1 is compared to src2.

The contents of word element i of VSR[XT] are set to all 1s if src1 is greater than or equal to src2, and is set to all 0s otherwise.

A NaN input causes the comparison to return false for that element.

Two zero inputs of same or different signs return true for that element.

Two infinity inputs of same signs return true for that element.

If Rc=1, CR Field 6 is set as follows.

- Bit 0 is set to indicate all vector elements compared true.
- Bit 1 is set to 0.
- Bit 2 is set to indicate all vector elements compared false.
- Bit 3 is set to 0.

If a trap-enabled exception occurs in any element of the vector, no results are written to VSR[XT] and the contents of CR field 6 are undefined if Rc is equal to 1.
